High cost of feed is a limitation to monogastric animal production in Nigeria which has been rated at 70 - 80 percent of total cost of production (Madubuike and Ekenyem, 2001). The overdependence on imported livestock products, ignorance, inadequate technical skills, diseases and parasitism, environmental stress and high cost of ingredients and competition between man and livestock for feed grains and inadequate production of farm crops to meet human and livestock needs have been implicated as remote causes of poor animal protein intake among Nigerians (Babatunde *et al.*, 1990). Consequently, the fight to reduce the cost of poultry production becomes critically urgent in order to salvage Nigerians from the scourge of sub-optimal animal protein intake and malnutrition. The poultry industry has a key role to play in many parts of the world as a most economical source of protein (Augusto *et al.*, 1999). The poultry industry is one of the fastest growing segments of the livestock industry. Poultry are highly prolific and very efficient in converting feed nutrients into high quality animal protein (Smith, 2001).

It is therefore very important to use unconventional materials such as cowpea waste, soybean waste, bambara groundnut offal, etc., that are locally available and can be obtained at lower prices. The inclusion of graded levels of raw bambara nut (*Voandzeia subterranea L*) offal in the diets of broiler chickens will help to enhance production by reducing the cost of production. Bambara groundnut is widely cultivated in the Northern and Southern States of Nigeria where the seeds are processed into flour and consumed as moi moi (Enwere, 1998). The processing of the seeds into flour results in the production of the waste that contains 16.40% crude protein (Okeke, 2000). Bambara groundnut waste has been used in the feeding of poultry and rabbits (Okeke, 2000; Ani and Okafor, 2004; Ani, 2007). However, its use in the feeding of monogastric animals is limited by the presence of high fibre and antinutritional factors (Ensminger *et al* 1996; Enwere, 1998). Poultry cannot fully utilize high fibre diets because they lack the digestive framework that can elaborately digest large amount of fibre. It becomes imperative, therefore, to incorporate exogenous enzymes into their diets in order to enhance the breakdown of the non-starch polysaccharides (NSPs) present in fibre (Doku and Karikari, 1981; Ensminger *et al.*, 1996; Enwere, 1998). Besides antinutritional factors, another limitation is its high fibre content. The enzyme being considered in this study is Natuzyme which has been shown to increase digestibility of fibrous feed ingredients by disrupting the plant cell walls, and by reducing the

viscosity of the gut contents, thereby enhancing nutrient absorption (Choct and Annison, 1992; Bedford *et al.*, 1992; Acromovic, 2001). The present study was therefore conducted to determine the effects of graded levels of raw bambara nut waste and supplementary enzyme (Natuzyme) on the coefficient of digestibility and growth performance of growing broiler chickens.

Materials and Methods

The study was conducted at the Poultry Unit of the College of Animal Science Teaching and Research Federal University of Agriculture, Makurdi, Benue State, Nigeria. The Bambara groundnut sievate was procured from a bambara groundnut processing mill in Makurdi town, Other feed ingredients used in the study were purchase from the Livestock feed stores. 216 day-old broiler chicks were obtained from a commercial farm. The birds were randomly assigned to 8 treatments and 3 replicates per treatment with nine (9) birds each. The groups were randomly assigned to diets in a 3 × 4 factorial arrangement involving four levels (0, 10, 20 and 30%) of treated and untreated Bambara grandnut offal with control diet (0) in a complete randomized design. Each treatment was replicated three times with nine birds per replicate. These chicks were weighed at the beginning of the experiment to obtain their initial weight per replicate. The chicks in each replicate were housed in clean and disinfected separated pens. The birds were brooded and vaccinated against Newcastle disease (i/o) at day old, Gumboro vaccine administer 7th and 14th days, while the Newcastle vaccine "Lasota" administered at 21st days respectively. Standard hygienic conditions and biosecurity of the environment was maintained.

Vitamin-mineral premix (animal care ^{R}) will supply the following additional nutrients per kg of feed. Vitamin (1,200,000 I.U), D_3 (300,000 I.U), E (3,000mg), k_3 (250mg), folic acid (10mg), Niacin (4,000mg), Calpan (1,000mg), B_2 (500mg), B_{12} (2mg), B_1 (9,200), B_6 (350mg), Biotin (8mg), Antioxidant (12,500mg), Minerals; Cobalt (25mg), Selenium (25mg), Iodine (120mg), Iron (4,000mg), Manganese (700mg), Copper (800mg), Zinc (6,000mg), Chlorine Chloride (20,000mg, BGO-Bambara groundnut offer, SBM-Soya bean meal, GNC-Groundnut cake.*

Natuzyme (R) is added at the rate of 0 (-) or 250mg (+)/kg of diet.

Data were collected on the initial body weight, final body weight, weight gain, feed intake, feed conversion ratio and digestibility Study was done**.** At end of 8 weeks of the finisher phase, two (2) birds were selected from each of the three (3) replicate, such that the weights was determine by the average weight of the whole replicate. The birds were transferred into metabolic cages and allowed an adjustment period of three days. The birds were fed with weighed amounts of feed daily for three days. Leftover feed was weighed to determine feed intake, faecal dropping was collected on daily basis, weighed and dried to a constant weight. The faecal sample collected from each replicate were thoroughly mixed to obtain a homogenous mixture, milled and subjected to proximate composition analysis.

Results and Discussions

The effect of feeding graded levels of enzyme treated and untreated BGO in diet of broiler chicken on coefficient of digestibility is as shown in table 2.

Table 2: Treatment effect on digestibility coefficient

^{abc}…Means with different superscript along the same row are significantly ($p<0.05$) different

T_1-Control T_2-0BGO+250mg enzyme T_3-10%BGO+mg enzyme T_3-10%BGO + 250mg Enzyme

T_4-20%BGO + 0mg Enzyme T_5-20%BGO +250mg Enzyme T_6-30%BGO +0mg Enzyme T_7-30%BGO +250mg Enzyme DM-Dry matter CP-crude protein EE-Ether extract CF-crude fibre.

Dry Matter digestibility (DMD) was significantly ($p<0.05$) different across the treatment groups.This similar to result other rearchers(Ani and Omeje,2012; Ani 2007) Treatments 1 which is the control had the highest value (97.10 %) of DMD while the least value (95.50 %) was observed in treatment 2. The Crude protein (CP) was significantly ($p<0.05$) different among the various treatment groups. Control group had the best CP digestibility (96.66 %) while treatment 2 had the least CP digestibility value (95.29 %). Ether extract was also significantly ($p<0.05$) across the different groups. While treatment 5 had the highest EE digestibility value (97.83 %), the least value (92.76 %) was observed in treatment 6. Digestibility of ash in treatment 1 (Control) was 95.49 % which was higher ($p<0.05$) the value of 88.47 % observed in treatment 4. Crude fibre digestibility was higher ($p<0.05$) in treatment 6 (92.77 %) with treatment 2 having the least value (84.71 %). In digestibility coefficient generally, all the birds fed the various diet containing both treatment and untreated BGO recorded high in all the parameters measured. In apparent digestibility coefficient of Dry Matter (DM), crude protein, ash and crude fibre. The results suggest that the broilers were able to digest and derive nutrients from the diets with the same level of efficiency, except EE digestibility. However, the high Crude Fibre (CF) content of the diets had the least value (84.71%). this agree with Ani (2007), poultry cannot utilize high fibre diets fully because they lack the digestive framework that can elaborately digest large amount of fibre. The recommended levels could have been responsible for the observed apparent digestibility coefficient of nutrients in this study.

Conclusion and recommendation

The result of this study showed that raw Bambara groundnut can be incorporated in broiler chicken diet at 20% inclusion level, without any deleterious effect on the coefficient of digestibility and performance of the birds. The study also showed that raw bambara groundnut offal can be used to supplement soya bean meal and maize in broiler chicken diets as in other birds and rabbit diets. Further investigation should be done in determining the proper inclusion rate of BGO as a feed resource.

***E-mail of corresponding author:** segunojebiyi@gmail.com

Abstract
One hundred (100) 18 weeks old ISA Brown Strain of layers were used to examine the performance and some egg quality characteristics of four commercial protein concentrates. Five experimental diets were formulated for the experiment such that diet 1was the control formulated from primary ingredients while diets 2, 3, 4 and 5 were formulated using four commercial protein concentrates (CPC) labeled as CPCA, CPCB, CPCC and CPCD respectively. The birds were allotted after weight balancing into five treatments of five replicates with four birds to make twenty birds per treatment in a completely randomize design. The experiment lasted for 12 weeks. The results shows daily feed intake, feed cost /kg diet, feed: egg ratio and percentage hen day production were significantly ($p < 0.05$) affected by CPC. Control diet had the highest feed cost per kg (₦125.00) while CPCB had the least (₦107.93). Hen day egg production was highest in birds fed the control diet (89.68%) and lowest (77.94%) was recorded among birds fed CPCB. The external egg quality results shows that all parameters measured except egg mass were not significantly ($p > 0.05$) affected. Egg mass for birds fed the control diet (48.96), CPCB (47.51) and CPCD 46.87 were similar ($p>0.05$) but higher than 43.20 obtained among birds fed CPCC. Although the percentage production was highest in the control, but where and when it becomes difficult to formulate layer diet from primary ingredients and the concentrates are available any of the commercial concentrates can be used.

Keywords: Quality evaluation, internal egg quality, external egg quality, Brown egg type layers

Introduction
The poultry production systems play an important role in human nutrition, employment and income generation Alam *et al.,* (2015). According to Sleman *et al* (2015), most attention is given to protein components in poultry nutrition, due to the importance of protein as a major constituent of the biologically active compounds in the body. Protein sources are the second largest component of practical poultry diets after energy and limited number of ingredients are used by the mainstream commercial poultry industry to supply protein; these are limited in distribution and are also generally more expensive an energy sources (Iji *et al* 2017). **Animal Protein concentrate** can be defined as animal dietary supplement with very high protein content extracted or prepared from vegetable or animal source. In addition to energy and protein sources there is the need for addition of feed additives (micronutrients, minerals and vitamins) in order have a balanced feed that meets daily nutrient requirements. However, with the consistent rise in the prices of primary ingredients and the need to get quality materials, most farmers have resulted to purchasing protein concentrates to be mixed with relatively available and affordable ingredients. Poor quality feeds will lead to lower performance with a negative consequence on the income of the farmers. Since protein concentrates are expected to contain high quality protein sources, vitamins, minerals, trace elements, enzymes and additives, using them in preparing good feed becomes easier.
The aim of the experiment is to compare performance and egg quality characteristics of Brown egg – type layers fed with different Commercial Protein Concentrates (CPC).

Materials and Methods
Experimental site: - The experiment was carried out at the Poultry Unit of the Teaching and Research Farm, Faculty of Agricultural Sciences of Ladoke Akintola University of Technology, Ogbomoso, Nigeria.
Test Ingredients: - Four commercial protein concentrates were used for the experiment which is labelled as CPCA, CPCB, CPCC and CPCD layer concentrate.
Experimental diets: - Five experimental diets were formulated (Table 1) as follows: Diet1: Direct formulation using primary ingredients (control), Diet 2: maize+ wheat offal+30% CPCA, Diet 3:

maize+ wheat offal+30% CPCB, Diet 4: maize+ wheat offal+30% CPCC, Diet 5: maize+ wheat offal+SBM+Limestone+5% CPCD.

Table 1: Gross composition of experimental diet (g/100)

Experimental animals and management: - One hundred (100) point of lay (18 weeks old) ISA brown birds purchased from a reputable farm were used for the experiment. The birds were weighed prior to the commencement of the experiment and distributed randomly after weight balancing into five (5) dietary treatment groups of five (5) replicates, each replicate had four birds. The birds were managed intensively in a two-tier battery cage system and three birds were stock per cell with dimension of 42 x 42 x 36 cm. All necessary medications and vaccinations were administered and birds were fed twice daily at 7:00hours and 12:00hours. Water was supplied *ad-libitum.* Eggs were collected twice at 12:00hours and 16:00hours for the period of the experiment which is 12 weeks.

Data Collection: Data were collected on the following parameters; initial body weight, final body weight, average feed intake, egg mass, Egg weight and hen egg day production.

External and internal egg qualities: The following egg quality traits (external and internal) were examined. Egg weight (g), yolk weight (g), albumen weight (g) and shell weight (g) were measured with analytic scale with 0.01 g accuracy. To determine the proportions of egg parts, each egg was carefully broken and shell separated. Egg shell (not dried) was weighed and the relative weight calculated by relating the shell weight to the weight of the egg. An egg separator was used to separate the yolk from the albumen. Relative yolk weight was calculated in percentages by relating the yolk weight measured to the nearest gram to the whole weight of that particular egg and multiplied by 100. The albumen weight was calculated by subtracting the yolk and shell weights from the whole egg weight. The albumen weight relative to the individual egg weight was calculated. Yolk index (%) was calculated according to the formula: Yolk index = yolk height (mm) x 100% / yolk width (mm). Haugh units were calculated according to the formula (Haugh, 1937): HU = 100 log (H +7.57 -1.7 *M0.37), H – average thick white height (mm), W – egg weight (g). Eggshell thickness (mm) was measured together with shell membranes using a micrometer screw.

Laboratory analysis: The experiment diets, as well as the test ingredient were analyzed for proximate composition by the method of AOAC, (2005).

Statistical analysis: All data collected were subjected to one way analysis of variance using the GLM of SAS (2000) and the means were compared using Duncan's Multiple Range Test of the same package.

Results and Discussion

The nutrient compositions of the experimental diets were within the values recommended levels for laying hens as reported by NRC (1994). The comparative performance of brown egg-type layers fed four different commercial concentrates is presented in Table 2. Daily feed intake, feed conversion ratio and percentage hen day egg production were significantly ($p < 0.05$) influenced by the different commercial protein concentrates. This is similar with the findings of Moustafa *et al*., (2005) who reported that feed intake and FCR were significantly affected by slight variation in dietary CP levels in the diets of laying hens.

Table 2: Comparative performance of brown-egg type layers fed four different commercial protein concentrates

Parameters	Control	Biacom	Livestock	Animal care	Hendrix	SEM	P value
Initial weight (kg)	1.63	1.54	1.46	1.61	1.63	0.03	0.25
Final weight (kg)	1.66	1.58	1.49	1.65	1.66	0.03	0.23
Feed to egg ratio	0.12^{b}	0.15^{a}	0.16^{a}	0.15^{a}	0.12^{b}	0.00	0.01
Feed cost(₦/kg)	125.00^{a}	108.20^{d}	107.93^{e}	110.16^{c}	116.80^{b}	0.36	0.01

%Hen-day production	89.68^{a}	87.19^{b}	77.94^{d}	82.39^{c}	84.52^{c}	0.08	0.02

^{abcde}Means on the same similar row with superscripts are not significantly different ($P > 0.05$)

Layers fed on diets formulated from commercial protein concentrates had higher DFI compared with birds fed control diet. This may be due to the type of protein sources and amino acid profile of the commercial protein concentrates used. %HDEP (89.68) was highest in birds fed control diet. Among birds fed supplemented concentrate diets, CPCA had a better %HDEP (87.19). However, %HDEP for birds fed control, CPCA, CPCC and CPCD diets were within desirable range of ≥80% HDEP (Agritech, 2018). The external and internal egg quality parameters are presented in Tables 3 and 4 respectively. The egg size is a function of quality and quantity of feed, stage of lay and management system (Onyimonyi and Ugwu 2007) and the amount of protein in the feed (Scott *et al*, 1976). In this study the egg weights are similar across the treatments.

Table 3: External Egg quality parameters of Brown Egg type layers fed protein concentrates

Parameters	T1	T2	T3	T4	T5	SEM	P-value
Egg weight(g)	54.80	55.21	55.85	54.78	55.20	0.18	0.34

Egg mass (g)	48.96^{a}	47.51^{a}	43.20^{b}	44.73^{b}	46.87^{a}	0.50	0.00
Egg shape index	0.82	0.81	0.82	0.81	0.84	0.02	0.98
Shell thickness (mm)	0.41	0.41	0.40	0.40	0.41	0.00	0.57

^{ab}Means on the same row with similar superscripts are not significantly different ($P > 0.05$)

Stadelmen and Owen, (1997) reported that shell thickness of 0.33mm is needed for egg is to have more than 50% chance of moving through normal market without breaking. The egg shell thickness obtained in this study is higher than the recommended 0 .33mm, this improvement in shell thickness may be consequence increased mineral and protein absorption.

Table 4: Internal Egg quality parameters of Brown Egg-type layer fed protein concentrates

Parameters	T1	T2	T3	T4	T5	SEM	P-value

Conclusion and recommendation

All the commercial protein concentrates used were able to meet up the nutrient requirements for layers based on their recommended mixing instructions. They can therefore be used in formulating laying diets where available and when it is relatively difficult to formulate from common fed ingredients.

Abstract

A 77 day feeding trial was conducted to comparatively evaluate some selected forages in combination with concentrate diet on the growth performance and carcass characteristics of weaner rabbits. A total of 36 weaner rabbits with an initial weight of 600-700g of mixed breeds and sexes, aged between 5-6 weeks, were randomly allotted to 4 dietary treatments with 9 rabbits per treatment and 3 rabbits per replicate in a completely randomised design. The rabbits were ratio 1:2 in their sex distribution (1 male and 2 female). Rabbits in T1 were fed with Tridax procumbens (coat buttons) which served as the control, T2, Senna occidentalis (Negro coffee), T3, Mangifera indica (mango) leaf and T4 with Luffa aegyptiaca (sponge gourd). The forages were fed dried and all the treatment rabbits were also fed the same concentrate diet. Growth performance result showed that final weight, weight gain, and feed conversion ratio were not significantly affected by the treatments. The carcass characteristics of the rabbits showed no significant differences among the treatment means.

It was concluded that the selected forages had no detrimental effect on the growth performance and carcass characteristics of rabbits.

Keywords: rabbit, forages, concentrate, performance, carcass

Introduction

The search for a novel, nutritionally viable, cheap and readily available source of plant nutrients, especially protein, to supplement the highly competed and demanding grains like soybeans is now a major concern in livestock production (Adeniji *et al*., 2005; Obun and Ayanwale, 2006). Gueye and Branckaert (2002) observed that in low-income food-deficit countries, surpluses of cereals are generally not available and therefore, not advisable to develop wholly grain based feeding system. They however, recommended a policy to identify and use locally available feed resources such as forages as supplements in rabbit diets with high nutritive value as an alternative and cheap source of protein for rabbits which could reduce total dependence on concentrate feeding thereby keeping the cost of rabbit production low and sustain growing interest in rabbit production (Omolade, 2016).

Forages are cheap and in abundance in tropical countries during rainy season and can be harvested and stored for use as feed materials during off seasons. Rabbits perform better when fed with a mixture of forage and concentrate (Adeyemo *et al.*, 2014). Forages such as *Panicum maximum* (guinea grass) and *Tridax procumbens* are acceptable by rabbits (Abu *et al*., 2008). The under-utilization of some forages due to inadequate information of their nutritive values and their effects on rabbit necessitated this research with the aim of comparing the performance of rabbits fed with different forage leaves as well as possibility of reducing total dependent on the conventional feed materials and the total cost of production for the small scale rabbit producers.

Materials and Methods

A total of 36 weaned rabbits of mixed sexes aged between 5-6 weeks with initial weight of 600-700g were weighed individually and randomly assigned to the 4 experimental treatments with each housing 9 rabbits and replicated 3 times with 3 rabbits in a completely randomized design (CRD). On arrival, the rabbits were given anti- stress drugs and multivitamins. Dewormer, coccidiostat and antibiotics were also administered for a healthy start. Weighed amounts of the experimental diets were given to the animals for a period of 11 weeks. Concentrate and forage were fed separately at different time interval. The concentrate diet was served between 8.00a.m–6.00p.m while the forage leaves were served between 6.00p.m–8.00a.m of the following day. The forage leaves were collected from the Poultry Production Unit premises, Minna, Niger state. They were cleaned, dried under room temperature of 35ºC and stored for use. A portion of the forage leaves were milled using 1mm sieve

and used for chemical analysis. Data was collected on growth performance (weight gain, feed intake, and feed conversion ratio) and carcass characteristics. The data collected were statistically analysed using SAS (2008).

Proximate composition: The dry matter, crude protein, ether extract and ash contents of the forage samples and the concentrate diet were determined according to A.O.A.C. (2000).

Table 1: Composition of the concentrate diet

Ingredient	(%)
Maize	50.0
Soybean meal	5.0
Maize offal	27.0
Ground nut cake	12.0
Fish meal	2.0
Bone meal	3.0
Salt	0.25
Methionine	0.25
Lysine	0.25
Vit/Min premix	0.25
Total	100

Table 2: Proximate composition of the selected forages

Parameters	T1	T2	T3	T4

Ether extract (%)	1.82	2.81	1.46	2.00
Ash (%)	19.50	16.50	13.00	25.50
NFE (%)	34.80	39.14	43.49	41.68
ME (Kcal/kg)	2062.03	2351.53	2063.61	2071.58

Means on the same row were not significantly (P>0.05) different: ME= metabolisable energy; NFE = nitrogen free extract; T1= tridax procumbens; T2= senna occidentalis; T3= manifera indica; T4= luffa aegyptiaca

Results and discussions

The result of growth performance of rabbits fed some selected forages shown in table 3 were not significantly different among the treatment means. This result was in line with the report of Adeyemo *et al* (2014). The authors concluded in their research that rabbits perform better when fed combinations of concentrates and forages. The selected forages compared well with the conventional one using *Tridax procumbens* as control. The result of carcass characteristics of rabbits fed some selected forages shown in Table 4 revealed no significant differences among the treatment means.

ABSTRACT
Eight (8) weeks feeding trail was carried out to determine the potential effect of boiled Delonix regia in rabbits' diet. Diet formulated contained 0% (T1), 2.5% (T2), 5% (T3), 7.5% (T4) and 10% (T5) of boiled Delonix regia seed meal. A total number of 30 rabbits age ranging between 6-8 weeks were randomly allotted to (5) treatments having 3 replicates of 2 rabbit per replicate. The rabbits were fed the experimental diet over a period of eight (8) weeks. Feed intake was measure daily and the rabbits were weighed weekly. Parameters taken in this experiment were body weight, hematological values, and carcass characteristics. There was significance increase in feed intake of rabbits in T2 inclusion level of the boiled Delonix regia seed meal compared to other treatments. Whereas, there were no significant variation between TI, T4 and T5. The White Blood Cell count was observed to be within values of 2.10 – 5.43x10(ml). The result also revealed that the red blood cell (RBC) is within the recommended range (5.0-8.0). From the experiment it could be concluded that dietary inclusion of Delonix regia seeds resulted in significant improvement in growth performance of rabbit and the difference observed at 5% level of inclusion could be due to the strain of the rabbits used.

Key words: Rabbits, Delonix regia, Hematology, Growth Performance

INTRODUCTION
The intake of animal protein is low in developing countries than in developed countries. The FAO recommends a minimum of 70g of protein daily per caput out of which at least 35g (50%) should come from animal proteins. Micro-livestock such as rabbit, have been suggested as a rapid means of obtaining animal protein (Orerede *et al.,* 2000) because the daily weight gain is high in proportion to the body weight which gives them a rapid growth rate and early sexual maturity. These resulted in the rabbit reaching the weight of sexual maturity and its 30% faster than other animals (Ajayi *et al.,* 2005) which makes it suitable as meat producing small livestock, in developing countries (Argeniwa, *et al.,* 2000). *Delonix regia* is also known as Flamboyant tree, it's a tropical, ever green shrub which belongs to the family of fabacae, (Christman, 2004). It is noted for its fern-like leaves and flamboyant displays of flower. Hematological parameter is an important and reliable medium used to monitor and evaluate health and nutritional status of animals, Gupta et al. (2007). The various function of the blood is made possible by the individual and collective actions of its constituents, this study therefore investigates the performance and hematological values of rabbits fed graded levels of boiled *Delonix regia* seed meal

MATERIALS AND METHODS
The study was conducted at the teaching and research farm, Federal College of Animal Health and Production Technology, Chaha Farm, Vom. Jos South Local Government Area of Plateau State. A total of 30 Rabbits were obtained from commercial farmers within Vom in Plateau State. They were of mixed breeds and sexes and were randomly allotted into five dietary treatments with six (6) rabbits per treatment in three (3) replicates using the completely randomized design (CRD). The experimental rabbits were fed with formulated diet containing 0% (T1), 2.5% (T2), 5% (T3), 7.5% (T4) and 10% (T5) inclusion rate of boiled *Delonix regia* seed meal and the recommended management and health practices were strictly adhered to. Feed and clean water was supplied *ad-libitum*. Daily feed consumption was recorded as difference of feed offered and the left-over. Weight gain was measured weekly. Blood samples were collected from the heart and marginal vein of the ear into bottles containing EDTA as anticoagulant. The samples were taken to laboratory for analysis to determine the Packed Cell Volume (PCV), Red Blood Cell (RBC), White blood cell (WBC), Neutrophils (N), Lymphocytes (L), total protein, cholesterol and Urea. The PVC, RBC, WBC, N and L were

determined using the Wintrobe-icrohaematocrit. Neuber-haematocytocytometer and Cyano-haemoglobin Results obtained from blood parameters was subjected to analysis of variance (ANOVA) using SAS (2008) software. Means were separated with Duncan multiple range test at 5% level of significance.

Table 5: Growth Performance of Rabbits fed boiled *Delonix regia* Seed Meal

Parameters	0%	2.5%	5%	7.5%	10%	SEM
Initial weight (g)	190	170	150	180	255	1.59
Final weight (g)	420	390	425	415	495	0.05
Weight gain (g)	230[a]	220[b]	235[a]	235[a]	240[a]	2.00
Total feed intake (g)	1059.9	1098.9	735.4	1016	1036.3	10.45
Feed conversion ratio	4.61[a]	4.90[a]	3.13[c]	4.32[b]	4.32[b]	0.54

Note: abc -means within a row with different superscripts are significantly Different (P<0.05)

The Table 5 above shows the performance of the rabbits fed graded levels of *Delonix regia* seed meal, at 5% with the feed conversion ratio and feed intake observed to differ significantly from other treatments 0%, 25%, 75% and 10% respectively. But the weight gain obtained at 10% inclusion rate was higher and this corresponded with the investigation made by Fatufe (2009) who also fed diet containing *Delonix regia* seed meal at 5% and 10% and discovered it has no adverse effect on body weight and carcass evaluation of the rabbits. Although, at 5% inclusion level, two (2) mortality were recorded with stunted growth, which could be attributed to the strain and type of the rabbit used for the experiment since the rabbits were obtained from different commercial farmers. From the result, the Packed Cell Volume (PCV) obtained fell within the range of 31.0-48.6%. Hence, the higher packed cell volume (PCV) obtained from the results shown a better nourishment of these diets on the rabbits during the trials. Also, the result of white blood cell count (WBC) values shows that the defensive system of the rabbit selected was not affected before and after the trial. The White Blood Cell count was observed to be within values of 2.10 – 5.43x10ml. The result also further revealed that the red blood cell (RBC) is within the recommended range (5.0-8.0). This implies that the seeds did not cause any inflammatory and allergic reactions to the rabbits, at 10% inclusion rate. Treatment with 10% dietary inclusion of cooked and fermented *Delonix regia* seed meal gave promising results which was comparable to the control (maize and Soybeans diets), thus, it is recommended for adoption by farmers.

CONCLUSION

The research shows how efficient *Delonix regia* is to the nutrition of rabbits and other livestock, it can be used to replace Soya beans in a diet. The results from the study is an indication that *Delonix regia* seed meal diets could be fed to rabbit from 2.5% - 10% inclusion without causing any side effect, thus providing a cheaper source of feeding. The study has shown that raw and processed *Delonix regia* seeds contain anti nutrients hence the need for detoxification before feed to the animal.

ABSTRACT

Six dietary treatments were formulated. Diet 1, 2 and 3 contained 200g kg-1 soya bean meal (SBM), wheat bran (WB) and rice bran (RB), respectively. Diets 4, 5 and 6 were the same as 1,2 and 3 but contained a multi-enzyme complex supplemented at the rate of 4g kg-1 diet. Each dietary treatment was fed to three weaner pigs and each pig served as a replicate for 42 days with daily performance measurement. Faecal sample were collected and analysed for nutrient digestibility calculations using standard procedures. Data were analysed using descriptive statistics and ANOVA at α0.05. Irrespective of enzyme addition or not, FI and feed efficiency of pigs on the SBM and WB diets were similar (P>0.05). Pigs on the RB diet had significantly higher FI than those on the SBM and WB diets. Enzyme supplementation had no effect on FI and feed efficiency. Daily weight gain was similar in pigs on the 3 diets without enzyme. Enzyme supplementation resulted in significantly higher daily weight gain in pigs on the RB diets compared to those on the SBM and WB diets. Crude fibre digestibility was significantly higher in pigs on the RB diet with or without enzyme supplementation. SBM resulted in significantly higher digestibility of ether extract with or without enzyme supplementation while similar results were obtained for CP and ash digestibility in RB diet. The use of exogenous multi-enzyme supplementation in rice bran diet can be recommended as alternative to soya bean meal diet.

Key words: Enzyme, Fibre sources, Growth, Nutrient Digestibility, Swine

INTRODUCTION

Pork production is a major segment of animal husbandry which involves the raising and breeding of pigs principally for food and sometimes for their skin. Pigs have short generation interval with rapid fecundity and good carcass yield of about 70% as compared to other livestock such as cattle, sheep and goats. Pigs have 15000 taste buds as against 9000 in humans (Ikani *et al.,* 1976) enabling them to eat everything edible including higher levels of dietary fibre diets. This has greatly expanded the range of feed resources for pigs (Ikani *et al.,* 1976). This new development also poses a new challenge in the level of nutrient availability to pigs as these dietary fibre contain antinutritional factors known as Non-starch polysaccharides (NSPs).

Soluble non- starch polysaccharides (NSP) have been reported to have antinutritional effect and cannot be degraded by young pigs due to their inability to synthesize NSP enzymes (Omogbenigun *et al*., 2004). These NSPs are prevalent in most of the conventional feed stuffs such as wheat, barley, rye, corn and soybean used in pig feed. Non-starch polysaccharides such as α-galactomanans and α-1,6-galactosides are antinutritional compounds in soya bean meal, which are still present even after heat processing. Arabinoxylan is the antinutritional compound found in maize while hemicellulose and hexosane are present in wheat, barley bran, cereals and legumes. Owing to decreased fibre content and high nutrient digestibility, it has been more challenging to obtain beneficial effect for corn and soya bean meal diets through the use of exogenous enzyme supplementation. Graham *et al.* (1988) suggested that a combination of different enzyme activities is required for the degradation of complex NSP and improve nutrient utilization. The objective of this study was to investigate the effect of an exogenous multi- enzyme supplementation in the diet of grower pigs containing soya bean meal (SBM), wheat bran (WB) and rice bran (RB).

MATERIALS AND METHODS

The experiment was carried out in the piggery unit of the Teaching and Research farm of the University of Ibadan, Ibadan. Nigeria. Eighteen large white weaner pigs of approximately 6kg initial weight were sourced from the farm. The pigs were de-wormed and other routine vaccination given to them. They were weighed and randomly distributed into pens with three pigs per treatment and one pig per pen serving as replicate in a completely randomized design

The experimental diets comprised of 6 treatments. Diet 1 was a corn soyabean meal (SBM)-based diet which served as the control and without enzyme supplementation. Diets 2 and 3 contained wheat bran (WB) and rice bran (RB) respectively also without enzyme supplementation. Diets 4, 5 and 6 contained SBM, WB and RB as in the first 3 diets but with a multi-enzyme (α Amylase 800,000 UA/Kg, Protease 8,000,000 U.P/Kg, Xylase 500,000 U.X/Kg, β-Glucanase 300,000 BG/Kg, Cellulase 700,000 U.C/Kg, Lipase 20,000 U.C/Kg, Fructo oligosaccharides (FOS) 1,000g and Moisture 5%) which was added at the rate of 4 g/kg diet. The nutrient composition of the experimental diets is shown in Table 1. Clean water and feed were provided *ad libitum* for 42 days.

Table 1: Nutrient composition of experimental diets (g/Kg DM) fed to weaner pigs for 42 days

Nutrient	Without Enzyme			With Enzyme		
	Soya bean meal	Wheat bran	Rice bran	Soya bean meal	Wheat bran	Rice bran
Metabolisable Energy, kcal/kg	2907.55	2587.15	2889.55	2906.21	2585.81	2888.21
Crude Protein, g/kg	172.82	158.82	163.57	172.78	158.78	163.83
Calcium (Ca), g/kg	6.89	6.92	6.86	6.89	6.92	6.86
Total Phosphorus (P), g/kg	5.18	6.62	7.43	5.18	6.62	7.43
Non-Phytate (NPP)	2.43	2.52	2.62	2.43	2.52	2.62
Ca:P	1.33	1.04	0.92	1.33	1.05	0.92
Ca:NPP	2.83	2.74	2.62	2.83	2.74	2.62
Crude Fibre	24.38	40.62	41.93	24.37	40.61	41.92

One kilogram of feed was measured to each pig across treatments daily. For daily feed intake determination, the left over per day was subtracted from the one kilogram of feed fed. Average daily weight gain was obtained by dividing the average final weight of the pigs by the duration of the trial (42 days).. The feed efficiency was calculated by dividing the total weight gain by the total feed intake. During the last 5 days, faeces were collected from each pig kept individually in metabolic cages for proximate analysis and calculation of nutrient digestibility.

Data obtained were analysed using the General Linear Model (GLM) procedures of SAS (2008) and means were compared using Duncan's multiple range test of the same package at α0.05.

RESULTS AND DISCUSSION

Growth performance of weaner pigs fed soya bean meal, wheat bran and rice bran diets with or without multi-enzyme

The results of the performance of the pigs are presented in Table 2. For both the group with and without enzyme inclusion, similar trend was recorded as feed intake of pigs fed rice bran (RB) diets was observed to be significantly higher than in those on the soyabean meal (SBM) diets though both were statistically similar to the feed intake of pigs fed wheat bran (WB) diets. The feed efficiency of pigs fed SBM diet with enzyme inclusion was significantly higher than those fed WB diet with enzyme inclusion. but both were similar to the feed efficiency recorded for pigs on other four diets. Similar observation was noted for the average daily weight gains of the pigs fed the experimental diets. The weight gains of pigs fed RB diet with enzyme, SBM diet with enzyme, RB diet without enzyme and WB diet without enzyme were observed to be significantly higher than those fed SBM diet without enzyme and WB diet with enzyme. The results showed that there was no significant difference in feed intake among the treatments but only in the fibre source. Rice bran among the three fibre sources was significantly consumed above SBM but there was no significant difference between RB and WB. This might be due to the desire of the pigs to meet their energy demand. The results also showed that there was no significant difference in the weight gain of the pigs in the six dietary treatments for the six-week trial. This is in line with the findings of Shyama *et al.* (2011) who found no significant difference in weaner pigs fed phytase- supplemented diets. Morcherla (2013), also observed no significant weight gain of grower pigs after substituting xylanase and phytase in their diet. Increased average daily weight gain as a result of enzyme supplementation has been reported by Omogbenigun *et al*. (2004). Conversely, Cervantes *et al*. (2004) reported no significant difference

between SBM diet and WB diet supplemented with enzyme on average daily weight gain of weaner pigs.

Table 2: Growth performance of weaner pigs fed soya bean meal, wheat bran and rice bran diets with or without multi-enzyme

Parameters (Kg)	Without enzyme			With enzyme			SEM
	Soya bean meal	Wheat bran	Rice bran	Soya bean meal	Wheat bran	Rice bran	
Initial body weight	6.33	6.67	6.67	6.00	6.00	5.67	0.52
Feed intake	33.6^{b}	36.3^{ab}	39.4^{a}	32.9^{b}	33.0^{ab}	38.6^{a}	1.44
Feed efficiency	0.41^{ab}	0.43^{ab}	0.39^{ab}	0.48^{a}	0.37^{b}	0.42^{ab}	0.02
Average daily weight gain	0.33^{b}	0.37^{a}	0.37^{a}	0.38^{a}	0.30^{b}	0.42^{a}	0.03

Nutrient Digestibility of weaner pigs fed soya bean, wheat bran and rice bran with or without enzyme supplementation

The results of nutrient digestibility are presented in Table 3. There was a significant difference ($P<0.05$) in crude protein (CP) digestibility among the treatments. Rice bran had the highest CP digestibility which was significantly higher than values for the other diets. Crude fibre digestibility of rice bran diet without enzyme was significantly higher when compared to other diets. Digestibility of ether extract in soyabean meal with or without enzyme was higher than in rice bran but similar to that of wheat bran. The ash result also showed a significant difference in digestibility of mineral among the treatments without enzyme supplementation over the enzyme supplemented diets. Energy digestibility was neither affected by diet type nor enzyme supplementation.

Table 3: Nutrient Digestibility of weaner pigs fed soya bean, wheat bran and rice bran with or without enzyme supplementation

	Without enzyme			With enzyme			SEM
	Soya bean meal	Wheat bran	Rice bran	Soya bean meal	Wheat bran	Rice bran	
Crude Protein	69.4^{b}	70.6^{b}	72.9^{a}	67.8^{c}	59.8^{d}	74.0^{a}	0.83
Crude Fibre	24.4^{b}	12.7^{c}	41.9^{a}	11.2^{c}	10.0^{c}	25.3^{b}	2.63
Ether Extract	76.3^{a}	72.9^{ab}	71.6^{b}	81.9^{a}	78.3^{ab}	70.4^{b}	1.52
Ash	36.9^{ab}	29.3^{b}	42.0^{a}	10.0^{c}	11.0^{c}	14.2^{c}	2.75
Energy	92.1	91.9	92.0	91.6	91.9	91.9	0.09

The result of CP digestibility is in line with Traylor *et al*. (2001) and Cervantes *et al.* (2004) who found no significant difference in crude protein digestibility after substituting the diet with enzymes. Crude fibre (CF) digestibility also did not follow a regular pattern across the treatment but CF digestibility was significant in diets without enzyme supplementation above each alternative diet with enzyme supplementation. This may be due to incompatibility of the enzyme to the fibre sources thereby resulting in a negative digestibility of CF. Soyabean meal showed a significant ether digestibility above RB. This may be due to a more soluble ether from SBM above RB. Energy digestibility was high and not significant across the treatments. This might be attributed to the high soluble energy diet used.

CONCLUSION

From the present study, exogenous multi-enzyme supplementation has succeeded in increasing the average daily weight gain of the weaner pigs but has also not succeeded in making any significant increase in the nutrient digestibility of the conventional feedstuff used in this experiment. Considering the result of this study and alternative fibre source for low cost production, the use of exogenous multi-enzyme supplementation in rice bran diet can be recommended.

Abstract
The increasing price and seasonal scarcity of maize, a major conventional livestock feedstuff in Nigeria, has prompted research into the possibility of replacing it with potential feed resources such as chinchin waste, that are of little or importance to humans. The feed intake (FI), weight gain (WG), feed conversion ratio (FCR), protein efficiency ratio (PER), specific growth rate (SGR) of one hundred and fifty-day old broiler chicks fed diets containing chinchin waste meal (CWM) was investigated for thirty-five days in a completely randomized design. CWM was fed at 0%, 12%, 24%, 36% and 48% levels of inclusion as a replacement for maize. Each dietary level of inclusion represented a treatment and replicated three times. Results revealed that CWM significantly (P<0.05) depressed FI, but had no significant (P>0.05) influence on WG, FCR, PER, and SGR of the birds. Hence, CWM can replace maize in the diets of broiler chicken without compromising their growth. Birds fed diets containing 36% CWM had the best performance, therefore, the inclusion of CWM at 36% level is hereby recommended.

Keywords: Chinchin waste meal, broiler chicken, growth response, substitute, maize.

Introduction

Poultry production is a vital and extremely important aspect of livestock production which deals with the raising of domesticated birds such as chicken, turkey, duck and guinea fowl, for their meat and eggs. It is an important subsector in agriculture that accounts for 25% of the agricultural Gross Domestic Product (GDP) of Nigerian economy (FAOSTAT, 2007). Poultry production is one of the major sources of animal protein (meat and eggs) to man; it is also a source of employment and income, source of manure useful for crop production as well as for research purpose (Atteh, 2004).

Broiler production is a fast growing poultry enterprise in the country accounting for about 35% of the meat consumed by man in the world (Esonu *et al.*, 2006; Sharif *et al.*, 2012). Broiler production takes the second position in the worlds volume just after pork (Yang and Jiang, 2005), and due to its short growth interval, has imparted so greatly on the supply of protein (Oluyemi and Robert, 2000). Poultry farmers have been challenged over the years by various production problems, among which are disease outbreak, poor biosecurity measures, resistance of livestock to drugs and many more, but the most challenging problem is high feed cost, as it covers over 70% of the total cost of production, hence it is a major determinant of profit in poultry industry (Lawrence *et al*., 2008).

Maize is the major source of energy in livestock feed but it is expensive due to its seasonal availability and its increasing use as food, feed and industrial raw material (Dairo, 2008). Therefore, extra effort should be made by researchers to source for other feed resources that are of little or no importance for use by man and thereby reducing the feed cost in the process (Onigemo and Anjola, 2013). Chin-chin is a fried snack well known in West Africa. It is a crunchy doughnut like baked or fried dough of wheat flour and other customary baking items such as butter, milk and eggs (Akubor, 2004). It is a traditional snack in Nigeria made mainly of wheat flour and its other ingredients to form a stiff paste thereby attaining the chosen shape (slant cylindrical or crumb) afterwards fried into a golden brown crisp (Adegunwa *et al*., 2014). It is mainly eaten for pleasure instead of nutritive purpose (Matz, 1993).

Chin-chin waste is a waste generated in the process of production and comprises particles that dissociate from dough and/or fried mixture immersed in the oil used for frying the products which is suggestive of high energy value. This project was therefore designed and executed to evaluate the growth performance of broilers fed chin-chin waste in a bid to determine its suitability as alternative feed resource in poultry production.

Materials and Methods

The study was carried out at the teaching and research farm of the Animal Production Technology Department, Lagos State Polytechnic, Ikorodu. Chin-chin wastes were obtained from a major distributor in Ikorodu, Lagos State and mix with other feedstuff in a pre-formulated manner as shown in Table 1. The experimental diets were fed to broiler chicks in a completely randomized design feeding trial with five treatments, T1(Maize Control diet), T2 (12% CMW), T3 (24% CMW), T4 (36% CMW) and T5 (48% CMW). One hundred and fifty (150) day-old broiler chicks of average weight of 37.5±1.06g were randomly assigned to the five dietary treatments replicated three times with ten birds per replicates. Prior to the arrival of the birds, the brooder house was washed, fumigated and sealed with polythene sheet and litter materials (wood shavings) was spread on the floor of the brooder house and pre-heated. The feeders and drinkers were washed with antiseptic, rinsed and shade dried. The birds were brooded intensively in deep litter pens under the same experimental condition and fed *ad-libitum* with the respective experimental diets for five weeks. All necessary management, medication and vaccination practices were strictly observed throughout the five weeks of the study. Data on feed intake and weight gain were collected weekly. Specific growth rate (SGR), feed conversion ratio (FCR) and protein efficiency ratio (PER) were determined as follows:

i. $$SGR = \frac{\text{Naturaln log of final weight} - \text{Naturaln log of Innitial weight}}{\text{Time}}$$

ii. $$FCR = \frac{Average\ feed\ intake}{Average\ body\ weig\ ht\ gain}$$

iii. $$PER = \frac{\text{Weight gain (g)}}{\text{Protein intake (g)}}$$

Table 1: Composition of experimental diet

Feed Ingredient	Experimental diet				
	T1	T2	T3	T4	T5
Maize	48	36	24	12	0
Chinchin	0	12	24	36	48
Corn offal	18	18	18	18	18
Full fat soya	7	7	7	7	7
Fishmeal	2	2	2	2	2
Groundnut cake	18	18	18	18	18
Blood meal	5	5	5	5	5
Bone meal	1	1	1	1	1
Limestone	0.4	0.4	0.4	0.4	0.4
Salt	0.25	0.25	0.25	0.25	0.25
Premix	0.25	0.25	0.25	0.25	0.25
Detoxyzme	0.1	0.1	0.1	0.1	0.1
Determined analysis					
Gross energy (Kcal/kg)	3855.44	4526.83	4613.71	4689.60	4828.78
Dry matter	87.50	88.50	89.50	88.00	89.00
Crude protein	22.43	22.68	22.87	23.23	23.58
Ether extract	6.00	16.00	17.00	20.00	21.00
Ash content	4.00	5.00	3.50	5.00	4.00
Crude fibre	3.22	2.89	2.57	2.24	1.92
Nitrogen free extract	41.85	42.43	43.56	38.03	38.50

The proximate analysis of the feed was determined using the methods of AOAC (2010), while the gross energy was determined using IKA® WERKE Calorimeter system, C 2000 control high pressure bomb calorimeter.

All data collected were subjected to analysis of variance (ANOVA) and significantly different means were separated using the multiple range test of Duncan. All statistical analysis was done using Assistat-Statistical Assistance 7.6 Beta software developed by Silva and Azevedo (2016).

Results and Discussion

Table 2 shows the performance of broiler chicks fed with chinchin waste based diet. The statistical analysis revealed that there was significant difference (P<0.05) in the level of feed consumed. Birds fed with experimental diet T2 consumed (59.91g) more than those on other diets while diet T5 consumed the least (50.28g). The significantly lower feed intake by T5 may be due to higher energy content in the feed, since, feed consumption is negatively correlated with metabolizable energy content of the diet (Nahashon, *et al*., 2006; Ball, *et al*., 2013; Zhai, *et al*., 2014). The weight gains of the birds fed with the experimental diets was not significantly (P>0.05) different, birds in T1 (21.07g) having the highest weight gain followed by birds on diets T2, T3, T4 and T5. The lowest weight gain observed in T5 might be due to the lowest feed intake recorded in this group of birds. Reduced feed intake has been reported to reduce weight gain in broilers birds (Leeson *et al*., 1996; Zhai, *et al*., 2014). Statistical analysis shows that there was no significant difference (P >0.05) in the feed conversion ratio among the birds. The feed conversion ratio of birds fed with T2 (2.92) had the highest numerical value followed by T4 (2.88), T5 (2.77), and T1 (2.71) while T3 (2.68) has the lowest. Statistical analysis revealed that there was no significant difference (P>0.05) between the protein efficiency ratio of the birds. The lowest protein efficiency ratio was observed among the birds in T4 (1.49) while the highest was found among birds on T1 (1.66). Statistical analysis revealed that there was no significant difference among the treatments for specific growth rate, the T4 birds (6.78) had the highest growth rate followed by T3, T5 while T1 and T2 has the lowest. Growth has been reported to be a function of feed consumption and increase in weight gain in broiler chicken (Carre and Meda, 2015).

Table 2: Growth Performance of Broilers Fed with Chinchin Waste Meal (0-6 Weeks)

Variables	Experimental diets					SEM
	T1	T2	T3	T4	T5	
Feed intake (g/bird/day)	56.73[a]	59.91[a]	54.52[ab]	57.27[a]	50.28[ab]	1.6
Weight gain(g/bird/day)	21.07	20.62	20.31	20.14	18.61	0.42
Feed Conversion Ratio	2.71	2.92	2.68	2.88	2.77	0.05
Protein Efficiency Ratio	1.652	1.52	1.61	1.49	1.54	0.03
Specific Growth Rate	6.53	6.52	6.59	6.78	6.55	0.05

NB: T1→ Maize Control diet, T2 →12% CMW, T3→24% CMW, T4→36% CMW, T5→ 48% CMW.

Conclusion and Recommendation

Chinchin waste significantly (P < 0.05) depressed the feed consumption of the birds fed with varying levels of chinchin waste, however, the weight gain, feed conversion ratio, protein efficiency ratio, and specific growth rate of the birds were similar to the maize based control diet. Therefore, chinchin waste could completely replace maize in the diets of broiler chicken without compromising their growth and its use in broiler diets is hereby recommended.

Abstract

A total of 18 grower rabbits were allotted to 3 dietary groups of six (6) animals in a completely randomized design (CRD) to determine the dietary effect of mixed saw dust as a substitute for wheat offal on organ weight changes of grower rabbits. Each group was replicated thrice consisting of two animals per replicate. Sawdust was substituted with wheat offal at 0% 5% 10% respectively. The result showed that they were significant (P<0.05) differences in the value of live weight, lungs and heart while there were no significant (P>0.05) differences in liver, kidney and testicle across the dietary treatments. However, the highest value of liver (1887) was recorded in diet 2 while the lowest live weight (1288g) was recorded in diet 3. The value obtained for liver, kidney and testicles followed a similar pattern across the dietary treatments. Rabbits on diet 1 recorded the highest value (1.15g) of lungs while the lowest value (0.70g) of lungs was recorded in diet 3 (10% substitution level). The highest (0.37g) of heart was recorded in diet 2 while the lowest value (0.23g) of heart was recorded in diet 3. The highest value of kidney (0.70g) and liver (3.77g) were recorded in diet 3 while the lowest value of kidney (0.60g) and liver (2.54g) were recorded in diet 1(control) and diet 2 respectively. It could be concluded that mixed sawdust is good alternative feed resources that could be effectively used in diet grower rabbits and at 10% conclusion level without adverse effect on the internal organs of the rabbit

Introduction

The increasing demand for animal protein coupled with more stringent economic conditions have encouraged greater interest in fast growing animals with short generation interval. Fetuga, (1997) reported on the disappointing rate and level of performance in the livestock industry in Nigeria. Thus he attributed, among other factors, to high cost of feeds arising largely from fluctuations in feed supplies, rising prices of ingredients, poor quality feeds, inefficiency in production and distribution in the feed industry. One of the cheapest producers of meat that can easily fit into the wider segment of the population but which has been neglected in Nigeria is the rabbit. The rabbit has the ability to convert feedstuff such as forages, most agricultural by-products, kitchen waste etc. that human being cannot consume directly into highly nutritious meat. Rabbits are highly prolific, cheap to feed because they can utilize roughage feeds, they have rapid growth rate, high dressing percentage, short gestation period and low purchasing price. However, efficient rabbit production is largely dependent upon adequate and correct nutrition (Standford, 1979). . In recent years, there have been renewed interests in the use of non-conventional ingredients in feeds formulation for livestock. Standford, (1979) reported that, there is a wide range of feedstuff on which rabbits can live on. Therefore, alternative feed sources need to be investigated such as, sawdust. However, its potentials as an animal feed supplement have not been properly documented in Nigeria. Studies in the management of sawdust as waste are not new in Nigeria, but most of these studies have had their focus on utilizing the waste as a soil amendment material, with promising results. Ibrahim, (2001) had attempted a study on exploring the potentials of sawdust as a livestock feed, and the results have been encouraging.

Materials and methods

Experimental site: The experiment was carried out at the Teaching and Research Farm, Oyo State College of Agriculture & Technology Igboora, Nigeria. Which is located within 7° 15° North and 3° east of the equator with annual temperature of 27°c (Sanusi, 2011).

Experimental Ingredient: The saw dust used in the experiment was obtained from the local saw mill at Igboora, Oyo State.

Experimental Design

A total of 18 grower rabbits were allotted to 3 dietary group of six (6) animals in a completely randomized design (CRD), each group was replicated thrice of two animals per replicate. Sawdust were substituted with wheat offal at 0% 5% 10% respectively.

Table 1: GROSS COMPOSITION OF EXPERIMENTAL DIET

INGREDIENTS	T1 (0%)	T2 (5%)	T3 (10%)
Maize	20.00	20.00	20.00
SBM	16.00	16.00	16.00
C/Bran	39.00	39.00	39.00
W/O	20.00	19.00	18.00
MSD	0.00	1.00	2.00
Bone meal	2.00	2.00	2.00
Limestone	2.00	2.00	2.00
Lysine	0.25	0.25	0.25
Methionine	0.25	0.25	0.25
Salt	0.25	0.25	0.25
Grower Premix	0.25	0.25	0.25
Total	**100**	**100**	**100**

Key: SBM= Soya bean meal, C/BRAN= corn bran, W/O = wheat offal, MSD= mixed sawdust. **Internal organs** evaluation: At the end of the 8th weeks of the experiment, two rabbits per treatment were selected in each treatment and used for international organs evaluation. The animals were slaughtered via the neck region; it was defured, detached, dressed and cut into parts each of the weight part were recorded. Internal organs measured were liver, kidney, heart, lung, spleen and stomach.

Statistical Analysis: Data obtained in the study were subjected to statistical Analysis of Variance, mean value of variables showing significant ($P<0.05$) difference were separated using Duncan's multiple range test (Duncan; 1955)

Results and discussion

Results

The result showed that they were significant ($P<0.05$) difference in the value of live weight, lungs and heart while there was no significant difference in liver, kidney and testicle across the dietary treatment. However, the highest value of liver (1887) was recorded in diet 2 while the lowest live weight (1288g) was recorded in diet 3. The value obtained for liver, kidney and testicles follow a similar pattern across the dietary treatments. Rabbits on diet 1 recorded the highest value (1.15g) of lungs while the lowest value (0.70g) of lungs was recorded in diet 3 (10% substitution level). The highest (0.37g) of heart was recorded in diet 2 while the lowest value (0.23g) of heart was recorded in diet 3. The highest value of kidney (0.70g) and liver (3.77g) were recorded in diet 3 while the lowest value of kidney (0.60g) and liver (2.54g) were recorded in diet 1(control) and diet 2 respectively.

Discussion

There were significant difference (P<0.05) in the value recorded for internal organ of grower rabbit across the dietary treatments. The result negate the finding of Ogungbero *et al*., (2016) which reported that there were significant (P<0.05) difference in all internal organs of broiler fed experimental diet except liver which showed that the rabbit fed (10% mixed sawdust) recorded the highest value (3.77g) of liver. This result support Akinwusi *et al*., (2017) who reported an increased organ weight in rabbit fed 10% cashew nut meal based diet. The grower rabbit fed diet 1 recorded the lowest kidney value (0.60g) while the highest value (0.70g) was obtained in grower rabbit fed diet 3. This can be attributed to the increased in the activity of kidney enzymes to detoxify the available anti-nutritional factor present in the text ingredient.

Table 2: Internal organ of rabbit fed mixed saw dust as a substitute for wheat offal

Parameters	T_1 (0%)	T_2 (5%)	T_3 (10%)	SEM
Live weight	165.53^{ab}	1653^{ab}	1288^{bc}	144.19
Kidney	0.60	0.68	0.70	2.53
Liver	2.96	2.54	3.77	2.70
Lungs	1.15^{a}	0.95^{ab}	0.70^{a}	1.05
Testicles	0.12	0.10	0.15	1.23
Heart	0.24^{c}	0.37^{a}	0.23^{bc}	3.59

Conclusion and recommendation

Conclusion

Based on the result of this research, it could be concluded that mixed sawdust is good alternative feed resources that could be effectively used in the diet of grower rabbits and at 10% conclusion level without adverse effect on the internal organs of the rabbit.

Recommendation

Based on the result of this research, it could be recommended that: mixed sawdust be included in the rabbit ration up to 10% replacement levels. Since sawdust could effectively replace wheat offal in diets for grower rabbits. Which is an unconventional feed resource to enhance high profitability of the business.

Abstract

A study was conducted to evaluate the growth performance and haematological indices of weaner rabbits fed varying levels of Saccharomyces cerevisiae. Thirty two weaner rabbits were weighed and randomly allocated into four treatment groups (T1, T2, T3 and T4) having eight rabbits per treatment. Each treatment was replicated four times with two rabbits per replicate. Treatment 1 served as the control and did not contain Saccharomyces cerevisiae supplement, while treatments 2, 3 and 4 contained 1, 1.5 and 2 g/kg of basal diet respectively of Saccharomyces cerevisiae supplement. The experiment lasted ten weeks. Results showed that there were no significant (p>0.05) differences among treatments in initial body weight and feed conversion ratio while average daily feed intake (ADFI), and average daily weight gain (ADWG) were significantly (p<0.05) affected. The study revealed significantly (P < 0.05) higher ADWG in the rabbits of treatment groups T2, T3 and T4 compared to the control group (T1). Lowest ADFI and haemaglobin concentration were recorded in T1. The packed cell volume of rabbits in T3 and T4 are significantly (p<0.05) higher than those of T1 and T2. The red blood cell count of rabbits in T4 was significantly (p<0.05) higher than those of other treatment groups. The total white blood cell count of rabbits in T2, T3 and T4 were significantly (p<0.05) higher than that of T1. The mean corpuscular volume, mean corpuscular haemaglobin, and mean corpuscular haemaglobin concentration were not significantly (p>0.05) affected. In conclusion dietary inclusion of Saccharomyces cerevisiae had effect on the rabbits. Based on the results obtained 2g/kg of Saccharomyces cerevisiae is recommended.

Keywords: *Saccharomyces cerevisiae*, growth performance, haematological indices, rabbits.

Introduction

The increasing demand for animal protein in Nigeria has stimulated great interest in the rabbit as a fast growing animal with short generation interval (Aduku and Olukosi, 1990). It has also been reported that rabbit meat plays an important role in the prevention of vascular disease due to extremely low cholesterol and sodium levels (Aduku and Olukosi, 1990).

Low level of antibiotics has over the years been used in rabbit production as growth promoters and prophylactic agents against diseases (Falcão-E-Cunha *et al*., 2007). However, the unreasonable use of antibiotics as a growth additive has given rise to a fear of the development of resistant bacteria (Aarestrup *et al*., 1998) that may lead to the transfer of resistant bacteria and its resistant factors from animals to humans (Stanton, 2013). Hence, non-antibiotic alternatives like *Saccharomyces cerevisiae*, a probiotic are being used in rabbit feed to improve growth and production performance.

Inclusion of live yeast in animal feed has been shown to improve the digestibility, efficiency of feed utilization, and performance of animals (Martin *et al*., 1989). Blood parameters are major indices of physiological, pathological and nutritional status of livestock. Haematological components are of great diagnostic importance in monitoring feed toxicity, especially feed constituents that may affect the formation of blood. The study was designed to evaluate the effect of dietary inclusion of *Saccharomyces cerevisiae* on growth performance and haematological indices of weaner rabbits.

Materials and Methods

The study was carried out at the Rabbit unit of the Department of Animal Science Teaching and Research Farm, University of Nigeria, Nsukka. The study lasted ten weeks. Thirty two weaner rabbits were used for the study. The rabbits were weighed and randomly allocated into four (4) treatment

groups having eight (8) rabbits per treatment in a completely randomized design. Each treatment was replicated four (4) times with two (2) rabbits per replicate. Treatment 1 served as the control and did not contain any *Saccharomyces cerevisiae*, while treatments 2, 3, and 4, contained 1, 1.5, and 2 g/kg of basal diet. The weaner rabbits were fed with a formulated ration of 16% CP. The percentage composition of the formulated ration is shown in table 1. Clean water and feed were provided *ad libitum*. The rabbits were housed in individual cages.

The rabbits were weighed at the beginning of the experiment to determine their initial body weights. Body weights of the rabbits were measured on a weekly basis. Daily feed intake was obtained from the difference between the quantity of feed offered and that of the left over from the previous day divided by the number of rabbits per replicate. Feed conversion ratio (FCR) was then calculated as quantity (gram) of feed consumed per unit (gram) weight gained over the same period.

At the end of ten weeks of the experiment, four rabbits were randomly selected from each treatment. Five mls of blood was collected from the ear vein of each rabbit using a sterilized syringe and emptied into sterilized sample bottles containing the anti-coagulant Ethylene Diamine tetra acetic acid (EDTA) for laboratory analysis to determine hematological indices. The packed cell volume (PCV) was determined by the microhematocrit method (Thrall and Weiser, 2002). The haemoglobin concentration (HB) was determined by the cyanomethaemoglobin method (Higgins *et al*., 2008). The red blood cell (RBC) and the total white blood cell (WBC) counts were determined by the haemocytometer method (Thrall and Weiser, 2002). The mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) were calculated using the standard formula (Schalm *et al*., 1975).

Data collected were subjected to analysis of variance in a completely randomized design as described by Steel and Torrie (1980). Significant differences between treatment means were separated using Duncan's New Multiple Range Test (Duncan, 1955).

Table 1: The percentage composition of the formulated diet

	% composition			
Ingredients	T1 (control)	T2 (1 g/kg)	T3 (1.5 g/kg)	T4 (2 g/kg)
Maize	36.9	36.9	36.9	36.9
Wheat offal	27.9	27.9	27.9	27.9
Soybean meal	10.57	10.57	10.57	10.57
Palm kernel cake	8.10	8.10	8.10	8.10
Oyster shell	4	4	4	4
Bone meal	2	2	2	2
Brewers dry grain	10	10	10	10
Vitamin premise	0.25	0.25	0.25	0.25
Salt	0.25	0.25	0.25	0.25
Total	100	100	100	100

Results and Discussion

The effects of different levels of dietary inclusion of *Saccharomyces cerevisiae* on growth performance of weaner rabbits are shown in Table 2. Significant ($p<0.05$) differences existed in the average daily weight gain (ADWG), and average daily feed intake (ADFI) while there were no significant ($p>0.05$) differences among the treatments in initial body weight, and FCR. The study revealed significantly ($P < 0.05$) higher ADWG in the rabbits of treatment groups T2, T3 and T4 compared to the control group (T1). Rabbits in T2, T3 and T4 had similar ADWG. The ADFI of rabbits in T3 and T4 are similar but these were significantly ($p<0.05$) higher than those of T1 and T2. Lowest ADFI was recorded in T1.

Table 2: Growth performance of rabbits fed varying dietary levels of *Saccharomyces cerevisiae*

PARAMETERS	T1 (control)	T2 (1 g/kg)	T3 (1.5 g/kg)	T4 (2 g/kg)	Probability
Initial body weight(g)	661	674	682	701	0.85
Average. daily weight gain (g)	12.93 [b]	14.82[a]	15.10[a]	15.93[a]	0.04
Average. daily feed intake (g)	51.71[c]	60.01[b]	67.16[a]	68.19[a]	0.03
Feed conversion ratio	3.99	4.01	4.45	4.28	0.10

[abc]Means on the same row with different superscript are significantly different ($p<0.05$).

The result is in agreement with the findings of Onafide *et al* (1999) who observed higher feed intake and weight gain between *Saccharomyces cerevisiae* treatment groups and control group. The result of the present study is in conformity with Chang *et al*. (2001) who reported increased weight gain in *S. cerevisiae* supplemented group compared with control group. The improved weight gain in the present study could be attributed to enhanced feed consumption and absorption of nutrients due to addition of *S. cerevisieae* (Chiofalo *et al*., 2004).

The effects of different levels of dietary inclusion of *Saccharomyces cerevisiae* on haematology of weaner rabbits are shown in Table 3. Significant ($p<0.05$) differences existed in the HB, PCV, RBC and Total WBC count while there were no significant ($p>0.05$) differences among the treatments in MCHC, MCH and MCV. The HB of rabbits in T3 and T4 are similar but these were significantly ($p<0.05$) higher than those of T1 and T2. Lowest HB was recorded in T1. The PCV of rabbits in T3 and T4 are similar but these were significantly ($p<0.05$) higher than those of T1 and T2. The RBC of rabbits in T4 was significantly ($p<0.05$) higher than those of other treatment groups. Lowest RBC was recorded in rabbits in control group. The total WBC count of rabbits in T2, T3 and T4 were similar but these were significantly ($p<0.05$) higher than that of T1.

Table 3: Haematological indices of weaner rabbits fed varying dietary levels of *Saccharomyces cerevisiae*

PARAMETERS	**T1 (control)**	**T2 (1 g/kg)**	**T3 (1.5 g/kg)**	**T4 (2 g/kg)**	**Probability**
HB (g/dl)	10.13[c]	10.70[b]	11.60[a]	11.57[a]	0.03
MCHC(g/dl)	32.23	31.13	34.21	33.25	0.97
MCH(pg)	19.55	19.55	19.86	23.04	0.55
MCV(fl)	70.87	70.55	70.56	70.88	0.65
PCV (%)	34.67[b]	35.33[b]	37.33[a]	38.00[a]	0.02
RBC ($x10^6$/µl)	5.16 [c]	6.22 [b]	6.19 [b]	7.37 [a]	0.03
Total WBC count($x10^9$/L)	6.15 [b]	7.82 [a]	7.42 [a]	7.90 [a]	0.04

PCV= packed cell volume, MCV= mean cell volume, MCH= mean corpuscular haemoglobin MCHC= mean corpuscular haemoglobin concentration, HB= Haemoglobin concentration, RBC= Red blood cell count, WBC= White blood cell count

[abc]Means on the same row with different superscript are significantly different ($p<0.05$)

The increase in PCV and WBC are in agreement with the findings of Aathour *et al* (2002). The result also conforms to Onifade *et al* (1999) who observed that the RBC, WBC, and PCV of rabbits fed diet supplemented with *Saccharomyces cerevisiae* had a significantly ($p<0.05$) higher value than that of the control group. Increased WBC counts might be related to the production of more immune cells (and thus antibodies) that play an important role in defending the biological system against different diseases. However, the result obtained in this study is in contrast with Shehu *et al*. (2013) who reported that yeast inclusion in the diet of weaner rabbits did not affect HB, RBC and PCV.

Conclusion and Recommendation

In conclusion dietary inclusion of *Saccharomyces cerevisiae* had effect on the rabbits. Based on the results obtained in this study T4 (diet containing 2g of *Saccharomyces cerevisiae* /kg of the diet) was recommended as the most favourable diet.

Abstract
Two popular strains of crossbred local chickens were used in the study for the purpose of establishing the fundamental growth information, from hatch to the age of sexual maturity at 22 weeks. A total of 200 birds comprised of equal number of males and females were used. Similar sigmoid growth curves and patterns were exhibited in their growth performance. A phase of accelerated growth observed reached a point of inflection (POI) at the ages of between 8 and 9 weeks. The POI coincides with the maximum growth rate which then starts to decline until maturity. Male birds were observed to be significantly superior to females from week 8 onwards, the superiority being most apparent between weeks 9 and 15 when significant differences in body weight gains were also observed. Two factorial designed was used, and ANOVA was the statistical tool.

Key words: crossbred**,** growth performance, local chicken, Point of inflection, popular strains,

Introduction

In poultry species, the phases of growth are generally characterized by an accelerating growth phase following hatch, a point of inflection (POI) coincide with maximum growth rate, a growth phase of declining rate, and a limiting mature weight which is approached asymptotically (Anthony *et`al* 1991). Within this general growth pattern, most of the differences in the shape of the growth curve among common poultry species such as the quail, chicken and turkey occurred between hatching and the POI (Anthony *et`al* 1991).

Engku azahan *et`al*. (2006) identified four phases of growth over a growth period of 16 weeks for the relatively slow-growing meat-type local (Village) chicken, based on body weight and feed conversion ratio. In breeding works, growth and growth rate would also provide useful information on the timing of selection studies (Mignon-Grasteau *et`al* 2000; Deeb and Lamont, 2002, Sengul and Kiraz, 2005). This study was carried out with the main objective of gathering fundamental growth information on the current strains of indigenous chicken, whilst concurrently evaluating differences between sexes.

Material and Methods

A total of 200 newly-hatched crossbred local chicks from two strains, Zaria in Kaduna and Wurno in Sokoto, were used in the study. Commercial feeds and water were provided ad libitum. Brooding heat was provided by kerosene stove for the first two weeks. The birds were weighted on day one for their initial weight; they are also weighted weekly until the age of 22 weeks when all pullets had laid at least an egg. This age was regarded as the age of sexual maturity for both male and female birds. Individual weekly body weight gains were calculated together with data on body weight. Two factorial designed was used, and ANOVA was the statistical tool.

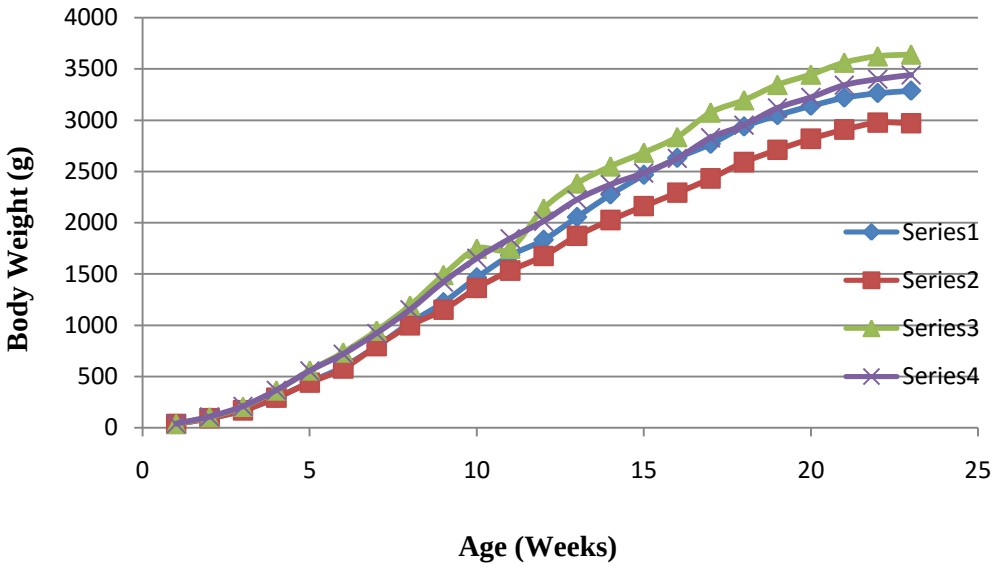

Figure 1. Growth curve of ِenous (local) chicken

Results and Discussion

In the research sigmoid curve of the growth pattern as described by Brody (1945) was observed for both strains of local chickens (Figure 1). After hatching, a period of accelerating growth was exhibited until the POI which was reached at between the 8th - 9th weeks, which coincide with the maximum growth rate. Growth rate was then seen to decline until all birds reached the age of sexual maturity at 22 weeks. The shape of the curves for the two local chicken strains was similar, although for different poultry species this could be markedly different (Knizetiva *et`al,* 1995). A difference in the shape of the growth curves was observed to be noticed mainly between hatching and POI (Tzeng and Becker 1981; Zelenka *et`al* 1986). The age of the POI was observed to be constant in both sexes of the chicken. In fast growing and early maturing poultry and chicken strains the POI may be reached at much younger ages. For chickens, turkeys, geese and ducks POI at ages of 21.1, 25.5, 47.7 and 74 days, respectively, have been reported (Knizetovo *et`al* 1995). For both strain and sex, a continuous increased in body weight were observed from day one until week 21-22. In the first seven weeks there was no any apparent superiority of one sex over the other but from eight weeks onwards, males were observed to be heavier ($p<0.05$) than females for both strains (Table 1). Similar reports of male superiority had been observed for Japanese native chicken breeds (Goto *et`al* 2010). This indicated the effect of sex-linked growth genes in chickens as similarly observed in geese (Knizetovo *et`al* 1994). Weekly growth rate increased gradually from week 1 until week 8, reaching peak at the 8th week for both strains. After the POI, growth rate was immediately observed to decline and was relatively stable from week 10 until the birds reached maturity age at 21-22 weeks. A common feature observed for the two strains was that from weeks 9-15, males gained significantly more than females except in week 11 when the difference was not significant.

Conclusion and Recommendations

Indigenous (local) chickens exhibited growth curves which were typically sigmoidal. The point of inflection coincides with maximum growth. In terms of body weight, males were significantly superior to females from week 8 onwards, the superiority being most apparent between week 9 and 15 when significant difference in body weight gain were also observed. It is recommended that more research to be conducted on the same breed and strain on their egg production performance.

Table 1: weekly body weight (g/bird) of two strain of indigenous chicken from hatch until sexual maturity (means ± std. error).

	Zaria strain		Wurno strain	
Age	Male	Female	Male	Female

ABSTRACT

A study aimed at investigating the response of broiler chickens fed dietary levels of maize offal at both starter and finisher phase. Proximate analysis were conducted and the results reveal that maize offal contain ME - 3253.11 Kcal/kg, DM - 10.46, CP - 10.98, CF - 8.68, EE - 3.10, Ash - 3.19, and NFE-72.08%. Five diets were formulated in which maize replaced wheat offal at 0, 25, 50, 75 and 100% levels designated as T1, T2, T3, T4 and T5 respectively. Throughout the experimental period, birds were fed ad libitum. Two hundred and fifty day old Anak 2000 breed of broiler chickens were used for the experiment. The feeding trial indicated that birds fed diet 1 had a significantly (P>0.05) lower average daily weight (27.19g) than other treatments at the starter phase but no significant (P>0.05) difference were observed on daily feed intake, and feed conversion ratio. At the finisher phase, there was no statistical (P>0.05) difference on daily feed intake, daily weight gain and feed conversion ratio of the birds. The feed cost in naira per kg and feed cost per kg decreases with increased level of maize offal. Diet 5 recorded the least feed cost of N112.09/kg and the highest cost savings of N103.60. It can therefore be concluded that, maize offal can replace wheat offal in the diets of broiler chickens at 100% level without adverse effect on performance, with a notable reduction in feed cost by 32.4 %.

INTRODUCTION

An advanced knowledge of poultry nutrition is not, by itself alone, an assurance that the management of poultry will be profitable. However, a fair knowledge of poultry nutrition will definitely promote the efficiency of management operations and in fact, many cases of business failure can be traced to poor feeding of the birds (Oluyemi and Roberts, 2013). Poultry birds especially broilers plays a significant role in the provision of animal protein required by man to meet his daily protein intake (Maidala and Istifanus, 2012). Daily protein intake in Nigeria is 6.5 grams per capital per day (Marquist, 1985) Maximum production of mono-gastric animals like poultry, which does not require a long period of time to mature with minimum space can meet this requirement. High cost of conventional feed stuff most especially protein and energy sources has been one of the major challenges of intensive poultry production in developing countries like Nigeria (Ani, 2008). The purpose of the study was to assess the replacement value of maize offal for wheat offal.

MATERIALS AND METHODS

Site of study: This study was conducted at the Abubakar Tafawa Balewa university Poultry Teaching and Research Farm Bauchi, Bauch state. Nigeria.

Chemical Analysis

A sample of maize offal was analysed for proximate composition according to the methods of the Association of Official Analytical Chemists (AOAC,2004) for determination of
ME Kcal/kg, and percentage CP Ash, EE,CF and NFE. The result is on table 3..

Experimental Birds and Management

Two hundred and fifty day old Anak 2000 breed of broilers were used for the study. The chicks were brooded for 4 weeks and vaccinated against Gumboro and New castle diseases. At first week, the birds were fed with commercial diet. On the 8th day, the birds were randomly alloted into 5 dietary treatments described as treatments l, 2, 3, 4 and 5 (0, 25, 50, 75 and 100% maize offal respectively, consisting of 50 birds per treatment and each treatment had 3 replicates, consisting of 16 or 17 birds per replicate.. Throughout the experimental period, feed and water were provided ad libitum

Experimental Diets:

Five experimental diets were formulated, and maize offal replaced wheat offal at 0, 25, 50, 75 and 100% level called diets 1, 2. 3, 4 and5 respectively. The ingredients used for the experiment were locally procured. The composition of starter and finisher diets are presented on table 1 and 2.

Total weight gain (kg)	1.99	2.42	2.52	2.51	2.74
Feed cost/kg gain (₦)	319.60	234.50	231.60	234.67	216.00
Cost saving (₦)	0.00	85.10	88.00	84.93	103.60

CONCLUSION

Base on the results obtained in the experiment, the following conclusions were drawn:

The replacement of wheat offal for maize offal in broiler's diets improved feed utilization and did not in any way compromise performance, with a reduction in feed cost.

Abstract
A 49 days study was conducted to examine the impact of Bitter leaf (Vernonia amygdalina) and Catmint leaf (Nepeta racemosa) meal supplement on performance, organ, carcass characteristics and meat quality of broiler from day old. 150 day old unsexed Abor-Acer broiler chicks were randomly allotted into five dietary treatments using completely randomized design experiment (CRD). Each treatment was replicated thrice with 10 chicks per replicate. Five experimental diets were formulated such that Diet 1 contained neither bitter leaf nor catmint leaf meal, diet 2 contained 5g of catmint leaf meal per kg feed, Diet 3 contained 5g of Bitter leaf meal per kg of feed, Diet 4 contained 2.5g each of bitter leaf and catmint leaf meal per kg of feed while Diet 5 contained 5g each of both bitter leaf and catmint leaf meal per kg of feed. The result of performance characteristics showed significant differences (P<0.05) only at feed intake and feed conversion ratio. No significant difference (P>0.05) was observed on the carcass parameters except at the thigh proportion, while proventiculus, pancreas, spleen and liver were significant (P< 0.05) among the organs. The meat quality was significantly (P<0.05) decreased in term of Colour, Flavour, Juiciness, Tenderness and General acceptability, only bitter leaf compete well with the control. It could therefore be concluded from the study that Bitter leaf and its mixture with catmint leaf meals can be included as supplements in broiler diet up to 5g/1kg at both the starter and finisher phase.

Key words: Catmint, Bitter leaf, Supplement, Broiler

Introduction
Feed additives are ingredients added to poultry diets to enhance feed utilization, improve health, promote growth and reduce morbidity as well as mortality (FAC, 1998). Hence, feed additives are added to diets for reasons other than supply of nutrients to the animals. The economic benefit of plant based feed additive has been the lowering of production cost as a result of their availability in our natural ecosystem and their affordability. These plant materials with bioactive ingredients could be used in diverse forms. Recently, plant based feed additives also known as phytogenic have been advocated to be included in broiler feed as growth promoting feed additives since they do not have residual effects (Ndelekwute *et al*.,2015). Phytogenic can improve the consumption and conversion of feed, the digestibility and weight gain of broiler chickens (Cardoso *et al*., 2012). Bitter leaf (*Vernonia amygdalina*) is a shrub or small tree that grows throughout tropical Africa. It is popularly called bitter leaf because of its abundant bitter principle (Ekpo *et al*., 2007). Proximate composition of *Vernonia amygdalina* shows a chemical composition of 527.83 ME kal/kg, 86.40% DM, 21.50% CP, 13.10% CF, 6.80% EE, 11.05% Ash and the result composition of mineral indicate that *Varnonia amygdalina* has 3.85% Calcium, 0.40% Magnesium, 0.03% Phosphorus, 0.06% Iron, 0.33% potassium and 0.05% sodium (Owen 2011). Research has shown that *Varnonia amygdalina* has some beneficial effects in disease management of poultry, such as anti-coccidiosis, anti-bacteria and anti-parasitic (Dakpogan, 2006), also as an anti-oxidant (Erasto *et al*., 2017) and as a growth promoter by enhancing the gastro intestinal enzymes thus increasing feed conversion efficiency (Huffmum *et al*., 1996; Olobatoke and Oloniruha, 2009).
Catmint (*Nepeta racemosa*) contains about 150 species and is largely in the horticulture as ornamental plant. A short essential oil of catmint containing *Nepeta lactonces* is largely responsible for the plants biological activities including lived perennial herbaceous plant, is perhaps the best known species, long recognized as the plant that induces a state of euphoria and stupor in domesticated cats (Clapperton *et al*. 1994; Herron 2003). Catmint has many reported benefits as herbal supplements for both lives stock and man; some of these include treatment for anxiety, insomnia, Coccidiosis and antistress (Debborm *et al*., 2016). The two beneficial plants were therefore investigated to determine their potential as feed supplements and growth promoters in broiler production.

Materials and Method

The experiment was carried out at the Teaching and Research Farm of Ladoke Akintola University of Technology, Ogbomoso, Oyo State, Nigeria and lasted for 49 days. The catmint leaf (*Nepeta racemosa*) and bitter leaf (*Vernonia amygdalina*) were sourced from Ladoke Akintola University of Technology, Ogbomoso's farm. The leaves were rinsed with clean water in order to remove foreign materials, and were air dry on a drying slab for 7 days and slightly sundried for 30 minutes, then ground into meal. The meals were kept in air tight containers till commencement of the experiment. A total of one hundred and fifty (150) day old unsexed Abor-Acre broiler chicks were brooded for 10 days and randomly divided into 5 dietary treatments of three replicates per treatment in a completely randomized design. Each replicate had 10 chicks. The chicks were managed on deep litter pens for seven weeks by providing *ad-libitum*, fresh and clean water and weigh quantity of feed when necessary. All routine and occasional management practices were strictly adhered except medication activity that was ceased for those on supplements. The control diet (T1) contained no bitter leaf and catmint leaf meal while diets 2, 3, 4 and 5 (T2, T3, T4 and T5 respectively) contained bitter leaf and catmint leaf meals at 5g of catmint leaf meal (CLM) per kg feed, 5g bitter leaf meal (BLM) per kg feed, 2.5gBLM + 2.5g CLM per kg feed and 5gBLM + 5g CLM per kg feed. Data were collected at the end of every week. Daily feed consumption, body weight gain and feed conversion ratio were monitored. At the end of the experiment the birds were weighed and two birds per replicate were slaughtered for carcass evaluation. Data collected were subjected to analysis of variance (ANOVA) using the general linear model of SPSS, 2010.

Results and Discussion

The performance of experimental birds was presented in Table 1. There were significant difference ($P<0.05$) in mean values obtained from the total feed intake, the average daily feed intake and feed conversion ratio while other growth parameters were not significantly influenced ($P>0.05$) however, only T3 (5g/kg bitter leaf) had feed conversion ratio compare favorably well to control and was in agreement with the report of Tangka (2003). Mohammed and Zakariya'u (2012) used bitter leaf meal at varying levels ranging from 300g to 900g per 100kg from starter phase and reported no significant difference in live weight and the bitter leaf significantly reduced feed intake which was attributed to the high level of the bitter leaf which could have made the feed unpalatable. Similar weight gain at a reduced feed intake resulted to various better feed conversion ratio reported.

T2; 5g of catmint/kg feed, T3; 5g of Bitter leaf/kg, T4; 2.5g/kg each catmint and bitter leaf, T5; 5g/kg each of catmint and bitter leaf.

Table 2 show the carcass characteristics of broiler chicken fed experimental diets supplemented with bitter leaf and catmint leaf meals. All parameters measured under carcass characteristics were not significantly ($P>0.05$) different except proportion of thigh. The proportion of primal cuts was numerically enhanced by the bitter leaf meal supplement (breast proportion). Combination of catmint and bitter leaf at 2.5g/kg of feed gave the best live weight. This is in line with the report that inclusion of bitter leaf in broiler diets leads to improvement in body weight, dressing percentage and carcass quality (Chiemela *et al*., 2015). The hypolipidaemic effect of bitter leaf that ensured the development of leaner meat, could be responsible for better conversion of feed nutrients to meat (Vivian *et al* 2015), as it was observed in the proportion of breast meat of this finding.

Table 2: Carcass characteristics of broiler chicken fed with Bitter leaf and Catmint Supplement

PARAMETERS	T1	T2	T3	T4	T5	SEM
Live weight	1816.33	1768.75	1857.75	1892.75	1748.00	32.43
Carcass weight	1393.00	1218.50	1326.75	1231.25	1167.33	26.20
Carcass (%)	76.52	68.89	71.42	70.34	66.78	0.61

Thigh (%)	18.53^{a}	17.19^{b}	17.12^{b}	16.01^{c}	16.42^{c}	0.24

[ab] means along the same row with different superscripts are significantly different (P<0.05)
T2; 5g of catmint/kg feed, T3; 5g of Bitter leaf/kg, T4; 2.5g/kg each catmint and bitter leaf, T5; 5g/kg each of catmint and bitter leaf.

Table 3 showed the organ parameters of birds fed with different supplements at varying levels. Significant differences (P<0.05) were recorded from mean proportions of Proventiculus, Spleen, Liver and Pancreas. Others (lungs, Hearth and gizzard) were not (P>0.05) significant. The variation or increase in their size recorded from organs, (especially liver at T2) obtained from treatments with supplements may be as a result of extra activities of the organ, like detoxification process to get read of excess phyto-chemical compounds inherent in the materials.

Table 3: Organ characteristics of broiler chicken fed with Bitter leaf and Catmint supplements.

Parameters	T1	T2	T3	T4	T5	SEM
Proventiculus(%)	0.482^{c}	0.767^{a}	0.583^{bc}	0.690^{ab}	0.591^{bc}	0.28

[abc] means within row having different superscripts are significant different (P<0.05)
T2; 5g of catmint/kg feed, T3; 5g of Bitter leaf/kg, T4; 2.5g/kg each catmint and bitter leaf, T5; 5g/kg each of catmint and bitter leaf.

Colour, Flavour, juiciness, Tenderness and General acceptable were significant (P< 0.05). The two additives did not support meat quality and only T3 was less affected and similar (P<0.05) to the control in term of meat colour, tenderness and general acceptability. Meat quality was significantly (P<0.05) affected by feed supplementation with catmint and bitter leaf meals (Table 4). All birds placed on catmint (either only or together with bitter leaf) were more affected in term of meat quality measured. Among those fed with supplements, only 5g/kg of feed, bitter leaf had similar quality with the control, indicating that these leaf supplements had negative impact on the organoleptic properties of chicken meat.

Table 4: Meat Quality of broiler chicken fed with Bitter leaf and Catmint supplements.

Parameters	T1	T2	T3	T4	T5	SEM
Colour	7.20^{a}	4.60^{c}	7.20^{a}	5.90^{b}	5.50^{bc}	0.177
Flavour	7.30^{a}	5.10^{b}	6.00^{b}	5.20^{b}	5.00^{b}	0.190
Juiciness	6.50^{a}	6.00^{ab}	6.50^{a}	6.10^{ab}	5.20^{b}	0.159
Tenderness	6.10^{ab}	5.30^{b}	6.50^{a}	6.70^{a}	5.60^{ab}	0.171
General acceptable	7.50^{a}	6.00^{bc}	6.70^{ab}	6.30^{bc}	5.20^{c}	0.193

[abc] means along the same row with different superscripts are significant different (P<0.05)
T2; 5g of catmint/kg feed, T3; 5g of Bitter leaf/kg, T4; 2.5g/kg each catmint and bitter leaf, T5; 5g/kg each of catmint and bitter leaf.

Conclusion and Recommendation

The result of this study has shown that catmint leaf and bitter leaf meal could be used to substitute antibiotics. However, catmint and bitter leaf meal supplement only numerically enhance(s) the growth rate of birds and can be utilized as natural growth promoters because of its non-residual effects. Addition of 5g/kg of bitter leaf meal to diets of broilers positively influenced growth and feed intake,

improve the carcass, organs and meat quality of broiler chicken. However, higher utilization level of Catmint leaf meal and Bitter leaf meal supplements above 5g/kg can be investigated in the broiler diet. This will help establish their potentials in reducing the production cost with normal medication potential.

EVALUATION OF VARYING LEVELS OF SUNDRIED CASSAVA STARCH EXTRACT PULP ON SERUM ENZYMES OF BROILER STARTER

Raji, M.O., Akinosun, A.A., and Mosobalaje, M.A
Department of Animal Health and Production Technology, Oyo State College of Agriculture and Technology, PMB 10, Igboora
Correspondence Author: papat4u@gmail.com 08052433781 and 07087089847

A feeding trial was conducted for four (4) weeks to evaluate the effect of feeding varying levels of sun dried cassava starch extract pulp on serum enzymes of broiler starter. It was carried out at Teaching and Research Farm, Oyo State College of Agriculture and Technology Igbo-ora, Nigeria. Two hundred (200) day-old cobs 500 were randomly allocated to five dietary treatments designated as (T1 (0%), T2 (10%), T3 (20%), T4 (30%), and T5 (40% respectively) of 40 birds each, replicated four (4) times with 10 birds per replicate in a completely randomized design (CRD). At three weeks of feeding trials, 3 ml blood was collected per replicate into plane bottle and transferred to the laboratory for assay, thereafter, it was subjected to statistics analysis. The result obtained showed that there were no significant differences (P>0.05) in Aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alanine phosphate (ALP). AST ranged between 175.67 to 189.33U/l, ALT ranged between 19.00 to 26.00 U/l while ALP gave values between 199.00 to 290.33U/l. Conclusively, Sun dried cassava starch pulp can be included to replace maize as source of energy in broiler diets without affecting serum enzyme of broiler. Base on outcome of this study, s Sun dried cassava starch pulp can be recommended to replaced maize up to 40% inclusion levels in the broiler diets and higher level of inclusion of sun dried cassava starch pulp above 40% can be carried out to ensure at what maximum level it can be included in broiler diets.

Keywords: Broiler, cassava starch pulp, serum enzymes, energy and inclusion

Introduction

As cassava starch production increases, a large volume of waste by-product like cassava starch pulp is also generated. Cassava starch pulp is the solid, moist by-product of cassava starch manufacture and comprises approximately 10-15% of the original root weight. The pulp is reported to contain between 1.7-2.8%, 1.6-2.0%, 13.6-27.8 and 0.1% ash, crude protein, crude fibre and ether extract respectively (Khempaka *et al*., 2014). The fibre of CP exists mainly as insoluble fibre. Suksombat *et al*. (2007) reported 36.7% neutral detergent fibre, 9.8% acid detergent fibre and 3.9% acid detergent lignin in CP. Kosoom *et al*. (2009) The high starch content of cassava pulp would make it a useful alternative energy source for poultry feedstuff. It's extremely low protein, bulkiness, dustiness and high fiber content may be the main factors that currently limit its use in poultry feed. Khempaka *et al*. (2009) reported that although dried cassava pulp can constitute up to 80 g/kg of broiler diets, the higher levels result in decreased growth performance and nutrient digestibility. Therefore, the objective of this study is directed toward investigating effect of varying levels of sun dried cassava starch extract pulp on serum enzyme of broiler starter.

Materials and methods

The experiment was carried out at the poultry unit, Teaching and Research Farm, Oyo State College of Agriculture and Technology, Igboora, Oyo State Nigeria, latitude $7^{o}15`N$ and longitude $3^{o}30`E$ with average annual rainfall of 1278mm and average temperature of $27^{o}C$ (Sanusi, 2011). The fresh cassava starch pulp was procured from Saltry starch processin industry, along Iseyin-Maya road, Oyo State. It was sundried on polythene nylon for 5 days and then taken to the laboratory for laboratory assay. The chemical composition of sundried cassava starch extract pulp was determined in the laboratory by using (AOAC, 2010) method. The metabolizable energy was calculated as described by Puazenga (1985), (37 x CP) + (81.8 x CF) + (35.5 x NFE). Nitrogen free extract (NFE) was calculated using the following formula; 100 – (CP – CF – Fat – Ash - MC). CP= Crude protein; CF= Crude fibre; NFE= Nitrogen free extract; MC = Moisture content.

Experimental diets

The birds were given formulated feed from day 1-8 before experimental diets. Thereafter, five diets were formulated having percentage crude protein that ranged between 20.70% - 22.15% with energy ranged between 2893.35ME kcal/kg – 2979.30ME kcal/kg. Maize was the main energy source for the control diet while the other four dietary treatments 2, 3, 4 and 5 was substituted with sundried cassava starch extract pulp at 10%, 20%, 30% and 40% nutrient to nutrient inclusion rates respectively.

Experimental birds and management

The 200 birds were randomly allocated to five dietary treatments, 40 birds per treatment consisting of 4 replicates with 10 birds each in a completely randomized design (CRD). The birds were fed *ad-libitum.* The dietary treatment was at inclusion levels of 0%, 10%, 20%, 30%, and 40% inclusion rate and designated as T1, T2, T3, T4 and T5 respectively. T1 was the controlled diet while the T2, T3, T4 and T5 were maize and sundried cassava starch extract pulp diet.

Statistical analysis

Data collected were subjected to analysis of variance (SPSS, 2012). Means were separated by using Duncan multiple range test of the same software

Table 1: Percentage composition of broiler starter (day 7-5 weeks)

Ingredients (kg)	T1 (0%)	T2 (10%)	T3 (20%)	T4 (30%)	T5 (40%)
Maize	51.00	45.90	40.80	35.70	30.60

Methionine (%)	0.63	0.55	0.54	0.53	0.52

SDCSP : sundried cassava starch extract pulp

Result: The results were on Table 3. There were no significant differences (P>0.05) in Aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alanine phosphate (ALP). AST ranged between 175.67 to 189.33U/l with least value of 175.33 in treatment five (40SDCSP %) while highest value was obtained in treatment four (30SDCSP%). ALT ranged between 19.00 to 26.00 U/l with least value of 19.00 from treatment five (40% SDCSP) while highest value of 26.00U/l was obtained from treatment four (30% SDCSP). ALP gave values between 199.00 to 290.33U/l, least value (199.00) of ALP was obtained in the treatment five (40% SDCSP) while highest value of 290.44U/l was recorded from treatment three (20% SDCSP).

Table 3: Serum enzyme of broiler starter fed dried cassava starch pulp (0-5 weeks)

Parameters	TI (0%)	T2 (10%)	T3 (20%)	T 4 (30%)	T5 (40%)	SEM
AST (U/l)	176.33	187.00	182.33	189.33	175.67	0.33
ALT (U/l)	21.67	24.67	21.33	26.00	19.00	0.00
ALP (U/l)	247.33	264.67	290.33	230.00	199.00	13.65

a,b,c mean with different superscript in a row are significantly different (P<0.05)

AST= Aspartate aminotransferase ALT= alanine aminotransferase ALP= alanine phosphate

Discussion: AST, ALT and ALP were analyzed to determine the toxicology of liver. The values found in this study were within the normal value reported by Coles, 2007. Thrall *et al*,. 2004 reported that an activity of AST greater than 800U/l indicated an sign of severe liver damage The normal range of AST, ALT and ALP in most birds is between 52 – 270 and 65 – 263 U/l respectively (Coles, 2007). These values can vary considerably according to animal species, sex, age and the environment (Coles, 2007). No significant differences among treatment found in this study and the values were in the normal range for poultry ALT is a more specific criterion of liver disorder than AST since the liver is the main tissue (King, 1965). Therefore, this suggests that sundried cassava starch pulp can be used in broiler diets without causing toxicity.

Conclusion: Conclusively, Sun dried cassava starch pulp can be included to replace maize as source of energy in broiler diets without affecting serum enzyme of broiler.

Recommendation: Sun dried cassava starch pulp can be used up to 40% inclusion levels in the broiler diets to replace maize as energy source.

Higher level of inclusion of sun dried cassava starch pulp above 40% can be carried out to ensure at what maximum level it can be included in broiler diets.

Abstract
A 56-day study was carried out to determine the haematological and biochemical characteristics of one hundred and twenty (120) broilers finisher fed varying levels of maggot meal (MM). The experiment was carried out in a completely randomized design (CRD) in which the birds were randomly grouped into four treatments and further replicated three times with ten birds per replicate. Four finisher broiler diets were compounded, incorporating (MM) at 0%, 50%, 75% and 100% respectively. The diets were designated T_1, T_2, T_3 and T_4, respectively, T_1 served as the control (with no MM). The birds were given feed and water ad-libtum and were subjected to similar sanitary and husbandry conditions throughout the experimental period. Data were collected for haematological and biochemical analysis. Statistics result revealed that only red blood cell (RBC), mean corpuscular haemoglobin concentration (MCHC), albumin, urea, aspartate aminotransferase (AST) and creatinine showed significant ($P<0.05$) differences, while others showed non-significant ($P>0.05$) differences. Result indicates that maggot meal can completely replace fish meal as a protein source as the birds are physiologically stable.

Keywords*:* Haematological, Biochemical, Maggot Meal and Broilers

Introduction

Nigeria is abundantly blessed with different varieties of animal protein sources yet there is the challenge of insufficient production and supply of animal protein to the fact that daily consumption is less than 10g against minimum requirement. FAO (2006) gave a daily protein requirement of an average adult as 65g/caput/day, of which 35g is expected to be of animal origin. Egbewande (2010) reported that in Nigeria, the available protein is given at 45g/caput/day with animal protein accounting for 8g/caput/day, representing a short fall of about 77% in animal protein recommended by FAO (2006). To bridge the gap, poultry production in general and broiler particularly is a sure way. Broilers have a fast growth rate, better feed conversion ratio; rapid return on investment, the meat contains more protein and essential amino acids than other meats and low in cholesterol content. Feeding alone accounts for 60-70% of the total production cost in modern poultry production systems (Wilson and Beyer, 2000).Conventional energy and protein sources used are heavily competed for, by other livestock, humans, and industries thereby leading to their high prices and minimal returns. Competition for conventional protein sources has prompted researchers to embark on research for alternatives like MM that are cheaply available and comparable to FM. The crude protein content of maggots is high (39-63%) (Aniebo and Owen, 2010) and akin to that of fish meal (Veldkamp *et al*., 2012). Both haematological and biochemical analyses of blood is of great importance in assessing the nutritional effect of feedstuffs on the animals. They serve as diagnostic tools and physiological indicators in birds has been documented (Harr, 2002; Hauptmanova *et al*., 2006). However, these parameters are greatly affected by sex, age and season (Fudge, 2000; Kececi and Col, 2011).This study, therefore, was designed to investigate the haematology and biochemical characteristics of broiler finisher fed different levels of maggot meal.

Materials and Methods

The research was carried out at the poultry project site of the Federal College of Agriculture, Ishiagu Ebonyi State. The maggot used for this experiment was cultured from fresh chicken manure. After about 5 days, larvas of maggots were produced. They were harvested, oven dried at 55^0C for one day and were grinded into maggot meal and were incorporated at different inclusion levels in the diets of broilers. One hundred and twenty (120) day old chicks were used for the experiment. They were randomly allocated into four treatment diets with thirty birds each and were replicated three times with 10 birds per replicate in a Completely Randomized Design (CRD). Four levels of diets were formulated 0%, 50%, 75% and 100% representing T_1, T_2, T_3 and T_4 respectively.

Blood Collection for Hematological and Biochemical Analysis.

At the end of the feeding trial, about 5mls of blood sample was collected for the analysis. The blood samples were taken from the wing vein of the bird using disposable needle and syringe. Blood samples were collected from two (2) birds per replicate ie six birds per treatment. For haematological analysis, about 2mls used for analysis was stored in a bottle containing anticoagulant, ethylene diamine tetra acetic acid (EDTA) to prevent clotting and subsequently analyzed to determine RBC, white blood cell(WBC), packed cell volume(PCV), haemoglobin(Hb), mean corpuscular volume(MCV) and MCHC. For serum biochemical analysis, about 3mls was used. It was store without anticoagulant, after coagulation it was separated and the harvested sera were used to determine the following parameters urea, total protein, albumin, AST, alanine aminotransferase (ALT) and creatinine.

Data Collection and Analysis

Data collected for haematological and biochemical parameters were analyzed using analysis of variance (ANOVA) as described by Steel and Torrie (1980) and differences among means were separated using least significant differences (LSD).

Statistical Model

The statistical model for CRD is shown below

Yij = μ□ + ti + eij□

μ□ = overall mean effect

ti = true effect of the ith treatment

eij = error term of the jth unit receiving ith treatment

Table 1: Composition of Experimental Diet

Ingredients	T_1 (0%)	T_2 (50%)	T_3 (75%)	T_4 (100%)
Maize	60.40	60.40	60.40	60.40
Maize offal	13.00	13.00	13.00	13.00
Fish meal	6.00	3.00	1.50	0.00

Results and Discussion

Table 2: Haematological Parameters of Broiler Finisher Fed Different Levels of Maggot Meal

Parameters	T_1 (0%)	T_2 (50%)	T_3 (75%)	T_4 (100%)	SEM
Hb (g/dl)	8.16	7.80	10.77	11.50	9.17
PCV (%)	24.50	23.40	32.33	34.50	6.92
WBC ($x10^3$mm)	6.93	7.27	7.87	6.67	0.69
RBC ($x10^6$μl)	3.20^a	3.20^a	2.90^c	3.10^b	0.32
MCV (fl)	76.67	72.00	111.33	111.00	27.10
MCHC (g/dl)	32.90^b	33.10^a	32.70^{cd}	32.83^c	0.61

Table 2 showed the haematological characteristics of broiler finisher fed different levels of maggot meal. MCHC and RBC showed significant differences ($p<0.05$), while Hb, PVC, WBC and MCV showed non-significant differences ($p>0.05$). The effect of diet on haematological parameters of broilers as reported in Table 2 showed that treatment groups had significantly higher values at 75% and 100% inclusion of maggot meal for Hb, PCV and MCV. Furthermore, the RBC result showed that

birds fed control diet (T_1) and 50% (T_2) had significantly ($p<0.05$) higher values than others. MCHC result showed that birds on 50% (T_2) had significantly ($p<0.05$) higher values when compared to other treatments. Furthermore, all the values obtained for the haematological parameters in this study were within their normal range (Bounous and Stedman 2000) except for WBC values that falls slightly below the normal range (12-30 x 10^3µl). The WBC values reported is at variance with that (53.25-56.00 10^3L) of Mahmud *et al.* (2016).

Table 3: Biochemical Characteristics of Broiler Finisher Fed Different Levels of Maggot Meal

Parameters	T_1 (0%)	T_2 (50%)	T_3 (75%)	T_4 (100%)	SEM
Total protein (mg/dl)	3.73	2.80	3.40	3.13	0.52
Albumin (mg/dl)	1.57^a	1.30^c	1.43^b	1.43^b	0.16
AST (Iu/l)	297.00^a	286.00^b	275.67^c	211.67^d	75.35
ALT (Iu/l)	47.00	24.33	16.67	20.33	18.08
Urea (mg/l)	2.90^a	2.57^c	2.03^{cd}	2.80^b	3.68
Creatinine (mg/dl)	1.03^c	1.07^b	1.07^b	1.13^a	0.30

Table 3 showed the biochemical characteristics of broiler finisher fed different levels of maggot meal. Albumin, AST, urea and creatinine showed significant differences ($p<0.05$), while other parameters total protein, globulin and ALT showed non-significant differences ($p>0.05$). Albumin, AST and urea results showed that birds on control diet T_1hadhighly significant values ($p<0.05$) than others. The highest value (3.73g/dl) of total serum protein was observed in T_1 (0%) inclusion of MM, while the least value (2.80g/dl) was obtained in T2 (50%) inclusion. Serum protein values fluctuate across the treatments. Albumin, AST and urea values differed significantly ($P<0.05$) higher among the treatments. Albumin, AST and urea highest values (1.57g/dl, 297.00 Iµ/l and 2.90 mg/l) observed in T_1 (0%) inclusion of MM while the least values were obtained in T_2, T_4 and T_3 respectively. Creatinine differed significantly higher ($P<0.05$) among treatment groups. Furthermore, the highest value (1.13mg/dl) was observed in T_4 (100%) inclusion of MM, while T_1 (0%/ control diet) had the least value. The result followed an increasing trend as the level of MM increases. The result agrees with the findings of Ayorinde *et al.* (2017) that reported (0.89-1.56 mg/dl). Values of both haematological and biochemical parameters obtained in this study were within the normal range. Graded levels of maggot meal did not have deleterious effect on the health of the birds. Maggot meal can completely replace fish meal as the physiological profiles of the birds are stable.

ABSTRACT

A fourty nine days experiment was carried out at poultry unit of Bauchi State College of Agriculture to evaluate the performance of broiler chickens fed varying levels of local fish meal (LFM) diets. Five experimental diets were formulated for both starter and finisher phases. Coded as diets 1 (0%), 2(25%), 3(50%), 4(75%) and 5(100%). Two hundred and ten (210) broiler chickens were randomly allotted to five dietary treatments in completely randomized design. Each treatment was replicated three times with fourteen birds per replicate. The result of this study indicated most of the performance attributes at both starter and finisher phases as well as the overall performance were not significantly influenced by the dietary levels of LFM. However starter phase final weight (575.09-779.65g) were significantly (P<0.05) influenced by the dietary levels of local fish meal. It can be concluded that LFM can completely replace imported one with no adverse effect on the performance attributes.

Key Words: Broiler Chicken, Imported Fish Meal, Local Fish Meal, Varying levels

INTRODUCTION

Poultry production forms an important component of livestock subsector as a provider of employment and income (Eduvie, 2002). Ogundipe and Sanni (2002) reported that, the primary purpose of keeping poultry in all parts of Nigeria is for both dietary and economic reasons. Kekeocha (1994) defined poultry as those species of birds that render economic services to man and produce freely under his care. Animal protein requirement in the developing countries including Nigeria has become critical due to rapid population growth (FAO/WHO, 1973), Yusuf *et al.* (2008) reported that the population in Nigeria is increasing at a rate much higher than that of food production especially with regards to the production of animal protein. The development of poultry industry has been described as the fastest way of ameliorating the animal protein deficiency in the 3rdworld countries due to the short generation interval of domestic fowl, their high feed utilization efficiency, ease of management and small space requirement (Depeolu *et al.*, 2004). Nworgu *et al*. (2000) and Rultu (2004) reported that the current acute shortage of animal protein in Nigeria and the rapidly increasing demand for livestock products could be alleviated through broiler production. Broiler chicken are fast growing strain of birds that are specifically produced for

their meat (Onibi and Bamigboye, 2000). Kosden (2010) described the term broiler as fast growing birds which reach market weight of 1.6 to 2.50kg at 8 weeks. High cost of inputs, most especially feeds and day old chicks limit opportunity and advantages of poultry production in Nigeria as feed utilization accounts for over 70% of the total cost of broiler production (Afolayan *et al*., 2002). The high cost of feed could be attributed partly to animal protein source of which imported fish meal (IFM) is the most common (NSA *et al.*, 2016). The importance of fish meal as feed ingredient, in poultry production is quite enormous. Among the animal protein sources fish meal is particularly suited to meet all the nutrients requirement of animals (Ijaiya and Eko, 2009). The conventional animal protein source (imported fish meal) is expensive and sometimes is unavailable. There is little or no information on the status of performance of broiler chickens fed with local fish meal diets. Therefore, there is needs towards looking for other unconventional animal protein source that could meet the nutritional requirement of the birds, with similar or better performance like local fish meal (LFM).

MATERIALS AND METHODS

Study area

The experiment was conducted at Bauchi state college of agriculture, poultry research unit of the Department of Animal Production Technology, Bauchi. Five (5) experimental diets were formulated for both starter and finisher phases respectively. Local fish meal was included at 0, 25, 50, 75 and 100% replacement levels coded as diets 1,2,3,4 and 5 respectively to substitute the conventional animal protein source (imported fish meal).

Experimental birds

Two hundred and ten (210) day-old broiler chickens were procured from Zartech Company, Ibadan Nigeria. The birds were randomly assigned to five dietary treatments. Each treatment was replicated three (3) times with fourteen (14) birds per replicate in completely randomize design (CRD). Feed and water were given *ad libitum.* All vaccination schedules for broiler chickens were given at appropriate time.

Data collection

Parameters measured were feed intake, weight gain and mortality. Feed conversion ratio was also computed. All the data generated for both starter and the finisher phases were subjected to analysis of variance (ANOVA) as outline by (Steel and Torrie, 1984). Where significant difference was observed, Duncan Multiple Range Test (DMRT) was used to separate the means. Table 1 and 2 shows the percentage and calculated proximate composition of the experimental diets at starter and finisher phases respectively.

Results and Discussion

The performance of broiler chickens at the starter phase presented in table 3 shows that birds on diet 5 (100%LFM) recorded significantly (P>0.05) higher final live weight. Daily feed intake, daily weight gain and feed conversion ratio were not affected by the dietary

treatments similar trend was observed at the finisher phase (Table 4). The results of this study are in agreement with the reports of Ojewola *et al*. (2005) who reported that, there was no significant influence among broiler chickens fed locally processed and imported fish meal diets in relation to performance attributes. The overall performance indicate significant ($P<0.05$) difference in relation to initial weight. This could be due to the significant influence observed at the starter final weight. Overall daily weight gain, feed intake and feed conversion ratio were not affected by the graded levels of local fishmeal in the diets. This findings also agreed with the reports of Ojewole *et al.* (2005) reported no significant difference was observed among broiler chickens fed with locally processed and imported fish meal. Similar results were also obtained by (Akpodiete and Inoni 2000; Ijaiya and Eko, 2009).

Conclusion and Recommendation

This result conclude that local fish meal can replace imported fishmeal up to 100% with better effect on performance attributes. Therefore, it is recommended that farmers should include LMF in formulating their diets to reduce cost of production.

INFLUENCE OF CASTRATION AND DIFFERENT DIETS ON GROWTH PERFORMANCE AND NUTRIENT DIGESTIBILITY OF WEANER RABBITS

Saheed, S., Tsado, D. N., Tiamiyu, S. A., Habu, T., and Habu, T.

DEPARTMENT OF ANIMAL PRODUCTION

FEDERAL UNIVERSITY OF TECHNOLOGY MINNA, NIGER STATE.

ABSTRACT

Twenty four castrate and non-castrate weaner rabbits fed different diets were investigated to determine the growth performance and nutrient digestibility. The rabbits were assigned randomly to four treatments, each with three replicates and two animals per replicate. One hundred grams of feed were offered per rabbit/day and their body weight were taken on weekly basis. Other parameters measured were initial weight, final weight, total body weight gain, average body weight gain, average feed intake and feed conversion ratio. The results shows that castrates had significantly higher values in all growth performance parameters. Apparent digestibility coefficient values shows that castrates had significantly higher values of all parameters measured over the control. It was concluded that castration had significant effect on growth performance and nutrient digestibility of weaner rabbits.

Key words: Rabbits, Castration, Different diets, Performance.

INTRODUCTION

Rabbits are pseudo ruminant animals that do not compete with man for food. The potential of rabbits can be fully maximized in areas where forages are readily available. Forage and cereal by-products can be utilized as the primary source of protein and energy with high level of production (Cheeke, 1986). Rabbits have been reported to be prolific with short gestation period of 30-32 days, producing 4-5 litter per year that consists of 6-8 kitten on the average (Biobaku, 1997). Animal protein supply and consumption is low in Nigeria especially among the low income and nonwage earners (Iyange&Orewa, 2009). The average estimated crude protein requirement of an adult Nigerian is between 65 and 85g per person daily, 35g of which should come from animal source (Adetunji and Adepoju, 2011). Atsu, 2002, put the average consumption of animal protein at 4.5g/head/day as against the 35g/head/day. Castration is one of the management activities practiced in different part of the country. Castrates have better meat quality and they grow faster than entire males. Castration can also be employed in controlling the rapid breeding capacity of rabbits whenever there is a female rabbit as well.

MATERIALS AND METHODS

Experimental location

The study was carried out at Teaching and Research Farm of Department of Animal production Federal University of Technology, Gidan Kwano Campus Minna. Minna is located in the North central zone of Nigeria with the geographical coordination of 9^0 37' North 6^0 33' East. Minna has land area of 6784 km and it is located at the latitude of 1475 m above the sea level in the southern guinea savanna vegetation of Nigeria. Minna is characterized with two different seasons which are the wet season (April to October) and dry season (November to March). The average annual rainfall is between 1100 and 1600 mm and mean ambient temperature ranges from 21°C to 36°C latitude and longitude (Ovimap, 2015).

Experimental Diet

The diets used for the experiment comprise of maize, GNC, maize offal, rice bran, bone meal, Methionine, lysine, premix and salt which are purchased from the local market in Minna town also known as Kure market. *Tridax procumbens* and milk weed was used as part of the experimental diet and was sourced around the Research farm.

Experimental Animal and Design

Twenty four (24) weaner rabbits with an average weight of 960.5gram aged between 10 – 12 weeks were used. The animals were randomly assigned to 4 treatments with 6 rabbits per treatment and 3 replicate with 2 rabbits per replicate. Some of the experimental rabbits were castrated using open castration method. Rabbits in treatment (T_1) were non-castrate and fed concentrate and roughage, T_2 were castrates fed concentrate only, T_3 were castrates fed roughage only, T_4 were castrates fed concentrate and roughage. The animals were sourced from Naij Integrated concept, Oshogbo in Osun state of Nigeria.

Management of animals

The animals were managed under intensive management system in hutches and two animals were kept in a hutch. Concentrate and forage were the main diet offered to animals in each replicate and one hundred grams of feed was served to each rabbit in a day with half ($1/2$) served between 7 – 8am daily and the remaining half was served between 3 – 4 pm daily. Water was also offered ad-libitum throughout the experiment period. Digestibility study was carried out at the end of the experiment.

Data analysis

All the data collected were subjected to analysis of variance (ANOVA) according to Steel and Torrie (1980) using statistical package for social science version 20 (SPSS).

RESULTS AND DISCUSSION

The growth performance characteristics of the experimental rabbits are presented in table 1

The values of final body weight gain of castrates fed concentrate only differ significantly from those of non-castrates (control). Similarly, castrates fed concentrates and forages differ significantly from the control in term of total body weight gain and average body weight gain. In average feed intake, castrates fed forages only differ significantly from those fed the control diets. Castrates generally recorded significant difference in their favour in feed conversion ratio compared to the non-castrates The better performance of castrates over non-castrates in most parameters measured could be as a result of castration. Higher average feed intake obtained by castrates fed roughages only over non-castrates in this study could be attributed to the type of diet and castration. In contrast to this Bello and Adama (2012), reported that the mean feed intake recorded for castrates (goat) was significantly ($p<0.05$) higher than the intact males (1107.1 vs. 1071.2g).

Table 2 showed that Dry matter and crude protein digestibility of castrates are significantly better than the non-castrates. Crude fibre and ash content values of castrates differ significantly from those of non castrates. The nitrogen free extract and total digestible nutrients of castrates fed concentrates only differs significantly from those of non-castrates (control). This agrees with the work of Bello and Adama (2012), who reported that castrates shows higher digestibility value in DM, CP, EE, ASH, and NFE but not in CF. This also agrees with the findings of (Muhikambele*et al*, (1994) who reported that castration significantly affects digestibility.

Table 1: Growth performance of castrate and non- castrates fed different diets

Parameters	T_1	T_2	T_3	T_4	SME	LSD
Initial weight (g)	891.50	1005.50	984.33	918.33	23.64	NS

Key

T_1= Non-castrates fed concentrate and forages.,T_2= Castrates fed concentrate only.,T_3= Castrates fed forages only., T_4= Castrates fed concentrate and forages.

Conclusion

It can be concluded based on the results of this work that:

Castrated rabbits are superior to non-castrates in final body weight gain, total body weight gain, average body weight gain and apparent nutrient digestibility.

Recommendation

From the results gotten from this study, it is recommended that male rabbits not required for breeding programme should be castrated for optimum growth performance and nutrient digestibility.

[3]Department of Animal Science, Ahmadu Bello University, Zaria, Nigeria

Abstract
Brachiaria ruziziensis and *mucuna pruriens* were used as the basal diet for grower rabbits, the forages were finely chopped and fed to rabbits. *Brachiaria ruziziensis* which served as the source of energy to the rabbits was fed at different proportions (100, 75, 50 and 25%) and *Mucuna puriens*, the main protein source in the experimental diet was fed at (0, 25, 50, 25 and 75%) across the four treatments. The feed was given in the morning and at evening and the feed intake was measured by subtracting feed given from left over. Proximate composition of the sole hay and mixtures showed 75:25 *B. ruziziensis* and *M. Pruriens* mixture had crude protein (24.98%) with *B. ruziziensis* having the least crude protein value (10.89%). The consumption of forage at different proportions in the four treatments shows that there is acceptance of *Brachiaria ruziziensis* and *Mucuna pruriens* at a high rate by rabbits. Experimental diet with 50:50 mixture of *B. ruziziensis* and *M. Pruriens* had the highest (74.28g) feed intake ($p<0.01$) when compared to other treatment diets. It is therefore recommended that *B. ruziziensis* and *M. pruriens* be mixed at 50:50 for optimum performance in rabbits.

Introduction
The uses of forages in rabbit feeding is normal practice and rabbit producers are advised to feed forages as a supplement to a basic concentrate diet in order to meet the fiber and some of the vitamin requirement, cost of grains and their by-products have increased dramatically and are often scarce (Nakande *et al*., 2015). Though optimum rabbit production has not been sustained on forages alone using most tropical forages, it is possible to reduce the cost of concentrates in the rations by utilizing forages that are nutrition's and palatable, to achieve a compromise between level of production and cost that is acceptable to producers.

(Aduku *et al*., 1989) conducted some studies on preference of rabbits for different forges, but the vast range of forage species in the tropics has not been properly harnessed for the purpose. Since legumes are high in protein, they have potential to reduce the quality and cost of concentrates for rabbits. However, for rabbits to perform well on forages diets, they need to consume the forages in significant amounts (Amaefule, 2004). This study was undertaken to evaluate the voluntary intake and performance of rabbit fed grass-legume levels of grass-legume mixtures.

Materials and methods
Experimental Site
The research was conducted at the Research and Teaching farm of the Department of Crop production, Faculty of Agriculture, Abubakar Tafawa Balewa University, Bauchi, Yelwa Campus. *Brachiaria ruziziensis* and *Mucuna pruriens* forages were harvested at week 8 from the pasture plot of the experimental site.

Experimental design and Animal management
Twelve (12) rabbits of similar age, breeds and sexes were purchased from Muda Lawal market, Bauchi, Bauchi state. The rabbits were randomly allotted into four (4) dietary treatment groups with three (3) replicates per treatment in a Completely Randomized Design (CRD). The rabbits were individually housed in cages measuring 40 x 40 x 60 cm^3. All the rabbits were given prophylactic

against internal and external parasites (Ivomec® ivermectin at 0.2ml/rabbit) and broad-spectrum antibiotic. The rabbits were provided feed and fresh, clean water *ad libitum* throughout the experimental period which lasted for eight (8) weeks, while feed intake was measured for 7 weeks. Forages offered to the rabbits were chopped into smaller sizes then mixed thoroughly with other ingredients. The experimental diets fed to rabbits were balanced across treatments to meet the minimum crude protein requirement (15%CP) for grower rabbits (Aduku, 1993).

Table 1, shows the percentage of legume and grasses and various composition of feed ingredients. The rabbits were given 100 grams of the experimental diet which was finely chopped to enhance palatability. In treatment 1 (T1) the rabbits were given 100% of *B. ruziziensis*, while in treatment 2 (T2) they were given *B. ruziziensis* 75% and 25% *Mucuna pruriens* also in Treatment 3 (T3) were given 50% proportion of Brachiaria and Mucuna mixture (50.50). In treatment 4, rabbits were fed 100% *Mucuna pruriens* in the experimental diet was chopped and mix with other fixed ingredients

Table 1. Levels of *Brachiaria ruziziensis* and *Mucuna pruriens* in the diet mixtures of Grower rabbits

Ingredients	**T1**	**T2**	**T3**	**T4**
B. ruziziensis	100	75	50	0
M. pruriens	0	25	50	100
Bone	2.5	2.5	2.5	2.5
Salt	0.30	0.30	0.30	0.30
Lysine	0.10	0.10	0.10	0.10
Methionine	0.15	0.15	0.15	0.15
Vitamin premix	0.25	0.25	0.25	0.25
Total	100	100	100	100

T1 = Treatment 1**, T2** = Treatment 2**, T3** = Treatment 3**, T4** = Treatment 4

Feed intake was in the morning and left over were weighted every day. Feed intakes were evaluated by subtracting the left over from the amount of feed offered. The feed convention ratio of daily feed conversion ratio was calculated as the ration of daily feed intake to unit weight gain by grower rabbit. Data for voluntary intake was collected for seven days using the weight scale balance. The feed intake was collected by subtracting the left over from feed offered to get the daily feed intake.

Result and discussion

The various proximate composition of grass and legume as shown in Table 2, indicates that dry matter in *Brachiaria ruziziensis* is 88.93% while the dry matter for *M. puriens* is 92.9%. The crude protein level indicated for the grass *(B. ruziziensis*) is 10.89% and for the *Mucuna pruriens* 24.98%. The table also shows that, the crude fiber for *B. ruziziensis* is 31.63% and for *Mucuna pruriens* as 10.73%. The nitrogen free extract (NFE) for *B.ruziziensis* is 38.56% and *Mucuna puriens* as 50.77%. The ash composition for *B. ruziziensis* is 9.46% while for *M. puriens* is 3.13%.

Table 2: Proximate composition of *Brachiaria ruziziensis* and *Mucuna pruriens* hay

Parameters (%)	***B. ruziziensis***	***M. pruriens***	**75:25**	**50:50**	**25:75**
Dry matter	88.93	92.9	90.1	91.3	92.8
Crude protein	10.89	24.98	22.1	18.2	12.5
Crude fiber	31.63	10.73	28.2	29.5	30.5
Ash	9.46	3.13	12.3	9.8	10.7
Nitrogen Free Etract	38.56	50.77	38.3	45.2	49.1

Table 3**,** shows the feed intake of *B. ruziziensis* and *M. pruriens* by the rabbits for seven weeks (49 days). In treatment one, the quantity consumed by the rabbit has an average intake of 57.86g when fed *Brachiaria ruziziensis* at 100g. Rabbits in Treatment 2 fed with *Brachiaria ruziziensis* at 75% and *Mucuna puriens* 25% had average intake of 61.42 grams and when fed *Brachiaria ruzuziensis* and

Mucuna puriens at 50:50, rabbits in Treatment three (3) consumed 74.2g which had the highest value compared to other treatment diets. In Treatment 4, rabbits fed 25% of *Brachiaria ruziziensis* and 75% *Mucuna puriens* had a relative intake of 55g.

The result obtained in T1 (57.86g) was significantly different from the intake in T2 and T3 but was statisitically at par (P>0.01) with value obtained in treatment (T4). The value for intake was highest in Treatment 3 (74.28g) and lowest in treatment 4 (55g) and was similar to the result obtained by (Iyeghe-Erakpotobo, 2008), in a similar study, but was lower than 120g reported by Aduku (1993) for daily intake of grower rabbits.

Table 3. Feed intake of *Brachiaria ruziziensis* and *Mucuna puriens* by rabbit when offered 100 grams in one allocation for seven (7) weeks

	Relative intake (g) in Weeks							
Feed offered (%)	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**Mean**
Brachiaria ruziziensis 100:0 (T1)	30	40	60	80	55	65	75	57.86[c]
Brachiaria + Mucuna 75:25 (T2)	50	30	40	80	75	80	75	61.42[b]
Brachiaria + Mucuna 50:50 (T3)	80	50	75	90	80	75	70	74.28[a]
Mucuna pruriens 0:100 (T4)	70	60	80	30	40	55	70	55.00[c]

[a,b,c]= Means with different superscript are significantly different **, T1 =** Treatment 1**, T2 =** Treatment 2**, T3 =** Treatment 3**, T4 =** Treatment 4

Conclusion and Recommendation

This study shows that experimental rabbits have preference for the grass-legume mixture in Treatment 3 when the forage mixture was at equal proportion of *Brachiaria ruziziensis* and *Mucuna pruriens* (50:50). The rabbits had the highest feed intake in Treatment 3, compared to other treatment diets. It is therefore recommended that *Brachiaria ruziziensis* and *mucuna pruriens* should be mixed in the diets of grower rabbit at 50:50 ratio for best feed quality and intake in Rabbits.

Abstract:

This study was conducted to determine the effect of orange(OP) and pineapple(PP) peel wastes as replacement for maize in poultry diets. The peels were collected from retailers and sun-dried until a 10 % moisture was obtained. Thereafter, the peels were grounded and mixed with other feed ingredients. The experiment lasted for 70days. One hundred and sixty (160) days old broiler chicks were allocated into four different treatments with four replicates and ten birds (10) each in a complete randomized design. Four diets containing pineapple and orange peels wastes were formulated to replace maize at 0 % (control), 5 % (PP), 5 % (OP) and 5 % (MPO) mixtures respectively. Data on growth performance such as weight gain, feed intake and feed conversion ratio were measured and apparent nutrient digestibility was also determined. Data were subjected to one-way Analysis of Variance (ANOVA); significant means were separated by Duncan's Multiple Range Test at (p<0.05) as contained in the SAS package (2015) version 15.0. The results showed that only the feed conversion ratio (FCR) was influenced by the peels based diets. The dry matter, crude protein, ash, nitrogen free extract and ether extract digestibility were significantly affected (p < 0.05) by the peel-based diets. Birds on the MPO compared favourably with the control in all digestibility parameters measured. It was concluded that broiler birds could tolerate up to 5 % dietary levels of OP, PP meal and their mixture (MPO). without adverse effect.

Keywords – Pineapple peel, orange peel, performance, poultry, digestibility.

INTRODUCTION

In the recent years, crop residue and agro-industrial by products are being evaluated to access their nutritive potential to support poultry productivity (Oluremi *et al*., 2007). A number of agro-industrial by-products are generated from fresh citrus and pineapple after the main products of interest have been removed or extracted during processing or peeled for direct human consumption as it occurs in the developing countries (Oluremi *et al*., 2007). Citrus and pineapple waste disposal is a problem for agro-industrial manufacturing companies. Some of the wastes from fruits processing may be good sources of essential nutrients and, therefore, could be utilized as part of the feed ingredients. If these wastes are properly processed and incorporated in poultry animal rations, these agro-wastes can serve useful purposes by imparting nutrients as well as flavour to the ration and hence increase its palatability and utilization, besides lowering the cost of feed. In Nigeria, all the varieties of orange and pineapple are consumed on a high scale, and the peels are usually considered as wastes and are seen littering the streets and roadsides. As such, orange and pineapple peels have become an environmental problem. It is on this note that Ipinloju (2000) suggested that rather than discarding these peels, they can be sun-dried and then milled to obtain fine-particles of orange and pineapple peel meals which can be included in poultry diets. Some studies were conducted to develop a procedure for converting pineapple waste into animal feed (Sruamsiri, *et al*., 2007; Makinde, *et al*., 2011). Problems related to the fresh form were overcome by the sun drying technique of pineapple peels developed by Aboh, *et al*. (2004) which gave dried peels of good quality.

Objective of the study. To investigate the performance of broiler birds fed sun-dried orange(OP) and pineapple(PP) peels wastes based diets.

METHODOLOGY

The research was carried out at the Poultry Unit of Department of Animal Production Teaching and Research Farm of School of Agriculture and Agricultural Technology, Gidan kwano campus Minna, Niger state. Niger state is located on latitude 10˚00 N and longitude 6˚01 E. Niger State experiences distinct dry and wet seasons with annual rainfall of 1400 mm. The rainy seasons last for about 120 150 days. The temperature is between 30˚C minimum and 34˚C maximum; the humidity is about 53.5

% while the altitude is about 299 m above sea level. Presently, the state covers a total land area of 76,363.0 km ^{2} (Afolayan *et al.*, 2012).

Diet preparation

Pineapple and orange peels were collected from retailers sell points in Minna metropolis, where the retailers peel the fruit for consumers and discard the peels. The peels were sun-dried to attain 10% moisture and milled to obtained pineapple and orange peels meals which were used to replace maize at 0 % (Control) 5 % pineapple peel (PP), 5 % orange peel (OP) and 5 % each of pineapple and orange peels (MPO). The other feed ingredients: soya bean, fishmeal, bone meal, limestone, maize offals, groundnut cake were purchased from Sammy Agro Venture, Nigeria limited, located at U.K Bello way Minna, Niger State. Maize, palm oil and salt were purchased from Central Market Minna, Niger State. The composition of the experimental diets and the nutritive value of the test materials is presented in Table1.and Table 2 respectively.

The Experimental Birds, Design and Managements

One hundred and sixty (160) day old (Ross 308) broiler chicks were purchased from a reputable hatchery (Agrited) in Ibadan which were used for the experiment. The experimental birds were randomly allocated into four dietary treatments namely, T1 (control), T2 (5 % pineapple peels meal), T3 (5 % orange peels meal), and T4 (2.5 % each of orange and pineapple peels meals) at the rate of 40 birds per treatment. Each dietary treatment was replicated four times and had 10 birds per replicate using a completely randomized design. The birds were raised on a deep litter system. Before the commencement of the feeding trial, the Poultry Unit was washed thoroughly with disinfectant (Vinkokill 150ml/25 litres of water) and allowed to dry to prevent the spread of diseases from the previous research. The experimental birds were subjected to brooding with kerosene lamp and charcoal as sources of illumination and heat respectively. Treatment diets and water were administered *ad-libitum*. Routine management practice such as vaccination, drug administration and cleaning of the pens and equipment were carefully applied.

Data Collection

Initial weights were determined at the start of the experiment with the aid of salter weighing scale (SGF 400) balance and thereafter at weekly intervals. The final weight was also taken by weighing the birds in each replicate on the last day of the experiment using the same weighing balance. The weight gain was calculated by subtracting the initial weight from the final weight. In addition, the feed intake was calculated by subtracting the feed remaining from the total feed supplied each day before serving fresh one. The feed conversion ratio was also calculated by dividing feed intake by weight gain. In the last week of feeding trial, a nutrient digestibility trial was conducted using the total collection method. This was done in specially designed metabolism cages having separate watering and feeding troughs. One bird per replicate was selected and placed in a metabolism cage. The birds were allowed to adjust to the conditions in the cages for three (3) days after which total faecal collection was carried out for four days. Dietary feed was weighed and water was served *ad-libitum* daily for 4 days. Total droppings were collected for four days and oven dried daily at 80° C using hot air oven (Gallenkamp 300-inch series) until a constant weight was obtained. The faeces from each treatment were bulked and used for proximate analysis at the Department of Animal Production Laboratory using the procedure of AOAC (2000).

Data Analysis. All data generated were analysed using one-way analysis of variance (ANOVA) and where significant differences occurred, the means was separated using Duncan Multiple Range Test as contained in the SAS package (2015), version 15.0.

RESULTS AND DISCUSSION

The results of the effect of replacement of maize with sun- dried pineapple and orange peels meal-based diets was presented in **Table 3.** The results showed that only the feed conversion ratio (FCR) was influenced ($p<0.05$) by the peel meal-based diets. The feed conversion ratio results showed that birds on T1, T2 and T3 treatments has similar ($p>0.05$) values. Birds on T2, T3 and T4 treatments also had similar ($p>0.05$) values. However, bird on T1diet had better ($p>0.5$) feed conversion ratio than those of T4 treatment. The utilization of sun-dried orange and pineapple peels as a replacement for maize depressed growth of broiler chickens and this negative effect showed that sweet orange and pineapple peels as processed in this study still have a low feed value. It had been reported that sweet

orange and pineapple peels has higher crude fibre content than maize (Oluremi *et al*., 2007). In addition, Nicolakakis, *et al, (*1999) and Ahaotu and Ekenyem (2009) observed that higher dietary fibre depresses weight gain in broiler chickens. The results of the effect of the experimental diets on nutrient digestibility of broiler chickens is presented in **Table 4.** The results showed that dry matter, ash and NFE (Nitrogen free extract) digestibility were influenced ($p<0.05$) by the peels bases diets. However, the crude fibre digestibility was not influenced ($p<0.05$) by the dietary treatments. The dry matter digestibility results showed that birds on T2 and T3 diets had similar ($p>0.05$) values. Birds on T4 treatment had highest dry matter digestibility (83.55 %) value, the least was recorded by birds on T3 diet (78.78 %). The crude protein digestibility values ranged between 69.39 % and 76.22 %. The birds on T1, T3 and T4 had similar ($p>0.05$) values. Similarly, birds on T2, T3 and T4 also had similar ($p>0.05$) values. However, birds on T1 diet had higher ($p<0.05$) CP digestibility. The ash content digestibility ranges from 44.52 % and 64.01 %. The ash content digestibility results showed that birds on T1 and T4 diets had similar ($p>0.05$) values; birds on T2 and T3 diets also had similar. However, birds on T1 and T4 had higher ($p<0.05$) ash digestibility value than birds on T2 and T3 diets. The NFE digestibility results showed that birds on diet T4 had the higher ($p<0.05$) value as compared to others treatments Birds on T1 and T2 had similar ($p>0.05$) values, however, they had higher value than bird on T3 diets. The ether extract digestibility result ranges between 87.57% and 89.51%. Birds on T1, T3 and T4 diets had similar ($p>0.05$) values, birds on T2, T3 and T4 diets also had similar ($p>0.05$) values. However, birds on T1 diet had the highest EE while the least was recorded by birds on T2 diet The result of this study is in line with the observation of several researchers (Rao *et al*., 2001; Adeyemi *et al*., 2008) who observed significant differences in the digestibility of all nutrients when fed maize, millet and sorghum as the main source of energy in broilers diets. However, it does not agreement with the report of Hon *et al*. (2009), which stated no significant difference was found in growth performance after 20% dried sweet orange (Citrus sinensis) pulp meal was added in rabbit feeds

SEM: = Standard Error of Mean,
NFE: = (Nitrogen free extract)

CONCLUSION: Base on the result of this study, the dietary inclusion of pineapple(PP) and orange(OP) peels does not depress growth below the acceptable range of weight. It was concluded that broiler birds could tolerate up to 5 % dietary levels of OP, PP meal and their mixture (MPO). without adverse effect. However, further research is needed to assess the effects of SDOP (Sun-dried orange peel) and SDPP (Sun-dried pineapple peel) to improve it suitability as feed resource.

ABSTRACT

This experiment was conducted to determine the effect of replacing maize with processed mango seed kernel meal (PMSKM) in the diets of weaner rabbit on performance, nutrient digestibility and economic of production. A total of thirty two (32) mongrel rabbits (8 rabbits per treatment, 2 per replicate) were randomly allotted to four experimental diets in which processed mango seed kernel meal replaced maize at 0, 20, 40 and 60% level designed as diets 1, 2, 3 and 4 respectively. The experiment lasted for eight weeks. The result showed that the Average initial weight (500.00-518.75), average final weight (1393.75-1412.50), average daily feed intake (52.98-55.05), average daily weight gain (15.74-16.19) and feed conversion ratio (3.29-3.48) obtained were not significantly (P<0.05) affected by the dietary levels of processed mango seed kernel meal. All the digestibility parameters analyzed were significantly (P<0.05) affected by the graded level of inclusion of the PMSKM. The lowest feed cost per kg weight gain was recorded in rabbits fed die 3(40%). Similarly, the rabbits fed diet 3 (40%) showed higher/better cost saving of ₦22.34. It was therefore concluded that processed mango seed kernel meal can replace maize at 40% level in the diet of weaner rabbit with better performance and tremendous reduction in feed cost.

Keywords: Mango seed kernel, Maize, Digestibility, Economic of production, Weaner rabbits

Introduction

Feed is one of the constraints to intensive rabbit production in Nigeria due to competition between man, animals and industries for conventional feed materials. This has lead to the escalating cost of conventional feed ingredients and has made feed cost to account for about 70% of total cost of production Akinmutimi (2008). This problem has been the prime stimulant for the continues search for alternative feed stuffs that can meet the nutritional requirement of micro-livestock, reduce the cost of feed and animal production (Olorede *et al*., 2011). It is recommended that such a feed stuffs should be one that has low human food preference and of low industrial usage.

Mango seed kernel meal (MSKM) has been reported to be a good non conventional ingredient. Faniyi (1997) reported its importance in poultry production while Arogba (1997) provided the physical, chemical and functional properties of Nigerian mango *(Mangifera indica)* kernel and it processed flour. Chemical analysis and metabolizable energy of mango seed kernel meal as determined by Arogba (1997) revealed that it contains Tannin an astringent compound, thus necessitate processing the seed before it could be safely fed to animals. The nutrient composition of Mango seed kernel on dry matter basis was estimated in Nigeria to be 6.16% crude protein, 13.63% ether extract, 2.23% ash and 73.35% nitrogen free extract (Farinu *et al.* 1999) while EI-Alaily *et al.* (1996) reported that the gross energy is 4.7Kcal/g. This study was designed to evaluate the growth performance, nutrient digestibility and economic of production of weaner rabbits fed diets containing processed mango seed kernel meal.

Materials and Methods

Experimental Site:

The experiment was conducted at the Rabbitery Unit of Bauchi State College of Agriculture Teaching and Research farm, Bauchi State. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East.

Collection and Processing of Mango Seed into Mango Seed Kernel Meal

The mango seeds were collected at Bauchi town and surroundings villages during the peak of its production period. They are readily available in the area of study. The collection was done during the months of April and May which represents the peak of the mango season in Bauchi town. The kernel were obtained by cutting the seed coat using a knife or crushed with a stone. The Mango Seed Kernel (MSK) obtained was then processed through soaking and boiling

Soaking of Mango Seed Kernel for 24 Hours

Mango Seed Kernel was soaked in water for 24 hours at the rate of 100g per liter of water in containers. There was change of water at regular intervals of 8 hours for 1 day. The Mango Seed Kernels were then removed and boiled.

Boiling of Mango Seeds Kernel

The Mango Seeds Kernel was then put in boiling water at the rate of 100g per litre of water at 100°C temperature for 30 minutes. The Mango Seed Kernel was then removed, drained, sun dried, and milled before incorporation into the diets.

Experimental Diets

Four diets were compounded manually. The diets contain 0, 20, 40, and 60% replacement level of proceed mango seed kernel meal for maize coded diets 1, 2. 3 and 4 respectively. The feed were prepared by mixing the various ingredient together at Abubakar Tafawa Balewa University feed mill.

Experimental Design and Management of Birds

A total of thirty two weaner rabbits were used for the experiment. They were randomly assigned into four dietary treatment groups of 8 rabbits per group in a completely randomized design (CRD) consisting of four replicates of 2 rabbits each. Feed and water were provided *ad libitum*

Digestibility Trial

During the seven weeks of the experiment, the weights of the rabbits were measured and a known quantity of feed was given to them. Total droppings from each treatment were collected on daily basis. The digestibility trial lasted for one week. From the total droppings voided, samples were taken for proximate analysis.

Economic analysis

The economics of production of weaner rabbits on the experimental diets were calculated base on the price of the ingredients in the market as at the time of the experiment

Determination of the Proximate Composition of Mango Seed Kernel

The proximate composition (Table 2) was obtained by analyzing the different samples of Mango seeds kernel according to the methods described by AOAC(1990).

Results and Discussions

Proximate Composition of Processed Mango Seed Kernel

The proximate composition of the test ingredients is presented in Table 2. The PMSKM used in the study contained 89.61, 2.23, 5.39, 9.62 and 3.87% for dry matter, ash, crude protein, ether extract and crude fibre respectively This contradict the values reported by Faniyi (1997) and El-Alail *et al*. (1976).

Performance of Weaner Rabbit Fed PMSKM Based Diets.

The results of performance of Weaner rabbits fed processed mango seed kernel meal (PMSKM) as replacement for maize were as presented in table 3. The performance characteristics in this experiment revealed that the replacement of maize by processed mango seed kernel meal at 0, 20, 40 and 60% recorded on average daily feed consumption of 52.98, 53.06, 54.45 and 55.05 (g) for treatment 1, 2, 3 and 4 respectively. There was no significant different amongst the treatment means. This agrees with the finding of Saleh *et al.*, (2015) and Shitu et al., (2013). They reported that the average daily feed intake were not significantly different (P<0.05) for weaner rabbit feed mango seed kernel meal and for growing crossbreed rabbit fed PMSK meal respectively. The result also revealed that there was no significant different (P>0.05) in the average daily weight gain of rabbits fed PMSKM as replacement for maize. The values ranged from 15.74-16.19g obtained in this study is higher than 10.1g reported by Adama and Nma (2002) when groundnut leaves were fed to rabbits. This also confirms the report of (Saleh *et. al*., 2015) and (Fayeye and Joseph, 2004). Shitu *et.al*; (2013) reported no significant effect on growing crossbreed rabbits fed processed mango seed kernel meal. The non significant effect of processed mango seed kernel meal based diets on feed conversion ratio among the treatments means contradicts the findings of Diarra *et.al;* (2004) but similar to the finding of Saleh *et al*., (2015).

Nutrient Digestibility of Rabbits Fed PMSKM Based Diets

The results of nutrients digestibility of weaner rabbits fed processed mango seed kernel meal (PMSKM) as replacement for maize were as presented in table 4. The dry matter digestibility varied from 69.09% to 72.37% in diet 1 and 4 respectively. All the DMD observed were significantly difference (P>0.O5) among the treatments. Also crude protein digestibility, there was significant difference (P>0.O5) between the treatments. The highest CPD of 81.13% was obtained in diet 3 and the lowest of 79.07% in diet 2. For ether extract digestibility also there was significant difference (P>0.O5) among the treatments. The highest EED of 97.28% was obtained in diet 4 and the lowest of 96.94% in diet 1. There was significant difference (P>0.O5) among the treatments. Highest CFD of 57.82% was obtained in diet 4 and lowest of 50.36% in diet 1. However, the ash digestibility observed range between 79.28% and 81.51% in diets 3 and 4 respectively. Also there was significant difference (P>0.O5) among the treatments. Although the digestibility values are too close to each other, the significant differences among the dietary treatment may be due to the variation of inclusion level of mango seed kernel meal in the diets.

Economic Analysis of Weaner Rabbit Fed PMSKM Based Diets.

Economic analysis of weaner rabbit fed varying level of processed mango seed kernel meal shown in table 5. Feed cost (₦/kg) decreased with increasing level of processed mango seed kernel meal in the diets, the values range from ₦87.50/kg for diet 1 (0% PMSKM) to ₦83.75/kg for 4 (60% PMSKM). This showed that mango seed kernel meal based diets are cheaper than the control diet. This also confirms the report of (Saleh *et. al*., 2015) reported decreased in feed cost (₦/kg) with increasing level of mango seed kernel meal for maize. The cost (₦) of total feed consumed equally decreased with increasing level of processed mango seed kernel meal from ₦269.50 in control diet to ₦252.42 in diet 3. The feed cost (₦/kg gain) was found highest in diet 1 (0% PMSKM) having ₦302.81 and lowest in diet 3 (100% MSKM) having ₦280.47. This showed that feed cost decreased per kilogram gain with increasing level of mango seed kernel meal for maize up to 40% level of inclusion. This also agreed with the finding of Shitu *et.al;* (2013) which reported similar trend on rabbits. However, highest cost saving was recorded in diet 3 (40% PMSKM).

Conclusion and Recommendation

It can be concluded that processed mango seed kernel meal can be use to replace maize in the

diet of weaner rabbits up to 40% level of inclusion as an energy source without any negative effect on their performance and nutrients digestibility with concomitant reduction in cost, thereby reducing competition and improving consumer access to animal protein.

Pig population and distribution pattern in Ibadan/Ibarapa area of Oyo state

Sosina, Adedayo Olalekan
Department of Animal Science, University of Ibadan, Ibadan
Corresponding Address: dayososina@gmail.com

Abstract

Pig production in the rural areas has not been linked with the market thus affecting pig business enterprises adversely. Many had opined that the various challenges confronting pig production to inadequate capital, land, etc. However, information on pig population and distribution is scanty, thus the need to investigate pig population and distribution in the Ibadan/Ibarapa area of Oyo state. A three-stage sampling technique was used to purposively select 180 respondents, nine respondents per village, three villages per cell and three cells randomly selected in the study area were evaluated. Parameters measured were average litter size (Tropical Livestock Unit, TLU), the pig distribution pattern of pigs across Oluyole, Ona-ara, Akinyele, Egbeda, Ido and Ibarapa East locations. The ARC-GIS software processed the Global Positioning Systems (GPS) data of the pig population using the ARC-GIS model 10.0. Data analyzed with descriptive statistics. The mapping of the pig farmers' distribution was done using the spatial analytical tool of the GIS. The farmers' average litter size of pigs (TLU) ranged 2 (Ona ara and Akinyele) to 100 (Egbeda). The average litter sizes (TLU) were 5, 20 and 40 in Oluyole, Ibarapa East and Ido, respectively. Only Egbeda had big piggery farms with an average size ranged above 20 piglets. The large pig production in Egbeda was influenced mainly by the abundance of agro-industrial by-products and feed resources. Off-takers of pig production value chain should focus on Egbeda for the supply of pigs with the advantage of resources and other production factors.

Key Words: Bioinformatics, ecological zones, marketing, population, pig distribution

Introduction

Sourcing for pigs is a major challenge to business thus adversely affecting marketing and profitable production, especially in the rural areas. There is a serious disconnect between production and marketing in the pig value chain system. There was no concerted effort towards the linkage of production to market to stimulate production efficiency among pig farmers in the Ibadan/Ibarapa area of Oyo state. The spatial distribution and population of these farmers make access to market a herculean task thus making the study relevant. There is a need to identify the location of the livestock producers for effective agricultural planning and policy implementation. Geographic Information System (GIS) is a computerized database management system for capture, storage retrieval, manipulation, analysis and display of spatial information (Gebber and Adamchuk, 2010). Information on the location and livestock production can be collected using spatial analytical tools of GIS (Sosina, 2017). Also, it forms a reliable data for agricultural planning and policy formulation (Rilwani and Ikhuoria, 2006).

In Nigeria, the relevance of space technologies in technological advancement becomes more pronounced after the launch of Nigeria SAT-1 in March 2003 in Siberia, Russia (Nigeria Sat 1 report, 2003). The high-resolution satellite was only useful in taking landmarks and settling boundary disputes (PrecisionAg.com.Org.2003). However in the launch of the low-resolution satellite of Nigeria, SAT-2 in 2005 in Siberia was more relevant to Agriculture (Oyinloye and Oloukosi, 2013). The spatial analytical tool of GIS was used to map poultry farmers in southwestern, Nigeria (Omodele and Okere, 2014) and its relevance in animal production management in Ibadan/Ibarapa area, Oyo state (Sosina, 2017). Olugaza *et al*. (2014) reported the relevance of bioinformatics in diseases epidemiology study among farmers in a rubber plantation in Liberia, Forest Resources (Olatoye and Odutaru, 2013), Land resources (Rilwani and Ikhuoria 2006), Nutrient evaluation for fertilizer application (PrecisionAg.com.Org.2003), Feed Resource management (Babayemi *et al*., 2014) and spatial patterns in crop-livestock evolution pathways in West Africa (Rilwani and Gbekeji, 2009).

It is necessary to provide (production) information about pig business enterprises in Nigeria. Such information is needed for proper planning and regulation of the industry in Nigeria (Rilwani and Ikuoria, 2006). Available data on the current entrepreneurial characteristics and constraints to the robust development of pig business enterprises in Southeastern Nigeria are scanty (RIM, 2010). Hence, the study tries to map the pig production business using the spatial analytical tool to identify the location and population of pigs among farmers in the Ibadan/Ibarapa area of Oyo state.

Materials and Methods

The study took place in the Ibadan/ Ibarapa Area of Oyo State of Nigeria, the area is ethnically heterogeneous with a high concentration of smallholder crop and livestock farmers. Oluyole, Ona-ara, Akinyele, Egbeda, Ido and Ibarapa East LGA locations were purposively selected for the study. The Global Positioning Systems (GPS) of the farmers' location, livestock population, and distribution were recorded. The recorded GPS data of pig respondents were transferred into the ARC-GIS. The ARC-GIS software processed the data into location using the ARC-GIS model 10.0 from the GIS unit of the Department of Geography, University of Ibadan. Data analyzed using descriptive statistics.

Results

The pig farmers' locations were mapped using the spatial analytical tool of the GIS (as in Fig.1) and the average litter size of pigs both indigenous and improved strain kept. The average litter size of pigs among respondents ranged from 2 to 100 as shown in Fig.2. Egbeda had the highest average litter size of 100 while the lower values were found among farmers in Ona-ara and Akinyele. Although, the average litter sizes of 5, 20 and 40 were found among farmers in Oluyole, Ibarapa East and Ido, respectively. The large population of pig farmers was attributed to other production factors aside from pig's omnivorous nature. The study showed that piggery business thrived best in Egbeda probably due to the presence of big agro-industrial companies that produce major feed ingredients for pig production. With the little sales from rural markets and patronage from eateries, pig business is on the increase in the urban areas which slightly favored Egbeda.

Discussion

The pig distribution patterns across the study areas result could be due to the management systems adopted by farmers of the semi-intensive and extensive systems of production practice. This agreed with Bolorunduro *et al.* (2004) who supported commercial pig production in the humid tropics. The population, distribution patterns, breeds and classes of the pigs identified could be important for policy framework. This agreed with Gebber and Adamchuk (2010), Oyinloye and Oloukosi (2013) and Olugaza *et al*. (2014) that reported relevance of bioinformatics data in livestock production. Moreover, off-takers of the pig production value chain should look in the direction of Egbeda for the supply with favorable climate and other production factors. The government should plan for policies and programs that could enhance the increase in the production of pigs in the study areas. Also, it will assist with interventions necessary to sustain the pig value chain program through increased funding and livestock extension. This agreed with Babayemi *et al*. (2014) that reported the need for more agricultural interventions.

Conclusion

The use of bioinformatics can link pig farmers to market easily and interventions from the government and policy makers reach farmers efficiently.

Growth Performance of Male Grower Rabbits Fed Diets with Iburu offal Replacing maize as energy Source

Sudik, S. D., Bagudu, I. A., Maidala, A. and Lawan, A.
Department of Animal Science, Federal University, Gashua, Yobe State, Nigeria
Corresponding author: davidsudik@fugashua.edu.ng Mobile No: +2348065633451

Abstract
A six week experiment was conducted to determine the growth performance of male grower rabbits fed diets with iburu offal replacing maize as energy source. Five diets were formulated with iburu offal (IO) replacing maize by 0%, 15%, 30%, 45% and 60%, respectively. Fifty (50) male grower rabbits were allotted to the 5 diets, 10 rabbits per diets replicated 10 times, and each replicate had one rabbit. The design used was a completely randomized design. The results showed that rabbits fed 30% and 45% IO had higher (p<0.05) total weight gain (2.10±0.12 and 2.08±0.08kg, respectively) *and better (p<0.05) FCR (2.20±0.18 and 2.16±0.10, respectively) similar to those fed 0% IO (2.18±0.27) while rabbits fed 15% and 60% IO had* lower total weight gain (1.68±0.12 and 1.68±0.09kg, respectively) and *poor FCR (2.33±0.13 and 2.66±0.13,* respectively). *It can be concluded that IO can replace maize in male grower rabbit's diets at 30-45% without negative effect on performance.*

KEYWORDS: Rabbits, Iburu offal, Maize, Performance

Introduction
In a quest to reduce the high cost of feed with the resultant high cost of livestock production, many agro-by-products have been used to substitute the conventional ingredients in the diets of rabbits (Safwat *et al*., 2014). Sudik *et al*. (2019) tested soybean curd residue up to 15%, Lounaouci-Oyed *et al*. (2008) used brewer's dried grains up to 30%, Onakpa *et al*. (2006) used maize bran up to 35% and Bhatt *et al*. (2005) used rice bran was used at 5%, without negative effect on performance of rabbits. However, many more alternative ingredients have not been identified as animal feed resources. One of such is iburu offal (IO), a by-product obtained from the milling of iburu gains. Iburu (black fonio) belongs to the family *Poaceae* and genus *Digitaria*. It is a popular staple food grown across West Africa and in Nigeria it is grown in the central zone and dominantly in Plateau and Bauchi States (Gyang and Wuyep, 2005). Iburu offal has been reported to be is rich in nutrients such that for 100g it contains 6.52% DM total ash, 12.49% DM crude protein, 4.15% DM ether extract, 10.54% DM crude fibre, 66.30% DM nitrogen free extract, 0. 05% calcium, 0.09% phosphorus, 3.25g/16gN lysine and 3.60g/16gN methionine (Sudik, 2016). Despite its high nutrient content, it is usually thrown as waste untapped. Incorporating IO into animal feeds will not only provide alternative feed resources or increase value-added-chain but also, help cleaning the environment. The objective of this paper was to determine the performance of male grower rabbits fed diets with IO replacing maize as energy source.

Materials and Methods
Location of the study
The experiment was conducted at the Rabbitry Unit of the Livestock Farm Complex, College of Agriculture, Garkawa, Plateau State, Nigeria. Garkawa lies within latitude 8.8955^{o}N and longitude 9.4537^{o}E. The annual average temperature is usually about 27.7^{o}C and annual average precipitation is usually about 1178mm (Wikipedia, 2019).

Formulation of experimental diets
A basal diet (D1) with 16.54% crude protein meeting the nutrient requirements of male grower rabbits as described by Szendro and Dalle Zotte (2011) was formulated. Thereafter, 4 other diets (D2, D3, D4 and D5) were formulated replacing maize with IO by 15%, 30%, 45% and 60%, respectively (Table 1).

Table 1: Gross composition and calculated values of the experimental diets

Ingredients	D1 0% IO	D2 15% IO	D3 30% IO	D4 45% IO	D5 60% IO
Maize	13.06	11.10	9.14	7.18	5.22
Iburu offal	0.00	1.96	3.92	5.88	7.84

Crude fibre	5.02	7.11	8.45	9.19	9.76

IO = iburu offal

Experimental design

The design used was a completely randomized design (CRD).

Source and management of experimental rabbits

Fifty (50) male grower rabbits about 5 weeks of age were purchased from a reputable Farm in Jos, Plateau state. Immediately the rabbits arrived at the farm glucose was added to their drinking water and a plain food mainly of maize and fresh leaves of *Moringa oleifera* and *Tridax procumbent* were given to them for three days to reduce the stress incurred from transportation and to acclimatize them to the environment. Thereafter, they were randomly allotted into 5 dietary treatments, group weight were balanced to ensure similar weight between treatments. Each dietary treatment had 10 rabbits and each served as replicate unit. They were individually kept in a hutch equipped with feeder and drinker. Feed and water were provided *ad libitum*. Antibiotics, coccidiostats and anti-stress were occasionally administered as prophylactic measures. The experiment lasted for 6 weeks.

Data collection

At the beginning of the experiment, each rabbit was weighed to determine the initial weight and thereafter, they were weighed weekly to monitor weight changes. Total weight gain (TWG) was calculated by subtracting the initial weight from the final weight. Average daily weight gain (DWG) was calculated by dividing the TWG by 42 days (experimental period). Feed consumption was determined daily by subtracting feed leftover from feed supplied. Total feed intake (TFI) was the

cumulative of daily feed consumed. Average daily feed intake was calculated dividing TFI by 42 days. Feed conversion ratio (FCR) was calculated by dividing feed consumed by weight gain.

Data analysis

Data generated were subjected to Analysis of Variance (ANOVA) using SAS (1999) Statistical Package Version 9 and significant means were separated using Duncan's Multiple Range Test (Duncan, 1955) at 5% level of probability.

Results

Table 2 shows the growth performance of male grower rabbits fed diets with iburu offal. Rabbits fed 30% and 45% IO significantly ($p<0.05$) had higher total weight gain (2.10±0.12 and 2.08±0.08kg, respectively) and better FCR (2.20±0.18 and 2.16±0.10, respectively) compared with those fed 0% IO (2.10±0.18kg and 2.18±0.27, respectively) while rabbits fed 15% and 60% IO significantly ($p<0.05$) had lower total weight gain (1.68±0.12 and 1.68±0.09kg, respectively) and poor FCR (2.33±0.13 and 2.66±0.13, respectively). Other parameters were not significantly ($P>0.05$) affected.

Table 2: Performance of male grower rabbits fed diets with soybean curd residue

Parameters	D_1 0% IO	D_2 15% IO	D_3 30% IO	D_4 45% IO	D_7 60% IO
initial weight (kg)	0.73±0.02	0.78±0.02	0.75±0.02	0.76±0.02	0.74±0.02
Total weight gain (kg)	2.10±0.18^{a}	1.68±0.12^{b}	2.10±0.12^{a}	2.08±0.08^{a}	1.68±0.09^{b}
Daily weight gain (kg)	0.05±0.00	0.04±0.00	0.05±0.00	0.05±0.00	0.04±0.00

Daily feed intake (kg)	0.11±0.00	0.11±0.00	0.11±0.00	0.11±0.00	0.13±0.00
Feed conversion ratio	2.18±0.27^{b}	2.33±0.13^{ab}	2.20±0.18^{b}	2.16±0.10^{b}	2.66±0.13^{a}
% Mortality	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00

Values are average of 10 male grower rabbits. IO = iburu offal

Column with difference superscripts are significance difference ($P<0.05$).

Discussion

The higher growth weights and better FCR observed between rabbits fed 30%-45% IO and those of control (0% IO) indicates that both rabbits were exposed to similar dietary nutrient composition while the poor FCR observed in rabbits fed 15% and 60% may probably means the diets were not well equipped to support proper growth rate. In the case of the rabbits fed 60% IO the poor FCR may be attributed to the higher fibre content (Table 1). Even though there was no significant difference in feed intake, however, the rabbits fed 60% IO were probably eating more feed to gain weight. This result agrees with Aduku (1993) who reported that higher fibre content in diets reduces nutrients availability to animals thereby animals tend to eat more feed to meet up energy requirements.

Conclusion

In this study maize was replaced with IO in male grower rabbits' diets up to 60% and the rabbits fed 30-45% IO had similar total weight gain and feed conversion ratio with those fed control (0% IO), therefore 30-45% IO is recommended for male grower rabbits.

PERFORMANCE CHARACTERISTICS OF BOILER CHICKENS FED DIET CONTAINING DIFFERENT OIL TYPES.

Tauhid, G.., Y.S. Kudu.., and B.A. Ayawale.

Department of Animal Production Technology
Federal University of Technology, P.M.B 65 Minna, Niger State

ABSTRACT

This study was carried out at the poultry unit of the Teaching and Research Farm, Department of Animal Production, Federal University of Technology Minna, Nigeria. A Total number of 180 day old chicks were used for the experiment. The birds were randomly allotted into five treatment of three replicate consisting of 12 birds in a complete randomized design (CRD). T_1 (birds fed control diet), T_2 (were birds fed 4% palm oil), T_3 (were birds fed 4% palm kernel oil), T_4 (were bird fed 4% ground nut oil) and T_5 (were bird fed 4% shea butter oil). The experiment lasted for 8 weeks. The result showed that at starter phase the final weight, body weight gained and feed intake were influenced (P<0.05)by the inclusion of oils while feed conversion ratio, protein and energy efficiency ratio were not significantly affected (P>0.05). The inclusion of 4% groundnut oil and shea butter oil (T_4 and T_5) showed significantly better growth performance in terms of final weight (214.43g) and (237.43g) compare to T_3 (203.0g). At the finisher phase no significant (P>0.05) difference was recorded in final weight, body weight gain, feed conversion ratio, protein and energy efficiency ratio with exception of the average feed intake which was significantly (P<0.05) affected by the inclusion of oils, with control and treatment T_5 showed best result (488.15g) and (453.74g) compare to those in treatment 3 and 4 (418.06g) and (441.96g). It can therefore be concluded that broiler chicken could tolerate 4% inclusion level of the various types of oil used in this research work without any adverse effect on their growth performance.

Key Words: Broiler chicken, palm oil, palm kernel oil, groundnut oil and shea butter oil.

INTRODUCTION

Poultry feeding is one of the most important aspect of production because feed cost alone account for 65 - 75% of the total cost of egg and meat production (McNab, 1999). Therefore, for profitable poultry rearing, provision of economical and balance diet is must. Use of oil as a source of energy on broiler fed has many advantages such as increasing the energy content of diet, addition of oil in broiler diet also provides increase growth rate, increase rate of gain, increases feed efficiency and also minimized the dustiness of feeds. Poultry farmers in Nigeria continue to experience a rise in the production cost due to the continuous increase in feed cost. (Ajighjigh *et al., 2018*). The insufficient know – how and the lack of alternatives and a more cost efficient feed stuff as well as the struggle between man and animals for most traditional feed stuff has been established as the main cause of increase in cost of production (Afolayan *et al., 2012*). This current study was therefore carried out to examine the effect of supplementing broiler chickens diets with different oil types at the same level of inclusion on the performance of broiler chickens.

MATERIALS AND METHODS

The research was conducted at Teaching and Research Farm, Federal University of Technology Minna, Gidan Kwano Campus Niger State. Minna located within the Latitude 09^0 31' 18.2"N and Longitude $6^0$27'40'E with an elevation that ranges from 230 – 250 m. The area of study lies within the Southern Guinea Savanna of Nigeria. The sub humid climate of the region has an average yearly rainfall of 1338mm, dry season of about 5 month and average temperature of about 30^0 c (FUTMIN, 2012). A total of 180 day old Ross 308 chicks were sourced from Agrited Farm Limited Ibadan, Oyo State and were used for the study. Five (5) nitrogenous and isocaloric diets were formulated using different oil types at 4% inclusion levels T_1 (0% oil), T_2 (4% palm oil), T_3 (4% palm Kernel oil), T_4 (4% groundnut oil) and T_5 (4% shea butter oil). The birds were randomly allotted to the treatment groups Each treatment was assigned 36 birds with three replicate of 12 birds in a complete randomized design (CRD) arrangement and The experiments lasted for eight (8) weeks.

RESULTS AND DISCUSSION

At the starter phase (table I) the result showed no significant difference (P>0.05) in initial body weight, protein and energy efficiency ratio and feed conversion ratio. The birds fed 4% shea butter oil (T_5) showed significance difference (P<0.05) over those fed 4% palm kernel oil (T_3) in the body

weight gain (155.97g) and average daily body weight gain (5.57g) but (T_5) 4 % shea butter oil was statistically the same with control (T_1) and those fed 4% groundnut oil (T_4). This result agree with the report of Harms e*t al.,* (2000) who reported that addition of 3% - 6% shea butter oil in broiler diet increases growth performance.

There was no significance different (P>0.05) between T_2 and T_5 in (Table 1) with reference to body weight gain, this agree with Ayed *et al.,* (2015) who reported that addition of palm oil to broiler diet increases their body weight gain, similar report has been documented by Yamany *et al.*,(2008) that 4% inclusion of shea butter oil tend to improve weight gain in broiler chickens as reported in this experiment. There was no significance difference (P>0.05) observed at the finisher phase of the experiment in average body weight, final body weight and feed conversion ratio, the only difference observed was at the average feed intake (Table 2) T_3, 4% palm kernel oil diet recorded the lowest value of feed intake (418.06g) which does not reflect on the feed conversion ratio. The non significance difference (P>0.05) observed at finisher phase may be due to ability of chickens to utilize dietary oil in diets which support the study of Firman *et al.,* (2008) who compared oils source such as soy bean oil, yellow grease and palm oil in ratio of broilers from hatch to market and reported that older chickens digest more dietary oil than the younger chickens.

It can therefore be concluded that broiler chicken could tolerate 4% inclusion level of the various types of oil used in this research work without any adverse effect on their growth performance.

Key: a,b,c = mean in the same row with different superscript are significantly different ($p<0.05$).

CONCLUSION AND RECOMMENDATION

It can be concluded from the experiment that the inclusion of the four oil types at 4% significantly affected ($p<0.05$) all the growth parameters at starter phase except feed conversion ratio, protein and energy efficiency ratio. While at finisher phase the initial weight and average feed intake were significantly affected. However final weight, body weight gain, feed conversion ratio, protein and energy efficiency ratio were not significantly affected.

It can therefore be recommended that farmers can use shea butter oil at 4% inclusion in the diet of broiler chickens for better growth performance at starter phase.

ABSTRACT
A trial was carried out to evaluate the effects of replacing wheat offal with rice bran on the growth performance and carcass characteristics of broiler chickens. The study was conducted at the experimental Unit Poultry Farm of Bauchi State College of Agriculture, Bauchi. A total of two hundred (200) day old broiler chicks were randomly allotted to five (5) dietary treatments containing 0%(T1), 25%(T2), 50%(T3), 75%(T4) and 100%(T5) level of inclusion of rice bran as a replacement to wheat offal. Each treatment was replicated three times with thirteen (13) birds per replicate in a Completely Randomized Design. Feed and water were supplied ad libitum and the experiment lasted for eight (8) weeks. The result show that carcass characteristics, significance difference(P<0.05) existed in live weight (1.59-1.91kg), pluck weight (1.35-1.73kg), eviscerated weight (1.13-1.38kg), carcass weight (0.94-1.28kg), intestinal length (166.67-217.17cm) and pancreas (0.16-0.67g) while dressing percentage and other gut characteristics does not differ. The feed cost in naira/kg body weight gain decreased with increased level of rice bran there by reduced the cost of production up to 20.06%, with the highest cost saving on (T5) 100% inclusion levels (₦52.21). From the experiment conducted, it is therefore concluded that dressing percentage and others gut characteristics were not influenced by the dietary levels of rice bran while Carcass weight, live weight, pluck weight, eviscerated weight, pancreas and intestinal weight were significantly (P<0.05) affected, feed cost in naira per kg body weight gain decreased with an increased levels of Rice bran.

Keywords: broiler chickens, rice bran, cost benefit, carcass

INTRODUCTION
There has been a steady increase in the cost of conventional feed ingredients such as maize, groundnut cake, soybean meal and fish meal in the past years and this has led to increase in the prices of animal protein sources (Adejinmi *et al*., 2007). Several workers have emphasized the need for utilizing alternative feed ingredients removed from human and industrial uses (Fanimo *et al*., 2007; and Nsa *et al*., 2007). There is, therefore, a dire need for the animal nutritionists to seek for alternatives to the inadequate and expensive conventional feedstuffs to forestall an impending serious food crisis. Some workers (Kwari *et al*., 2004; Okah, 2004) have stressed the need for utilization of alternative feed ingredients. To avert the problem of low animal protein deficiency, the production of animals with short generation interval such as poultry is needed. Among the different kinds of livestock that are produced in Nigeria, animal scientists generally agreed that developing the poultry industry is one of the fastest ways of bridging the protein deficiency. According to Ogundipe and Sanni (2002) and FAO (2006) reports poultry is considered to be a mean of livelihood and a way of achieving a certain level of economic independence of Nigeria. This study aimed at evaluating the effect replacing wheat offal with rice bran on Carcass Characteristic and cost benefit of Broiler Chickens.

Materials and Methods
The experiment was conducted at the Poultry Unit of Bauchi State College of Agriculture Bauchi Teaching and Research farm. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East (BSD, 2009).

The room was washed, disinfected and the cemented floor was covered with saw dust. A total of 200 day old chicks were used. The chicks were brooded for seven (7) days. After the brooding period, the chicks were randomly allotted to five experimental treatments, and replicated three times with thirteen (13) birds per replicate. Feed and water were supplied *ad-libitum*. The necessary vaccine such as Infectious bursal disease vaccine (IBDV) and Newcastle disease vaccine (NDV) was carried out at appropriate time.

Five (5) diets were formulated and designed as diets A, B, C, D and E. Diet A was the control (no rice bran). While diets B, C, D and E contain rice bran as replacement for wheat offal at 25, 50, 75 and 100% at level of inclusion respectively. The various diets were compounded manually. The formulated diet contains 23 and 20% crude protein at starter and finisher respectively. The percentage

composition and calculated analysis of experimental diets are shown in Tables 1 and 2. The experimental design adopted was a completely randomized design (CRD). The four diets formed the treatments and each treatment was replicated three times and had 13 birds per replicate.

The carcass evaluation was done at Poultry Farm of the Department of Animal Health and Production, College of Agriculture Bauchi, Bauchi State. At the end of the finisher phase (8 weeks), two chickens were randomly taken from each treatment, fasted for 12 hours and weighed. They were slaughtered by making a clean cut through the carotid arteries and jugular veins in the neck with a sharp knife and allowed to breed completely. They were defeathered, eviscerated, and cut into legs, head and the visceral organs (liver, intestine, lung, kidney, pancreases, and gizzard).

Results and Discussion

Results of carcass characteristics are shown in Table 3. The results show significant differences ($P > 0.05$) between treatments for the live weight, carcass weight, pluck weight, eviscerated weight, intestinal length and pancreases weight, this could be due the different levels of inclusion of rice brand. This report is not in harmony with the observation of Abdulraheem *et al*. (2006) who observed no significant differences between treatments when rice bran was used to replace maize in broiler chicken diets. However, dressing percentage and others gut characteristics did not differ significantly ($P < 0.05$) between treatments, this could also be as a result of quality ingredients used and utilization of diets across all the treatments. The results obtained in this study agreed with those of Amaefule *et al*. (2006) who observed no significant differences in carcass and organ characteristics of broiler chickens fed RMW-based diets**.**

The highest feed cost (98.46₦/kg) was observed in diet 1 control (wheat offal based diet) while the lowest value (73.1₦/kg) was recorded in diet 5 (rice offal based diet), total feed cost was also higher (364.30₦/kg) in diet 1 control (wheat offal based diet) while the lowest value (255.85₦/kg) were recorded in diet 5 (Rice offal based diet). This could be attributed to difference in prices of these Agro industrial by-products as of the time of experiment. Higher feed cost ₦ per kg gain (260.22₦/kg) was observed in diet 1 (Wheat offal) based diet compared to diet 5 (Rice bran) based diet which recorded the lowest value (208.01₦/kg. These values were higher than those (82.62-113.02₦/kg and 157.18-179.75₦/kg) reported by (Grace *etal*.,2007; Ezieshi *et al.* 2011) on broiler chickens fed diets containing maize replaced with wheat offal and varying levels of palm kernel cake with maize offal respectively. However, the total feed cost ₦/kg (73.10-98.46 ₦) obtained in this study were at variance to (628.04 -771.24₦/kg) those reported by (Odeh, *et al*., 2016; Nnenna, *et al.,* 2006) when broiler chickens fed graded levels of rice milling waste and maize offal based diets supplemented with Roxazyme G Enzyme.

Conclusion and Recommendation

Dressing percentage and others gut characteristics were not influenced by the dietary levels of rice bran while Carcass weight, live weight, pluck weight, eviscerated weight, pancreases and intestinal weight were significantly ($P<0.05$) affected. The use of rice bran in poultry nutrition particularly broiler chickens should be encouraged where the feed ingredient is available to help reduce feed cost which accounts for 70- 80% of the cost of production.

ABSTRACT

Experiment was conducted at the Bauchi State College of Agriculture, Bauchi Poultry Farm to evaluate carcass characteristics and economic benefits of broiler chickens fed graded levels of Super SOSAT millet (SSM) based diets. Four experimental diets were formulated and designated as diets 1 (0%), 2 (33%), 3 (66%) and 4 (100%) SSM inclusion levels. A total of 208 day-old unsexed Marshal broiler chicks were randomly allotted to four dietary treatments of 52 birds per treatment in a completely randomized design. Each treatment was replicated four times with thirteen birds per replicate. At the end of the feeding trial, representative samples of the birds from each replicate were randomly selected. A total of thirty-two (32) birds with two (2) birds from each replicate were slaughtered, scalded plucked and eviscerated. Live weight of each bird was taken before slaughtering. Live, plucked, eviscerated and dressed weights were determined. Dressing percentage and gut organ's weight were expressed as percentage of live weights. The result revealed that most of the carcass characteristics were not affected except liver (1.81-2.37%), lungs (0.48-0.59%) and intestinal (6.62-9.02%) weights (P<0.05). Abdominal fat (1.17-2.24%) and pancreas (0.29-0.38%) were also affected at ((P<0.001; P<0.01 respectively). Both the feed cost (₦/kg) and feed cost in naira per kg body gain decreased with increasing levels of SSM. It can be concluded that SSM can completely replace maize as dietary energy source in the diets of broiler chickens with no adverse effect on carcass yield as well as reduction in feed cost.

Keywords: Super SOSAT millet, carcass yield, economic benefits.

Introduction

One of the major suspects in food crises in most African countries including Nigeria is protein in adequacy in diets especially the animal protein (Nwokoro *et al.,* 2000). The average animal protein intake in Nigeria is less than the FAO/WHO recommended (35g) (Ngele *et al*., 2008). The average protein intake in Nigeria is 34.6g of which only 10.6g (19.4%) is of animal origin. (Ajimohun *et al.,* 2012). The current acute shortage of animal protein in Nigeria and the rapidly increasing demand for livestock could be alleviated through broiler production (Nworgu *et al.,* 2000). In many parts of the world, broiler production offers the most rapid and cost effective means of making available high quality animal protein to man (Egbo *et al.*, 2000; Dafwang, 2002). In poultry production, it is known fact that feeding alone accounts for 70 – 80% of the total cost of production in Nigeria (NSA *et al., 2016).* Maize, the most expensive feed ingredient accounts for the largest proportion of about 50 – 55% of the poultry diets. (Ijadunola *et al.*, 2012). The demand for maize (the chief energy source for poultry) by man as food and other industrial uses coupled with low production locally has placed additional constraints on its continual use in poultry diets (Adamu *et al.,* 2012). There is the need to evaluate other grains like pearl millet (*Pennissetium glaucum*) of Super SOSAT variety as an alternative to maize in broiler chicken diets. Any reduction in the cost of feed will extensively reduce the overall cost of production and increase the profit margin of the farmer.

Materials and Methods

This study was conducted at poultry research unit of the Department of Animal Health and Production, Bauchi State College of Agriculture, Bauchi. Two hundred and ten (210) unsexed marshal day old broiler chicks were procured from chi-chicks hatchery at Ibadan, Nigeria. The birds were reared on deep litter system from1-7days they were fed commercial broiler starter diet (Hybrid feed) during this period. Four experimental diets were formulated for the

starter (23% CP) and finisher (20% CP) phases. Super SOSAT millet was included at 0, 33, 66, and 100% levels coded as diet 1, 2, 3, and 4 respectively as presented in tables 1 and 2.

Table 1: Ingredients and percentage composition of dietary levels of SSM fed to broiler chickens at the starter phase (2 – 5 weeks).

After a week of brooding period, about 208 broiler chickens were randomly allotted to four dietary treatments. Each treatment was replicated four times and for every treatment there were fifty two birds with thirteen birds per replicate in a Completely Randomize Design (CRD). The initial weight of the birds was taken for every replicate and average weight per bird was also determined. The bird's weights were recorded on weekly intervals thereafter. Experimental diets and clean water were given *ad libitum.* Feed intake was also recorded. At the end of the feeding trial representative samples of the birds from each replication were randomly selected. A total of thirty two (32) birds, two (2) birds from each replication were slaughtered, scalded plucked and eviscerated. Live weight of each bird was taken before slaughtering. Plucked, eviscerated dressed weights were measured in kilograms. Dressing percentage and gut organ's weights were expressed as percentage of live weight. Data on feed cost for each treatment were also evaluated. All the data generated were subjected to Analysis of variance (ANOVA) using special statistical package (SPSS). Where significant difference between means was observed, New Duncan Multiple Range Test (DNMRT) was used to separate the means.

Results and Discussion

The results of this study (Table 3) indicated live weight (2.16 – 2.49kg), plucked weight (2.06 – 2.35kg), eviscerated weight (1.51 – 1.85kg), dressed weight (1.39 – 1.79kg) and dressing

percentage (64.43 – 68.68%) were not influenced by the graded levels of super SOSAT millet (SSM) based diets. These observations were similar to the findings of Davis *et al.* (2003) which stated that pearl millet inclusion in broiler chicken diets resulted in performance and carcass characteristics similar to or better than corn based diets. This could be due to higher oil content in millet diets and better nutrient utilization than other cereal grains in the diets which has been reported to enhance growth and feed conversion ratio due to improve appetite (Moran, 1996).

Organs weight like gizzard (2.58 – 3.49%), heart (0.47 – 0.51%), spleen (0.14 – 0.15%), head and legs (5.51 – 6.05%) were also not affected. However, liver (1.81-2.37%) lungs (0.48-0.59%) and intestine (6.62-7.75%) (P<0.05) were all influence by the dietary treatment. Similar trend was observed in abdominal fat (1.17-2.24%) (P<0.001) and pancreas (0.29-0.38%) (P<0.01). These findings agreed with the report of Adamu *et al.* (2000) in which pearl millet was fed to broilers at different levels as substitute for maize and reported that organ's weights were significantly (P<0.05) affected by the dietary treatments with the millet fed group recorded higher weights.

Financial Analysis of Broiler Chickens Fed Varying Levels of Super SOSAT Millet (SSM) Based Diets

The financial benefit of using SSM for broiler feeding is presented in table 4. The highest feed cost in naira per kg (₦ 67.31/kg) was found in diet 1 (0% SSM) and the lowest value (₦ 59.09/kg) was observed in diet 4 (100% SSM) based diet). The feed cost decreases with an

Table 4: Financial analysis of the experimental diets fed to broilers chickens

	Diets			
Parameters	**1 (0%)**	**2 (33%)**	**3 (66%)**	**4 (100%)**
Total feed intake (kg)	5.12	5.51	5.32	5.59
Feed cost (₦/kg)	67.31	64.59	61.88	59.09
Total feed cost (₦/bird)	344.63	355.89	332.29	330.31
Total weight gain (kg)	1.46	1.76	1.51	1.78
Feed cost ₦/kg weight gain	236.05	202.21	211.60	185.57
Cost Saving (₦)	0.00	33.84	24.45	50.48
Percent Cost Saving (%)	0.00	14.34	10.36	21.39

increasing level of SSM in the diet. This could be due to differences in prices of these grains as at the time of purchase. This is in agreement with the findings of Clement *et al.* (2010) which reported the lowest cost of feed/kg in millet based diet, followed by high tannin sorghum, then low tannin sorghum and maize diets. Similar report was made by Yunusa *et al.* (2015) in which the lowest feed cost in naira/kg was observed on gero millet diet when compared to dauro, sorghum and maize diets.

The cost of total feed intake per/bird also decrease with increasing level of SSM in the diet. Although the highest total feed cost per bird (₦ 355.89) was found in diet 2 (33% SSM) while the lowest (₦ 330.31) obtained in diet 4 (100% SSM). This could be attributed to high price of maize and its inclusion level in this diet as well as the rate of feed consumed by the birds. Highest feed cost in naira per kg weight gain of ₦ 236.05 was obtained on diet 1 (control) while the lowest (₦ 185.57) was recorded on diet 4 (100% SSM). The result obtained in this study conformed with the findings of Ibe *et al.* (2014) and Yunusa *et al.* (2015). They reported that gero millet based diet seems to be most economical for broiler feeding as the best and economical feed cost in naira per kg was found in this diet when compared to other common cereal grains.

Conclusion

It can be concluded that SSM can completely (100%) replace maize as dietary energy source in the diets of broiler chickens with no adverse effect on carcass yield as well as reduction in feed cost.

Abstract

Fifty-six (56) days experiment was conducted at the Bauchi State College of Agriculture, Bauchi, Poultry Farm to evaluate the performance of broiler chickens fed graded levels of Super SOSAT millet (SSM) based diets. Four experimental diets were formulated and designated as diets 1 (0%), 2 (33%), 3 (66%) and 4 (100%) SSM inclusion levels. A total of 208 day-old unsexed Marshal broiler chicks were randomly allotted to four dietary treatments of 52 birds per treatment, replicated four times with thirteen birds per replicate in a completely randomized design. The results revealed that most of the performance attributes at starter and finisher phases as well as overall performance were significantly influenced by the dietary levels of SSM. At the starter phase: initial weights (IWT) (119.24-127g) were statistically similar. However, starter final weight (FWT) (555.61-705.99g); daily feed intake (DFI) (61.80-67.79g), and feed conversion ratio (FCR) (3.27-4.09) were significantly (P<0.05) affected. Daily weight gain (DWG) (15.27-20.75g) was also affected at (P<0.01). Similar trend was observed at the finisher phase: initial weight ranged from (555.61-705.99g), FWT (1592.10-1899.50g) and DFI (121.27-131.93g) were significantly (P<0.05) influenced by the dietary treatments. However, DWG (37.02- 43.40g) and FCR (3.04-3.34) were not affected. The overall performance indicated (IWT) (341.75-415.53g), FWT (1073.86-1302.75g), DWG (26.15-31.69g) was significant at P<0.05. DFI (91.39-99.86g) and FCR (3.19- 3.72) were significantly (P<0.01) influenced by the dietary levels of SSM. In most of the parameters measured, the best performance was obtained in broiler birds fed diet 4. It can be concluded that SSM can completely replace maize as dietary energy source in the diets of broiler chickens with no adverse effect on performance.

Introduction

Poultry in Nigeria had undergone tremendous changes over the past four decades, both in genotypes, management and technological advancement (Adejoro, 2000). Poultry production forms an important component of livestock subsector as a provider of employment and income (Eduvie, 2002). Ogundupe and Sanni (2002) reported the primary purpose of keeping poultry in all parts of Nigeria is for both dietary and economic reasons.

Animal protein requirement in the developing countries has become critical due to rapid population growth, this creates adverse consequences on food security and has resulted in high incidence of hunger and malnutrition (Yusuf *et al*., 2008). About 10g of animal protein on average is consumed in Nigeria per day which is a shortfall of 25g of the 35g recommended by FAO (Oke *et al.*, 2012). The current acute shortage of animal protein in Nigeria and the rapidly increasing demand for livestock could be alleviated through broiler production (Nworgu *et al.*, 2000). The demand for maize (the chief energy source for poultry) by man as food and other industrial uses coupled with low production locally has placed additional constraints on its continual use in poultry diets (Adamu *et al.*, 2012; Summan, *et al.*, 2017).

Nigeria is an important millet producing country, ranks second after India in global millet production. At the national level, millet ranks third after maize and sorghum among cereal food crops (Adamu, 1998). Summan (2017) reported the pearl millet crude protein ranging from 10-16%. Millet is superior to maize and sorghum in protein content and quality. Ibitoye *et al*., 2012). It does not contain any condensed polyphenols such as the tannins in sorghum that can interfere with or slow down digestibility (Olomu, 1995). Out of the 4.6 million tonnes of millet produced in Nigeria in 1992 – 1994 only 0.1 million tonne was used as feed.

(Aminu-Kano *et al.*, 1998). There is the need towards looking for cheap, easily available energy sources that are less or no industrial uses. At the same time could help to meet the nutritional requirements of the birds.

Materials and Method

Four experimental diets were formulated for both starter (23% CP) and finisher (20% CP) phases. Super SOSAT millet was included at 0, 33, 66 and 100% levels coded as diets 1, 2, 3 and 4 respectively, as presented in Tables 1 and 2.

Table 1: Ingredients and percentage composition of dietary levels of SSM fed to broiler chickens at the starter phase (2 – 5 weeks).

Two hundred and ten (208) unsexed marshal day old broiler chicks were procured from chi-chicks hatchery at Ibadan, Nigeria. The birds were brooded for one weeks on deep litter and they were fed commercial broiler starter diet (Hybrid feed) during this period. After a week brooding period, they were randomly allotted to four dietary treatments in a Completely Randomize Design (CRD). Each treatment was replicated four times and for every treatment there were fifty-two (52) birds with thirteen birds per replicate. Initial weight of the birds was taken for every replicate and average weight per bird was also determined. The bird's weights were recorded on weekly intervals thereafter. Experimental diets and clean water were given *adlibitum.* Feed intake per each replication and per bird were determined. Feed conversion ratio were also computed. Data generated were subjected to analysis of variance((ANOVA) using spss, where different exist among means DMRT was used to separate the means.

Results and Discussion

The daily feed intake (DFI) at the starter (61.80 – 67.79g) and finisher phase (121.27 – 131.93g) phases were significantly (P<0.05) affected as well as the overall (DFI) (91.39 – 99.86g) was also significantly ((P<0.01) influenced by the dietary levels of super SOSAT millet (SSM) as presented in tables 3, 4 and 5.

These findings agreed with the report of Ibitoye *et al.* (2012) which stated that millet did not impairs feed intake when compared to maize based diet. Kawu (2010) reported significant difference (P<0.01) when gayamba millet was fed as energy source to replace maize in broiler chicken diets at the starter phase. This could be due to high fat content of millet as compared with maize which has been reported to improve appetite (Moran, 1996).

Daily weight gain (61.80-67.79g) at the starter phase and overall gain (26.15-31.69g) were significantly (P<0.05) affected by the dietary levels of SSM table 3 and 5. The body weight gain at the finisher phase ranged from (37.02-42.39g) however, they were not affected by the dietary treatments (table 4). The results of this study are in agreement with the reports of Luis *et al.* (1980) who stated that broil*er* chickens fed millet diets performed better than the maize and sorghum groups. (Kawu, 2010 and Afsharmanesh *et al.,* 2016) reported that broiler chickens fed millet based diets gave higher average body weight than those on diet containing maize. Ibitoye *et al.* (2012) reported similar findings in broiler chicken at the finisher phase.

Feed conversion ratio (3.27-4.09) were significantly (P<0.05) affected at the starter phase. Similar trend (P<0.01) was obtained at the overall conversion ratio table 3 and 5. However, the conversion ratio (3.04-3.43) at the finisher phase were not affected (Table 4). The best conversion ratio was observed in birds fed 100% SSM based die. These findings are in agreement with the reports by (Afsharmanesh *et al.,* 2016) that better feed conversion ratio was obtained in birds feed millet based diets.

Mortality recorded during the experiment was 14. Four birds for diets 1 (100% maize) and 4 (100% super SOSAT millet). Diets 2 (33% SSM) and 3 (66% SSM) had three each (Table 3). The mortality occurred at the first and second day of the experiment due to sudden change in weather condition. Abeke (2002) reported that chicks are very susceptible to environmental temperatures because they are born naked. Too low or high temperatures especially at the brooding period can accounts for up to 50% of the chick's mortality.

Conclusion

It was concluded that super SOSAT millet (SSM) can completely replace maize in the diets of broiler chickens with no adverse effects on growth performance.

ABSTRACT
A study was conducted to evaluate the effect of feeding scent leaf oscimum gratisimum meal on haematological profile of weaner rabbits. Thirty (30) mixed breeds of weaner rabbits with an average weight of 1675g were used to investigate the haematological profile of rabbits fed diets containing different inclusion levels (0, 5, 10, 15 and 20%) of scent leaf Ocimum gratissimum meal. The rabbits were randomly assigned to five dietary treatments comprising of six rabbits per treatment, in a completely randomized design (CRD), the study lasted for 72 days. The rabbits were individually housed in iron gauze cages. Diet was formulated to contain 18% CP, and the controlled diet was free of O. gratissimum. Feed and clean water were provided ad libitum. Blood samples were collected for haematological profile analysis after the feeding trial. The inclusion of scent leaf O. gratissimum in the diets significantly (P<0.05) influenced haematological profile of the rabbits. The Packed Cell Volume (PCV) values ranged from 27-38g/dl and was significantly higher (P<0.005) for rabbits fed diet containing 5% O. gratissimum meal. Haemoglobin (Hb) values were highest (P<0.05) for rabbits fed diet containing 5% O. gratissimum meal (38.333) but ranged from 27-38g/dl in the animals. Rabbits fed diet with 0% level of inclusion of O. gratissimum had the highest white blood cells count (WBC). All the haematological profile obtained were within the normal range of healthy rabbits, thus the scent leaf had no detrimental effect on the haematological profile of the rabbits.

Keywords: Haematology, rabbits, *Ocimum gratissimum*, scent leaf

INTRODUCTION
The growing interest in the use of natural herbs and medicinal plants as alternative feed additives in rabbit diets has led to evaluation and use of bio-active botanicals. Such alternatives are currently being promoted as prebiotics, probiotics, organic acids, essential oils, and other medicinal plants products (Charles and Simon, 1992). Phytochemical analyses of these botanicals have shown the presence of essential oil and phytochemicals that improve performance and reduces bacterial load in non-ruminant livestock (Poole, 1987), *Ocimum gratissimum* is one of such plants. Scent leaf possesses all the potentials of an effective natural growth promoter which can safely replace antibiotic growth promoters. From enhancing growth and productive performances, to influencing carcass traits and improving blood profile of the rabbits (Poole, 1987; Yashim, *et al.* 2017).

Blood is an important reliable medium for assessing the health status of an individual animal. Gupta *et al.*, (2007) reported that blood constituents are used to monitor and evaluate health and nutritional status of animals. It is a medium through which nutrients are conveyed to various parts of the body system of an organism. A readily available and fast means of assessing clinical and nutritional status of an animal on a feeding trial is by the use of blood analysis (Yashim *et al.*, 2016). Therefore, this study was carried out to evaluate the haematological profile of weaned rabbits fed diets containing scent leaf (*Ocimum gratissimum*).

MATERIALS AND METHODS

The experiment was conducted in the Department of Animal Science teaching and research Farm, Ahmadu Bello University Zaria, Kaduna State. The experimental material *Ocimum gratissimum* (Scent leaf) leaves were locally sourced, milled and stored in jute bags until it was used. Thirty mixed-breeds weaned rabbits with an average weight of 1.53 kg were randomly allocated to five dietary treatments in a completely randomized design with 6 rabbits per treatment, the study lasted for 8 weeks.

The rabbits were kept individually in all-wire metabolic cages which has a provision for feeder, drinker and for easy collection of urine and faeces. Five iso-nitrogenous diets were formulated to contain 18% CP with *Ocimum gratissimum* at inclusion levels of 0, 5, 10, 15 and 20% (Table 1). The cages were properly disinfected using Morigald® before the commencement of the study. The animals were prophylactically treated for internal and external parasites using subcutaneous injection of Ivomec® and a broad-spectrum antibiotic (Oxytetracycline 10%) was administered intramuscularly at the manufacturer's recommended rate. Fresh and clean drinking water was provided to the rabbits daily *ad libitum* as well as the experimental diets. Blood samples were collected using blood sample collection techniques for rabbits as described by Yashim (2017). Data collected from this study were subjected to statistical analysis and significant means were compared (SAS, 2002).

RESULTS AND DISCUSSION

The result of the haematological indices of weaner rabbits fed diet containing different inclusion levels of *Ocimum gratissimum* was shown in Table 2. The inclusion of *O. gratissimum* significantly ($P<0.05$) affected all parameters measured. Packed cell volume (PCV) was significantly ($P<0.05$) affected, with 5% inclusion level having higher value (38.33%) and the least value (27.07%) in 20% inclusion. The observed PCV values in this study were within the normal range of healthy rabbit as reported by Hillyer (1994). Haemoglobin (Hb) ranged from 9.20 to 12.63g/dl with the higher ($P<0.05$) values observed at 5% inclusion (12.63 g/dl) while 20% had the least value of 9.20g/dl. The haemoglobin concentration compared favourably with the values of 10.00 to 15.00g/dl reported by Hellyer (1994); 9.10-15g/dl by Njidda *et al.* (2014) and 11.86 to 13.91g/dl by Yashim *et al.* (2017). The white blood cell (WBC) count in this study ranged from 4.46-7.03 x 10^9/l, the values compared favourably with the normal values of 4.71 to 9.23 x 10^3/mm^3 in healthy rabbits (Yashim *et al*., 2017). These results indicated that the animals were healthy at the beginning of the experiment, because decrease in number of WBC below the normal range could be an indication of allergic conditions, anaphylactic shock and certain parasitism. While elevated values (leukocytosis) may indicate the existence of a recent infection, usually with bacteria (Poole, 1987). Neutrophils and Lymphocyte values also differed ($P<0.05$) across treatment groups. Animals on 10% inclusion had higher concentration of lymphocytes. The observed values were within normal range of 40-80% reported by Poole (1987) and Yashim *et al.* (2017).

^{abcd} Means within row with different superscript are significantly different at P<0.05; SEM= Standard error of [mean

CONCLUSION

From this study, it can be concluded that the inclusion of *Ocimum gratissimum* in the diet of rabbits had no negative effect on the haematological indices, as all parameters investigated were within the normal range.

ABSTRACT

This study investigated the growth performance of broiler chickens fed diets containing graded levels of Brewer's Dried Grain (BDG). One hundred and fifty 2 weeks old Arbor acre breeds of broiler chickens were divided into 5 groups (treatments) of 30 birds. Each group was further divided into 3 replicates of 10 birds in a completely Randomized Design. The 5 groups of birds after 2 weeks of brooding on commercial broiler starter diets were allotted to 5 different formulated diets containing 0 (control), 10, 20, 30 and 40% levels of inclusion of (BDG). The birds were fed the experimental diets for 6 weeks (42) days. Average total feed intake (5120.00, 5343.33, 5366.67, 5386.67, 5400.00) average total weight grain (2283.33, 2143.33, 2076.67, 1546.67, 1303.33), average final live weights 2546.67, 2430.00, 2386.67, 1850.00, 1603.33g) feed conversion ratio (2.25, 2.51, 2.67, 3.49, 4.14) and feed cost per kg gain (₦ 300.23, 288.70, 334.48, 427.13, 491.32) were significantly different (P<0.05) between treatment groups. Growth performance parameters decreased with increasing levels of BDG inclusion. It was concluded that inclusion of BDG should not exceed 30 % in broiler diets for cost effective feeding

Key words: Growth performance, broilers, brewer's dried grains

INTRODUCTION

Brewer's Dried Grain (BDG) is a solid waste from the Brewer's industries. It is available and cheap but difficult to dry to low moisture content for easy storage and use, especially during the wet seasons (Rijal, 2009). Jacquie (2015) stressed that agro-industrial by-products such as Brewer's Dried Grain (BDG) are primarily fed to dairy cattle but have some nutritional value for poultry as well. Rijal (2009) stated that with shortage and increasing prices of feed ingredients, continuous efforts are being made to make use of the cheaper and available agro industrial by-products in animal feeds in order to reduce cost without any deleterious effects on their performance. Some problems limiting the use of BDG in poultry rations are high fiber content (Jacuie, 2015), nucleic acid toxicity, poor palatability and limitation of sulphur amino acids in the product. Nucleic acid toxicity is said to be solved naturally due to the availability of the enzyme (uricase) in mammals which enables them overcome the problem (McDonald *et al*., 1998). Palatability is improved by blending it with other feedstuffs and sulphur amino acid limitation is overcome by supplementation with synthetic products. In Nigeria with several brewing industries, BDG is readily available. This study was aimed at determining the effects feeding diets containing graded levels of BDG on growth performance of broilers.

MATERIALS AND METHODS

Experimental Site

The experiment was conducted at the poultry unit of the Livestock Investigation Department (L.I.D) of the National Veterinary Research Institute in Vom, a quiet rocky village in Jos South Local Government Area of Plateau State with an altitude of 1285 meters above sea level and a cool climate between December and January with temperatures as low as 8°C. The wet season extends from late April to middle October (NVRI, 2019).

Experimental Diets, Birds, Design and Management

Five (5) experimental diets were formulated such that Brewer's Dried Grain was included in the diets at 0 (control), 10, 20, 30 and 40 % levels at starter and finisher phases (Table 1) The diets were formulated to contain the same levels of dietary protein. After 2 weeks brooding on commercial broiler starter feeds, the birds were allotted to the five different diets, each having 30 birds. The five groups were further divided into 3 replicates of 10 birds in a Completely Randomized Design. The starter diet was fed to the birds for a period of 2 weeks while the finisher diet was fed for duration of 4 weeks. The parameters taken were the initial and final weights, feed intake, weights gained. Feed Conversion Ratio (FCR) and feed cost per kg weights gained were calculated from the values obtained from the aforementioned parameters.

Table 1: Ingredient Composition of Broiler Finisher Diets

Ingredients	Levels of BDG inclusion in diet (%)				
	0	10	20	30	40

Proximate composition of Brewer's Dried Grain (BDG)

The proximate composition of BDG used in this study is presented in table 2. The values obtained for most of the nutrients are similar to 8.50 % Moisture, 17. 80 % Crude Fibre, 6.80 % Ether Extract, 50.80 % NFE, %.00 % Ash and 19.68 % Crude Protein reported by Imonikebe and Kperegbeyi (2014). However, the result is different from the composition obtained by Isikwenu (2011) who reported that BDG contained 24.21 % Crude protein, 11.20 % Crude fibre, 3.69 % lipids, 8.04 % Ash and 46.20 % NFE. The differences may be due to differences in geographical locations or soil compositions where the various grains were cultivated, the types of varieties or cultivars of crops used, stage of ripeness at which the grains were harvested (Bolton and Blair, 1986) or even differences in accuracy or precision of laboratory techniques used for the analyses. It may also be due to differences in processing methods of the grains in the different locations.

The Effect of Brewers Dried Grain on Feed Intake of Broiler Chickens

Based on the findings of this work presented in table 3, feed intake increased (P<0.05) with increasing levels of BDG inclusion across the treatments. A similar report was given by Swain *et al* (2012), who recorded significant (P<0.05) increases in feed intake as levels of brewer's dried grain incorporated in chick diets increased. However, the results of this work is not in agreement with what was obtained in the study undertaken by Denstadli *et al*. (2010), who reported that inclusion of brewer's dried grain had no effect on feed intake. The difference between this work and that of Denstadli *et al.* (2010) may be due to differences in compositions, methods of processing of BDG and differences in feed forms (mash and pellets respectively) fed to the birds in the different studies respectively. Weight gains decreased significantly (p<0.05) across the treatments. The birds fed diets containing 0 % BDG recorded the highest weight gain, followed by those fed diets containing 10, 20, 30 and 40 % in that order agreeing with reports of Denstadli *et al.* (2010) who stated that increasing levels of BDG reduced the rate of body weight gains of broilers. The feed conversion ratio (FCR)

values for birds in this study were 2.25, 2.51, 2.67, 3.49 and 4.14 respectively which increased (P<0.05) with increasing levels of BDG inclusion in the diets. Calculated Metabolizable Energy values decreased with increasing levels if BDG inclusion which could be why FCR values were increasing across treatments as birds are known to increase feed intake in order to meet their energy requirements (Davidson *et al*., 1961). The higher FCR values of birds fed diets containing BDG is as a result of the diets containing lower energy and higher fibre contents. Feed cost per kg weight gain of the birds in this study are ₦300.23, ₦ 288.70, ₦334.48, ₦427.13 and ₦ 491.36 were significantly different (P<0.05) across treatments with broilers fed diets containing 40 % level of BDG recording the highest cost per unit weight gain. Those fed 10 % BDG diet recorded the least cost per unit weight gain which was not significantly different from those fed 0 and 20 % BDG levels.

CONCLUSION AND RECOMMENDATIONS

Based on the results of this study, the growth rate of broiler chickens is influenced by levels of BDG in their diets. The rate of weight gain decreased with increasing levels of BDG in the diet and vice versa. Also, the higher the level of BDG in the diet, the higher the FCR and feed cost per kg gain values. It is therefore, recommended that broilers diets can contain up to 20 % level of BDG without any adverse effect on growth performance.

ABSTRACT

The experiments was conducted to evaluate the performance of broiler starter fed different levels of maize milling residue (MMR) as replacement for millet offal (MO) at graded levels of 0, 25, 50, 75 and 100%. Two hundred broiler chicks were randomly assigned to five dietary treatments in a completely randomized design with forty birds per treatment (four replicates). Feed and water were offered ad-libitum. The feeding trials lasted for four weeks. The results of the daily feed intake (DFI) were similar across the dietary treatment. The DFI ranges from 69.26-73.10g. The highest value was obtained on diet 4 (75% MMR) and lowest on diet 1 (0% MMR). No significant dietary effect was observed in daily weight gain (DWG) across the treatment groups. Similarly no significant dietary effect observed among the treatments on feed conversion ratio (FCR). However, FCR was better in diet 1 (0% MMR). Based on the results obtained, MMR can completely (100%) replace millet offal (MO) as dietary fibre source for feeding broiler starter with no negative effects on performance.

Key words: Broilers Starter, Millet offal, Maize milling residue, Performance.

INTRODUCTION

Nowadays, one of the most important nutritional problems in most developing countries is that of inadequate protein intake, more especially that of animal origin (Fielding, 1991). Animal protein contains the essential amino acids which are more balanced and readily available to meet human nutritional needs than plant proteins. FAO (1986) asserted that out of 45.0 g total protein consumed by an average Nigerian, only 7.0 g comes from animal sources. This low protein intake has been attributed to low level of animal production and high cost of animal products. The consequences of this low protein intake are retarded growth, high incidence of kwashiorkor, high rate of child mortality, short life-span and wide-spread protein-energy malnutrition.

Therefore the need for increase in animal production is absolutely critical and this can be achieved by producing highly productive animals with short generation intervals like broilers, rabbits and pigs. These animals are known to have high fecundity, short generation interval and fast growing rate (Yusuf *et al* 2015). Despite their rapid rate of multiplication, one of most important constrain in producing monogastric animals is the high cost of production due to high cost of feed which discouraged many farmers from engaging in poultry business. The situation has drawn the attention of nutritionist, scientist and agriculturist to the need for research in to the use of simple agro-industrial by-product that are not staple food for man to meet the nutritional needs of the monogastric. If this is achieved, it would lower the cost of production and consequently lead to availability and affordability of animal protein for the increasing human population of Nigeria (Yusuf *et al*. 2019).

One of the agro-industrial by-products that are cheap and available all year round throughout the tropical region is maize milling residue (MMR). MMR is suitable in formulating broiler diets as a source of fibre and to some extend can provides a reasonable amount of energy in the diets. MMR is a by- product obtained during the processing of maize grain into flour mainly from small scale millers. It consists of the outer covering (coat) of the maize seed and few broken maize and relatively cheap and available in all communities in Nigeria. The amount of broken maize found in MMR is depended on the efficiency of the milling process and the variety of the maize. Generally, MMR is said to contain 89.41%Dry matter, 11.00% crude protein, 1.8% ether extract, 6.60% crude fibre, 68.07% nitrogen free extract, 62%Total digestible nutrient, 1.99% Ash, 0.30% Calcium and 0.16% phosphorus (Ogundipe, 2002).

MATERIALS AND METHODS

Experimental Site

The experiment was conducted at the Poultry section of Department of Animal Production Program, Teaching and Research farm, Abubakar Tafawa Balewa University Bauchi, Bauchi State, Nigeria. Bauchi town is located within Southern Guinea Savannah on latitude 13°13'' N and longitude 11° 50'' E at an altitude of 690.20m above sea level. It is characterized by two distinct seasons, the dry season from November to May and wet season from June to October. Ambient temperatures range from 15-19°C in December to January (cool season) and 33-44°C in March to June (hot season) and low relative humidity ranging from 5-43.5% (Alaku, 1983).

Experimental Materials

The ingredients for formulating the experimental diets include maize, maize milling residue, ,millet offal, Soya bean, fish meal, common salt, bone meal, methionine, lysine and mineral-vitamin premix. All ingredients were purchased in the local market within Bauchi and Yobe State. Experimental starter and finisher diets were formulated to meet protein and energy requirement of the birds

Experimental stock and management

Two hundred unsexed day-old Anak 2000 broiler chicks were used for the experiment. The chicks were placed on commercial starter diet during brooding for a week, before they were randomly assigned to experimental starter diets for four weeks. The experiment consisted of five treatments (diets) replicated four times with ten birds per replicate making it forty birds in a completely randomized design (CRD). Experimental diets and clean drinking water were provided *ad-libitum* during the conduct of the experiment. The experiment was concluded when the birds were five weeks on the diets. All management practices such as routine vaccination, proper sanitation and treatment of sick birds were strictly adhered to. Initial live weights of the chicks were measured at the beginning of the experiment; daily feed intake and weekly live weight gain during the conduct of the experiment were measured. At the end of the experiment, feed conversion ratio was evaluated.

3.4.2 Experimental diets

Five starter diets were formulated in which maize milling residue replaces millet offal at 0, 25, 50, 75, and 100% and designated as diets 1, 2, 3, 4, and 5 respectively. The compositions of the experimental diets and calculated analysis are presented in Tables 1.

Results

Productive performance

The productive performance of broiler chicks fed dietary levels of maize milling residue (MMR) as replacement for millet offal is presented in Table 2. The initial live weights of the birds ranged from 215.75-231.550g and were similar. The daily feed intake (DFI) of broiler chicks ranged from 69.26-71.68g for broiler chicks on diets 1 and 4 respectively and the values did not differ significantly across the treatments. The daily weight gain (DWG) of broiler chicks ranged from 34.61-38.49g for chicks fed diets 5 and 1respectively, however, all the values recorded were not significantly affected by dietary treatment. The final body weights of the birds varied between 949.80 and 1025.80g in broiler chickens on diets 5 and 1respectively, and were not significantly affected by MMR levels. Feed conversion ratio varied between 1.82 and 2.04 in broiler chickens on diets 1 and 3. However, all values obtained were not significantly affected by levels of MMR in the diets.

Mortality

No mortality was recorded at the starter phase of the experiment.

Discussion

Productive performance

The results of the daily feed intake (DFI) were similar across the dietary treatment which ranges from 69.26-73.10g. Though not significant, higher value was obtained on diet 4 (75% MMR) and lower on diet 1 (0% MMR). High feed intake in diet 4 may result from fibrous nature of the test materials as MMR is more fibrous than millet offal. The values obtained were similar to the findings of Ezieshi and Olomu (2008) in broiler chickens fed palm kernel cake and millet offal. No significant dietary effect was observed in daily weight gain (DWG). Though not significantly different, the higher DWG was also recorded on diet 4. This cannot be attributed to dietary effect as the values did not follow a definite trend. The values are similar to findings of Ezieshi and Olomu (2004) in broiler chickens fed palm kernel cake and millet offal. The replacement of millet offal with maize milling residue has no

significant dietary effect among the treatments on feed conversion ratio (FCR). However, FCR was better in diet 1 (0% MMR). The values were also similar to those reported by Diara *et al.* (2002) in broiler chickens fed millet offal as replacement for wheat offal.

Table 2: Productive Performance of Broiler Starter Chickens Fed Dietary Level of Maize Milling Residues as Replacement for Millet Offal

	Diets					
Parameter	**1(0%)**	**2(25%)**	**3(50%)**	**4(75%)**	**5(100%)**	**SEM**

Mortality (number)	0	0	0	0	0	-

CONCLUSIONS

MMR can completely (100%) replace millet offal (MO) as dietary fibre for feeding broiler starter with no negative effects on performance.

Recommendations

Based on the results obtained, the following recommendations were made:

i. Maize milling residue (MMR) is a suitable feedstuff and can be incorporated at 100% level in starter diets of broiler chickens as sole fibre source. It is a valuable substitute to most cereal fibres like millet offal particularly in the areas where it is cheap and readily available.
ii. Further research should be conducted to evaluate the suitability and its utilization in the diets of other monogastric animals such as layers, guinea fowl, turkey, ducks and rabbits.

Abstract

Present experiment was conducted to evaluate the effect of diets containing varying levels of crude protein (20, 22, 24 and 26%) and metabolizable energy (2600, 2800, 3000 and 3200 kcal/kg) on growth performance of growing Japanese quail. A total of 576 two-week old quail chicks were assigned into 16 treatments. Each treatment were replicated three times and each replicate had 12 birds using a 4 by 4 factorial arrangement in a completely randomized design. Data on performance and nutrient digestibility were recorded and analyzed using a completely randomized design with a 4×4 factorial arrangement during 6 weeks of age. Results of the study showed that both the main and interaction of varying dietary protein and energy levels had no effect on the growth performance of Japanese quails. It could, thus, be recommended that the lowest protein (20 %) and energy (2600 kcal ME/kg) levels be used in the diets of Japanese quails for optimal growth performance since their performance is similar even at the highest protein and energy levels.

Introduction

The world population is growing at an alarming rate. According to PRB (Population Reference Bureau) Projects, Africa's population will more than double to 2.6 billion by 2050 and will account for about 58 percent of the global population increase by that date (Rosen *et al.*, 2016). With this population and the increased concern over low dietary animal protein supply. There is urgent need to increase the animal protein supply. This has led to search for animal that can supply the needed protein. If there is to be progress in this, effort must be placed on identification of alternative food resources that can meet to pace of the population growth (Rosen *et al*, 2016). The incorporation of game birds has been recommended, particularly for developing countries (Geldenhuys *et al.*, 2013) and one of the game birds that has identified is quail.

Quail has attained economic importance as an agricultural species producing eggs and meat that are enjoyed for their unique flavor. They have low maintenance cost because of their small body size (80-300 g), short generation interval having three to four generations in a year). Quail birds are more resistance to diseases and they have high egg production, thus they are an excellent laboratory animal because of their short generation interval. However, the nutritional requirement of this birds for the tropics have not been well established. Studies has shown that the nutrient of birds varies from species to species and from one location to another. Presently, in Nigeria, the diets fed to quail are mostly based on 24 and 20 % of crude protein for rearing and production, respectively, as recommended by NRC (1999) and there are also variations in the dietary crude protein and energy recommendations for quails.

Woodard *et al*., (1973) reported that quail can be raised on turkey starter diets containing 25 – 28 % crude protein while Lee *et al*. (1977) on the other hand indicated that dietary crude protein level of 24 % is needed in starter diet for quail and the protein content may be reduced to 20 % by 3rd week of age. Nwokedi *et al*. (2010) observed that when four crude protein levels of 20, 22, 24 and 26% were evaluated for Japanese quails, birds on 20 % crude protein level resulted in best performance from 1 to 42 days of age. Murakami *et al*. (1993) discovered that 18% crude protein was adequate at the laying phase this is, however, lower than the 20% recommended by NRC (1994) and 22.42% recommended by Pinto *et al*. (1998).Report of Reda *et al*. (2015) indicated that Japanese quail fed crude protein and energy levels of 22 % and 2900 kcal ME/kg, respectively, as adequate during the first few weeks of growth. While Jahanian and Edriss (2015) reported that Japanese quail fed CP and energy levels of 26 % and 3000 kcal ME/kg, respectively, for the same period.

For the review above, that there are variations in the Japanese quail requirements for energy and protein. The variation might be attributed to region (climatic), breed of quails, time of rearing among others. This study will therefore, determine the effect of four different energy (2600, 2800, 3000 and 3200 Kcal) and four dietary protein levels of 20, 22, 24 and 26 % on the growth performance of Japanese quail raised under intensive management system in Nigeria (a tropical country).

Materials and Methods

The study was conducted at the teaching and Research Farm of Animal Production Department Federal University of Technology Minna, Niger state. Minna lies between latitude $9^0 15^1$ and $9^0 45^1$ N and between longitude $6^0 15^1$ and $6^0 45^1$ of the equator. The mean annual rainfall is between 1200 and 1300 mm and mean temperature ranges from 38 – 42°C

A total of five hundred and seventy-six (576) two weeks old Japanese quails obtained from the National Veterinary Research Institute, VOM, Nigeria. The two-week old quail chicks were assigned into 16 treatments. Each treatment was replicated thrice and each replicate had 12 birds using a 4 by 4 factorial arrangement in a completely randomized design. The experimental diets were corn-soybean based with 4 levels of protein (20, 22, 24 and 26% CP) at either of 4 levels of energy (2600, 2800, 3000 and 3200 kcal ME/kg diet). The composition of the experimental diets is presented in Table 1. The birds in all the treatments were subjected to similar management practices throughout the six weeks experimental period.

Initial weights were determined at the start of the experiment with the aid of salter weighing scale (SGF 400) balance and thereafter at weekly intervals. The final weight was also taken by weighing the birds in each replicate on the last day of the experiment using the same weighing balance. The weight gain was calculated by subtracting the initial weight from the final weight. In addition, the feed intake was calculated by subtracting the feed remaining from the total feed supplied each day before serving fresh one. The feed conversion ratio was also calculated by dividing feed intake by weight gain.

Data Analysis. All data generated were analyzed using two-way analysis of variance (ANOVA) and where significant differences occurred, the means was separated using Duncan Multiple Range Test as contained in the SAS package (2015), version 15.0.

Results and Discussion

The main effect of dietary protein and energy levels on the growth performance results of Japanese quails is presented in Table 2. All the growth performance parameters measured there were no significant differences observed between the treatment group on the performance value recorded.

The interaction results between protein and energy levels on performance were presented in Table 3. There were similar in the main performance of the Japanese quail in all the parameters. The interaction of protein and energy on all the performance parameters was not significant.

Conclusion

Results of the study showed that both the main and interaction of varying dietary protein and energy levels had no effect on the growth performance. It could be recommended that the lowest protein (20 %) and energy (2600 kcal ME/kg) levels be used in the diets of Japanese quails for optimal performance since their performance is similar even at the highest protein and energy levels. Further study on the digestibility and economic of production can be carried out to ascertain the effect on the quails.

Abstract

The study was conducted to evaluate the effect of cocktail of enzymes (Avemix XG 10) which comprised xylanase and glucanase on the performance of grower pigs fed a basal diet containing corn bran, wheat bran and palm kernel cake. A total of 48 grower pigs with an average initial body weight (BW) of 27.81±0.84 kg were randomly allocated to three treatments based on BW and sex (16 replicate pens with one pig) were used in this 56-day trial. Dietary treatments were: (T1) control: basal diet plus 0% Avemix XG 10; (T2) basal diet plus 0.01% Avemix XG 10 and (T3) basal diet plus 0.03% Avemix XG 10. The enzyme (Avemix XG 10) supplementation did not have significant (P>0.05) effect on final body weight, daily weight gain, average daily feed intake and feed conversion ratio. The pigs fed the control diet without Avemix XG 10 had the highest final body weight (43.882 Kg), daily weight gain (0.374 Kg) and average daily feed intake (1.544 Kg) while the lowest values for the aforementioned parameters were observed in the pigs fed diet supplemented with 0.01% Avemix XG 10. The pigs fed diet with 0.03% Avemix XG 10 (T3) had the best feed conversion ratio. The enzyme supplementation increased (P<0.05) the cost of feed/kg diet and also increased the feed cost/kg live weight by 2.64 and 7.92% at 0.01 and 0.03% respectively when compared to the control. In conclusion, dietary supplementation of Avemix XG 10 1in the diet containing high dietary fibre did not improve the performance of grower pigs.

INTRODUCTION

Animal nutritionists continuously search for a cost-effective optimum between ever changing dietary formula and increasing demands on performance. This has led to inclusion of Non-starch polysaccharides rich ingredients in the diets of animals, which often reduces feed cost. However, this hinders a proper digestion due to high fibre and presence of anti-nutritional factors (De Keyser *et al*., 2016). Non-ruminants are physiologically unable to hydrolyze NSP in their small intestine. Dietary fiber is one of the most significant factors that affect gut physiology and health in livestock (Viladomiu *et al.,* 2013; Lindberg, 2014). Non-starch polysaccharide (NSP)-degrading enzymes have been indicated to increase the utilization of fibre with a consequent increase in energy and other nutrients. Again, it has been reported that the addition of non-starch polysaccharides degrading enzymes improve animal growth performance, nutrient digestibility and responses to infectious diseases (Lan *et al*., 2017). Cocktail of enzymes (AveMix® XG 10) is a multi-enzyme concept with high glucanase and high xylanase activity, designed for monogastric feeds. The enzyme activities work synergistically to break down fibre structures. Through the capability of AveMix® XG 10 to break down also soluble fibres into smaller particles, intestinal viscosity will be reduced. This lower viscosity will enhance intake of nutrients in the small intestine, this effect is important in poultry (AVEVE Biochem, 2010). Therefore, the potency of cocktail of enzymes (Avemix XG 10) was assessed to upgrade dietary energy, total protein and amino acid digestibility as well as fibre utilization in growing pigs.

MATERIALS AND METHODS

Experimental location and duration

The feeding trial which lasted for a period of 56 days was carried out at AK farms located at Eleyele, Ibadan, Oyo state, Nigeria. A basal diet deficient in energy, crude protein and high in crude fibre was formulated using the nutrient requirement recommendations for growing pigs

by National Research Council (1998) as a guide (Table 1) for other nutrients. The basal diet was in pellet form, consisting of maize bran, wheat bran and palm kernel cake and other micronutrients. The basal diet served as control (T1) had no Avemix XG 10 while the enzyme (Avemix XG 10) was added to the basal diet at 0.01% (T2) and 0.03% (T3). The control diet (T1) contained 11.05 % crude protein (CP) and 2166 Kcal/ Kg metabolizable energy. All the treatments contained the same percentage of crude fibre (14.17%). Forty-eight growing pigs with average initial live weight of 27.81±0.84 kg were randomly allocated according to body weight and sex to the three experimental treatments with sixteen replicates and each animal represented a replicate in a completely randomized design. The pigs were kept in Pens with area (234 cm × 216 cm) which had concrete floors without litter. Each pen had a concrete feeder (97 cm × 33 cm) and a concrete drinker (97 cm × 33 cm). All the pigs were fed with the experimental diets throughout the experimental period**.** The experimental diets and water were given to the animals unrestrictedly for the period of the experiment. Standard management practices were duly observed. Data were collected on daily feed intake and body weight gain. Daily weight gain, feed conversion ratio and indices for economic analysis were evaluated. All the data were subjected to analysis of variance using General Linear Model of SAS (2002) and the means were separated using Duncan Multiple Range test.

Results and Discussion

The indices used to measure the performance of the growing pigs fed the experimental diets are shown in Table 2. These indices include the final body weight, body weight gain, daily weight gain, average daily feed intake and feed conversion ratio. The differences in all the parameters across the treatments were not significant (P>0.05). The pigs fed the control diet without Avemix XG 10 had the highest final body weight (43.882 Kg), body weight gain (15.721 Kg), daily weight gain (0.374 Kg) and average daily feed intake (1.544 Kg) while the lowest values for the aforementioned parameters were observed in the pigs fed diet supplemented with 0.01% Avemix XG 10. The pigs fed diet with 0.03% Avemix XG 10 (T3) had the best feed conversion ratio while the worst feed conversion ratio was observed in the pigs fed 0.01% Avemix XG 10 (T2), though, these variations were not significantly (P>0.05) different. The use of enzyme (Avemix XG 10) did not show any beneficial effect on the performance of the pigs. This may be as a result of high fibre content in the diets (14.17%) as revealed by the proximate analysis. The enzyme (Avemix XG 10) whose primary function is to break the non-starch polysaccharides in the diets could not make the nutrients encapsulates by the high fibre available to the animals. This has resulted in low bioavailable of several nutrients. The results of this study indicate that pigs fed diets supplemented with the Avemix XG 10 (xylanase and glucanase) had similar performance with those fed the control diet (T1). These results are in disagreement with earlier findings of Fang *et al*. (2007), who reported xylanase supplementation improved the average daily gain and feed efficiency in growing pigs fed corn, soybean and rapeseed based diets. The lack of significant effect of the cocktail of enzymes used in this study (Avemix XG 10) on average daily gain and feed conversion ratio is also in contrary to the report of Nortey *et al*. (2007) who indicated that xylanase supplementation to wheat-based diets improved the average daily gain and feed efficiency. However, the results are inconsistent. The results of this study corroborate the earlier findings of Passos *et al*. (2015) who reported that dietary supplementation of xylanase had no effect on average daily gain, average daily feed intake or feed efficiency in grower pigs fed a corn-soybean meal based diet**.** The seeming contradictions in the effectiveness of enzyme supplementation among studies may be due mainly to differences in pig age and the compositions of the experimental diets (Lan *et al*., 2017). There was a significant (P<0.05) difference in the costs of a kilogram of the diets across the treatments. The significant

difference that exists in the cost of feed per kilogram was ascribed to the inclusion of the enzyme (Avemix XG 10). At 0.01 and 0.03% inclusion levels, enzyme supplementation significantly ($P<0.05$) increased the cost of the feed per kilogram by 2.64 (T2) and 7.92 % (T3) respectively when compared with that of the control (T1).

Conclusion

It could be concluded that Avemix XG 10 (Xylanase and glucanase) supplementation did not improve the performance of grower pigs fed diets marginal in crude protein, metabolisable energy but high in crude fibre.

ABSTRACT

Seeds of Cucumbar sativus L, Acacia nilotica, L, Glycine max L, Parkia globosa, Hibiscus subdariffa L, Mangifera indica, Moringa oleifera, Citrullus lanatus, Adonsonia digitata and Mesocarp of Hypalina theibecca indigenous to semi-arid zone of North Eastern Nigeria were analyzed for proximate composition, minerals and phytochemical properties to assess their potentials as alternative sources of protein, energy and other nutrients for non-ruminant animals. The Samples were purchased from Garin Alkali in Bursari local market in Yobe State. The samples were air dried and milled to pass through 1mm sieve screen and stored in a cleaned well labeled polythene bag prior to laboratory analyses. Triplicate of representative samples of the feed ingredients were used for analyses. The proximate compositions of the samples were determined using conventional standard analytical methods of Association of Analytical chemists. Mineral contents were determined using Flame Atomic absorption Spectrophotometer Photometer while the Iron contents were determined calorimetrically. All data collected were subjected to analyses of variance using statistical analytics software (SAS). The results of the proximate composition analysis showed considerable variations between samples in Crude Protein (CP), Crude Fiber (CF), Dry Matter (DM) and Ether Extract (EE), Nitrogen free extracts (NFE), Carbohydrates (CHO) and ash. The CP, DM, CF, EE, ash, NFE and CHO values of the samples under investigation ranged from 7.51 to 35.22, 77 to 94.00, 0.05 to 25.00, 2 to 26, 3.00 to 14.00, 10.27 to 70.46 and 30 to 74.48% respectively. The highest level of CP 35.22% was recorded in Glycine max seed while the lowest value of CP 7.51% was recorded in Mangifera indica seed. Minerals such as Sodium (Na), Potassium (K), Magnesium (Mg),Chromium (Cr), Zinc(zn), Copper(cu),Manganese(Mn) and Iron (Fe) ranged from 0.64 to 3.20, 0.06 to 0.77, 2.04 to 9.04, 0.29 to 0.89,0.88 to 2.72, 0.16 to 2.59, 0.83 to 4.96, 0.19 to 1.15 and 0.52 to 2.26 ppm respectively. Highest concentration of important minerals such as Calcium (2.72 ppm), Sodium (3.20 ppm), iron (2.26 ppm), Zinc (2.59 ppm) and Magnesium (9.06 ppm) were obtained in Acacia nilotica, Acacia nilotica and Moringa oleifera, Hibiscus subdariffa and Parkia globosa. Phytochemical screening revealed the presence of alkaloids, tannins, Phenols and Flavonoids. The highest values of total phenol 417 mg/GAE/100g, tannin 4.54 mg/GAE/100g, Flavonoid 2.21RE/100g and Alkaloid 11.00 % was recorded in Acacia nilotica, Glycine max, Citrullus lanatus and Hypalina theibecca. The study revealed that Acacia nilotica, Hibiscus subdariffa, Parkia globosa and Glycine max are rich in calcium and sodium, iron and Magnesium and zinc. Similarly the crude protein and carbohydrate values of Acacia nilotica, Hypalina theibecca, Citrullus lanatus and Adonsonia digitata are comparable to most cereal grains and can be used when processed.

Key Words: Proximate, Minerals, Phytochemicals and Feed ingredients.

Introduction

The production of conventional feed ingredients such maize and soya beans may no longer be able to keep pace with the demands (Diarra *et al*., 2011). Consequently, determination of other suitable alternative plants to serve as sources of protein, energy and other nutrients for non-ruminant animals are timely. The utilization of non-conventional feed resources is justified by serious feed deficits, rising cost of production, continuing low animal productivity, and inability of the components of the animal industries to meet national targets, especially of animal protein (Iyayi, 2017). Babiker *et al*. (2009) observed that tables of chemical composition of feed ingredients are in fixed figures without considering the variability in nutrients which may happen due to intrinsic (variety) and external factors such as soil type, climatic conditions, geographical locations, storage and season of growing. Several authors have also reported that energy value in feed ingredients is not constant and that may happens due to the conditions of harvesting (Zijlstra *et al*., 1999), post-harvest storage (Kim *et al*., 2003) or growing location (George and McCracken, 2003). Feed analyses are essential for ensuring accurate information on the composition of feed ingredients and determining the level of desirable and undesirable substances, enabling the production of safe, balanced diets for livestock. The study

was conducted to investigate the Proximate, Mineral and Phytochemical composition of some selected feed ingredients in semi-arid area of Yobe state, Nigeria.

Materials and Methods

Sample collection and preparation

The selected feed ingredients are *Cucumbar sativus L* seed, *Acacia nilotica*,L seed, *Glycine max L* seed, *Parkia globosa seed, Hypalina theibecca, (*mesocarp), *Hibiscus subdariffa L.*seed, *Mangifera indica* seed, *Moringa oleifera* seed, *Citrullus lanatus seed* and *Adonsonia digitata* seed. Samples were purchased from Garin Alkali in Bursari local market in Yobe State. The samples were identified and authenticated at the Agronomy and Forestry and Wildlife Departments, Federal University Gashua. The samples were air dried and milled to pass through 1mm sieve screen and stored in a cleaned well labeled polythene bag prior to laboratory analyses.

Sampling and Laboratory analysis

Triplicate of representative samples of the feed ingredients were obtained and placed in clean plastic containers properly labeled and tightly sealed. Samples were analyzed in the Department of Animal Science, Land Mark University Omu-Aran Kwara State, Nigeria.

Proximate analysis

Proximate chemical compositions for all samples were determined according to Official Methods of Analysis (A.O.A.C., 1990). Nitrogen free extract (NFE) was obtained by difference.

Mineral analysis

The Minerals were determined according to procedure described by (Martin Prevel, 1984) using flame atomic absorption spectrophotometer and photometer, Iron contents was determined calorimetrically.

Phytochemical

Total Flavonoid determination

The total flavonoid contents were determined using the Aluminum colorimetric methods (Chang *et al*., 2002, Stankovic, 2011) with some modification using Rutin as the standard.

Tannin determination

The tannin content was analyzed using the method reported by Ejikeme *et al*. (2014). One gram of the sample extracts was macerated with 50 ml of Methanol and filtered. 0.3ml of 0.1N Ferric Chloride, 0.1N HCl and 0.3ml of 0.0008m of Potassium Ferricyanide was added and the absorbance was read at 720nm.

Alkaloid determination

0.5g of the test samples was weighed and 20ml of 20% Acetic acid was added to it in 100ml beaker. The beakers were covered and allowed to stand for 4 hours. They were later filtered and placed in water bath to reduce the weight to one quarter. Concentrated Ammonium hydroxide was added drop-wisely until precipitation was complete. It was then collected by filtration and weighed. The total phenol content was analyzed using Folin-Ciocalteu method as reported by Agbenorhevi and Marshall (2012).Triplicate absorbance readings were taken for each sample. The results for the samples were expressed as concentration of gallic acid equivalent (mg GAE/100 g) using the equation obtained from the standard calibration curve.

Statistical analysis.

All measurements were replicated three times and expressed as mean ± SEM. Data collected were subjected to one way analysis of variance (ANOVA) and significant means were compared using Duncan multiple Range Test (DMRT).

Results and Discussion

Table 1 presents the result of the proximate chemical composition of some selected feed ingredients. The crude protein values of the samples under investigation ranged from 7.51 to 35.22 %. The highest level of CP was recorded in *Glycine max* seed while the lowest CP value of 7.51% was recorded in *Mangifera indica* seed. There were significant differences (P < 0.05) in CP, CF, EE, ash and NFE for the feed ingredients in this study. The DM, CP, EE, CF, ash and NFE values for *Mangifera indica* seed obtained in this study differed from the values earlier reported by other studies (Diarra *et al.*, 2011 and Fowonola, 2010).The highest value of NFE, EE, CF was recorded in *Mangifera indica*, *Parkia globosa* and *Glycine max* respectively. The DM, CP, CF, EE, ash and NFE values of 86, 9.02, 7.14, 21.00, 7.00 and 55.84 % obtained in this work for *Cucumis sativus* was not in agreement with values of 87.7, 24.5, 3.00, 0.07, 9.34 and 50.1% reported by Niyi *et al.* (2019). Similarly the values of 35.22, 20, 23 and 5% for CP, CF, EE and Ash for *Glycine max* was not in agreement with values of 39.08, 4.68, 21.08, and 3.40% reported by Diarra *et al.* (2011) and Fowonola (2010).The differences could be attributed to intrinsic (variety) and external factors such as soil type, climatic conditions, geographical locations, storage and season of growing. The mineral content of the various feed ingredients are presented in Table 2. The highest value of calcium, iron and magnesium was recorded in *Acacia nilotica* and *Hibiscus subdariffa.* The results showed significant difference (p<0.05) among the various feed ingredients investigated in this study. The present report showed that *Parkia globosa* had the highest concentration of Zinc. The highest values of total phenol 417mg/GAE/100g, tannin 4.54mg/GAE/100g, Flavonoid 2.21RE/100g and Alkaloid 11.00% was recorded in *Acacia nilotica, Glycine max, Citrullus lanatus* and *Hypalina theibecca* while the lowest values of 58.05 mg/GAE/100g, 1.24 mg/GAE/100g, 0.08 RE/100g and 1.09% were recorded in *Adonsonia digitata*, *Acacia nilotica, Parkia globosa and Glycine max,* and *Cucumis sativus* respectively as reflected in Table 3. The values of Flavonoid, Alkaloid, Tannin, and Phenol obtained in this study are at variance with values of 3.84 RE/100g, 1.64%, 0.46 mg/GAE/100g and 0.06 mg/GAE/100g reported by Okwu and Orji (2007).

Conclusion and recommendation

The study provided information on nutrient levels and phytochemical substances of some feed resources in semi-arid zone of Nigeria. This will serve as baseline upon which other studies can be done. It will also encourage the use of the less expensive and less competitive feed ingredients, thus, reducing the cost of feed, improve the profit margin of farmers. Further studies are recommended on processing of these feed ingredients to ensure effective utilization of these ingredients

Abstract
The study evaluated the effect of choline chloride on growth, haematology, serum biochemistry, and relative organ weight of broilers. A total of 120-day-old chicks were randomly divided into four groups of 30 birds each, which was further sub-divided into 3 replicates of 10 birds each. Group A served as the un-supplemented control while the diets of groups B, C and D were supplemented with 0.5g/kg, 0.75g/kg and 1g/kg of choline Chloride (CC), respectively. The study lasted for six weeks. Result showed that dietary supplementation with CC did not enhance feed intake and weight gain. Group C had a significantly (P<0.05) higher feed efficiency (49.18%) than other choline-supplemented groups and control. There was no significant difference (P>0.05) in the mean values of AST, ALT, total protein and creatinine across all groups. However, the ALP and cholesterol values of group D were significantly (p<0.05) higher and its lymphocyte level significantly lower than all other groups. There was no significant (p>0.05) difference in the mean organ weights across all four groups, but the spleen weight (0.27g) of group D was significantly (p<0.05) higher than all other groups. Supplementation with CC at the level of 1g/ kg of feed seemingly had negative effect on serum cholesterol level and liver hepatocytes as evidenced in elevated values of these parameters in group D broilers.
Key words: Broiler, feed supplementation, choline, cholesterol, liver enzymes.

Introduction
The quest for cost-effective feeding and sustainable production of broilers have led farmers to compound feeds using relatively low-cost ingredients and supplemented with varied feed additives. Farmers have used antibiotics, hormones and many other feed additives to achieve this (Aidara-Kane, 2012). The potential threat to public health from inappropriate antibiotic use in food animals has led to a search for stable and healthier feed additives with positive effects.

Choline plays an essential role in several biological processes within the body such as building and maintaining cell structure as well as ensuring normal maturation of the cartilage matrix of bone, and the prevention of perosis in broilers (Workel, 2002). Very important to the poultry species, is the fact that choline provides the labile methyl groups necessary for the formation of methionine from homocysteine, by being oxidized to betaine (Zhang *et al*., 2013). However, Choline requirement of growing chicks decreases with age.

Conventional feed ingredients like maize and soybean contain choline chloride (CC) at levels lower than what is recommended for broilers (Fouladi *et al*., 2011). Broilers require about 1, 200 – 2,000 mg/kg choline in their feeds (depending on their growth rate). Yet, a typical diet based on corn and soybean (65% maize, 25% soybean, and 10% other) will contain about 1,040 choline from natural sources (Mavromichalis, 2015). Moreover, it is economical to add choline chloride directly to concentrate feed mixture (Erdman and Sharma, 1991).

This study was undertaken to evaluate the effect of CC on growth and health indices in broilers.

Experimental animals/design:

A total of 120 broilers (Ross breed) were procured from Agrited, Ibadan and randomly allocated into 4 groups (A – D) of 30 birds each. The groups were further divided into 3 replicates of 10 birds each. Experimental birds were acclimatized for one week before commencement of the study.

Composition of experimental diet

	Maize	Full-fat soya	Palm kernel meal	*Concentrate
Broiler starter:	60 %	30 %	0 %	10 %
Broiler Finisher:	50 %	30%	10 %	10 %

*Concentrate: Crude fibre 1.8%, Crude fat 4.13%, Sodium 1.41%, Lysine 2.45%, Methionine 32.53%, Methionine + cysteine 3.07%, calcium 5.80% and phosphorus 1.15%.
The compounded feed was divided into four parts; and CC was added at 0g, 0.5g, 0.75g and 1g/kg of feed, representing treatment groups A-D, respectively. Each group was fed their respective diet *ad lib* from day 1 of the experiment to day 42 (6 weeks)

Data collection
Feed intake was recorded daily and weight gain weekly using a sensitive weighing balance.
At the 6th week, 3 birds were randomly selected from each replicate and 5ml of blood collected from the jugular vein, 2 ml was discharged into prelabelled heparinized bottles and remaining 3 ml into clean sample bottles kept in slanted positions and allowed to clot. Serum was harvested after centrifuging the non heparinized blood samples at 3,000 revolution per minute for 3 – 5 minutes. Harvested sera were subjected to biochemical component assays while adhering to manufacturer's recommendations, and using commercial enzymatic kits. Alanine transaminase (ALT) and Aspartate transaminase (AST) activities were assayed by Reitman – Frankel colorimetric method and Alkaline phosphatase activities (ALP) by Phenolphthalein Monophosphate methods as described by Peters (1995). Serum cholesterol and triglyceride levels were assayed by enzymatic colorimetric method as described by Richmond (1973). Total protein and creatinine levels were assayed by Biuret method and modified Jaffe method respectively as described by Kohn and Allen (1995).
For relative organ weight, 12 birds were randomly selected (3 per group) and humanely sacrificed. The relative organ weights of the spleen, heart, liver, proventriculus, gizzard and abdominal fat were determined for each bird.

Statistical analysis
Data obtained were statistically analysed using Analysis of Variance (ANOVA). Significance was accepted at probability values ≤ 0.05. Means were compared using Duncan's new multiple Range Test (DVMRT) (Steel and Torre, 1960).

Results and Discussion
Results of the feed intake, weight gain and feed conversion ratio of broilers fed diets supplemented with varied level of choline chloride is presented in Table 1. The mean weight gain of group A was significantly ($p<0.05$) higher than group B and D but did not differ significantly from that of group C; of the supplemented groups, C and D had higher weight gain than group B. The mean feed intake of the birds across groups A, B and C did not vary significantly but were significantly higher than that of group D. Also, the mean feed efficiency of group C was significantly higher than that of groups A, D, and C.

The result of the serum biochemical parameters suggests that there was no significant difference ($P>0.05$) in the mean values among the four groups for AST, ALT activities and total protein and creatinine levels (Table 2). However, the mean value of ALP activities for group D was significantly ($P<0.05$) higher than group A, B and C. The mean cholesterol value of group D was significantly ($P<0.05$) higher than groups A and B and group C. While the mean triglyceride level of group A was significantly ($P<0.05$) lower than all other groups. Relative organ weight: There was no significant ($P>0.05$) difference in the mean of relative weights of the liver, heart, gizzard, abdominal fat and

proventriculus for the four groups (A, B C and D). However, the mean relative weight of the spleen in group D was significantly (P<0.05) higher than group A.

Supplementation of broiler diets with the choline chloride used in this study did not improve production performance. However, at the inclusion level of 0.75g/kg feed, a slightly improved feed efficiency was observed but without a corresponding improvement in carcass yield. Elevated serum cholesterol levels are indicted with atherosclerosis (Glass and Witztum, 2001); elevated ALP levels are mostly seen in cases of liver damage (Senanayake *et al*., 2015). Dietary supplementation with CC

at the level of 1g/ kg of feed appears to be detrimental to liver hepatocytes and overall health of broilers and by extension could impact negatively on carcass quality of the meat.

Lack of significant difference between supplemented groups and the control was in contrast to McDevitt *et al*. (2000) report that CC could enhance production performance and overall carcass characteristics of broilers. Ratriyanto *et al*, (2009) reported lower activities of lipogenic enzymes and stabilization of protein and cell components against denaturing effect of high ionic strength; both, were not substantiated from our study.

It is recommended that Assay/analysis of 'industrial choline' should be carried out to estimate its actual choline content as well as its level of contamination before use.

CARCASS CHARACTERISTICS OF BROILER CHICKENS FED ACHA HUSK AS REPLACEMENT FOR WHEAT OFFAL

Chomo, F.K., Kalla, D. J. U., Igila, T. T. and Jatutu, S. S
Department of Animal Production, Abubakar Tafawa Balewa University Bauchi, Bauchi State, Nigeria

ABSTRACT
The study was conducted to evaluate the carcass traits of broiler chickens fed acha husk in place of wheat offal. Five different varying levels of acha husk were used in formulating the diets. The design used for the experiment was a completely randomized design. Birds were managed under the deep litter system for a period of 6 weeks. At the end of the experiment, four birds were randomly selected from each treatment for carcass evaluation. The values obtained were subjected to statistical analysis and the results showed that there were significant differences (p>0.05) in some of the parameters such as eviscerated weight, gizzard, liver, heart and spleen where birds on the acha husk base diets did better than the control diet. However, no significant differences were noted in the lungs, small intestine and large intestine of broiler birds under different treatments of acha husk. It was therefore concluded that using acha husk in place of wheat offal in broiler chickens' diets at 24.20% level produced broilers of better carcass traits compared to that fed wheat offal under conventional commercial feeds (p>0.05)

Keywords: Broiler chickens, acha husk, wheat offal, carcass

INTRODUCTION
Global consumption of poultry products (meat & eggs) has consistently increased over the years and this trend is expected to continue (Dale, 2009). The increase in the world population, high cost of conventional animal feed ingredients and low protein intake in most of the developing countries has necessitated animal scientists to search for alternative sources of feed ingredients (Medugu *et al*. 2011). The demand is higher in developing countries and such growth in poultry industry is having a profound effect on the demand for feed and raw materials. Corn and soybean meal are the major ingredients of poultry feed. The cost of virtually all feed ingredients like maize, soybean meal, Di-calcium phosphate, fat and even vitamins has gone beyond exception (Dale, 2009). Due to the ever increasing demand and less supply of raw feed ingredients, cost of feed production has increased. Alternatives for energy and protein sources in poultry diets will be an important means to meet future feed requirement and minimize the cost of feed production. Use of locally available raw feed ingredients like jowar, wheat, barley etc. is now getting importance. Thus, in order to reduce the cost of feed production without affecting the performance of poultry birds, the use of alternative feed sources is gaining importance. A wide range of alternative feedstuffs like jowar, wheat, barley etc. are available for feeding all three poultry production systems. Similarly, in most households and locations, several by-products from cereal milling are available for animal feeding, including bran, hulls and screenings. Despite their high fiber contents, these can be valuable source of energy. Economic quantities, price and nutritive value are the most important criteria to determine the use of a feedstuff in commercial poultry diets. Presently, various alternative protein sources are used like green materials, industrial by-products, animal and fish by-products, insects etc. Similarly, energy sources can be replaced by jowar, wheat, barley and rice. The energy sources are chiefly used at levels of about 50-70% and incidental to their inclusion at these levels, they contribute about 1/4 - 1/3 of the total protein requirement of poultry (Medugu *et al*. 2011).

MATERIAL AND METHODS
The study was conducted in Jos, Plateau Sate. Plateau State is located in Nigeria's middle belt. With an area of 26,899 square kilometers, the State has an estimated population of about three million people. It is located between latitude 08°24'N and longitude 008°32' and 010°38' east. Two hundred day old chicks of mixed sexes were used for the experiment. The chicks were raised/ brooded on deep litter management system for a period of one week. During the brooding, all the necessary management practices were strictly adhered to as appropriate. After the brooding, the chicks were then allocated to the various experimental treatments. The birds were provided with a known quantity of feed. Water was also provided *ad libitum*. The birds were vaccinated appropriately.

The design used for the experiment was a completely randomized design (CRD). The two hundred birds were randomly allocated to five different treatments (table 1) with forty (40) birds per treatment

and each treatment was replicated three times with thirteen birds per replicate. The experiment lasted for a period of eight (8) weeks.
The ingredients for diet formulation were maize, wheat offal, soya bean, cabbage leaves, bone meal, premix, lysine, calcium, methionine and salt with cabbage leaves serving as the test ingredient. Experimental diet was formulated to meet protein and energy requirement of broiler chickens table 1

RESULTS AND DISCUSSION

The result on dressed weight was not significantly different among the treatment mean values but numerically higher in birds fed diet 5. Birds fed Diet 5 had the highest live weight per bird. This observation therefore implied that the dressed weight of chicken may not necessarily be directly proportional to the performance traits. A high weight gain value does not imply a concomitant increase in dressed weight as a percent of live weight (Fasuyi, 2000). The percentages of the eviscerated weight were significantly higher ($p<0.05$) in birds fed diet 5 than those fed the control diet but similar to those fed diet 3 and 4. The result indicated that the diets promoted the development of identical eviscerated weight percent. The values for eviscerated weight in this study ranged from 73.77 – 77.07 % which surpassed the normal range of 65 – 70 % reported for broiler chicken (Oluyemi and Robberts, 1999). Organs are body parts, composed of several types of tissues, capable of carrying out specialized function. The weight of organs in broilers according to Atteh, 2004 reflects the anatomical response of birds to the type of diet consumed. The relative organs weight measured in this study were comparable in all the dietary treatments. Though there were significant differences ($P<0.05$) in the values obtained for heart, gizzard, liver and spleen. The chickens fed the control diet had similar values with acha husk base diet, suggesting that the diets were not detrimental even though the husks may have contained some anti-nutritional factors. The presences of anti-nutritional factors have been associated with abnormal enlargement of organs such as liver and pancreas due to detoxifying activities (Adeyemi, 2003). The significant variation among the treatment mean values of heart, liver, gizzard and spleen follow a particular pattern in relationship with the dietary treatments. It could generally be surmised that the control diet and the test diets enhanced identical organ development. The values obtained for organs weights were in agreement with the finding of Oforjindu, (2006).

Abstract

A study of 6 weeks was conducted to determine the effect of different water sources on the performance of growing Japanese quails. A total of two hundred 2-week old quail birds of mixed sexes were randomly allocated to four water treatments in a completely randomized design. The birds were allocated fifty per replicate. Every replicate has 15 birds with the extra birds distributed without bias at a bird per replicate. Feed given was an on-farm quail chick mash with feed and water supplied ad libitum for 6 weeks. The water sources were from borehole (control), well, stream and dam respectively. Birds on treatment A consumed the highest feed (17.42g), followed by those on treatment C (17.13), D (15.17) and B (15.16). However, the differences were not significant (p>0.05). Water intake of birds on treatment A was higher (39.97ml/bird) than those on treatment C (35.84), B (33.32) and D (32.86) respectively. However, differences were not significant (p >0.05). Birds on treatment D had a higher weight gain (3.88g/bird), followed by those on treatment C (3.67), B (3.62) and A (3.29) in that order. The differences were not also significant (p>0.05). Feed conversion ratio of birds seemed to follow a similar trend with water intake. It was better on treatment D (3.98) followed by those on B (4.14), C (4.76) and A (5.36) respectively. Result of this investigation showed that birds can be raised on any of the water sources. However, water from borehole and well have better control than those from other sources.

Key words: Water intake, feed intake, weight gain, Japanese quails.

Introduction

Japanese quails are little-known birds that are small-sized and early maturing (Robbins, 1981). This early maturing nature enables them to start laying as early as from the 5th week of life (Martins, 1987). It is recommended that persons prone to high blood pressure and related diseases could consume the meat and eggs with less risk. Recommended levels of some nutrients (CP, 25; ME, 2,600kcal/kg) when maintained in the feed is useful in achieving optimal performance in growing Japanese quails, (Edache *et al*., 2005). There is paucity of information regarding the use of water sources for growing quails hence the need for this study.

Water is the most important of all nutrients. Unfortunately, water is neglected in nutritional studies (Osuhor *et al*.2001) and survival time is limited with its absence (Atteh and Leeson, 1983). Water is needed in quantity and quality. In its pure form it is odourless, tasteless and transparent and it is essential to the developmental growth and survival all animals (Swick, 2003). According to Arujo (2010), water is available to animals through drinking water, water in the diet and metabolic water through catabolism of nutrients. Broilers are reported to have large appetite for water about twice or more than that of feed (Fairchild and Riz, 2012). It's usual for birds to consume more water when ambient temperature increases as a means of regulating body temperature (Fairchild and Riz, 2012). The possibility of water shortage affects livestock and therefore, all procedure involving water use must be reviewed (Gherman *et al*., 2012). Anaemia is indicated in the feeding of crude oil polluted water to cockerels (Eastham *et al*. 1993). An adequate knowledge and understanding of the behavior of an animal is inevitable in talking of the production, management and wellbeing and productivity of the animal (Kron *et al*. 2000). Wiseman (2010) opined that for efficient growth and production performance, rabbits need clean water at all times. Poultry house litter and fecal droppings became the major contaminants of water delivery systems, while algae, oil spills and gas flares became the most important contaminants as well as seepages and sewages disposed into water sources (Etuk *et al*., 2018). According to Enukwevwere *et al*. (2018), heavy metal concentrations in drinking water samples were high compared to WHO standards for drinking water. The objective of this study is to determine the effect of different sources of water on the performance of growing Japanese quails owing to the paucity of information regarding this.

Materials and Methods

Birds, housing and management: 200 two-week old Japanese quail birds of mixed sexes obtained from the National Veterinary Research Institute poultry farm were used in this study. They were uniform in size and housed in deep litter house partitioned into several pens with wire mesh to allow for adequate ventilation. The birds were offered one of four treatments involving borehole (control), well, stream and dam water respectively. The birds occupied 12 pens with 16 birds per pen. The experimental treatments were designated A, B, C and D respectively. The remaining birds were distributed without bias to treatments. All birds from each unit were weighed at the beginning and weighed weekly for six weeks. Feed and water were given *ad libitum*.

Water sources: borehole, well, stream and dam. The water was fetched fresh from the borehole, well, stream and dam and used for the experiment. A total of 200 birds were randomly assigned to the water sources in a completely randomized design at 48 birds per water source. This amounted to about 16 birds per replicate. The borehole was the control.

Diets: The diet used was the on –farm feed which was carefully prepared for the purpose..

Table 1. Composition of experimental diet (%)

	Diet
Ingredients	A
Maize	33.22
Rice offal	2.00
Ground nut cake	39.08
Calculated composition	
CP	25.00
ME (Kcal/kg)	2706.92
Ca	1.63
P	0.65
CF	5.25
Feedcost/kg(₦)	84.62

****Others:** palm kernel cake (20.00%), fish meal (1.50%), bone meal (2.00%), lime stone (1.50%), *premix (0.25%), salt (0.25%), methionine (0.10%), lysine (0.10%).

***** Hi Nutrient premix supplied the following per 100kg of diet: Vitamin A, 1,200,000 I.U; Vitamin D_3 250,000 I.U; Vitamin E, 3,000 I.U; Vitamin K, 200mg; Thiamin (B_1), 225mg; Riboflavin (B_2), 600mg; Pyridoxine (B_6), 450mg; Niacin, 4000mg; Vitamin B_{12}, 2mg; Pantothenic acid, 1,500mg; Folic acid, 150mg; Biotin, 8mg; Choline chloride, 30,000mg; Anti oxidant, 12,500mg; Manganese, 8,000mg; Zinc, 5,000mg; Iron, 2,000mg; Copper, 500mg; Iodine, 100mg; Selenium, 20mg; Cobalt, 50mg. Key: C.P, crude protein; M.E, metabolizable energy; Ca, calcium; P, phosphorus; C.F, crude fibre

Data Collection and analysis: The mean weekly body weights, water intake and feed intake were recorded throughout the experimental period. From the mean body weight and feed intake, feed conversion ratio was calculated. Feed cost/kg diet was calculated from prevailing local market price of feed materials. Data collection was subjected to analysis of variance; ANOVA (Steel and Torrie, 1980) and where significant differences occurred, means were separated by Duncan's new multiple range test (Obi, 1990). The analysis was carried out using Minitab version 14 (Minitab, 1991).

Results and Discussion

Data on feed intake, weight gain and feed conversion ratio are presented in Table 2. Data on feed intake was not significant throughout the period. The different water sources were significant for final body weight. This has been agreed to by Jegede *et al*. (2016) that different water levels affected final weight in their work with broilers. However, feed intake, weight gain and feed conversion ratio were not affected by the different water sources which is different from the findings of Jegede *et al*.(2016). Water intake for the different water sources were similar indicating tasteless and sweet water. This is

attested to by Folorunsho *et al*. (2016) and Czarick *et al*. (2001) that birds will consume more water with a sugar additive. Lower water intake is indicative of bitter water which was attested to by Watkins (2000) that it may be a natural response for birds to consume less of such water. Crina (1994) reported that chicks are sensitive to bitter –tasting substances and salt. Feed intake and weight gain were similar across the treatment even though the values were fluctuating but the levels of water intake are similar to that (39 – 44ml/bird/day) reported by Tuleun *et al*. (2009) for Japanese quails. However, quails have been reported to adjust feed intake across a wide range of energy levels (Weber and Reid, 1967) probably due to intrinsic habit developed in the wild. This adjustment may also include water intake.

Table 2. Effects of different rice offal levels on parameters measured

Parameters	A	B	C	D	SEM
Feed intake (g/b/d)	17.42	15.16	17.13	15.17	3.75NS
Water intake (ml/b/d)	39.97	33.32	35.84	32.86	7.70NS
Weight gain (g/b/d)	3.29	3.62	3.67	3.88	0.76NS
Feed/gain ratio	5.36	4.14	4.76	3.98	0.92NS
Initial weight (g/b)	78.27^{b}	52.05^{a}	78.27^{b}	52.53^{a}	1.36*
Final weight (g/b)	204.67^{b}	197.67^{c}	225.00^{a}	208.83^{b}	5.36*

a,b, means with different superscript letters within rows are significantly different ($p<0.05$)

Conclusion

Water is available all year round in many places in Nigeria. The choice of where to get water for birds is important consideration. Looking at the effects of the different water sources on feed intake, weight gain and feed conversion ratio, only the final body weight was significantly affected. Other values were not affected. Therefore, in order to obtain consistent water of high quality, water from borehole and well are recommended.

ABSTRACT
The study was designed to evaluate the effects of processing on the proximate composition and anti nutritional factors in Lablab purpureus seeds. The raw seeds were processed by directly cooking the seed at various duration of time (30, 45 and 60 mins) and by soaking the seed in excess water overnight for about 14hours before cooking at various duration of time (30, 40 and 50 mins). Samples of the raw and processed seeds were analysed for proximate and anti nutritional factors. Result for proximate analysis showed that, the raw lablab seeds contained 93.88%DM, 4.73%Ash, 37.01%CP, 9.67%EE, 6.76%CF and 41.79%NFE. The result for anti nutritional factors revealed that, the raw lablab contained 8.39% Alkaloids, 0.01mg/l00g terpenoids, 0.32mg/l00g, trypsin inhibitor, 8.91mg/l00g cyanide, 1.45% tannin, 18.90mg/l00g oxalate and 0.30% phytate. Generally, both the proximate components and anti nutritional factors analysed were reduced with processing. Directly cooking the lablab seedsfor 30, 45 and 60 minutes yield reduction in both the proximate and anti nutritional factor content. Soaking the seeds before cooking also yields significant reduction in the proximate and anti nutritional factors contents of lablab seeds.

Keywords: Lablab beans, Anti nutritional factors, Proximate compositions.

INTRODUCTION

One of the major problems facing the livestock industry in Nigeria is the increasing unavailability and high cost of conventional feedstuffs like maize, groundnut, soya beans, etc (Bawal *et al*, 2007). This has been attributed to the high level of competition between livestock and man for the same ingredients. The overall effect of this competition is shortage of animal protein production and hence, shortage of animal protein intake due to scarcity and high cost of animal products (Akinmutimi *et al*, 2007).The need therefore, to source for alternative feedstuffs cannot be over emphasized. Such alternative should be cost efficient, available and less competed for by man and industry. Lablab bean can be one of such alternative feedstuff. Lablab bean *(Lablab purpureus)* is an annual leguminous crop that is grown in many tropical and sub tropical areas, particularly in Asia and Africa. It is grown as seed, fodder and vegetable crop. Lablab bean seed is very nutritious and generally estimated to contain 20%-23% protein, 48%-53% carbohydrate and 1.3% fat (Elsiddig *et al.,* 2002). Other nutrient composition of lab lab seed includes; 0.48% calcium and 0.4% phosphorus.The nutritive value of the seed protein is determined by its amino acid content and the magnitude of susceptibility to hydrolysis by the digestive enzymes. However, the nutritional value of *lablab purpureus* beans is shrouded by the presence of anti nutritional factors such as tannin, phytate, trypsin inhibitors, etc which would limit its u se in monogastric nutrition (Shaahu *et al.*,2014*).*Tannin is considered the major anti nutritional factor in lablab bean. Tannin is known to interact with proteins to form Tannin-Protein complexes, which lead to either inactivation of the enzymes or make the protein insoluble (Salunkhe *et al.*,1989). Tannins cause growth depression in animals due to reduction in feed intake of animals. The coat colour of the seed has been associated with tannin content with

the brown seeded cultivar being more tannin containing . Deka and Sarkar (1990) reported that tannin content of five cultivars of lablab bean ranged from 2000-2005 mg/100g, while Elsiddig et *al* (2002) reported a range of 201- 353. Phytate or phytic acid chelates minerals like Calcium, Iron, Magnesium and Zinc. Such chelates make the elements nutritionally unavailable thereby inducing dietary deficiency (Nelson *et al.,* 1999*).* All these anti nutritional factors limit the use of lablab bean in monogastric nutrition.

MATERIALS AND METHODS

This study was conducted at the Livestock Teaching and Research Farm of the university of Agriculture Makurdi, Benue State, Nigeria. Makurdi lies between latitude 7.41° North and longitude 8.3^0 East with ambient temperature range of 17.3^0C to 35.6^0C and a relative humidity of 47-85% and 95 metres above sea level. The area has an annual rainfall of 1200-1500mm.

Cooking

The 25kg of the beans was added in 50 litres of water and then placed on a well stoked fire. Timing commenced immediately the pot was placed on the fire. The beans were cooked at varying duration of times (30,45 and 60 minutes).

Soaking

25kg of the beans were soaked in 50 litres of water overnight for a period of about 14 hours. The beans were then drained and placed in 50 litres of fresh water. The beans were then cooked for varying duration of times (30, 40 and 50 minutes).

Chemical Analysis

Samples of the processed *Lablab purpureus* were oven-dried, weighed and sent for laboratory analysis.

RESULTS AND DISCUSSION

The results of the effect of processing of lablab beans at various duration of time on their proximate composition and anti nutritional factors content are presented in table 1, 2, 3 and 4

[abc]: means with different superscripts within a row are significantly different; SEM: Standard error of mean; RS: Raw seed; SC30: Soaked and cooked beans for 30 minutes; SC40: Soaked and cooked beans for 40 minutes; SC50: Soaked and cooked beans for 60 minutes

Proximate Analysis

The proximate analysis showed that, the raw lablab seeds contained 93.8%DM, 4.73%Ash, 37.01%CP, 9.67%EE, 6.76CF and 41.79% NFE.

Dry matter: The dry matter content of the lablab seeds ranged from 93.88% in the raw seeds to 92.26% when directly cooked for 60min and 92.25% in soaked and cooked seeds (SC50). The variations in DM content may mean that the seeds were not equally dried as it is the level of dryness that can affect the dry matter of seeds.

Crude protein: Directly cooking the beans for 30, 45 and 60 min effected a 36.58, 36.55 and 35.76% reduction respectively in the crude protein content of the seeds, while soaking and cooking the seeds for 30, 40 and 50 mins effected 35.79, 34.58 and 32.19 reduction respectively in the crude protein content of the lablab seeds. These decreases in crude protein content of the seeds with boiling could be as a result of leaching of soluble or proteineous part of the seeds into the boiling water. Singh (1990) reported similar reduction when pigeon pea seeds were cooked for at different temperatures.

Anti Nutritional Factors

The level of anti nutritional factors (ANFs) as influenced by boiling periods is in table 5 and 6. Results of anti nutritional determination have revealed that, lablab bean seeds contained alkaloids, terpenoids, trypsin inhibitor, cyanide, tannin oxalate and phytate. This finding confirm the reports of D'Mello (1995) Udeibie and Carlini (2002).Cooking resulted in reduction of all the anti nutritional factors analysed in this study in agreement with Bawa *et al,* (2003) who reported that cooking of lablab beans significantly decreasedthe level of trypsin inhibitor activity, phytic acid, tannin and cyanide.The reduction increased as cooking periods increased.

CONCLUSION

Directly cooking of the lablab seeds and soaking of the seeds in excess water for about 14 hours before cooking had reducing effects on the level of anti nutritional factors measured therby enhancing its utilization.

RECOMMENDATION

Processing of lablab seeds is beneficial and should be done for 60 minutes when the seeds are to be cooked directly in water without soaking and 50 minutes when the seeds are to be soaked in water before cooking.

ABSTRACT
An experiment was conducted to evaluate the performance of broiler chickens fed self-formulated and three different commercial diets. A total of 240-day old cobb broiler chickens from a reputable hatchery were fed a self-formulated diet and 3 different commercial feeds for duration of 21 days to compare their growth performance. Daily feed intake of the dietary groups differed significantly (P<0.05). T2 dietary group showed high trend of feed consumption (99.27g) while the lowest feed intake was recorded on diet 3 (91.41g).The daily body weight gain was highest (58.60g) on diet 5 (P<0.05) which was statistically different (P<0.05) with value obtained on diets 2 (54.50). Lowest body weight gain was observed on diet 3 (35.91g) which was statistically similar with the value obtained on diet 1 (38.29). Higher FCR level (P<0.05) was observed on T3 dietary group which indicated low feed conversion efficiency. The result of the experiment from biological responses of birds gave an impression that commercial feeds of the feed mills T2 and T4 were found to be better than that of T3 and the self-formulated diet. The study recommended diet 4 for broiler starter production.

INTRODUCTION
The production of poultry meat safe for human consumption is dependent on many factors which include suitable environment, breeds, nutrient requirement and health status of the birds. Among these factors, meeting the nutritional requirement of the animals with the objective to optimize digestibility and absorption of nutrients is certainly one of the most important elements. Onabanjo *et al* (2018).
Efficiency of production of any animal depends on the provision of adequate protein, energy, vitamins and minerals in the right proportion in their diet. In broiler nutrition, energy and protein level are of great importance. Presently, poultry occupies a unique position in the livestock sector of Nigeria Kareem *et al* (2015).
Expansion of the industry depends to a large extent on the availability of good quality feed at affordable price. An overview of the poultry industry in Nigeria shows that majority of the producers are small scale holder farmers that rely on commercial feed millers for the supply of feed. Olarinmoye *et al* (2009).
Poultry feeds are made up of many ingredients which are broadly grouped into providers of energy (fat and carbohydrates), protein (amino acids), vitamins, minerals and feed additives. Cereal grains such as maize, sorghum, wheat and millet provide energy while soya beans and groundnut provide protein. These ingredients are combined in such a way as to provide energy, protein, vitamins and minerals for poultry through the process of feed formulation. However, several factors may affect both feed quality and feed manufacturing parameters. (Loar and Corzo, 2011).
The nutritional value of grains used in poultry feed varies with the grain cultivars, its chemical characteristics and non-starch polysaccharide content, diet physical form, availability of energy and bird category (Gutierrez-Alamo *et al.,* 2008). These factors in addition to the choice of feedstuffs and quantity incorporated in the finished feed by different feed manufacturers has given to variation in the nutritive value of manufactured feeds and performance of birds fed different brands of feeds.

Materials and Methods
The experiment was conducted at the Poultry Unit of Bauchi State Agricultural development programme (BSADP). Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East (BSD, 2009).
A total of two hundred and forty (240) broiler chicks were used for the experiment. They were randomly divided into five treatment groups of 60 chicks per group in a completely randomized

design (CRD) consisting of four replicates of 20 birds each. Birds were reared on a deep litter, with feed and water provided *ad libitum*. Left over feed and body weight of birds were monitored on a weekly basis for the starter phase of the experiment and routine vaccines were given as recommended. All feed not consumed were removed, weighed and deducted from feed given daily to get the daily feed intake.

A self- formulated and three (3) broiler starter diets of different selected commercial brand were purchased and label as diet 1, 2, 3 and 4 which were given to treatment groups 1, 2, 3 and 4 respectively. All these feeds differ in composition of energy, crude protein, crude fibre, ether extract among others.

Results and Discussions

The daily feed intake values ranged between 99.42g on diet 2 and 91.41g on diet 2 which is similar with the result of Kareem *et al* (2015) who reported a range of between 80.36 and 62.20g in his work titled studies on performance, haematology and serum biochemistry of broilers fed three types of commercial feed.. The daily weight gain value of 58.60g on diet 4 was observed to be highest followed by 54.50 on diet 3 while the lowest daily weight gain was 35,41g on diet 3 which was statistically ($P<0.05$) with 38.29g on diet 1. These levels are in conformity with levels of Opoola et al (2015) who reported daily weight gain values of between 36.48 and 41.56g in performance of broiler chicks fed dietary levels of tryptophan and commercial diet. Feed conversion ratio was significantly affected by the dietary treatment. The result is similar to what was obtained by Sanusi *et al* (2015). Birds on diet 4 were having better feed conversion ratio of 1.65 which differed significantly ($P<0.05$) with 1.82, 2.43 and 2.55 levels of dietary treatment groups 2, 1 and 3 respectively.

The highest feed cost/kg is recorded on diet 4 and 2 (164 and N160/kg) while diet 3 had relatively low feed cost of N148/kg and the lowest feed cost was recorded on the self-formulated diet (N128//kg}. The feed cost/gain ranged between 200.70 and N409.49 on diet 1 and 4.. This result differs with the values of between N124.67 and N190.29 reported by Sanusi et al (2015).

Conclusion and Recommendation

Birds on diets 4 and 2 performed better than those on diets 1 and 3. And low feed cost/gain was recorded to be lowest on the self-formulated diet (diet 1) while broiler chickens on diet 4 had the highest feed cost/gain of N409.49 during the experiment. Diets 2 and 4 were therefore recommended for production broiler starter.

Table 1: Composition of control diet fed to Broiler Chickens at starter phase

ABSTRACT
This study was conducted to compare the performance of broilers fed with different commercial feeds at the starter phase. A total of 200 birds were used for the experiment which lasted for 8 weeks. The birds were randomly divided into 5 treatment groups which were assigned to the 5 experimental diets. The experimental design used was completely Randomized Design (CRD). Growth performance parameters were measured weekly and feed intake measured daily. Feed conversion ratio and cost per kilogram weight gain were also determined. Data collected were subjected to analysis of variance (ANOVA) and separated using DMRT. The result indicated that the final body weight of broiler chicks fed the various commercial starter diets range from 683g in treatment D to 876g in Trt E. The daily weight gain of broiler starter ranges from 21.36 in birds fed with Trt D to 28.25 for bird fed with Trt E. The feed intake (FI) of commercial broiler fed with Trt A, B, C, D and E were 94.7g, 91.3g, 81.0g and 99.0 respectively. The feed conversion ratio (FCR) of birds in the five treatments were similar (p>0.05). This implies that commercial feeds are better utilized. The result showed that diet B has the lowest cost (N124/kg), while E had the highest cost (N156/kg) at the start phase. From the economic point of view, it seems that diet E would increase production cost for the poultry meat producer considering that feeding is known to take up to 70% production cost in livestock production.

INTRODUCTION
The poultry industry has been the most dynamic sector within the global meat business since the last decade, with an increased production driven by global population growth especially in developing countries (Delgado 2005). The high demand for animal products in Nigeria coupled with her teeming population, an increasing number of people are venturing into the poultry business. Consequently, this has led to high demand for commercial feed. There is now the tendency for feed manufacturers to produce substandard feeds, especially as the quality control agencies in Nigeria are non-existent or non-functional (Okoli *et al*., 2007: Omede, 2008., Okoli, *et al*., 2009), hence, leaving farmers and consumers at the mercy of commercial feed millers.

Poultry feeds are expected to contain a certain level of protein and energy for proper growth and development in birds. However, the feeds offered to birds constitute varied mixtures of ingredient. Moreso, the tendency of feed producer to maximize profit, might contribute to differences in the quality of the manufactured feeds sold in the market. It is important, therefore, to ensure that quality commercial feeds with proven nutritional value capable of achieving efficient production performance are patronized by the farmers. Hence, this study was conducted to compare the performance of the broilers fed different commercial feeds and to evaluate the economic implication of using these feeds.

MATERIALS AND METHODS
Location and duration of study
This study was conducted at the poultry unit of the Department of Animal Science Teaching and research farm, University of Nigeria, Nsukka in Enugu state. Nsukka is located on latitude 05˚ 22’ north and longitude 07˚ 24’ east with annual rainfall ranging from 986-2098mm (Asadu, 2002). The climate of the study area is typically tropical, with relative humidity ranging from 65 – 80% and mean daily temperature of 26.8˚C (Agbagha *et al.,* 2000). The rainy season is between April and October while dry season is between November and March with annual rainfall range of 1680 – 1700mm (Breinholt *et al.,* 1981). The study lasted for 8 weeks.
Experimental birds and management
A total of 200 broiler day-old chicks from a commercial farm at Ibadan were procured for the experiment. The birds were randomly divided into 5 treatment groups. Each bird in the group served

as replicate. The five groups were assigned to different experimental diets TA, TB, TC, TD, and TE. There was no control diet. The birds were housed in a deep litter system and subjected to the same experimental and management conditions. Water and feed were given ad-libitum. Feed and water intake were recorded daily while body weight (BW) measurement was also taken on a weekly basis.

Experimental materials and diets

The experimental diets were different commercial broiler feeds produced by different feed manufacturing companies in Nigeria. These feed were bought from their various distributors in Nsukka in Enugu State, Nigeria. The study involved the use of five commercial feeds TA, TB, TC, TD and TE of the starter diet. The composition of diets is given in the table below.

Data collection

Data were collected on daily feed intake, weekly body weight, weekly body length and shank length, daily water intake, feed conversion ratio and rearing phase mortality of the birds.

FCR (feed: gain) = $\frac{\text{feed consumed}}{\text{Weight gain}}$

Experimental Design

The feed trial experiment was carried out in a completely randomized design (CRD) with five treatments. The statistical model was as follows:

$X_{ijk} = \mu_1 + T_j + E_{ijk}$

Where X_{ijk}= the record of body weight, body length and shank length of individual broiler

μ_1 = overall mean

T_1 = the random effect of various feeds

E_{ijk} = the error

Statistical Analysis

Data collected were subjected to analysis of variance (ANOVA) in completely randomized design using a statistical package to social science (SPSS 2007). Significant difference among mean was separated using Duncan's New Multiple Range Test (DNMRT) as outlined by Obi (2000).

RESULTS AND DISCUSSION

Table 1: Proximate composition of experimental diets.

Treatment	Moisture	Ash	Fat	Crude protein	Crude fibre	M.E (Kal/kg)
A	8.150	3.100	6.00	18.00	5.00	3200.00
B	12.000	7.000	8.00	15.00	15.00	2600.00

[ab]Means within a row with different superscript are significantly (p<0.05) different.

The performance of starter broilers fed with different commercial feed is presented in Table 2.

This result indicated that the final body weight of commercial birds fed with treatment A, B, C, D, and E was 747g, 710g, 700g, 683g and 876 respectively. The final body weight gain for commercial

starter broiler ranges from 683g among birds in Trt D to 876g among birds in Trt E which was not in agreement with Uchegbu *et al*. (2009). It may be due to the problem of disease that affected my birds during the course of the study.

Daily Weight Gain: The daily weight gain of broiler starter was 23.64, 22.32, 21.96, 21.36 and 28.25 respectively. It ranges from 21.36 among birds fed with Trt D to 28.25 for bird fed with Trt E. The commercial broilers fed with Trt E at the starter phase recorded significantly ($p<0.05$) higher daily weight than birds in Trt A, B, C and D. This result is in agreement with report of Uchegbu *et al*. (2009).

Feed Intake: The result of this study shows that the feed intake of commercial broilers fed with Trt A, Trt B, Trt C, Trt D and Trt E at 8 weeks of age were 1.32, 1.31, 0.97, 1.23 and 1.36 respectively. The result further revealed that the feed intake (F.1) of broiler birds fed with different commercial feed is not significant ($p>0.05$). At the starter phase, the feed intake (F.1) of commercial broiler fed with Trt A, B, C D and E were 94.7g, 91.3g, 81.0g and 99.0 respectively. The feed intake was similar in Trt A, B, C and E ($p>0.05$) but significantly ($p<0.05$) higher than those on treatment D. The low feed intake of birds on treatment D relative to those on treatment A, B, C and E might have resulted from metabolizable energy requirement (Leason and Caston, 1993). It has also been reported that birds overeat under moderate protein insufficiency which is not necessary a craving for protein insufficiency but a compensatory increase in feed intake in response to the deficient essential nutrients (Lipstein and Bronstein, 1975).

Feed conversion ratio: The result of this study revealed that the feed conversion ratio (F.C.R) of commercial broilers fed with Trt A, Trt B, Trt C, Trt D and Trt E was 5.19, 5.31, 3.61, 5.47 and 4.93 respectively. It also revealed that the FCR of commercial broiler fed with Trt A, Trt B, Trt C, Trt D and Trt E is not significant ($p>0.05$). At the starter phase, the FCR of commercial broiler fed with Trt A, B, C, D and E were 2.661, 2.682, 2.740, 2.940 and 2.373 respectively. F.C.R ranges from 2.373 (Trt E) to 2.740 (Trt C). The FCR ranges from 2.373 (Trt E to 2.740 (Trt C). The FCR of birds in these five treatment are similar ($p>0.05$). It was in agreement with the report of Martin *et al*. (2009). This implies that commercial feeds are better utilized. This may have resulted from the likelihood that the manufacturers used better and utilizable feed raw materials for compounding their feeds.

Feed Cost: The study pointed out that in the starter phase the feed cost per diet A, B, C, D and E were N136/kg, N124/kg, N128/kg, ₦136/kg and N156/kg respectively. The result shows that diet B has the lowest cost, while E had the highest cost at the start phase. From the economic point of view, it seems that diet E would increase production cost for the poultry meat producer considering that feeding is known to take up to 70% production cost in livestock production.

Mortality: Mortality records in treatment A, B, C, D and E were 6, 3, 3, 2 and 1 respectively. The study showed that Trt A had the highest mortality, while Trt E had the least. High mortality in Trt A could be due to infected feedstuff or poor quality of feedstuff.

CONCLUSION AND RECOMMENDATION

The response of birds to body weight and daily weight gain were highest in Trt E while Trt B was poorest from the result in terms of feed utilization. Trt B was the cheapest of the five commercial feed while treatment E was the costliest in terms of the cost of feed used to produce 1kg of broiler meat. Variability in the nutrient contents of commercial feeds appeared to be an important factor that resulted in the performance differences in this study.

The farmer who depends on commercial feeds and who want his birds to reach market weight at the shortest possible time and at a lower cost of production should consider treatment B, C, and D feed.

Abstract
Phytochemicals are organic substances in plants that play various roles in maintaining healthy living of an organism; they achieve that in conjunction with the roles played by other nutrients such as vitamins and minerals. Fresh fluted pumpkin leaf, Moringa leaf, tomato, and garlic bulb were obtained, dried and milled. They were later analysed to quantify phytochemicals such as phenolics using the folinciocalteu's as oxidizing reagent, alkaloids, flavonoids and β-carotene using emulsion preparation method. Minerals such as calcium, magnesium, sodium, iron, phosphorous, copper and zinc were determined. The result showed significantly (P<0.05) higher flavonoid and alkaloid in fluted pumpkin, phenol and β-carotene were significantly (P<0.05) higher in moringa. Calcium, phosphorus and iron were significantly (P<0.05) higher in moringa, fluted pumpkin had significantly (P<0.05) higher magnesium and iron. The test supplements contain appreciable crude protein to be used in dietary formulation. It is concluded that leaf meals contain more phytochemicals and mineral than tomato and garlic.
Key words: fluted pumpkin, moringa, tomato, garlic, phytochemical

Introduction
Phytochemicals such as alkaloids, carotenoids, phenolics, and flavonoids reduce the deposition of fat in the arteries (Anderson, 2004). Sulphur compounds such as allixin and S-allyl-cysteine, as examples of phytochemicals, are known to decrease the cholesterol synthesis in the body and consequently keep the blood pressure low (Anderson, 2004).
Telfairia occidentalis has antioxidant, antidiabetic, haematological, anticancer, anti-Inflamatory, male fertility, hepatoprotective, antimicrobial, antimalaria, toxicity and biochemical activities. These activities may be due to the phytochemicals, vitamins and minerals present in the plant (Imosemi 2018). Umaya (2014) reported the health benefits of *Moringa Oleifera* include regulation of hyperthyroidism, radio-protective effect, vitamin A supplement, antihypertensive effect, hypoglycemic effect, antioxidant and enhanced milk yield. Garlic contains a compound, allicin (organosuphur compound), which is an oily liquid that contain more than 60% thiosulfinates, (Harunobu *et al.,* 2001). Allicin has odour and it is highly unstable compound that decomposes to sulfides, including ajoene and dithiins, (Freeman and Kodera, 1995). It has been tested to have antimicrobial effect, (Harunobu *et al.,* 2001). Tomato is a good source of vitamin, mineral, flavonoid and carotenoid (Campbell, *et al*., 2004). Because of their nutrients composition, they can serve the poultry sector as non-conventional feeding materials.
This study intends to screen four selected non-conventional feed supplements; fluted pumpkin leaf meal (*Telfairia occidentalis*), moringa leaf meal (*Moringa oleifera*) tomato powder (*Lycopersicom esculentus*), and garlic bulb powder (*Allium sativum*) for their chemical constituents

Materials and Methods
Fresh fluted pumpkin leaf (*Telfeiria occidentalis*), Moringa leaf (*Moringa oleifera*), tomato (*Lycopersicom esculentus*), and garlic bulb (*Allium sativum*) were obtained from local market in Ile-Ife and were dried, milled and stored in freezer for subsequent chemical analyses. They were later analysed to quantify phytochemicals such as phenolics as described by Othman *et al* (2007) using the folinciocalteu's as oxidizing reagent, alkaloids, flavonoids as described by Zhilen *et al.* (1999) and β-carotene using emulsion preparation method of Sarker *et al*. (1993). Minerals such as calcium, magnesium, sodium, iron, phosphorous, copper and zinc were determined using the method described by Sharma and Sangha (2009). Data collected were subjected to Analysis of Variance (ANOVA) of SAS (2002) and means were separated using Duncan's Multiple Range Test.

Results and Discussion

The result of phytochemicals analysed (Table 1) showed the flavonoid composition of the test supplements was higher significantly (P≤0.05) in fluted pumpkin leaves meal followed by moringa leaf meal. Flavonoids (myrecytin, quercetin and kaempferol) have high antioxidant ability as cited in the report Vergara-Jimenez *et al*. (2017). The alkaloid composition of fluted pumpkin (226.67 mgAAE/g) and moringa (215.88 mgAAE/g) were higher than those found in dried tomato fruit (199.61 mgAAE/g) and dried garlic bulb (94.44 mgAAE/g). This may be responsible for their medicinal properties. Vergara-Jimenez *et al*. (2017) reported that alkaloid contain several nitrogen compounds which include N,α-L-rhamnopyranosyl vincosamide, phenylacetonitrile pyrrolemarumine which have an anti-inflamatory effect on patients with ailments such as hypertension and heart related diseases. The result of phenol in moringa and fluted pumpkin were higher significantly (P≤0.05) than that of tomato and garlic. Phenolic acids such as gallic acid and chlorogenicacid have free radical scarvenging activities which have health promoting effects (Nour *et al.,* 2018). The β-carotene was however, significantly (P≤0.05) higher in dried tomato powder than other test supplements. Tomato contained high lycopene (a form of carotenoid) which was reportedly essential for the alleviation of oxidative stress in chicken (Sahin *et al.* 2016), meaning that tomato could be used to address challenges of oxidative stress.

Table 1: The phytochemical composition of test supplements

Parameters	Fluted pumpkin leaf meal	Dried tomato fruit meal	Moringa leaf meal	Dried garlic bulb meal	SEM
Phenol (mg GAE/g)	57.48[b]	43.28[c]	60.21[a]	11.20[d]	0.55
Flavonoid (mgQUE/g)	29.81[a]	23.44[c]	26.34[b]	24.24[c]	2.14
Alkaloid (mgAAE/g)	226.67[a]	199.61[c]	215.88[b]	94.44[d]	6.23
β-Carotene (mg/kg)	138.48[b]	174.81[a]	179.64[a]	66.50[c]	6.50

[abcd]Means in the same row having different superscripts differ significantly at P≤0.05

The result of mineral content of the test supplements (Table 2) showed that calcium was higher significantly (P≤0.05) in moringa leaf meal compared to other test supplements. Sebola *et al.* (2017) reported significantly higher calcium content (19.15g/kg) in moringa. The magnesium content was significantly (P≤0.05) higher in fluted pumpkin leaf meal compared to other test supplement followed by moringa leaf meal. This was in line with the result reported by Nworgu *et al. (*2007). The phosphorus content of the test supplements was significantly (P≤0.05) higher in moringa leaf meal followed by dried garlic bulbs. This shows the potentiality of moringa in improving egg shell thickness. The iron in fluted pumpkin and moringa were higher significantly (P≤0.05) than the content of other test supplements. This may be responsible for their effectiveness in the treatment of anaemia. Ustundag and Ozdogan (2016) reported significantly (P≤0.05) higher iron in fluted pumpkin and moringa, respectively. The zinc content of the test supplement was however significantly (P≤0.05) higher in dried garlic bulb than other test supplement. Ustundag and Ozdogan (2016) reported higher content of zinc in moringa than copper. Revell *et al*. (2009) reported an increased in the total iron content by over 15% compared to the control when an iron rich diet was fed to laying hens.

Table 2: The mineral composition of test supplements

Parameters	FPLM	DTFM	MOLM	DGBM	SEM
alcium (g/kg)	10.10[b]	1.5[d]	13.13[a]	1.76[c]	0.004
Magnesium (g/kg)	4.32[a]	2.00[c]	2.58[b]	1.06[d]	0.003
Sodium (g/kg)	1.80[d]	3.02[a]	2.92[b]	2.01[c]	0.009
Phosphorus(g/kg)	0.27[d]	0.28[c]	0.66[a]	0.46[b]	0.004
Iron (mg/kg)	155.00[a]	76.00[c]	154.00[a]	94.00[b]	0.763
Copper (mg/kg)	8.00[c]	12.33[a]	4.00[d]	11.00[b]	0.004
Zinc (mg/kg)	49.00[d]	62.33[c]	73.00[b]	76.00[a]	0.287

[abcd]Means in the same row having different superscripts differ significantly at P≤0.05

Table 3 shows the results of the proximate composition of test supplements. The crude proteins (18.07-27.96%) in the test supplements were moderately higher to furnish requirement for farm animals except in garlic which had 8.93%. This tallied with result sited by Karangiya *et al.* (2016) who cited low crude protein in garlic when fed to broiler chicken. The fibre content of the test supplements were significantly low in dried tomato fruit and dried garlic bulb, this showed their potentiality for inclusion into the poultry diet as they cannot withstand high fibre diet. Ether extract was higher in fluted pumpkin (9.06%) than dried garlic (1.13%). The nitrogen free extract was significantly high in dried garlic than other test supplements. This was the same with 85.83% nitrogen free extract reported by Karangiya *et al.* (2016).

Table 3: The proximate composition of test supplements and experimental diets

	Supplements			
Parameters (%)	**FPLM**	**DTFM**	**MOLM**	**DGBM**
Dry matter	90.81	92.79	90.13	87.39
Crude protein	25.27	27.96	18.07	8.93
Crude fibre	10.91	3.37	10.63	3.5
Ether Extract	9.06	3.97	5.10	1.13
Ash	5.15	4.29	4.59	2.44
Nitrogen Free Extract	49.61	60.41	61.60	84.00

FPLM=fluted pumpkinleaf meal, DTFM=dried tomato fruit meal, MOLM=moringa leaf meal, DGBM=dried garlic bulb meal, Mix=mixture of FPLM and MOLM in a ratio of 1:1.

Conclusion

It is concluded that fluted pumpkin and moringa leaf meals contain more phytochemical and mineral than tomato and garlic. The crude protein in tomato is higher than other test supplements

Abstract

The study was conducted to determine growth performance, dietary selectivity of feed ingredients and nutrient profile of broiler chickens at 42 days of rearing. Two hundred and eighty-eight (288) unsexed day-old FUNAAB ALPHA Strain broiler chicks raised in battery cages were randomly distributed in a completely randomized design into 5 cafeteria dietary treatments and a basal dietary treatment groups of 6 replicate each containing 20% crude protein and 300kcal MC/kg. The results showed significant differences (P<0.01) among the treatment for all production variables except for feed: water radio. Weight gains were better (P>0.01) in broiler fed Red sorghum-soyabean meal-concentrate and Red sorghum-millet-soyabean meal-groundnut cake-concentrate. The feed conversion ratio showed similar trends with the weight gains and final body weights. The co-efficient of preference (%) indicated higher values (74g 5%) for millet in millet-soyabean concentrate diet compared to 67.43% for red sorghum in Red sorghum-soyabean meal- concentrate diet. Nutrient profile of the cafeteria dietary treatments showed similar trends with other measured variables. It was shown that Red sorghum and millet can nutritionally and suitably be used with soyabean meal for cafeteria-fed broilers that can select and consumed feedstuffs to meet energy, protein and mineral needs for growth and production.

Keywords: Cafeteria, coefficient of preference, dietary selectivity, nutrient profile, growth indices.

Introduction

Birds' performance and their products are affected by nutrition and feeding systems. Poultry can be managed under different feeding systems.Feed intake is influenced by the interface between nutrition, management and animal responses (Church and Pond, 1988; Leeson and Summer, 2005). About 86.2 percent of the poultry are managed under traditional husbandry systems (Tewe, 1998). Cafeteria system could be an option to *ad libitum* complete diet feeding. It allows the animals to select their own diet (Forbes and Shariatmadari, 1994; Forbes and Covasa, 1995). Cafeteria feeding has recently not received considerable research attention to meet the current needs of the poultry industry. Cafeteria study will serve as a basis for establishing semi intensive system for rural small-scale poultry production. The objective of the study was to evaluate the production response, dietary selectivity and nutrient profile of broiler chickens on a cafeteria feeding system.

Materials and Methods

The experiment was conducted at the poultry unit, Teaching and Research Farm, Agricultural Education Department, Adeniran Ogunsanya College of Education, Otto/Ijanikin, Lagos. Two Hundred and Eighty-eight unsexed day-old broiler chicks obtained from the hatchery of the Federal University of Agriculture, Abeokuta were randomly allotted to six experimental diets with six replicates of 48 broiler chicks each in a completely randomized design and raised in constructed cage system. The dietary treatments are presented in Table 1.

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

The feeds were presented in a mash form with 3 - compartment feeding troughs to separate the sources of energy, protein and concentrate with the exception of 5 - compartment feeder for treatment containing all the energies and protein sources.

The following parameters were measured; weight gain, feed intake, feed conversion ratio, feed/gain ratio, water consumption, feed to water ration co-efficient of preference and nutrient profile. The data obtained were subjected to analysis of variance using the General Linear model procedure (SAS Institute, 2012).

Result and Discussion

The results of the growth performance, co-efficient of preference and the nutrient profile of the broiler chicken at the finisher stage (22-42 days) are presented in Tables 2, 3 and 4 respectively.

MBW=Mean Body weight
a, b, c, d Means with different superscripts in the same row are significantly different

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

There were significant differences (P<0.01) among the treatments for all variables except for feed to water ratio. Feed intake was greater in broilers on cafeteria feeding of red sorghum - soya bean meal - concentrate differing significantly (P<0.01) from birds on free-choice feeding of sorghum-GNC-concentrate and millet-GNC concentrate. Feed intake was not statistically different (P>0.01) among the treatments of red sorghum-soyabean meal concentrate, millet-soyabean meal- concentrate and millet- red sorghum-soyabean-GNC-concentrate.

Table 3: Co-efficient of Preference and Proportion (%) of each Ingredient consumed by Broiler chicken at Finisher Phase (22-42 days)

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

The result indicated higher preferences for millet, red sorghum and soyabean meal as good sources of energy and protein for better performance. Birds consumed less groundnut cake probably due to its low protein quality, poor palatability and unattractiveness compared to soyabean meal.

ME - Metabolisable Energy CP - Crude Protein
a, b, c, d, Means with different superscripts in the same row are significantly different.
SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

The birds utilized the nutrient in feedstuffs according to their choice to meet their nutritional needs. Poultry has been reported to adjust voluntary intake of feeds with different energy and protein densities (*Cruz et al, 2005; Rose, 1997).*

Conclusion and Recommendations

Red sorghum and millet as energy sources can adequately be utilized in combination with soya bean meal as the broilers on the diets containing these ingredients presented better growth performance, dietary selectivity and nutrient profile than when groundnut cake was used. This therefore will provide a guide for the improvement of feeding and nutrition of the rural poultry system, which will ultimately improve smallholder poultry production in a sustainable and economic manner for higher animal protein intake.

Abstract:
Twenty weaner rabbits of mixed sexes with an average initial weight of 0.62kg were used to determine the effect of varying level of sun-dried yam peel meal (YPM) as a source of fibre on their growth performance, carcass characteristics and economics of production. The rabbits were randomly allotted to five diets formulated with sun dried yam peel meal (YPM) replacing wheat offal (WO) at 0, 25, 50, 75 and 100% level of inclusion. The final live weight of rabbits were significantly higher ($p<0.01$) in diet 2 (25% YPM), the feed conversion ratio and feed efficiency compare favourably among the dietary treatments. There was significant difference ($p<0.05$) with higher daily feed intake on diets 1 and 2 value compared to others. Weight of organ expressed as a percentage of live weight did not show any significant difference between the treatment means accepts in the carcass weight which shows a highly significant difference ($p<0.01$). The cost in Naira per kilogram gain was highest on diet 1 (0% YPM) and lowest on diet 5 (100% YPM). The result indicates that yam peel meal can be used to replace wheat offal at up to 75% in the diet of weaner rabbits with good performance and tremendous reduction in feed cost.

INTRODUCTION

Animal protein consumption in Nigeria and other developing countries has been reported to be comparatively low (Ayorinde and Aromolaran 1998). (Food and Agricultural organization FAO (1996) recommended a protein consumption level of 65g per day of which 35g should be from animal source. However, the consumption of protein especially animal protein is about 6.8g (OYenuga, 1995).This problem has generally been attributed to shortage of animal protein products. This has led to current high cost of animal products making them out of reach of an average Nigerian. This problems can bridged by directing efforts at the production of animals that are highly prolific, with short generation interval (Akinmutimi and Onwukwe, 2002). One of such is the rabbit. It has high fecundity with short gestation period (Fielding and Metheron 1991). They are fast growing and can obviously convert forage and kitchen wastes into meat with high efficiency (Nworgu and Ogbosuka, 2003). Rabbit supply animal protein to Nigeria especially in rural and peri-urban areas (Egbo *et al*., 2001). Rabbit production has the potential to improve on the diet and income of many poor households due to its growth and fecundity rate, low investment and labour cost (Spore. 2007: Soyebo. 2006).

According to Oseni *et al*. (2008) a major limitation to the development of small holder rabbit production in Nigeria is the absence of reliable sources of quality genetic stocks of rabbits suitable for such units. Rabbit meat is delicious, tasty, well accepted and contains low fat and cholesterol levels. The nature of rabbit in terms of size, short generation interval, rapid growth rate (Ensminger, 1991), easy conversion of available proteins in cellulose-rich plants to meat (Nowak, 1991) and good source of high quality animals protein (Fielding and Metheron 1991) make rabbit production attractive. According to (Omole *et al*, 2005), the white meat of rabbit is very nutritious, easily digestible and extremely low in cholesterol and sodium levels. However, the major constrains in animals production has being compounded with the present economic depression and the fact that most of the feed ingredients such as maize, sorghum and soya beans used in preparing rabbit diets face serious competition from man as food (Ijaiya and Awonusi, 2002). Consequently, there was a need to search for alternative sources of feed ingredients that will be cheap, locally available and nutritionally adequate. One of such feed ingredient is the yam peels which are usually regarded as waste products.

This work therefore attempts to study the performance and cost effectiveness of varying levels of yam peel and meal and wheat offal as a fibre source in the diets of weaner rabbits. This forms the basis of this study.

MATERIALS AND METHODS

Experimental site and housing: The experiment was conducted at Abubakar Tafawa Balewa university teaching and research farm. Located in southern part of Bauchi town about six kilometers along Dass road in Bauchi state. Bauchi state occupied a land area of about 60,000sq km approximately 7% of Nigeria total land area. The state lies between latitude $90^0$30'n and $120^0$30'N and longitude $80^0$42'E and $11^0$8'.The average rainfall ranges from 130mm to 600mm. The vegetation is guinea savanna (B.S.A.D.P. 1999).
The experimental weaner rabbits were housed in hutches located inside the rabbitry building. Each hutch had a feeder and waterer attached.

Experimental Diets: The test feedstuff (fresh yam peel) were collected as kitchen waste from Muda Lawan market in Bauchi metropolis and sun-dried on clean floor until it is crispy to touch it was then milled using the hammer mill at the feed milling unit of the Abubakar Tafawa Balewa University to produce yam peel meal.

Five experimental diets were formulated. In the diets sundried yam peel were used to replace varying levels of wheat offal in the weaners diets. Sundried yam peel meals replaced 0, 25, 50, 75, and 100% dietary inclusion levels of wheat offal. The table were designed as T1, T2, T3, T4, and T5 respectively.

Experimental animals and their management: Twenty weaner rabbits of mixed breeds (mongrels) and sexes with an initial weight of 435-600g were used for the investigation. They were randomly assigned to five dietary treatments in four (4) rabbits per treatment in a complete randomized design (CRD) arrangement. The experiment lasted for six weeks (42 days). Experimental diets and water were made available *ad-libitum* throughout the study period.

Prior to arrival of the weaner rabbits, the house and the cage were cleaned and disinfected, the feeder and waterer were equally cleaned before the beginning of the experiment, also the feeders and drinkers were cleaned before the next feeding and watering. The surrounding was kept clean by sweeping and cleaning on daily basis.

Data collection: Initial average weight of the rabbits was taken on the first of the experiment. They were subsequently weighed on weekly basis. Feed conversion ratio (FCR) was calculated by dividing the average feed intake by the average weight gain. Percentage mortality was calculated using number of dead rabbits divide by number of rabbits X100.
Gross margin/profitability test of the diets were calculated according to Saniya(2007). Evaluations of carcass quality and organ weight were carried out as described by Ojewola and Longe (1999).
Statistical analysis: data collected were analyzed using SPSS (1996) statistical package 7.5.

RESULT AND DISCUSSION

The growth performance and cost analysis of weaner rabbits fed experimental diets as is shown in table 2. There was no significant difference ($p>0.05$) in the parameters measured except in the daily feed intake and daily weight gain ($p<0.05$.) T4 and T4 has the lowest and highest daily feed intake respectively i.e. 59.08g and 79.50g and the values are lower than 80.08g and 89.13g as reported by Akinmutimi (2008) who fed weaner rabbits with similar diet. The difference may be due to ambient temperature and fibre content (Preston, 1987). Diets 5 and 3 has the lowest and highest daily weight gain (13.22g and 19.49g) respectively. These values were higher than 9.23g and 11.3g reported by Akinmutimi (2008).

The mean total weight gain obtain in this result shows that Diet 3 has the highest (818.75g) value and Diet 5 has the lowest value (635.25g) this shows that the higher the inclusion level of yam peel the lower the total weight gain. The value obtained are to those reported by Akinmutimi *et al*, (2006) who fed weaner rabbits with ripe plantain and yam peels base diet. The result for final body weight shows that animal fed Diet 3 and diet 2 have the highest final body weight of 1505.5g and 1458.80g respectively. The values obtained are higher than 1375.00g and 1308.33g reported by Akinmutimi(2006).The fed conversion ratio ranged from 3.92-4.28g were lower than 6.56-7.99g reported by Akinmutimi and Anakebe (2008) who fed rabbits with yam peels, sweet potato peels meal in place of maize and also lower than (4.39-6.64g) as reported by Osakwe and Nwose (2008) for rabbits fed graded levels of cassava meal. The fed efficiency was similar for all the treatment (0.24-0.26g).

The economic analyses of the experimental diets were presented in table 2. The cost (per kg) of feed ingredient favoured diets 4 and 5, this may be due to the cheaper price of the test ingredients. This may be due to effect of the cost of kg of feed reported by Akinmutimi (2004). Thus increase in the levels of yam peel meal may result in considerable reduction in the cost of rabbits production which in extension makes the product affordable to consumers thereby achieving the major objective of this trial.

Table 3: shows carcass characteristic of weaner rabbits fed experimental diets. There was no significant ($P>0.05$) treatment effect on the carcass parameters measured except live and carcass weight ($P<0.01$) this result is higher than the reported by Ijaya and Awonusi (2002) when they replace maize with yam peel meal. Dressing percentage of 47.8-55.7% recorded were not significantly different this result agrees with value of 47.42 –

54.08% for rabbits (Akinmatimi (2004) the differences could be attributed to breed, age and feed to the animals. The percentage weight of liver, kidney, heart and spleen were similar to those reported by (Akinmuti, 2004) for rabbits fed yam peel meal in place of maize based diets. The percentage small intestine (5.89-8.84%) and large intestine (0.64-081) were statistically similar. The values are higher when compared to those reported by Ironke (2004) for rabbits fed agricultural by-products based diets.

CONCLUSION

Judging from the performance, carcass characteristics and economic analysis yam peel meal, which is economically cheaper than wheat offal can replace up to 75% of wheat offal in weaner rabbits diets without adverse effects on performance. This would go a long way especially during periods of feed scarcity to increase animal protein availability and reduce accumulation of waste (SDYPM) in the environment.

NUTRIENT DIGESTIBILITY AND CARCASS CHARACTERISTICS OF WEANER RABBITS FED DRIED CABBAGE LEAF MEAL

Igila, T. T., Bello, K.M., and Kalla, D. J. U

Department of Animal Production, Abubakar Tafawa Balewa University, Bauchi

Correspondence authors email: igilatimothy17@gmail.com; 08063128409

The study was conducted to determine the nutrient digestibilty and carcass characteristics of weaner rabbits fed dried cabbage leaf meal. A total of sixty (60) mongrel rabbits (12 rabbits per treatment, 4 per replicate) were fed five (5) experimental diets containing graded levels of cabbage leaf meal at 0, 5, 10, 15 and 20% designated as diets T1, T2, T3, T4 and T5 respectively. The experiment lasted for eight (8) weeks. The result showed that, most of the carcass traits showed significant differences (P<0.05) among the treatments except for organs such as heart, kidney, head, feet, tail, shoulder and thigh. The digestibility result also showed significant treatment (P<0.05) effect except for nitrogen free extract. Diet 4 also gave the highest digestibility values. Diet 1 gave the least value for dry matter, crude protein and crude fibre, while diet 5 (20% cabbage leaves inclusion) gave the least values for ether extract, ash, nitrogen free extract and total digestible nutrients. It was therefore concluded that cabbage leaf meal can be used in the diet of weaner rabbits at 20% level of inclusion for efficient nutirents digestibilty and optimum carcass yiels. Cabbage leaf meal was therefore recommended to farmers as a feed material so as to improve digestibilty and carcass yield of their weaner rabbits.

INTRODUCTION

The increasing demand for dietary protein in Nigeria due to population increase has aroused the interests of Nigerians in the production of animals with short production cycles, which are prolific, good converters of feed to flesh, relatively easy to care for and require low capital investment in raising such as rabbits, poultry and swine. Poultry and pigs on the other hand require more of commercial feeds which often incorporate ingredients in direct competition with humans and are usually too expensive for most small scale farmers. Therefore, in order to maximize food production in developing countries like Nigeria all viable options including the use of non-conventional livestock must be explored and evaluated (Owen *et al* 2008). Rabbits *(Oryctolagus cuniculus*),which can be considered as non conventional livestock specie appear to be a cheap and sustainable means of producing high quality animal protein for the expanding populations of the developing countries. This is due to the rabbit's established prolificacy, early maturity, fast growth rate, high genetic selection potential, high feed conversion efficiency and economic utilization of space (Hassan *et al* 2012). Also Rabbit meat is low in fat, caloric value, sodium and cholesterol, but high in protein, thereby making it the meat of choice for coronary heart patients and people on low cholesterol and sodium diets. Generally, it is agreed that feed cost accounts for between 60-85% of the total cost of livestock production. Livestock feeds particularly for non- ruminants are becoming prohibitively costly in the developing countries because of the increasing competition between man and livestock for food. One way of reducing cost and increasing animal protein production in the developing countries such as Nigeria is through use of the cheap and readily available feed ingredient in the diets of livestock. Cabbage leaves, one of such cheap ingredients having potential values as a feeding resource is a by-product of the local processing of cabbage and is a rich source of crude protein and energy (Choi and Park, 2003). As cabbage production increases, there is a concomitant increase in the quantity of residues produced. These residues are often discarded into the environment where they pose major environmental concerns (e.g., landfill and nitrate leaching to water sources). Consequently, there is growing interest in alternative and non-polluting methods of management such as composting and recycling through livestock feeds. Cabbage leaves are characterized by high crude protein (CP) and mineral concentrations (Choi and Park, 2003).

MATERIALS AND METHODS

The experiment was conducted at the Abubakar Tafawa Balewa University Research Unit Bauchi, Bauchi State. The feeding trial was conducted with sixty (60) mongrel weaner rabbits obtain from different rabbit farmers and open markets. The rabbits were randomly allotted to the experimental diets. The weaner rabbits were managed intensively. Water and feeds were given *ad libutum*. Drugs were also administered and deworming done appropriately. The experiment lasted for a period of eight weeks. The cabbage leaves were collected from different markets across Bauchi metropolis. They were then sundried for duration of 6-7 days until completely dried. The cabbage leaves were then milled and mixed with other ingredients to formulate a balanced diet for the weaner rabbits. There were five treatments and each treatment was replicated three times with four rabbits per replicate in a completely randomized design. Cabbage leaf meal was included at 0, 5, 10, 15 and 20% designated as diets T1, T2, T3, T4 and T5 respectively.

These results showed marked improvement in the digestibility of nutrients up to 20% cabbage leaf meal inclusion level reflecting efficient utilization of nutrients with increasing level of cabbage leaf meal inclusion. These results corroborate the findings of Obeh and Tewe (1992) who reported that feeding of cassava leaf meal to pigs resulted in better utilization of nutrients from leaves, improved digestibility of nutrients as well as better growth and higher feed intake. However the result observed in this study did not agree with the findings of Iyayi (2001) who reported that digestibility values of dry matter, crude

protein, crude fibre, ether extract, ash and nitrogen free extract were not significantly ($P<0.05$) different when growing rabbits were fed diets containing graded levels of moringa leaves.

The result of carcass yields obtained in this study is similar to the report of Jamroz *et al*. (1996) who observed increased dressing percentage when broiler chickens were fed vegetable based diets. The decline in dressing percentage (20% inclusion of cabbage leaf meal) may have resulted from the rapid impact of the cabbage leaves on caecal fermentation thus resulting in higher microbial activities.

CONCLUSION AND RECOMMENDATIONS

Cabbage leaf meal can be included in the diet of weaner rabbits at up to 20% without compromising carcass yields and nutrients digestibility of the rabbits. It is therefore recommended for use in weaner rabbits diets. Farmers are therefore encouraged to make use of this cheap and easily available feed material especially during the dry season when it is readily available and concides with period of rabbit feed scarcity.

ABSTRACT

The study was conducted to determine the utilization of sun dried cabbage leaf meal by weaner rabbits. A total of sixty (60) mongrel rabbits (12 rabbits per treatment, 4 per replicate) were fed five (5) experimental diets containing graded levels of cabbage leaf meal at 0, 5, 10, 15 and 20% designated as diets T1, T2, T3, T4 and T5 respectively. The experiment lasted for eight (8) weeks. The performance variables recorded in this study were significantly affected by the graded levels of inclusion of cabbage leaf meal. In all the parameters, diet 4 (15% inclusion of dried cabbage leaves) gave the best performance, while diet 1 (0% cabbage leaves) gave the least performance. The haematological parameters also showed significant differences (P<0.05) across dietary treatments except for mean corpuscular haemoglobin. Diet 4 recorded higher values in all the parameters analysed while diet 1 and 3 recorded least values. All the parameters analysed for biochemical indices showed significant (P<0.05) differences across the dietary treatments. Diet 4 recorded higher values in all the parameters considered except for cholesterol, where diet 3 recorded higher values, while diet 1 recorded least values. The highest feed cost savings was recorded in diet 5 (20% inclusion of cabbage leaf meal) while the highest cost was recorded in diet 1. It was therefore concluded that cabbage leaf meal can be used in the diet of weaner rabbits for up to 20% level of inclusion for optimum performance. Cabbage leaf meal was therefore recommended to farmers as a feed material so as to reduce cost and increase productivity.

INTRODUCTION

The increasing demand for dietary protein in Nigeria due to population increase has aroused the interests of Nigerians in the production of animals with short production cycles, which are prolific, good converters of feed to flesh, relatively easy to care for and require low capital investment in raising such as rabbits, poultry and swine. Poultry and pigs on the other hand require more of commercial feeds which often incorporate ingredients in direct competition with humans and are usually too expensive for most small scale farmers. Therefore, in order to maximize food production in developing countries like Nigeria all viable options including the use of non-conventional livestock must be explored and evaluated (Owen *et al* 2008). Rabbits *(Oryctolagus cuniculus*),which can be considered as non conventional livestock specie appear to be a cheap and sustainable means of producing high quality animal protein for the expanding populations of the developing countries. This is due to the rabbit's established prolificacy, early maturity, fast growth rate, high genetic selection potential, high feed conversion efficiency and economic utilization of space (Hassan *et al* 2012). Also Rabbit meat is low in fat, caloric value, sodium and cholesterol, but high in protein, thereby making it the meat of choice for coronary heart patients and people on low cholesterol and sodium diets. Generally, it is agreed that feed cost accounts for between 60-85% of the total cost of livestock production. Livestock feeds particularly for non- ruminants are becoming prohibitively costly in the developing countries because of the increasing competition between man and livestock for food. One way of reducing cost and increasing animal protein production in the developing countries such as Nigeria is through use of the cheap and readily available feed ingredient in the diets of livestock. Cabbage leaves, one of such cheap ingredients having potential values as a feeding resource is a by-product of the local processing of cabbage and is a rich source of crude protein and energy (Choi and Park, 2003). As cabbage production increases, there is a concomitant increase in the quantity of residues produced. These residues are often discarded into the environment where they pose major environmental concerns (e.g., landfill and nitrate leaching to water sources). Consequently,

there is growing interest in alternative and non-polluting methods of management such as composting and recycling through livestock feeds. Cabbage leaves are characterized by high crude protein (CP) and mineral concentrations (Choi and Park, 2003).

MATERIALS AND METHODS

The experiment was conducted at the Abubakar Tafawa Balewa University Research Unit Bauchi, Bauchi State. The feeding trial was conducted with sixty (60) mongrel weaner rabbits obtain from different rabbit farmers and open markets. The rabbits were randomly allotted to the experimental diets. The weaner rabbits were managed intensively. Water and feeds were given *ad libutum*. Drugs were also administered and deworming done appropriately. The experiment lasted for a period of eight weeks. The cabbage leaves were collected from different markets across Bauchi metropolis. They were then sundried for duration of 6-7 days until completely dried. The cabbage leaves were then milled and mixed with other ingredients to formulate a balanced diet for the weaner rabbits. There were five treatments and each treatment was replicated three times with four rabbits per replicate in a completely randomized design. Cabbage leaf meal was included at 0, 5, 10, 15 and 20% designated as diets T1, T2, T3, T4 and T5 respectively.

[abc]: Means within the same row bearing different superscripts are significantly different ($P<0.05$); LOS: Level of significance

The average daily weight gain was significantly affected by the dietary treatments. The average daily weight gain ranged from 17.41g in treatment 1 to 21.54 in treatment 4 which follow the same trend as daily feed intake and final live weight. The result for average daily weight gain recorded in this study were similar to the values reported by Agunbiade *et al*. (2003) on weaner rabbits fed cabbage waste base diets. There was significant difference in the feed cost across the treatments. The least feed cost was recorded in diet 4 while the highest cost was observed in diet 1. The result of this study showed that, using cabbage leaf meal in the diet of weaner rabbits is cheaper than using conventional feed ingredients.

The packed cell volume values (37.40 to 47.90%) were within the range of 33 to 50% reported by Hillyer (1994) for growing rabbits. The values obtained for all the treatment groups indicate nutritional adequacy of all diets since values did not indicate mal-or-under nutrition (Church *et al*. 1984). The values for white blood cells which ranges from 6.40 to 12.90 $x10^3mm^3$ reported were within the range reported by Hillyer, (1994) for healthy young rabbits. This shows that the animals were healthy because decrease in number of white blood cells below the normal range is an indication of allergic conditions, anaphylactic shock and certain parasitism, while elevated values (leucocytosis) indicate the existence of a recent infection, usually with bacteria (Ahamefule *et al*.,2008).

CONCLUSION AND RECOMMENDATIONS

Cabbage leaf meal can be included in the diet of weaner rabbits at up to 20% without compromising growth performance and haematological indices of the rabbits. There was reduction in cost in the use of cabbage leaves based diets. There was also increased productivity in the use of cabbage leaf meal.

Diet 5 (20% inclusion of cabbage leaf meal) gave the least feed cost and is therefore recommended for use in weaner rabbits diets. Farmers are therefore encouraged to make use of this cheap and easily available feed material especially during the dry season when it is readily available and concides with period of rabbit feed scarcity.

ABSTRACT
Performance of weaner rabbits fed varying levels of Moringa oleifera meal (MOLM) was investigated using sixteen mixed breed weaner rabbits of average weight of 400-600 grams (5-7 weeks) old. The rabbits were randomly allotted to four dietary treatment groups in a completely randomized design (CRD) and each treatment was further sub-divided into four replicates, each having one rabbit per replicate. They were fed growers ration supplemented with Moringa oleifera leaf meal at varying levels of 0%, 5%, 10% and 15%. Results obtained showed that rabbits on 10% Moringa Oleifera Leaf Meal diet achieved the highest weight gain (1575g) while T_2, T_1 and T_4 recorded weight gains of 1500, 1400 and 1066.67g respectively. The result of the mean effects of the treatment on the feed intake revealed that treatment 1, 2 and 4 has significant effect on the feed intake but there was no significant difference between 2 and 3 as well as treatment 3 and 1. The carcass evaluation revealed a very strong, positive and highly significant relationship between dressed weight and carcass length (0.98, $P \leq 0.01$). The result of this experiment revealed that MOLM at 10% level of inclusion can support the growth of rabbit without any deleterious effect on growth performance and health status of weaner rabbits.

INTRODUCTION
The rapid growth of human and livestock population create increasing demands for food and nutrition security in the least developed countries that alternative feed resources must be identified and evaluated (Olugbemi *et al*., 2010). The inadequate supply and intake of animal protein in developing countries is high due to high cost of feeding with the accompanying high cost of production. One of the ways of reducing the cost of production and making protein available to people at cheaper prices is by the use of agricultural by-products and tropical plants which are not directly used by humans as food to feed livestock (Asar, 2010).

Rabbit plays a vital role in the utilization of fibrous by-products which can be converted into animal protein for the Nigerian populace. They are efficient converters of feed to meat and can utilize up to 30% crude fibre as against 10% by most poultry species (Egbo *et al*., 2001). Rabbits can utilize unconventional feedstuffs such as blood meal and diverse forage materials such as wild sunflower. This is why attention is now being shifted to rabbit production in order to solve the problem of shortage of protein. Therefore, alternative feed sources need to be investigated such as, *Moringa oleifera*, the leaves of which have been used as animal feed in many places.

For the past two decades the interest of animal producers has been centred mostly on search for cheaper feed ingredients that are always available and have no competition with man's dietary demand. Feed alone accounts for up to 70% of the total cost of production and there can be no success in raising rabbits if proper attention is not given to diet and if wholesome feed in adequate quantity are not provided (Compaoré *et al*., 2011). *Moringa oleifera* leaves, fruits, immature pods and flowers are integrated into the traditional food of humans in several tropical and subtropical countries (Siddhuraju & Becker 2003, Anhwange *et al.,* 2004).

This study is designed to investigate the feeding varying levels of moringa leaf meal on the performance and carcass characteristics of weaner rabbits.

MATERIALS AND METHODS

Experimental Procedure

The research was conducted at the Piggery and Rabbitry unit of Federal College of Forestry Jos, Plateau State, Nigeria. Twelve (12) cross bred rabbits of both sexes made up of four males and eight females were used for the experimental study. Three (3) rabbits were randomly assigned to each treatment in the ratio of one (1) male and two (2) females per treatment. The experiment lasted for six (6) weeks after a one week of pre-feeding trial. *Moringa oleifera* leaves were harvested from mother tree, air dried and ground into powder before incorporating into the rabbit's diets. Four experimental diets were formulated containing 0%, 5%, 10% and 15% *Moringa oleifera* leaf meal (MOLM). Known quantities of feed were fed daily to each group. Water was given ad libitum. Prior to the commencement of the experiment, the rabbits were prophylactically treated against parasites (internal and external).

Data Collection, Experimental Design and Statistical Analysis

At the end of the experiment, the parameters assessed include; average daily feed intake; average body weight; average weight gain; carcass characteristics (live weight (kg), dressed weight (kg),dressed percentage (%), carcass length (cm), head weight (g), thorax width (g), loin weight (g), fore limb weight (g), hind limb weight (g), liver weight (g), heart weight (g), kidney weight (g), lungs weight (g) and spleen weight (g)).

A completely randomised design was adopted for the study. All data collected at the end of the six weeks were subjected to analysis of variance (ANOVA) using SAS (2001), and differences between the treatment means were separated using Duncan's New Multiple Range Test (DMRT) at 5% level of significance.

RESULTS AND DISCUSSION

Performance of Rabbit Fed Graded Level of *Moringa oleifera* Leaf Meal

The performance of rabbit fed graded levels of *Moringa oleifera* leaf mean on the growth performance of weaner rabbits (1-6 weeks) revealed that that there was significant in Daily Feed Intake (DFI) among the treatments. Rabbits fed diet at 15% level of inclusion had the lowest numerical value of 1.60g followed by diets 10%, 0% and 5% respectively. As the quantity of the *Moringa oleifera* increases the intake decreases, although these was no significant difference (P> 0.05) in feed intake among the treatment. This collaborate that of Shaalu *et al.*, (2008) and Kakengi *et al.,* (2007). Daily Weight Gain (DWG) of the rabbits shows that there was significant difference among the diets. The highest value was obtained on rabbit fed at 15% level of inclusion of the experimental diets with a value of 4.61 (15%) followed by 4.06 (10%), 4.05 (5%) and 3.96g (0%) respectively. This shows that diets containing 15% MOLM produced rabbits with higher body weights and higher weight gain than rabbit in the other diets (Table 1). The higher body weight gain might be an indication that the diets were more palatable and easily assimilated by the rabbits. This is in agreement with (Kakengi *et al.*, 2007), who reported that MOLM diets were highly preferred by chickens because of its palatability. Similar result was reported by Onimisi *et al;* (2007), when they fed MOLM to rabbits.

A very strong, positive and highly significant relationship was observed between dressing weight and carcass length (0.976 at 0.01 level). This implies that an increase in the dressing weight will lead to an increase in the carcass length and vice versa. There was a strong, negative and insignificant relationship between carcass length and spleen weight (-0.762). The implication of this is that, an increase in the carcass length will result in a decrease in the spleen weight and vice versa (Table 2).

CONCLUSION AND RECOMMENDATION

It can be concluded that MOLM can be incorporated up to 15% level in the diets of weaner rabbits, since it met the growth performance without any deleterious effects. In this study, the best performance was observed by rabbits at T3 (15%) level of MOLM inclusion. This indicates that rabbits tolerate MOLM up to 15% level of incorporation for optimal performance. However, more research may be required on the use of *Moringa oleifera* leaf meal, as a protein supplement on the diets of other livestock species.

Abstract
The aim of determining the proximate analysis of red finger millet/*Tamba* (*Eleusine coracana*) was to ascertain its nutritional composition and its ability to be used as feed ingredient. Proximate analysis of red finger millet was carried out at the biochemistry laboratory of the department of Animal Science, Ahmadu Bello University, Zaria. The result of the analysis revealed that it contained Dry Matter-88.48; Crude Protein (CP)-13.98; Ether Extract (EE)-3.70; Crude Fiber (CF)-6.67; Ash-4.90; Nitrogen Free Extract (NFE)-59.22. Therefore, it can be concluded that finger millet is a nutritious feed resource and can be incorporated into animal feed. It is recommended for farmers to use it by incorporating it into livestock feed because of the prospects it has shown in the proximate analysis result.

Key words: Finger millet, Proximate, Feed resource, Analysis, Nutrients

Introduction

The term millet is derived from the French word "mille'' which means thousand, with a handful of millet containing up to 1000 grains (Shahidi and Chandrasekara, 2013). *Eleusine coracana* is called *kpana* by the Beroms, *tamba* in Hausa (Fernandez *et al.*, 2003). Millet belongs to the group of small seeded species of cereal crops or grains which are annual plants (Shiihii *et al*., 2011). The grain belongs to the family Poaceae which originated in Ethiopia and the sub-family *Chloridodeae* (Pradeep&Sreerama, 2015; Sood *et al*., 2016; Ramashia *et al*., 2018). The brown cultivar is utilized for brewing traditional opaque beer in Southern Africa (Sood *et al*., 2017). The grain is a semi-arid region crop cultivated in dry areas with limited rainfall and can adapt to various agro-climatic conditions (Gull *et al*., 2014). Hence, it is important to look at ways of how to economically and effectively substitute some of the conventional feed resources since they are becoming scarce and beyond the reach of the small and medium entrepreneur farmers. Hence, the proximate analysis to find out the nutritional contents of red/brown finger millet so that farmers can be encouraged to adopt its usage.

Materials and method

Source of finger millet

The grain which is popularly called finger millet or *tamba* locally was purchased from Ganawuri local market located in Riyom local Government Area of Plateau State and Manchok in Kaduna State.

Determination of finger millet proximate composition

The proximate composition of finger millet was carried out at the biochemistry laboratory of the department of Animal Science, Ahmadu Bello University, Zaria, Kaduna State, Nigeria. The analysis was carried out according to the standard method of (AOAC, 2005).

Results and Discussion

The proximate analysis results obtained for red finger millet revealed that it had a crude protein of 13.98%, The value obtained here is higher than 9.1g/100g recorded byRavishankar *et al*., (2003); D'Andrea *et al.* (1999) who reported 7.3%; Chethan and Malleshi, (2007) 5-8%, Gull *et al.,* (2015), Gupta *et al.*, (2011) 7.5 – 9.56, brown/red 8.7 g /100 g (Rao, 1994) for other members of the millet family, such as foxtail millet (10.29%), burnyard millet 6.93% (Verma *et al*., 2014), These differences could be due to the variations experienced in geographical locations and soils where the finger millet was planted or the amount of rainfall in those areas. Therefore, this high CP of red finger millet makes it a very nutritionally important ingredient for animal feed, since protein is very vital for normal functioning of the entire body system. Proteins are essential components of the diet needed for survival of animals and humans; their basic function in nutrition is to supply adequate amount of required amino acids (Pugalenthi *et al*., 2004).

The ether extract or crude fat obtained from the analysis of red finger millet revealed that it had 3.70%. This is higher than what was reported by Ravishankar *et al*., (2003) 1.2g/100g, David *et al*., (2014) 0.83%, 1-2% (Chethan and Malleshi, 2007), 1.3-1.8% (Bhatt *et al*., 2003; Lupien, 1990). However, it is comparable to what was obtained 2.1% (Anthony *et al*., 1996).The differences and variations seen may be as a result of different methods of laboratory analysis by different laboratory personnel that carried out the analysis. High fat ingredients are suggested for inclusion in weight gaining diets because of the energy embedded in them. Leeson, (1997) reported that fats are widely used energy sources in addition to improving the consistency and palatability of mash feed.

The result of the proximate analysis revealed Ash content of 4.90% for red finger millet, this is higher than what was reported by David *et al*., (2014) 2.37%; 1.7% (Rao, 1994). The differences recorded may be due to the different types of fertilizer used and the methods of application found in those areas. This suggests that red finger millet has more content of inorganic or mineral in it. This result agrees with what was reported by Singh and Raghuvanshi, (2012) that the Ash content in finger millet is higher than what was obtained in the commonly used cereal grains.

The result of crude fiber showed that Red finger millet had 6.67%, This is higher than what was reported in foxtail millet 4.25% and burnyard millet 2.98% (Verma *et al*., 2014); 72% obtained by D'Andrea *et al* (1999). These wide variations could be as a result of using different cultivars on different soils with various rainfalls ranges, probably the stage of maturity at which the crop was harvested. Crude fiber is nutritionally important as it aids the absorption of trace elements in the gut and elimination of undigested waste through the bowel (Abolaji *et al*., 2007).

The nitrogen free extract (NFE) obtained from the result revealed that red finger millet had 59.22% which is lower than 72% obtained by D'Andrea *et al* (1999); 77.9g/100g (Ravishankar *et al*., 2003). These wide variations could be as a result of using different cultivars on different soils with various rainfalls.

Table 1: Proximate composition Finger millet (*Eleusinecoracana)*(%)

Parameter	**Composition**	
	Red colour	**Black colour**
Dry matter	88.48	87.55
Crude protein	13.98	13.14
`Ether extract	3.70	3.10
Crude fiber	6.67	7.02
Ash	4.90	4.36
Nitrogen Free Extract	59.22	59.84

Sub theme –Monogastric Nutrition. Oral Presentation

Abstract
A feeding trial of 84 days was conducted to assess the replacement value of African Locust bean fruit pulp for maize in weaner rabbits diet. Five diets were formulated, such that 100% maize and 0.00% fruit pulp of African fruit pulp at (T1), 75% maize and 25% inclusion of African locust bean at (T2), 50% maize and 50% African locust bean pulp as (T3), 25% maize and 75% African fruit pulp at (T4) while (T5) contain 100% fruit pulp of African locust bean and 0.00% maize respectively. Seventy five (75) weaner rabbits (5-6wks old) with average initial weight between 610.67g -622.60g were randomly allocated in a complete randomized design (CRD) experiment to the five diets with fifteen (15) weaner rabbits in each treatment which were subdivided into three (3) replicates having five (5) weaner rabbits in each replicate. The weaner rabbits were housed in individual cage compartment. Proximate composition of the experimental diets fed to weaner rabbits carried out indicated that T1 had dry matter content of 93.28 %, crude protein of 19.80 % and also 12.41 % of crude fiber. Ether extract was higher in T5 with 8.48 %, while nitrogen free extract contained in T3 had the highest value of 51.17 %. However ash content in T5 has the highest value of 7.83 %. The metabolizable energy in all the dietary treatment shows that T5had the highest value of 3013.21 ME/Kcal/Kg. Data were collected on daily feed intake and weekly weight. Feed conversion ratio, protein efficiency ratio, energy efficiency ratio, nutrient digestibility and feed cost benefit ₦ (kg) were calculated. Weaner rabbits fed 75% maize and 25% African fruit pulp (T2) consumed more feed and significantly gained more weight P<0.05 than those fed the other diets. Feed conversion ratio, protein efficiency ratio and energy efficiency ratio were not significantly (P>.0.05) influence by the treatment diets. Average feed cost of production with inclusion of maize was estimated at ₦311.25 in T1 while the African locust bean fruit pulp inclusion was ₦161.81in T5, a cost difference of ₦149.44, this resulted to a progressive reduction in the cost treatment of feed with increase in the level of fruit pulp of African locust bean meal. The results of this study indicated that when 25% fruit pulp of African locust replaced maize, the rabbits performed better than the control diet and also of more economical option.
Keywords: Fruit pulp, weaner rabbits, diet, proximate, metabolizable.

INTRODUCTION

There is an estimate of an annual five to seven percent growth rates for meat consumption, such increase cannot be met easily by large animals like sheep and cattle because of their slow production cycle, they may however be met by short cycle animals such as rabbits, poultry and pigs. The growing demand for maize in the last few years for both human and livestock consumption has pushed its market price to an alarming rate and that has directly affected the production cost of farm animals particularly the non –ruminants.(Igwebuike *et al*., 2003). The fruit pulp is obtained from the locust bean tree. The African Locust bean, (*Parkia biglobosa*) is a perennial tree. It grows in the savanna region of West African up to the edge of the Sahel zone. The fruit of the plant is straight or sickle shaped 15.6cm -31.20cm long and 2.6cm broad with thick waxy margin. When dried it is light brown with black seed embedded in yellowish mealy tasting pulp (Edigwe *et al*., 2012). The study herein conducted is to evaluate the replacement value of African locust bean fruit pulp for maize in weaner rabbits diet.

MATERIALS AND METHOD.

Experimental site – The experiment was carried out at the Rabbit unit of Animal Teaching and Research Farm, located at Gidan Kwano, Federal University of Technology Minna, Niger State.

SOURCE OF EXPERIMENTAL INCREDIENTS – Pulp of locust bean was purchased at Dandaudu village 56km away from Minna. Five dietary treatment were formulated at 16% crude protein requirement
with energy level of 2884.16(Kca/kg) for the rabbits using Pearson square method of feed formulation. Scwartz and Allen (2012).

EXPERIMENTAL DESIGN

A total of seventy five (75) rabbits of mixed sexes and breeds (New Zealand and chinchilla) were randomly allotted to five treatment groups as T1, T2, T3, T4, and T5 with three (3) replicate each, containing (5) rabbits in each replicate.

MANAGEMENT OF EXPERIMENTAL RABBITS.

Rabbits were kept in hutches made up of wood and mesh wire, with height of 60cm, and width 40cm. Hutches were enclosed in a house under intensive system were the floor of the house is cemented on the. All hutches and house were disinfected before commencement of the experiment work. (Olomu, (2008)

DATA COLLECTION AND ANALYSIS

Initial weight of weaner rabbits were taken at the first day on commencement of the experiment. Formulated feed were weighed each morning on daily basis and fed to rabbits in each treatment. Left over feed were weighed the following morning and feed intake obtained. by difference. Initial body weights of all the weaner rabbits were obtained on the first day of commencement of the experimental work, while the weekly body weight were obtained by weighing the weaner rabbits at the end of each week

Table 1 Feed composition and calculated nutrients of experimental diets fed to rabbits at weaner stage

	T1	T2	T3	T4	T5

RESULTS AND DISCUSSION

Rabbits fed 25% replacement level of fruit pulp of African locust bean diet had a higher feed intake and with a significant ($P<0.05$) weight gain than diet containing 75% and 50% levels respectively. This result agrees with Gernah *et al*., (2007) that low level of sweetness in the pulp yield a higher intake at

25% inclusion compared to the increased level of 50% and 75%. The high average weight recorded in 25% replacement level could be as a result of high level of feed intake by the rabbits in the treatment, this result agrees with Osagie (2011) that weight gain is directly related to feed intake, while low growth rate in diet 4 could be as a result of low intake of feed. The feed conversion ratio did not show a significant different (P>0.05) in all the dietary levels. Diet 2 shows lowest value, this is in agreement with the work of Okah (2004) who reported that the higher the weight gain per unit feed consumed, the lower the value of feed efficiency obtained. Protein and energy efficiency ratio did not show a significant difference (P>0.05) in all the diet. The ₦311.25 cost of fruit pulp of African locust bean, and maize ₦161.81gave rise to a cost differential of ₦149.44, this resulted to reduction in the cost of feed as level of fruit pulp of African locust bean meal is increased ((Kwari and Igwebuike 2010)

CONCLUSION AND RECOMMENDATION

The result of this study reveal that fruit pulp of African locust bean could replace maize at 25% level for weaner rabbits diet without adverse effect on their performance. This level of replacement had less cost than maize based diet. However the effect of dietary fruit pulp of African locust bean on the performance of rabbits depends on the nutrient profile. The levels of maize in the reference diets might also influence performance of the rabbits.

HAEMATOLOGICAL PROFILE AND BIOCHEMICAL RESPONSE OF WEANER RABBITS FED GRADED LEVELS OF AFRICAN STAR APPLE *CHRYSOPHYLLUM ALBIDUM* SEED MEAL

AMAO, E. A., ADEOTI, T. M., OLAOGUN, Y. A. and OLADOKUN, A. A.
Department of Animal Production technology, The Oke Ogun Polytechnic, Saki
Corresponding author E-mail: amaoemmanuelayodeleamao@gmail.com

Abstract
This study was carried out to determine the haematological profile and serum biochemical indices of rabbits fed graded level of African star apple (Chrysophyllum albidum) seed meal. The study involved forty eight (48) mixed breed weaned rabbits of seven - eight weeks old, with average weight of 186.87±0.03g.The rabbits were allotted into four dietary treatments comprising twelve (12) rabbits per treatment. The dietary treatments were 0%, 5%, 10% and 15% ASASM inclusion levels. The experimental diet contained 15% crude protein and 2488.68 Kcal/Kg metabolizable energy. The feeding trial lasted eight weeks, during which period feed and water were provided ad – libitum. Data generated were subjected to analysis of variance. Results obtained from this study revealed that the haematological profile and serum biochemical indices of rabbits recorded no significant (P > 0.05) differences among dietary treatments except cholesterol, AST and ALT (P <0.05) . The study concludes that inclusion of graded levels of C albidum seed meal up to 15% will not pose any adverse effects on the blood characteristics of rabbits.

KEYWORDS: Weaner rabbits, *C albidum*, haematology, serum biochemistry

Introduction
Feed scarcity has remained a major limitation to livestock production and productivity (Agbede and Aletor, 2003). The high cost of animal feeds precipitated by the ever increasing cost of feed ingredients has resulted in poor nutrition leading to declining productivity of animals in developing nations like Nigeria (Nodu *et al*., 2014). According to Fetuga (1997) there is a disappointing rate and low level of performance in the Nigerian livestock industry, due to high cost of feeds, poor quality feeds and inefficiency in production and distribution in the feed industry. The low level of livestock production has affected adequate protein intake. However, intensive rabbit production and domestication can help bridge the meat supply gap in Nigeria and ensure animal protein adequacy. Increase in meat production can be achieved through proper nutrition, inclusion of feed ingredients at normal or required levels (Etim and Oguike, 2010).

The domestic rabbit (*Oryctolagus cunniculus*) is an important non-ruminant herbivore for meat production. Rabbit meat is a source of healthful food as it is low in cholesterol, but high in protein, 22g/100g (Aduku, and Olukosi 1990). Rabbits can also utilize the available proteins in cellulose rich plants, whereas it is not economical to feed these to chicken and turkeys. Since there is high demand for additional source of food worldwide the exploitation of plants of low economic importance would be a step towards better resource utilization (Telek, and Martin 1983) which is in line with the strategy to achieve sustainable animal production systems by matching them with locally available feed resources (Preston and Sansoucy 1987).

African star apple (*Chrysophyllum albidum)* is a dominant canopy tree of lowland and mixed rainforests, sometimes, riverine (Madubuike and Ogbonnaya, 2003). The plant is propagated by seedlings, wildings and direct sowing. It is a seasonal fruits-bearing tree. The fruit is fleshy and juicy, producing whitish gummy exudates (Adewusi, 1997). It is widely eaten in South Western Nigeria, popular among women and children (Amusa *et al.*, 2003).

The seeds of *C. albidum* are about 1-1.5 x 2 cm, beanlike, shiny when ripe, compressed, with one sharp edge and a star-shaped arrangement in the fruits (Orwa *et al.*, 2009). The seed coat is hard, bony, shiny, and dark brown, and when broken reveal white-colored cotyledons (Amusa *et al.*, 2003).

The physiology of farm animals is affected by several factors, one of which is nutrition (Ajao *et al.*, 2013). Nutritional status of an individual is dependent on dietary intake and effectiveness of metabolic processes. These can be determined by either or combinations of chemical, anthropometric, biochemical or dietary methods (Bamishaiye *et al.,* 2009). Haematology refers to the study of the numbers and morphology of the cellular elements of the blood – erythrocytes, leucocytes, and thrombocytes and the use of these results in the diagnosis and monitoring of disease (Merck Manual, 2012). Haemtological studies are useful in the diagnosis of many diseases as well as investigation of the extent of damage to blood (Onyeyili, *et al.,* 1992; Togun *et al.,* 2007). Haematological parameters are good indicators of the physiological status of animals (Khan and Zafar, 2005). Haematological parameters are those parameters that are related to the blood and blood forming organs (Waugh *et al*., 2001; Bamishaiye *et al*., 2009). Blood act as a pathological reflector of the status of exposed animals to toxicant and other conditions (Olafedehan *et al.,* 2010). As reported by Isaac *et al.* (2013) animals with good blood composition are likely to show good performance.
However, there is no information on the effect of seeds of *C. albidum* on haematology and serum biochemical parameters of rabbits. Therefore, this study was carried out to investigate the effect of feeding graded levels of seeds of *C. albidum* on the haematological and serum biochemical parameters of rabbits.

Materials and Methods
The study was carried out at the rabbitary unit of the Oke-Ogun Polytechnic, Saki. Oyo State, Nigeria.

African Star Apple seeds were collected from primary and secondary schools in Saki, Oyo State, Nigeria. The seeds were sun dried and further broken to obtain the cotyledons. The cotyledons were sun dried and milled for inclusion in diet mixture of growing rabbits.

Experimental Animals and Management
A total of Forty-eight (48) growing rabbits (7 – 8 weeks of age with average weight 186.87 ±0.03g) of mixed sexes were obtained from a reputable farm in Oyo State, Nigeria for the purpose this study. The animals were housed in wooden cages raised from the ground level. Before the animals were brought into the rabbitary, the cages were thoroughly washed and disinfected and allowed to dry. The floor of each cage was covered with wire mesh to allow for the passage of waste materials. Feed and water troughs were provided in each cage, while feed and water were provided *ad – libitum.* The rabbits were caged individually in clearly marked cells. The feeding trial lasted eight weeks.

3.3 EXPERIMENTAL DIET

Four experimental diets were formulated with the inclusion of 0%, 5%, 10% and 15% African Star Apple seed meal (ASASM) as substitute for maize in rabbit diet.

Parameters	0% (ASASM)	5% (ASASM)	10% (ASASM)	15% (ASASM)
Maize	40.00	38.00	36.00	34.00
ASAS	0.00	2.00	4.00	6.00
Maize offal	25.00	25.00	25.00	25.00
Rice offal	18.00	18.00	18.00	18.00
Soybean meal	2.00	2.00	2.00	2.00
Fish meal	1.20	1.20	1.20	1.20
Groundnut cake	10.00	10.00	10.00	10.00
Limestone	1.00	1.00	1.00	1.00
Bone meal	2.00	2.00	2.00	2.00
Salt	0.20	0.20	0.20	0.20
Premix	0.30	0.30	0.30	0.30
Methionine	0.20	0.20	0.20	0.20
Lysine	0.10	0.10	0.10	0.10
Total	100kg	100kg	100kg	100kg

Blood collection:

Blood collection was done at end of the 8th week of feeding trial from six rabbits per treatment. Blood samples were obtained from the prominent ear vein with the aid of a hypodermic needle and syringe. Two blood samples each were collected per rabbit; one set of the blood samples was collected into plastic bottles containing Ethylene Diamine Tetra acetic acid (EDTA) for haematological studies while the other sample was collected into plain sterile bottles for the serum biochemical indices determination. All haematological parameters were determined by conventional laboratory methods of Baker and Silverton (1982); Bitto and Gemade (2001), while serum biochemical indices were determined by methods described by Ochei and Kolhathar (2007).

STATISTICAL ANALYSIS

All data collected were subjected to analysis of variance (ANOVA) technique using statistical analysis software.

Results and Discussion

Table 2: Haematological indices of rabbit fed African Star Apple seed meal.

Parameters	0%ASASM	5%ASASM	10%ASASM	15%ASASM	SEM

Results and discussion

It is well established that changes in haematological and biochemical parameters reflect the physiological status of animal. Packed cell volume (PCV) values obtained in this study were not significantly ($p>0.05$) influenced by dietary treatments. The values (39 – 40.66%) were within the reference range of 33 to 50% reported by MediRabbit (2007). The red blood cell (RBC) range of 6.33 – 6.64x106/mm3 and haemoglobin (Hb) range of 12.76 to 13.60 were within standard range of 4 – 8.6 to 7.9 x 106/mm3 for RBC and 10 - 15g/dl for Hb respectively (RAR, 2009). This result indicates that *C. albidum* seed support red blood cell synthesis. The platelet counts recorded in this study ranged from115 to 146 $x10^9$/L for rabbits fed graded levels of *C. albidum* seed. The values were however lower than the normal range (250.00 – 600.00 $x10^9$/L) for rabbits reported by Medirabbit (2011). The white blood cell (WBC) values obtained in this study which were not significant among treatments were within the normal range of 4.5x 10^9 /l to 11 x 10^9 /l reported (RAR, 2009). The white blood cell differentials namely lymphocytes, neutrophils, monocytes and esonophils were not significantly influenced by dietary treatments.

Biochemical response of rabbits fed *C. albidum* seed was presented in table 3. No significant difference ($p>0.05$) was observed in the values of glucose, total protein and albumin. Values for glucose range from 64.18 to 78.39mg/dl, only animals on control diet falls within the standard range of 75 – 140mg/dl (Medirabbit, 2011) animals placed 5%, 10% and 15% had values below the standard range and this implies hypoglycemia in the rabbits. Values of total protein (5.28 – 7.14g/l) and values of albumin (3.14 – 3.89g/l) were within the standard reference of 5.0 – 7.5g/l and 2.7 – 5.0 g/l respectively (Medirabbit, 2011). This suggests that normal protein metabolism occurred in rabbits, since protein synthesis is related to the amount of protein available in the diet (Iyayi and Tewe, 1998). Cholesterol and Aspartate aminotransferase (AST) followed the same trend with animals placed on 5% having highest values, cholesterol ranged from 70.83 – 113.33 while AST value ranged from 43.40 – 97.90 values for the two parameters falls within the standard range of 10 to 80mg/dl and 10 to 98mg/dl respectively (Medirabbit, 2011). This implies no deleterious influence of ASASM on rabbit biochemical response.

Conclusion and Recommendation

Results obtained in this study have shown that *C. albidum* seed can be included in weaner rabbits' feed without adverse effects on their haematological profile and serum biochemical indices.

Abstract

The effect of supplementing lemon grass (Cymbopogon citrates) leaf meal on the growth performance and haematological profile of starter broiler birds formed the basis of this study. A total number of one hundred and twenty (120), one week old "Agric-tech" broiler chicks were randomly allocated to four dietary treatments, each replicated three times with ten birds per replicate in a completely randomized design (CRD). Four different diets were formulated such that the lemon grass leaf meal was incorporated into the diets at the rate of 0.75%, 1.50% and 2.25% respectively, while treatment 1 served as the control with 0% level of lemon grass leaf meal. Feed and water were given ad-libitum throughout the experimental period of twenty one day. Results obtained from the growth performance in terms of initial body weight, final body weight, average daily body weight gain, average daily feed intake and feed conversion ratio showed significant ($p<0.05$) difference across the treatment group. Haematological profile results showed that there was significant ($p<0.05$) effect of lemon grass leaf meal across the treatment groups. From the present results, it can be concluded that lemon grass leaf meal can be added up to the levels of 2.25% in the diet of starter broiler birds without any negative impact in terms of growth performance and no detrimental effect to the health of the birds at this phase of growth.

Keywords: Growth performance, starter broiler birds, lemon grass leaf meal, haematological indices

Introduction

High quality feed together with clean environment, clean water and subsequently good managerial qualities can ensure the production of nutritious animal products with desirable traits for man consumption. Thus the use of additives of natural origin as alternatives to antibiotics in animal and human nutrition has been encouraged recently. Feed additives like probiotics, prebiotics, organic acids and plant derivatives with their biochemical structures and physiological functions of various degrees have been reported. The subsequent consumption of medicinal herbs, aromatic plants and spices in man's nutrition for improvement of taste, aroma and colour of feed as additive have been carefully substituted into animal nutrition for growth and health of the animals. With the recent ban of antibiotics use in animal nutrition due to the emergence of microbes' resistance alternative growth promoters must be evaluated. Thus the removal of antibiotics as growth promoters has been reported (Ceylon and Fung, 2004). A wide range of herbs, spices and their extracts exerts beneficial effects within the digestive tract, such as laxative acid, spasmolytic effects and reduction of flatulence (Onyimonyi *et al*., 2009). These active components effects largely depends on its dosage administered. Increased in quantity of doses can even be detrimental to animals and subsequent doses reduction in quantity poses no effect to the animal.

Lemon grass (*Cymbopogon citratus*) is an aromatic plant belonging to the gramineae family (Akhila, 2010). The compounds identified in *Cymbopogon citrates*are mainly terpenes, alcohols, ketones, aldehyes and esters.Studies indicate that *Cymbopogon citrates* possess various pharmacological activities such as anti-amoebic, antibacterial, antidiarrheal, antifilarial, antifungal and anti-inflammatory properties. Other effects such as antimalarial, antimutagenicity, antimycobacterial, antioxidant and hypoglycemic have also been studied (Mirghani *et al*., 2010)

Materials and Method

The experiment was conducted at the poultry unit of the Animal Production Department, Federal College of Agriculture, Ishiagu, Ebonyi State. The lemon grass leaf that was use for the experiment was sourced from Afikpo and Ishiagu, both in Ebonyi state. The lemon grass leaves was obtained fresh and wash, then air-dried for a week at room temperature after which it was sun-dried for about 2 hours to get a cripsy-like leafy material. The cripsy leaves was then turned to leaf meal by means of grinding. One hundred and twenty (120) day old broiler chicks were used for the research work. The birds were brooded for one week after which they were randomly distributed into four treatments. Each treatment was replicated three times in a completely randomized design (CRD) with ten (10) birds per replicate. The birds were purchased from a reputable farm in Enugu, Enugu state.

Prior to the arrival of the birds, the pens were washed and cleaned so as to avoid pathogenic and disease infection. A good source of light was provided, which served as insulator to keep the chicks warm. Feeders and drinkers were thoroughly washed and cleaned. The birds were raised on a deep litter system with wood shavings which served as a source of litter. The chicks were brooded for one week after which they were randomly distributed to their various pens. The initial weight of the birds was obtained after distribution to their various pens. Feed and water were given *ad-libitum*. All the routine vaccination and medication necessary for the birds' good health during the entire growth cycle from day old to the end of the experiment were strictly adhered to according to specification.

Experimental diets

Four experimental diets were formulated with diet 1 containing 0% lemon grass leaf meal which served as the control. Diets 2, 3 and 4 contain the lemon grass leaf meal at the levels of 0.75%, 1.50% and 2.25% respectively..

Table 1. Composition of starter broiler diet fed supplemental levels of lemon grass leaf meal

	Treatments			
Ingredients	T1	T2	T3	T4
Maize	54.00	53.25	53.25	52.50
Wheat offal	7.25	7.25	6.50	6.50
Lemon grass leaf meal	0	0.75	1.50	2.25
TOTAL	**100**	**100**	**100**	**100**

Other feed ingredient had same value across treatment group: Soybean meal-7.00; Groundnut cake-22.15; Fishmeal- 3.00; Blood meal-2.50; Bonemeal-2.00; Limestone-1.00; Salt-0.25; Starter premix-0.30; Lysine-0.25; Methionine-0.30.

Feed intake was recorded as the difference between the quantity of feed given the previous day and the quantity that was left the next day. Feed conversion ratio was obtained as the ratio of feed intake divided by the body weight gain. Data collected were subjected to analysis of variance (ANOVA) and significant difference mean were separated according to the method of Duncan multiple range test as outlined by Obi (2002).

Results and discussion

Table 2 showed the results of starter broiler birds fed diet supplemented with graded levels of lemon grass leaf meal. The result of final body weight showed that birds in treatment 4 had the highest value of 1193.33g which was similar ($p>0.05$) to those of birds in treatment 3 (1173.33g g), but differ ($p<0.05$) from those in treatment 2 (1150.00g) and 1 (1113.33g) respectively. The significant increase in value of final body weight across the treatment group may be due to the ability of the birds' enzymatic system to stimulate protein synthesis and also optimized the antioxidant activities of lemon grass leaf meal. This present research work is similar with the work of Mmereole (2010) who observed significant ($p<0.05$) higher body weight and body weight gain when compared with the control in starter broiler birds fed diet supplemented with lemon grass leaf meal.

Table 2. Growth Performance Characteristics of Starter Broiler Birds fed Supplemental levels of Lemon Grass Leaf Meal (lglm)

	Treatments				
Parameters	T1	T2	T3	T4	SEM
*Initial Body Weight (g)	115.00	115.00	113.33	113.33	-
*Final Body Weight (g)	1113.33	1150.00	1173.33	1193.33	23.78
*Av. Daily Body Wt. gain (g)	47.5	49.29	50.48	51.4	1.11
*Av. Daily Feed Intake (g)	93.12	94.99	96.21	92.49	0.79
*Feed conversion ratio	1.96	1.93	1.91	1.80	0.04
*Packed Cell Volume (%)	30.09^{bc}	32.91^{b}	31.31^{b}	35.07^{a}	0.89
*Haemoglobin (g/l)	8.95^{a}	8.60^{ab}	8.99^{a}	9.13^{a}	0.09
*Red Blood Cell ($x10^{12}$/l)	3.00^{ab}	3.70^{a}	3.40^{a}	3.72^{a}	0.11
*White Blood Cell ($x10^{9}$/l)	7.94^{c}	8.21^{b}	8.56^{a}	8.56^{a}	0.09

^{abc} Means on the same row with different superscripts are significantly ($p<0.05$) different.
SEM = Standard error of mean

Average daily feed intake showed significant ($p<0.05$) effect among treatment group. Values for birds in treatment 3 (96.21g) was significantly ($p<0.05$) different from those obtained for birds on treatment 2 (94.99 g), 1 (93.12g) and 4 (92.49g) respectively. The result was in variance with the observation made by Mehala and Moorthy (2008) where they claimed that there were no significant ($p>0.05$) difference between the control and the treatments groups, probably due to the iso-caloric and iso-nitrogeneus nature of the experimental diets. The blood parameters for hematology were significantly ($p<0.05$) affected by lemon grass leaf meal across the treatment group, even though they did not follow a particular pattern. All values obtained for packed cell volume (PCV), hemoglobin (Hb), red blood cell (RBC) and white blood cell (WBC) studied falls within the normal ranges for broiler as reported by The Merck Veterinary Manual (2015). The improvement in the haematological constituents observed in the present study is an indication that the inclusion of lemon grass leaf meal did not show any pathological effect on the bird thus did not cause or create any haematological disorder.

Conclusion

Thus it can be concluded from the results obtained that the inclusion of lemon grass leaf meal in the diet of starter broiler birds up to 2.25% is acceptable by the birds without any decrease in growth performance and no negative effect in terms of their health status as reflected in the percentage mortality value and haematological profile results.

PERFORMANCE AND HAEMATOLOGICAL PARAMETERS OF LAYING HENS FED DIETS SUPPLEMENTED WITH SELENIUM AND VITAMIN E

Jemiseye, F. O., Ogunwole, O. A., Adedeji, B. S. and Mosuro, A. O.
Agricultural Biochemistry & Nutrition Unit, Department of Animal Science, University of Ibadan, Ibadan, Nigeria

Abstract
An experiment was conducted to assess the effect of supplemental selenium and vitamin E on performance and blood profile of laying hens. In a completely randomised design, ISA brown hens (n=192) at week 20 of age were assigned to six experimental diets: T1 (Basal diet), T2 (Basal diet + 0.5 mg selenium), T3 (Basal diet + 1.0 mg selenium), T4 (Basal diet + 1.5 mg selenium), T5 (Basal diet + 20 mg vitamin E), T6 (Basal diet + 40 mg vitamin E*). Each treatment was replicated four times with eight birds per replicate. Data were recorded daily for performance characteristics.* At week 26, blood was sampled from hens and analysed using standard procedures. Supplemental selenium and vitamin E had no significant effect (p>0.05) on hens' performance. However, dietary supplemental selenium and vitamin E had significant influence on eosinophils and monocytes. Eosinophils of hens on T1 (4.25) was similar to 4.00, 3.50, 4.33 and 3.75 recorded for hens on T2, T3, T4 and T5, respectively but higher than 1.33 obtained for hens on T6. Similarly, monocyte value in T1 (2.0) was similar (p>0.05) to T2 (3.25) and T3 (3.25) but lower than 4.00, 3.75 and 4.00 obtained in hens on T4, T5 and T6, respectively. It was therefore concluded that supplementation of vitamin E and selenium up to 40 mg/kg and 1.5 mg/kg, respectively had no significant effects on hen's performance.

Introduction

Stress exerts negative effects on the body such as disturbance of acid-base balance of the blood, various changes in metabolism and oxidative damage to the cells (Ertas and Sahik 2002). This often has resultant effect on egg production and quality, feed consumption, live weight and overall productivity in chickens.

When formulating feed for animals, nutritionists take into account several factors including stress management and immunity enhancement as very critical (Linge, 2005). The use of antioxidant nutrients in this respect cannot be overemphasized. Antioxidants are substances that can scavenge, suppress or reduce the formation of reactive oxygen species (Khan *et al*., 2011; Lu *et al*., 2010) that are constantly produced *in vivo* in the course of the physiological metabolism in tissues (Surai, 2015). Reactive oxygen species are detrimental to productive performance in laying birds (Assar *et al*., 2016). Antioxidants nutrients such as vitamin E and selenium *have been implicated in immune functions of domestic animals (Finch and Turner, 1996) and* with important roles in maintaining chicken health, productive and reproductive performance (Surai, 2002). However, there have been conflicting reports (Scheideler, 2010: Adebiyi *et al*., 2004) on the benefits of Selenium and vitamin E in poultry. *Therefore, t*he objective of this study was to evaluate the effect of dietary selenium and α-tocopherol supplementation on performance and haematological status of laying hens.

Materials and methods

Experimental Site and Animal Allotment

The experiment was carried out at the Poultry Unit of the Teaching and Research Farm, University of Ibadan, Ibadan, Nigeria. *A total of 192, ISA brown hens at the point of lay (20 weeks of age) were assigned to six experimental diets in an experiment that lasted twenty weeks. The experiment was a completely randomized design with each treatment replicated four times and with eight birds per replicate.*

Experimental Diets

Basal diet was supplemented with selenium and vitamin E as follows: T1=Basal diet, T2=Basal diet + 0.5mg selenium/kg, T3= Basal diet + 1.0mg selenium/kg, T4= Basal diet + 1.5mg selenium/kg,

T5=Basal diet + 20mg vitamin E/kg, T6=Basal diet + 40mg vitamin E/kg*)* Feed and water were supplied *ad libitum*. (Jemiseye and Ogunwole 2019).

Data collection and analysis

During the period of the trial, pen temperature-humidity index was monitored three times daily, between the hours of 7:00-8:00, 12:00-13:00 and 17:00-18:00 using digital thermo-hygrotherms placed strategically at different locations within the pen house. Temperature Humidity Index (THI) was calculated from the average ambient temperature and relative humidity obtained using the formula: THI = 0.6 T_{db} + 0.4 T_{wb}, where, T_{db} = dry bulb temperature and T_{wb} = wet bulb temperature.
Eggs were collected daily and recorded, hen day egg production was calculated by number of eggs laid divided by number of chicken at the period of data collection, feed intake was calculated by subtracting left over from feed offered to the chickens, egg were weighed with sensitive scale to obtain egg weight and egg mass was calculated from the percent hen day egg production and average egg weight. At week 26 of laying, blood was collected from two birds per replicate via the jugular vein into heparinized test tubes for haematology. Packed cell volume (PCV), haemoglobin (Hb), red blood cells (RBC), white blood cells (WBC) and differential counts were determined using standard procedures (Schalm *et al.*, 1975).

Statistical analysis

Data were subjected to analysis of variance using the SAS (1999) package. Means were separated using Duncan's multiple range test of the same package.

Results and Discussion

Temperature-humidity index of the experimental pen: Temperature-Humidity index of the experimental pen is shown in Figure 1. The maximum and minimum values were 30.40 and 25.10, respectively. The reported temperature and relative humidity were higher than thermoneutral temperature range (18-22 ^{o}C) of laying chicken reported by Charles (2002). Pen house temperatures beyond thermoneutrality have been reported to aggravate stress in chickens (Adedeji and Ogunwole, 2018) as higher ambient temperature and relative humidity have direct implications on feed consumption.

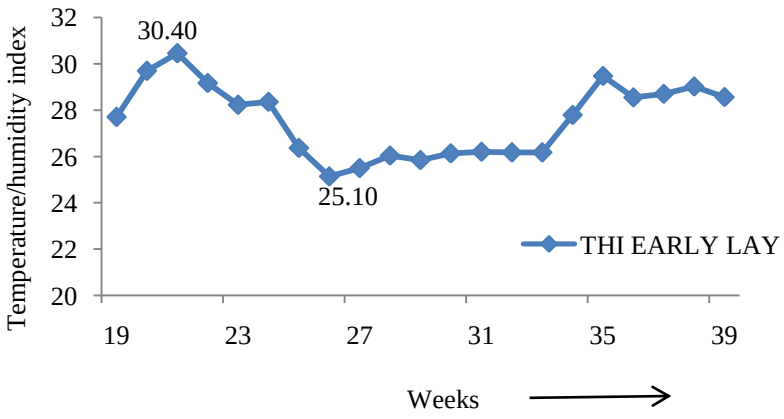

Figure 1: Temperature-humidity index of the experimental pen

Performance of laying chickens: Performance of laying chicken fed diet supplemented with selenium and vitamin E is shown in Table 1. **S**upplementation of layers' diet with selenium and vitamin E at the early laying phase did not have any significant effects ($p>0.05$) on the performance parameters measured. This observation corroborated earlier findings of Adebiyi *et al.* (2014) that neither vitamin E nor selenium and their combination increased hen day percentage and weight in turkeys. Also, Scheideler (2010) reported that there were no overall effect of vitamin E on egg production. Although, high temperatures have been reported to reduce production performance in

laying hens (Deng *et al.*, 2012), this was not so as observed in this study. This may further emphasise the alleviating effect of antioxidants (Se and vitamin E) in stress management *(*Khan *et al*., 2011*)*.

Table 1. Performance of laying chicken fed diet supplemented with selenium and vitamin E

Parameters	T1	T2	T3	T4	T5	T6	SEM
Hen day egg production (%)	40.80	36.98	43.88	35.60	46.34	42.99	1.79

Egg weight (g)	53.28	57.77	51.95	50.93	53.69	58.72	1.56
Egg mass (g)	21.79	21.46	22.88	17.90	24.94	25.63	1.25

T1-Basal diet, T2-Basal diet+0.5mg selenium/kg, T3-Basal diet+1.0mg selenium/kg, T4-Basal diet+1.5mg selenium/kg, T5-Basal diet+20mg vitamin E/kg, T6-Basal diet+40mg vitamin E/kg. Means in the same row with different superscripts are significantly different (P<0.05). SEM-standard error of mean

Haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation. Table 2 shows the haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation. There were no significant differences (p> 0.05) across treatments for all haematological parameters measured except for monocytes and eosinophils. Eosinophils of hens on T1 (4.25) was similar to 4.00, 3.50, 4.33 and 3.75 recorded for hens on T2, T3, T4 and T5, respectively but higher than 1.33 obtained for hens on T6. Similarly, monocyte value in T1 (2.0) was similar (p>0.05) to T2 (3.25) and T3 (3.25) but lower than 4.00, 3.75 and 4.00 obtained in hens on T4, T5 and T6, respectively. Blood is significant in measuring the physiological, nutritional and pathological status of animals (Olorode *et al*., 2007). Elevated monocyte and eosinophil levels observed in this study was an indication that inclusion of the supplements improved the responsiveness of the immune cells to invading germs. This observation supports earlier position of *Finch and Turner (1996)* on the relevance of Se and vitamin E in immune function. Bush (1991) had earlier pointed out that low levels of WBC especially eosinophil and basophil in chickens could lead to poor immunity against diseases and may be an indication of poor health conditions due to parasitic disturbances. A slight deviation from this was observed in T6 for eosinophils. This however could imply that supplemental vitamin E beyond 20mg/kg of diet may lower eosinophil count in chicken.

Table 2: Haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation

Parameters	T1	T2	T3	T4	T5	T6	SEM

Abstract

Twenty (20) weaned crossbred (Landrace × large white) pigs with an average body weight of 8.5±0.4 kg were used to evaluate performance and nutrient digestibility of weaned pigs fed five experimental diets containing cereal milling by-products. Diet 1 contained maize offal, while diets' 2, 3, 4 and 5 contained wheat offal, sorghum offal, millet offal and rice offal respectively. The animals were balanced for sex and weight and allotted to five dietary treatments and replicated four times in a completely randomized design. Data were collected on feed intake and weight gain for a period of eight weeks. A digestibility trial was carried at the end of the feeding trial using four pigs per treatment. Average daily weight gain ranged from 0.21kg/ day (T5) to 0.44kg/day in (T1). The result of growth performance and nutrient digestibility showed that average feed intake, final body weight as well as digestibility of dry matter, crude fibre, ether extracts, crude protein and ash were higher ($P<0.05$) for pigs fed T1, T2, T3 and T4, while those on T5 had the lowest growth and nutrient digestibility. It was concluded that maize offal, wheat offal, sorghum offal, millet offal can be used in weaner pigs' diet.

Introduction

High cost of feeding has been identified as one the major impeding factors affecting the pig industry in developing countries (Uddin and Osasogie, 2016). This is as a result of continued increase in prices of conventional feedstuffs which are mostly used as sources of dietary energy and protein. However, for the pig industry to remain profitable, development of low- cost feeding strategies which are locally available to pig farmers has been the major challenge of animal nutritionist (Nelson *et al.* 2007). The use of agro-based by-products in pigs has been evaluated by various researchers indicating improved growth performance (De Lange *et al*. 2010; Kim *et al.* 2011) while others reported depressed performances (De la Llata *et al*. 2001) as a result of high dietary fibre depending on the cereal type (Freira *et al*. 2000; Galassi *et al.* 2004), type and extent of milling (Amaefule *et al.* 2009) as well as climate and soil conditions where the grain is produced (Wenk 2001). The comparative evaluation of feeding the cereal milling by products on pig performance and nutrient digestibility is scanty. This study therefore assessed the performance of weaned pigs fed diets containing cereal milling by-products.

Materials and methods

Experimental animals and their management

Twenty (Landrace × Large white) pigs with an average initial body weight of 8.00±0.56 kg were used. Each pen had solid concrete floor and were fitted with water and feed troughs. The pigs were treated against parasites using Ivomectin®. The pigs were offered experimental diets and water *ad libitum*.

Experimental diets

Five experimental diets (Table 1) were formulated based on the five cereal milling by-products i.e. maize offal, wheat offal, sorghum offal, and millet offal and rice bran. They were purchased at the agro-by product market in Yola. Diet 1 contained maize offal, while diets' 2, 3, 4 and 5 contained wheat offal, sorghum offal, and millet offal and rice bran.

Experimental design and data collection

Twenty weaner pigs were randomly allotted to five dietary treatment groups replicated 4 times in a Completely Randomized Design. Data were collected for eight weeks. Pigs were weighed at the beginning of the experiment and weekly, subsequently. Weight gain was calculated as final live weight minus initial live weight. Feed intake was obtained as the difference between the quantity offered and quantity not consumed. Feed conversion ratio (FCR) was calculated as feed intake divided by weight gain

Statistical analysis

Data collected were subjected to one way analysis of variance means were separated using Duncan's Multiple Range Test using SAS (2003).

Results and discussion

The crude protein and fibre of the cereal offal are represented in Table 2. The values recorded were similar to that of Aduku, (1993).

Crude protein and fibre composition of cereal offals

Parameter	Crude protein	Crude fibre
Maize offal	11.8	10.52
Wheat offal	12.00	10.56
Sorghum offal	12.56	9.23
Millet offal	11.1	7.50
Rice bran	13.20	11.50

Growth performance of weaner pigs fed cereal offal in diets

Table 3 shows the effect of the cereal offal on the growth performance weaner pigs. Final body weight, average daily feed intake (ADFI), average daily gain (ADG) and feed conversion ratio (FCR) were significantly (P<0.05) influenced by experimental diets. ADWG, ADFI and final weight were significantly higher (P<0.05) for pigs fed T1, T2, T3 and T4 diets than those fed T5 diet. This could be due to the palatability and acceptability of this diets as demonstrated by high intake of the diet and high ADG. The result agreed with the findings of García-Valverde *et al.* (2008) and Mwesigwa *et al.* (2012) who fed by-products of maize and that of wheat. The dietary fibre in T1, T2, T3 and T4 diets could have improved pig gut morphology, hence stimulating mucosa enzyme activity which eventually improves nutrient digestibility and growth olist *et al.* 2009). Pigs fed T5 diet had significantly (P<0.05) lower feed intake. Low protein intake has been reported to result in slow growth rate of pigs (Nyachoti *et al.* 2006)

Table 3 Growth Performance of weaner pigs fed offals

	Dietary treatments					
Parameter	T1	T2	T3	T4	T5	SEM
Initial body weight (kg)	8.56	8.77	8.69	8.69	8.76	0.23
Final body weight (kg)	38.25^{a}	31.75^{a}	30.00^{ab}	32.75^{a}	21.00^{c}	1.70
Average daily weight gain (kg)	0.44^{a}	0.41^{a}	0.37^{a}	0.42^{a}	0.21^{b}	0.03
Average daily feed intake (kg)	1.42^{a}	1.47^{a}	1.42^{ab}	1.47^{a}	0.90^{c}	0.04

Mean on same row bearing different superscript differ significantly (P<0.05)
SEM = Standard error mean

Nutrient digestibility of weaner pigs fed offals in diets

Nutrient digestibility of the diets is presented in Table 4. DM, CF, CF, EE and ash digestibility were significantly higher (P<0.05) for pigs fed T1, T2, T3 and T4 diets than those fed T5 diet. Nutrients digestibility of pigs fed T5 diet was significantly lower (p<0.05). Lower values of nutrient digestibility observed in T5 diet could be attributed to the decrease in the mean retention time of this diet in the gastro-intestinal tract (Bindelle *et al.* 2008) brought about by higher levels of fibre, compared with those in T1, T2, T3 and T4 diets. High dietary fibre depresses apparent digestibility of dry matter and nitrogen, decreases daily body weight and increase feed to gain ratio The higher fibre digestibility observed for pigs fed T1, T2, T3 and T4 diet could have resulted from fermentation of CF in the hind gut with the volatile fatty acids produced contributing to the net energy requirement of the pigs. Birkett, (2005) reported VFAs contribute about 5–28 % of the energy required for maintenance in the growing pig resulting from fermentation of fibre in the gastro-intestinal. Utilisation of CF by non-ruminants has been shown to vary considerably according to the fibre source (Freira *et al*. 2000; Galassi *et al*. 2004), degree of lignification, level of inclusion and the extent of processing (Amaefule *et al.* 2009).

Table 4 Nutrient digestibility of weaner pigs fed cereal milling by –products In Diets

	Dietary treatments					
Parameter (%)	T1	T2	T3	T4	T5	SEM
Dry matter digestibility	86.42^{a}	82.57^{a}	81.50^{a}	80.94^{ab}	74.13^{c}	1.34
Crude protein digestibility	66.15^{a}	69.06^{a}	69.80^{a}	68.62^{a}	50.67^{b}	1.55
Crude fibre digestibility	72.94^{a}	73.42^{a}	69.38^{ab}	72.38^{a}	49.19^{a}	1.97
Ether extracts digestibility	73.93^{a}	72.17^{a}	70.73^{a}	70.81^{a}	52.13^{b}	2.64
Ash digestibility	60.56^{a}	62.53^{a}	69.39^{a}	59.67^{ab}	50.53^{c}	1.09

Mean on same row bearing different superscript differ significantly (P<0.05)*
SEM = Standard error mean

Conclusion

The study reveals that using maize offal, sorghum offal, wheat offal and millet offal in the diet of weaned pigs improves their growth and nutrient digestibility, compared to rice bran. It is therefore recommended that pig farmers, animal nutritionist and feed milling industries should include maize offal, sorghum offal, wheat offal and millet offal in the diet of weaner pigs.

Abstract

As the search for alternative sources of energy for monogastrics animals to reduce competitions between humans and industries for available conventional feedstuffs continues, this study was undertaken to investigate the effect of sundried cassava starch extract pulp on nutrient digestibility of crossbred weaned pigs. Cassava starch extract pulp from cassava processing factory in Ado-Awaye near Iseyin in Oyo State were processed into meal by sundrying for three weeks and included in diets at graded levels of 0%, 25%, 50% and 75% in a complete randomized design experiment using eight weeks old crossbred (largewhite x landrace) weaned pigs. Crude protein, ash, crude fibre, ether extract, dry matter, nitrogen free extract similarly gave values on the processed sundried cassava starch extract pulp diets that were comparable or even superior to values on the control diet ($p<0.05$). Based on the findings of this study, it is concluded that inclusion of sundried cassava starch extract pulp meal in diet at 75% has no deleterious effects on nutrient digestibility of crossbred weaned pigs.

Keywords: nutrients, digestibility, weaned pigs, sundried, cassava starch extract, pulps

Introduction

The high nutritive value, relative cheap cost of production and short gestation period of pig enable pig product (pork) to be the ideal animal protein source for feeding the world human population. Despite this, high feed cost remains a major bottleneck to efficient and improve pig farming. Cribb, (2010) opined that orthodox feed ingredients used in formulating pig diets are in short supply mainly as a result of the increase in human population and unfavorable climatic conditions. The high demand for conventional energy and protein feed ingredients as food by the ever growing world human population and other industrial uses has increased research interest in alternative cheaper ingredients for pig feeding. Cassava pulp is a solid by product of starch production from cassava root. During starch production, cassava pulp yields from 10 – 15% of the root which is a readily available material in major starch producing countries (Khempaka *et al*., 2009).Cassava pulp is rich in starch ranging from about 54 -70% (Khempaka *et al*., 2014) and the pulp is reported to contain between 4.40%, 1.30%, 3.15%, and 0.71% of ash, crude protein, crude fibre and ether extract respectively (Ogunbode, *et al*., 2019). Suksombat *et al*., (2007) opined that cassava pulp contains 36.7% neutral detergent fibre, 9.8% acid detergent fibre and 3.9% acid detergent lignin. The by- products of cassava processing stand out as cheaper energy substitutes for feed formulation for animals and this would probably enhance the reduction of agribusiness waste which are often discarded indiscriminately in the environment. All these by- products are generally found in the vicinity of factories where cassava tubers are processed into starch. As cassava starch production increases, so does the large volume of waste by – product generated. This study was therefore conducted to investigate the nutrient digestibility of crossbred weaned pigs fed sundried cassava starch extract pulp.

Materials and Methods

The experiment was carried out at the piggery unit of the Teaching and Research Farm, of the Oyo State College of Agriculture and Technology Igboora, Nigeria. The experimental areas lie in savannah forest zone on latitude 7^0.43N and latitude 3^0.28E in an elevation of 140m, above the sea level. The average minimum temperature is above 21.5^0C and maximum average temperature is about 32.5^0C. The cassava starch extract pulp was collected from Psaltery Farm International along Ado- Awaye Maya Road. The fresh cassava starch pulp collected was sundried for three weeks based on intensity of the sun and environmental temperature after which it was milled using hammer mill and stored for proximate analysis. Sixteen (16) crossbred large white X landrace weaned pigs in their 8th weeks of age was obtained from the piggery unit of the College. The pigs were dewormed to eliminate both endo and ectoparasite using ivomec at1ml per body weight and offered feed at 4% of their body weight at the beginning of the experiment and with subsequent increase as the animals' age while water was supplied *ad libitum*. The pigs were allowed three (3) days of acclimatization and were fed twice daily in the morning (7:30am) and evening (4:00pm). The experiment lasted 56 days. Proximate analysis of sundried cassava starch extract pulp was carried out according to the procedure of AOAC (2010). Two pigs per treatment was randomly selected and housed separately in individual pens and were acclimatized for two days prior to the commencement of a five - days metabolic trial. A known weight of feed was fed to the pigs housed in individual pen. Total daily faecal sample was collected once in a day, sundried and later stored for analysis according to the procedure (Mc Donald *et al.,* 2002) as shown below:

Nutrient in feed = Amount of feed consumed x Nutrient of diet analyzed.

Nutrient in faeces = Amount excretal x % of excretal analyzed

$$\text{Nutrient Digestibility} = \frac{\text{Nutrient in feed} - \text{Nutrient in faecal}}{\text{Nutrient in feed}} \times \frac{100}{1}$$

The experimental design used was completely randomized design and data collected was subjected to one way analysis of variance and where significant differences exist between the means Duncan Multiple Range Test (Duncan, 1955) was used to separate the means.

Table 1. Nutrient digestibility of weaned pigs fed sundried cassava starch extract pulp

Parameters (%)	1	2	3	4	SEM
Crude Protein	14.55^{c}	15.40^{ab}	14.96^{bc}	16.01^{a}	0.23
Ash	10.50^{c}	13.10^{a}	11.04^{b}	11.10^{b}	0.30

NFE: Nitrogen Free Extract

Results and Discussion

The results of nutrient digestibility of crossbred weaned pigs fed sundried cassava starch extract pulp meal are presented in Table 1.There were significant ($p>0.05$) difference in crude protein, ash and crude fibre digestibility. Their improvements observed was as a result of processing techniques employed in reducing the toxins in cassava. Pigs in T4 reported the highest crude protein digestibility value of (16.01%) followed by those in T2 with a value of (15.40%), while the least values from pigs in T3 and T1. Ash digestibility were highest (13.10%) in pigs fed T2 while the least value (10.50%) was recorded for pigs in the control diets. Crude fibre digestibility was highest (9.30%) in pigs maintained on T2 and the pigs on the control recorded the lowest value (7.50%). Ether extract, dry matter and nitrogen free extract digestibility were not significantly ($p<0.05$) different across the treatment group as the values obtained on test ingredient compared favourably with those on the control. Higher crude protein, ash and crude fibre digestibility observed might be an indication of the better palatability of the diets contrary to the energy-diluting effects of higher dietary fibre in the diets. There was no significant ($p<0.05$) difference in the ether extract digestibility as the pigs on the test ingredient compared favourably with the pigs on the control diet. Dry matter and digestible energy digestibility follow the same pattern. This indicated that the appetite of pigs was not affected when sundried cassava starch extract pulp was incorporated in the diet up to 75%. Lizardo and Aumaitre (2001) stated that six to twelve percent of beet pulp in piglet diets did not affect total tract digestibility of energy and nitrogen. The values obtained for crude fibre digestibility increased with increased level of inclusion of sundried cassava starch extract pulp. The result implied that the inclusion of sundried cassava starch extract pulp had a positive effect on the digestion of dietary fibre. This result was in line with the findings of Zhang *et al.*, 2013 who opined that fibre digestibility was improved when total dietary fibre increased. The better digestibility of crude protein, ash and crude fibre could be attributed to increased short-chain fatty acid production and absorption in pigs fed with the high fibre diet (Ziemer *et al*., 2012).

Conclusion and Recommendation

It can be concluded that the inclusion of sundried cassava starch extract pulp up to 75% level has no adverse effect on nutrient digestibility.

Abstract

A total of fifty growing quail birds of two weeks of age were randomly assigned to five dietary treatments at 0, 7.91, 15.81, 23.73 and 30.51% in a completely randomized design experiment to evaluate the effect of unripe plantain peel meals on the growth performance of growing quails. A feeding trails lasting for 42 days was carried out. Results on performance showed that the dietary treatments influenced ($P<0.05$) final weight, total weight gain, total feed intake , average feed intake and feed conversion ration of the quail birds with the highest total weight gain (10.11) recorded for T_1 in the control diet . For total feed intake the values were 21.57, 22.60, 14.50, 4.07 and 6.00g. This study showed that incorporation of unripe plantain peel could economically replace maize at level of 30.51%; but for optimal growth performance of unripe plantain growing quail birds, feeding of UPPM at the level of 23.73% is advised.

Key words: Japanese Quails, Unripe Plantain Peel Meal, Maize, Performance, Feed efficiency.

Introduction

Quails (*Coturnix coturnix japonica*) are popularly known as a game bird since its domestication in the world. Presently, quail rearing has been popularized because of rapid economic return from commercial quail production. Meat and eggs of quail are highly accepted by people in many countries.

The high cost of feed ingredients in most tropical countries clearly indicates that the production of cereal grains for livestock business in these countries is grossly inadequate (Ahaotu et *al.*, 2010a). Feed cost alone accounts for 75-80% of the total costs of raising livestock (Ahaotu *et al.*, 2010b). This is due to ever increasing competition between man, and livestock for available feedstuffs.

Thus, there is an urgent need to divert our attention toward exploitation of other tropical sources. One such potential source that is not realized to its fullest extent is unripe plantain peels which are generally not used for human consumption. Therefore, any attempt to substitute maize in poultry feed will significantly reduce cost of production. As quail production attention is needed in the country, more effort should be geared towards increased research into possible use of alternative feed resource to improve cost effectiveness or gains in the production of quail meat and eggs. Quail birds are highly prolific and hardy. The meat is lean, both eggs and meat are low in cholesterol (Robbins, 1981). The effort at multiplying these birds, the more readily available will be the meat and eggs for human consumption with less risk of public health implications.

Plantain peels, a waste from plantain is observed to have some nutritional values as it contains about 12% crude protein, 16% crude fibre and 1300KCal/Kg energy on dry matter basis (Uwalaka *et al.*, 2013). The plantain peel waste is known to constitute menace to the society thereby adding to the worse problem of environmental pollution particularly in places where ruminants (sheep and goat) are not allowed to roam about (Ahaotu *et al.*, 2013). The authors further reported no significant difference in the weight gain of weaned rabbit fed 15% plantain peels in place of maize. Von Loesecke (1990) revealed that fresh plantain peels are good sources of energy for broilers.

The use of plantain peels in poultry has been limited because of possible deleterious effects arising from the presence of tannins. Tannins exist in plantain in two different forms (a) free or active tannins which are insoluble, supposedly inert and which have little or no effect on the palatability (Ukachukwu, 2000). The objectives of the study were to determine the performance of quail birds

feed graded levels of unripe plantain peels meal, determine the optimum level of inclusion of unripe plantain peels meal and to evaluate the proximate chemical composition of the test ingredient.

Materials and Methods

This experiment was carried out at the poultry unit of Teaching and Research Farm, Imo State Polytechnic Umuagwo – Ohaji, Nigeria..

Management of the birds

A total of fifty growing quail birds of two weeks of age were randomly assigned to five dietary treatments at 0, 7.91, 15.81, 23.73 and 30.51% in a completely randomized design experiment to evaluate the effect of unripe plantain peel meals on the growth performance of growing quails. A feeding trails lasting for 42 days was carried out. The birds were stabilized with commercial broiler starter diets for seven days after which their initial weight were measured and consequently weekly thereafter to determine their weight gain. Adequate medication was done using broad spectrum antibiotics and vitamins via drinking water.

Experimental diets

Five experimental broiler starter diets represented by T_1, T_2, T_3, T_4 and T_5 were formulated. Treatment (T_1) was the control and contained 0% unripe plantain peel meal. Feed and clean drinking water were supplied *ad libitum*.

Key: UPPM= Unripe Plantain Peel Meal, GNC= Groundnut cake, PKC= Palm kernel cake

Experimental Procedure

At the end of the seventh day of the stabilization period with commercial feed, the birds were allocated to their various treatment diets. Their initial weights were determined using a weighing balance. Their feed intakes were calculated by subtracting the weight of left over feed from the weight of quantity of feed offered each day.

Data Analysis

Data generated was subjected to Analysis of variance (ANOVA). Means were separated using Duncan multiple range test (DMRT) (Gordon and Gordon, 2004).

Results and Discussion

The result of the nutrient composition of UPPM agrees with the report of Uwalaka *et al.,* (2013) who reported that UPPM contains 10.64% Crude protein, 5.82% Crude fibre, 9.57% Ether extract, 12.82% Ash and 71.2% Nitrogen free extract. Also, the values obtained on the nutrient composition of UPPM agrees with the values of 10-12% Crude protein, 8-11% Crude fibre, 11-16% Ash, 8-12% Ether extract reported by Nwifa and Hedo (2010).

abcde: Means with different superscripts within the same row are significantly($P<0.05$) different.
SEM= Standard error of the means.

The general increase in feed intake of birds in treatment 2 groups with increase in the dietary levels of UPPM could be attributed to the increased crude fibre content of the diet. As the inclusion levels of UPPM increased, there was a reduction in the feed intake of the diets. Thus, quails had to increase their feed intake to satisfy their energy needs. In addition, the higher the UPPM level, the higher the expected concentration of tannins which was reported to cause growth depression and increased feed conversion ratio (Calles *et al.*, 2010). Tannins also interferes with the digestive action of trypsin and α-amylose by forming an indigestible complex with the substrates (Ferket *et al.,* 1999) leading to poor digestibility.

Decrease in daily feed intake at higher levels of UPPM in this study did not agree with the findings of Uwalaka *et al.*, (2013) who observed a linear increase in feed intake as the level of maize replaced by UPPM increased. Also, Ahaotu *et al.,* (2013) observed that feed consumption and body weight gains especially in meat type birds decreased when birds were fed high fibre diets. There was a reduction in daily weight gain of birds with increased UPPM and with reduced maize levels of inclusion in the tested diets. This revealed the superiority of the quality of the control diet which contained higher levels of maize than other diets containing UPPM and maize.

Conclusion

UPPM was beneficial for inclusion in the diets of quails but separate use of either 7.91% or 15.81% UPPM (T_1 and T_2) gave good results during the grower phase. Also, utilization of UPPM at 30.51% inclusion levels during egg laying phase gave the best performance and did not affect egg production and egg quality. There is an economic advantage of using UPPM in quail diets with lower feed cost per kg weight gain and therefore, their usage should be encouraged.

Abstract

Effect of enzyme (Natuzyme) fortification of Bambara groundnut (*Voandzeia subterranea* L) offal diet on growth performance and carcass characteristic of finisher broiler chickens was investigated. One hundred and eighty nine (189) day old commercial broiler chicks were randomly divided into 7 groups of 27 birds each. The groups were randomly assigned to diets in a 3 × 2 factorial arrangement involving four levels (0, 10, 20 and 30%) of treated and untreated Bambara nut offal with control diet (0) in a complete randomized design. Each treatment was replicated three times with nine birds per replicate. Results showed that increasing levels of treated and untreated Bambara nut offal in the diets increased ($P < 0.05$) average daily feed intake and feed cost per kg weight gain, but decreased ($P < 0.05$) final body weight, average daily weight gain, feed conversion efficiency and protein efficiency ratio. Final body weight and average daily weight gain of control diet, feed conversion ratio at the 10, 20 and 30% treated and untreated Bambara groundnut offal levels, and reduced average daily feed intake and feed cost per kg weight gain at all the Bambara groundnut offal (BGO) inclusion levels. The results of the study indicate that 20% Bambara groundnut offal treated and untreated can be included in broiler diet without adverse effects on broiler chickens and also to reduce cost of production.

Key words: Bambara groundnut offal, dietary enzyme, broiler chickens, performance, carcass

Introduction

High cost of feed is a limitation to monogastric animal production in Nigeria which has been rated at 70 - 80 percent of total cost of production (Madubuike and Ekenyem, 2001). Consequently, the fight to reduce the cost of poultry production becomes critically urgent in order to salvage Nigerians from the scourge of sub-optimal animal protein intake and malnutrition. With the food situation rapidly worsening, the poultry industry has a key role to play in many parts of the world as a most economical source of protein (Augusto *et al.,* 1999). The poultry industry is one of the fastest growing segments of the livestock industry. Poultry are highly prolific and very efficient in converting feed nutrients into high quality animal protein (Smith, 2001). It is therefore very important to use unconventional materials such as cowpea waste, soybean waste, bambara nut offal, etc., that are locally available and can be obtained at lower prices. The inclusion of graded levels of raw bambara nut (*Voandzeia subterranea L*) offal in the diets of broiler chickens will help to enhance production by reducing the cost of production. Bambara nut is widely cultivated in the Northern and Southern States of Nigeria where the seeds are processed into flour and consumed as moi moi (Enwere, 1998). The processing of the seeds into flour results in the production of the waste that contains 16.40% crude protein (Okeke, 2000). Bambara nut waste has been used in the feeding of poultry and rabbits (Okeke, 2000; Ani and Okafor, 2004; Ani, 2007). However, its use in the feeding of monogastric animals is limited by the presence of high fibre and antinutritional factors such as protease inhibitors, haemaglutinins, tannins, cyanogenic glycosides and flatulence factors in the raw bean (Ensminger *et al*, 1996; Enwere, 1998). Poultry cannot fully utilize high fibre diets because they lack the digestive framework that can elaborately digest large amount of fibre. It becomes imperative, therefore, to incorporate exogenous enzymes into their diets in order to enhance the breakdown of the non-starch polysaccharides (NSPs) present in fibre (Doku and Karikari, 1981; Ensminger *et al.,* 1996; Enwere, 1998). Besides antinutritional factors, another limitation is its high fibre content. The enzyme being considered in this study is Natuzyme which has been shown to increase digestibility of fibrous feed ingredients by

disrupting the plant cell walls, and by reducing the viscosity of the gut contents, thereby enhancing nutrient absorption (Choct and Annison, 1992; Bedford *et al.,* 1992; Acromovic, 2001). The present study was therefore conducted to determine the effects of graded levels of raw bambara nut waste and supplementary enzyme (Natuzyme) on the growth performance and carcass characteristics of finisher broiler chickens.

Results and Discussion

The effect of feeding different levels of enzyme treated and untreated BGO in finisher diet of broiler chicken is as shown in TTable 1

Table 1: Effect of feeding diet containing enzyme treated or untreated BGO on finisher growth characteristics of broiler chicken (Treatment effect)

The average daily weight gain was significantly ($p<0.05$) different across the various treatment groups as treatment 2 had the highest value (44.82g) while treatment 6 had the least value (37.25 g). Average daily feed intake was highest in treatment 2 (102.26 g) and differed significantly ($p<0.05$) from the other treatment groups with the least value (92.17 g) found in treatment 1(Control group). Feed conversion ratio was also significantly ($p<0.05$) different across the treatment groups. Treatment 3 had the best feed conversion (2.21) while Treatment 6 had the least feed conversion ratio (2.66). Feed cost per kilogram feed produced was not significantly ($p<0.05$) affected by different levels of enzyme treated and untreated BGO.

The effect of feeding different levels of enzyme treated and untreated BGO in diet of broiler chicken on carcass and organ characteristics is shown in Table 2. Treatment 5 had the best dressed weight and dressing percentage (2203.00 g and 81.65 % respectively) while the least values were observed in treatment 1 (1849.67 g and 72.07 % respectively). Breast weight was higher in treatment 5 (809.67 g) and least in treatment 1 (641.00 g).Back weight highest in treatment 3 (351.67 g) while the least value is in treatment 1 (289.67 g). Thigh weight was highest in treatment 3 (322.67 g) and least in treatment 6 (245.67 g). Drum stick weight was best in treatment 5 (335.67g) while treatment 6 had the least value (265.00 g). The Wing weight was highest in treatment 2 (240.00 g) and least in treatment 7 (203.00 g). Neck weight was highest in treatment 3 (181.67 g) and least in treatment 6 (147.67 g). Head weight was highest in treatment 3 (57.67 g) while the least and similar values were observed in treatment 4 and 7. Shank weight was highest in treatment 5 (118.00 g) and least in treatment 7 (84.67 g). Liver weight was highest in treatment 5 (49.67 g) and least in treatment 3 (38.67 g). Gizzard weight was highest in treatment 4 (69.67 g) and least in treatment 7 (53.00 g).

Table 2: Effect of feeding diet containing graded levels of enzyme treated or untreated BGO on carcass/organ characteristics of broiler chicken (Treatment effect).

^{abcde}--- Means with different superscript along the same row are significantly ($p<0.05$) different

T_1-Control T_2-0BGO+250mg enzyme T_3-10%BGO+mg enzyme T_3-10%BGO + 250mg Enzyme T_4-20%BGO + 0mg Enzyme T_5-20%BGO +250mg Enzyme T_6-30%BGO +0mg Enzyme T_7-30%BGO +250mg Enzyme Wt.-Weight Evis.-Evisceration S-Small L-Large int.-Intestine

Pancreas was highest in treatment 6 (7.00 g) and least in treatment 1 (3.33 g). The spleen weighed highest in treatment 5 (5.00 g) while the list and similar value was found in treatment 1 and 2 (1.67 g). Heart weight was found to be highest in treatment 5 (13.67 g) and the least value was found in treatment 7 (8.00 g). The caecum was similar and highest in treatment 5 and 6 (43.67 g) and least in treatment 4 (37.33 g). Feed intake decreased significantly as BGO inclusion level increased beyond 10%. This result agrees with earlier report of Onyimonyi and Onukwufor (2003), who replaced soybean meal and maize with bambara groundnut offal in broiler diets. They further reported that bambara groundnut offal could replace the 2 feedstuffs up to 10% in the diets without adverse effect on feed intake of broiler chickens. The control treatment group, treated and untreated diets had lower fibre content and therefore birds on the control diets had the highest feed intake values when compared with the other diets. According to Ani (2007) poultry cannot utilize high fibre diets fully because they lack the digestive framework that can elaborately digest large amount of fibre. In the finisher phase, the birds fed diets containing treated BGO consumed more feeds than those fed with untreated BGO. This was attributed to improved energy availability and utilization for the growth of poultry (Odetallah *et al.*, 2005 and Wang *et al.*, 2005). Results of the carcass parameters showed significant differences ($P < 0.05$) between treatments for the live weight, carcass weight and dressed weight, head and shank weight, wings, thigh and breast had significant differences ($P < 0.05$). There was a consistent reduction in the values of parameters as the inclusion level of BGO increased beyond 20%. As shown in Table 2, the marked effect of dietary levels of BGO had significant ($p<0.05$) effect on live body weight, dressed carcass weight and carcass dressing %, especially as the level of BGO in the diets increased beyond 20 %. Perhaps the increased anti-nutritional factors (ANFs) in the Bambara groundnut offal could have been responsible for the observed reduction (Huisman and Tolman, 1990). The slaughter weights of birds, plucked weight (dressed weight), eviscerated-carcass percentage, dressing percentage and internal organs were significantly different ($P<0.05$). Birds fed on diets containing BGO dressed better than those fed control diet.

Conclusion and Recommendation

The result of this study showed that raw Bambaranut offal can be incorporated in broiler chicken diet at 20% inclusion level, without any deleterious effect on the performance of the birds. The study also showed that raw bambara groundnut offal can be used to supplement soya bean meal and maize in broiler chicken diets .Further investigation should be done in determining the proper inclusion rate of BGO as a feed resource.

Abstract

The aim of this study was to evaluate the changes in lipid profile of broiler finisher fed diets containing processed *Balanite aegyptiaca* Fruit Meal. A total of 315-day old broiler finisher chickens of Ross breed were used. The birds were assigned to five dietary treatments with three replicate consisting of twenty one (21) chickens per replicate in a completely randomized design and lipid profile of the birds were evaluated. It was found that *Balanite aegyptiaca* Fruit Meal did not reduce lipid parameters in the chicken as significantly ($P<0.05$) high values of lipids profile were recorded but were within the normal range for broilers. It was concluded that the use of *Balanite aegyptiaca* Fruit Meal had no effect on lipid profile of broilers and cannot be used as a fat reducing agent.

Key Words: Lipid Profile, *Balanite aegyptiaca*, Broiler finisher

Introduction

In recent time, a lot of people are paying attention to the type of diet they consume in order to maintain a healthy life style. Some of the diets that pose potential health threat are fatty and oily food, red meat (because of their high cholesterol) amongst others. Lyon, (2000) observed a gradual shift from the consumption of conventional animal protein sources (cattle, sheep, swine, goat and poultry) to a class of livestock referred to as non-conventional livestock. It now becomes pertinent for animal scientist to produce lean meat to meet with these recent demands of the populace.

Broiler industry is a source of nutrition, provides rural employment and fulfils all nutritional standards. Broilers as a meat source also have fast growth rate and the meat is generally accepted by all categories of people. In addition, depressed hepatic cholesterol levels in chicken were observed by Sklan *et al*. (1992).

The different parts of *Balanite aegyptiaca* plant (leaves, bark, fruit or root) can serve multipurpose medicinal application as antidiabetic, hypocholesterolemic, hepatopro-tective, cardioprotective**,** antioxidant, antiviral, antibacterial, anti-inflammatory, anti-nociceptive, analgesic and anthelmintic (3).

The aim of this study is to evaluate the changes in lipid profile of broiler finisher fed diets containing processed *Balanite aegyptiaca* Fruit Meal.

Materials and Methods

Experimental Site

The experiments were carried out at the teaching and research farm, of the Department of Animal Science Ahmadu Bello University, Zaria. The Departmental farm is located on latitude 11^0 $9^{'}$ $45^{''}$ N and longitude 7^0 $38^{'}$ $8^{''}$ E, at an altitude of 610m above sea level. The temperature of the area ranges between 26-40°C depending on the season while the relative humidity during the dry and wet seasons

are 21 and 72% respectively. The wet periods in Zaria are between May and October with annual rainfall of about 1500mm (IAR, 2012).

Collection of *Balanites aegyptiaca* fruits

Raw samples of *Balanites aegyptiaca* fruits were collected from various locations in Mai-Adua Local Government Area of Katsina State.

Processing of *Balanites aegyptiaca*fruit

Balanites aegyptiaca fruit meal was processed by soaking, boiling, roasting and fermentation.

Experimental design and management of experimental chickens

Three hundred and fifteen (315) day old broiler chicks of Ross breed were used in this experiment. The chicks were weighed and allotted to five dietary treatments each replicated thrice with twenty-one (21) chickens per replicate in a completely randomized design. The chickens were raised on deep litter with feed and water provided *ad libitum*. Management practices ideal for broiler chickens was strictly adhered to.

Experimental diets

Five broiler starter and finisher diets were formulated to meet the nutrient requirement of the chickens according to recommendations by NRC (1994). Treatment 1 is the control (T_1) and treatments 2 – 5 contained 20% each of the differently processed seeds. The composition of the experimental diet is presented in Tables 1.

Lipid profile evaluation

Blood samples (5ml) were collected by severing the jugular vein at 10.00h from four birds chosen randomly from each treatment of birds respectively into sample bottles without anticoagulant. Serum harvested was used to evaluate for lipid profile. They were determined by using chemical commercial kits with the help of auto analyzer.

Statistical Analysis

All the data collected from the experiment were subjected to analysis of variance (ANOVA) using general linear model of Statistical Analysis System (SAS, 2003) Software package. Significant differences between means were compared using Dunnetts Test in the SAS package.

Results and Discussion

Table 2 shows the lipid profile of broiler chickens fed diets containing differently processed *Balanite aegyptiaca* fruit meal. Triglycerides, low and high density lipoprotein differ significantly ($P<0.05$) across the dietary treatments with the exception of total protein and cholesterol which were similar ($P>0.05$) across the dietary groups. The normal ranges observed in cholesterol and total protein across the treatment groups imply adequate protein and energy metabolism. This showed that the diets had adequate nutritional quality and good amino acid balance as was reported by Eggum (1989).

Although there was no significant difference in cholesterol levels across the treatments, however the rising numerical trend observed showed that *Balanite aegyptiaca* may have limited capacity to lower cholesterol level at higher inclusion levels. This could be attributed to the higher crude fiber of *Balanite aegyptiaca* which may have affected carbohydrate metabolism (Abdullahi, 2018). The same phenomenon could possibly explain the low level of triglyceride in the serum of chickens fed the control diet, which in turn resulted in less fatty adipose tissues recovered from the treatment group.

Chickens fed *Balanite aegyptiaca* based diets showed increased high density lipoprotein (HDL) levels compared to those on the control diet. This shows that *Balanite aegyptiaca* improves animal health as it encourages the build-up of high density lipoprotein (good cholesterol). This may also play a significant role on the consumers' viewpoint of chickens raised on *Balanite aegyptiaca* based diets, as medical studies have shown that HDL can reduce the risk of developing atherosclerotic plaques around the soft organs in the body.

Conclusion and Recommendation

It was concluded that the use of *Balanite aegyptiaca* Fruit Meal had no effect on lipid profile of broilers and cannot be used as a fat reducing agent. *Balanite aegyptiaca* can be used to improve the nutrient quality of the diet, body metabolism and nutritional status of the birds. It was recommended that 20% *Balanite aegyptiaca* can be used in broiler finisher's diet for nutritional adequacy of the birds without adverse effect.

ABSTRACT

An experiment was conducted to evaluate the haematological and carcass of differently processed mango seed kernel meal (MSKM) on broiler chickens for eight weeks. The processing includes: soaking for 24 and 72hours, boiling and soaking and boiling. Two hundred and twenty-five (225) day old broiler chicks were randomly allotted to five dietary treatments with three replicates of 15 birds each in completely randomized design. The experimental diets consisted of raw, soaked for 24hours, soaked for 72hours, boiled and soaked and boiled mango seed kernel meal included at 10% in both broiler starter and finisher diets designated as T1, T2, T3, T4 and T5. The proximate composition, carcass and haematology of broiler chickens were obtained. T3 has the highest crude protein (8.37%) compared to T1 (6.03%) and the crude fibre ranges from 1.99-2.82% for T4 and T2 respectively. The carcass analysis shows that there was significant difference in dressing %, liver and abdominal fat across the treatments. Haematological evaluation shows that all the parameters were significant. From the experiment conducted, it is therefore concluded that mango seed kernel based diets does not affect the carcass characteristics of broiler chickens

Keywords: Mango seed kernel meal, Soaking, Carcass, Haematology, broiler chickens

Introduction

Poultry production is gaining popularity in the developing countries due to its role in bridging the protein malnutrition, economic empowerment of the resource poor segment of the society and its ability to fit well in the farming systems commonly practiced (Gebremedhn and Alemu, 2015). Such growth in the poultry industry is having a profound effect on the demand for feed and raw materials. However, it is also becoming clear that the requirements for the four traditional feed ingredients (maize, soybean meal, fish meal and meat meal) cannot be met (Adewale *et al.,* 2016). The gap between local supply and demand for these traditional ingredients are expected to be widening over the coming decades thus, providing a compelling reason for exploring the usefulness of locally available alternative feedstuffs in feed formulation (Adewale *et al.,* 2016). Substituting maize with another non-conventional energy sources such as cassava peels (Ojebiyi *et al*., 2014), mango seed kernel meal (Diarra, 2014) etc, had been discovered to be of great importance. This research is aimed at evaluating the effect of feeding diets containing differently processed mango seed kernel on the carcass and haematology of broiler chickens

Materials and Methods

Experimental Site:

The experiment was conducted at the Poultry Unit of Bauchi State College of Agriculture Bauchi Teaching and Research farm. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East (BSD, 2009).

Experimental Design and Management of Birds

A total of two hundred and twenty-five (225) broiler chicks were used for the experiment. They were randomly divided into five treatment groups of 45 chicks per group in a completely randomized design (CRD) consisting of three replicates of 15 birds each. Birds were reared on a deep litter, with feed and water provided *ad libitum*. Routine vaccines were given as recommended.

Collection and Processing of Mango seed into Mango Seed Kernel Meal

Mango Seed Kernel were collected from various locations in Sibire, Ardo kola LGA of Taraba State. The kernels were obtained by cutting the seed coat using a knife or crushed with a

hammer. The Mango Seed Kernel (MSK) obtained were divided into five parts. The parts processed either by soaking for 24 and 72 hours, boiling and soaking for 24 hours and boiled.

Soaking of mango seed kernel for 24 hours

The Mango Seed Kernel were soaked in water for 24 hours at the rate of 100g per 1.5 litre of water in containers. The water was changed at regular intervals of 8 hours. The Mango Seed Kernels were then removed and sundried. The dried MSK were then milled before incorporation into the diets.

Soaking of mango seed kernel for 72 hours

The Mango Seed Kernel were soaked in water for 72 hours at the rate of 100g per 1.5 litre half of water in containers. There was change of water at regular intervals of 8 hours for 3 days. The Mango Seed Kernels were then removed and sundried. The dried MSK were then milled before incorporation into the diets.

Boiling of mango seeds kernel

The Mango Seeds Kernel were put in boiling water at the rate of 100g per 1.5 litre of water at 100°C temperature for 30 minutes. The sample were removed, drained, sun dried, and milled before incorporation into the diets.

Soaking for 24 hours and boiling of mango seeds kernel

The Mango Seed Kernel were soaked in water for 24 hours at the rate of 100g per 1.5 litre of water in containers. The Mango Seeds Kernel was put in boiling water at the rate of 100g per litre and half of water at 100°C temperature for 30 minutes. The sample was removed, drained, sun dried, and milled before incorporation into the diets.

Experimental Diets

Five broiler starter and finisher diets were formulated. Diet 1 was the control 10% raw MSKM, diet 2, 3,4 and 5 contained soaked for 24 hours, soaked for 72 hours, soaked for 24 hours and boiled and boiled MSKM respectively all at 10% level of inclusion as replacement for maize.

Determination of the proximate composition of mango seed kernel

The proximate composition (Table 3) was obtained by analyzing the different samples of mango seeds kernel according to the methods described by AOAC(1990).

Results and Discussions

Proximate composition of mango seed kernel Meal

The Mango seed kernel meal with a protein content of 6.03-8.37% is higher than 4.7% CP of mango fruit reported by Palma Castillo and Hurtado (2009) and similar than 6-10% reported by Diarra (2014). The raw mango seed kernel content 6.03% CP, 2.47% CF, 5.52% EE and 1.67% Ash which is lower than 8.75% CP, 3.01% CF, 14.82% EE and 3.24% Ash reported by Diarra and Usman (2008); Diarra and Usman (2008) also reported composition of boiled mango seed kernel meal to contain 7.81%CP, 2.94%CF, 15.97%EE and 2.21% Ash which is higher than 6.38% CP, 1.99% CF, 5.47% EE and 1.07% Ash. The decrease in crude protein values as a result of boiling is in line with the observation of reported by Akinmutimi and Onwukwe (2002). This has been attributed to the leaching of nutrients due to boiling. Ether extract of 5.52%, fibre 2.47% and ash 1.67% were all below the reported values of 5.3%, 14.6% and 7.7%, respectively (Palma Castillo and Hurtado, 2009). Naveen *et al*. (2007) reported the proximate of mango fruit pulp alone as 4.2% CP, 6.9% crude fibre, and 2.4% EE. Kansci *et al*., (2008) reported that mango fruit composition varies greatly. It may therefore be normal to have differences among different reports. It is also likely that the factors making the mango fruits to be rejected by humans such as bruises, infections, premature ripping and or premature fallen from the tree etc. contribute in reducing the protein content as compared to some reports above which were not necessarily of rejected mango fruits but rather by-products. It could also be due to varietal differences (Orayaga *et al.,* 2015).

Carcass Characteristic of Broiler Chicken Fed MSKM

The values of dressing percentage of 58.86-67.90% were similar to 60.82-65.22% earlier reported by Joseph and Abolaji (1997) also similar to 62.70-65.20% as reported by Diarra *et al.,* 2011 who fed similar diets to broiler bird. The abdominal fat (0.74-2.53%) was similar to 1.82-1.95% reported by Diarra *et al.,* (2011). The spleen, kidney and liver were also not affected by dietary treatment. Bawa *et al*. (2003) reported that the effects of feeding processed legume grain on organ yield were observed to be the best means of testing processing methods. The result was an indication that soaked and boiled mango seed had no effects on carcass characteristics of the birds and the nutrients were well utilized.

Haematological Indices of Broiler Finisher Fed Differently Processed Mango Seed Kernel Meal

The haematological indices are the reflection of the effect of dietary treatments on the birds. PCV was significantly higher ($p < 0.05$) in treatment 4 birds (boiled mango seed kernel meal), though all the values across the five diets were within the normal range (21 to 45%) reported by Amao and Siyanbola (2013). All the RBC mean values across the treatments falls within the normal range (1.58 to 3.82) reported for broilers by Amao and Siyanbola (2013). This means bird placed on differently processed mango kernel were not anemic nor show sign of polycythemia. The haemoglobin concentration ranged from 5.80-9.13g/dl was similar to 9.58-962g/dl as reported by Diarra and Usman (2008). All the haematological parameters analyzed were comparable to values reported in literature as normal for chickens (Awoniyi *et al*., 2000; Faniyi, 2002).

Conclusion and Recommendation

Mango seed kernel based diets does not affect the carcass characteristics of broiler chickens. Proper assembling and storage of mango seed kernel which will make it more readily available should be encouraged.

PERFORMANCE OF BROILER STARTER BIRDS FED SORGHUM WITH DIFFERENT ENERGY LEVELS AS REPLACEMENT FOR MAIZE

H. B. USMAN, M. ANANDE AND M. N. SABO

DEPARTMENT OF ANIMAL SCIENCE, FEDERAL UNIVERSITY DUTSIN-MA

Abstract
The effect of substituting maize with sorghum using different energy levels was studied on broiler birds. Broiler chicks were assigned to one of the following experimental diets. T1: maize based diet containing 2,900kcal ME/Kg (control). T2, T3 and T4: were all sorghum based diets 2,900, 3,000 and 3,100 ME kcal/kg respectively. Feed intake, weight gain and feed conversion ratio were measured and determined. The results showed that final weight, weight gain, feed conversion ratio (FCR) and cost of feed per kg gain were similar (P>0.05) among the treatment means. Feed intake differ significantly (P<0.05) among the treatments with T1 having higher feed intake than T3. T2 and T4 have similar (P>0.05) feed intake to both T1 and T3. Total cost of feed consumed (₦/b) differ significantly (p<0.05) with T3 (209.37) having the lowest compared to T1 and T4 (251.76 and 236.71). T2 (215.71) had similar total feed cost to T3 and T4. was statistically similar with T4 having (177.89/kg) compared to the other treatments (213.91, 208.80 and 200.53 for T1,T2 and T3 respectively). In conclusion T4 was the most economical as it had lower FCR and cost per kg gain.
Keywords: Sorghum, maize, energy, broiler, weight gain

INTRODUCTION

Cereals are the most widely available and cheap source of high energy feed ingredients for the African farmer. Energy sources constitute the largest component of poultry diets. Globally, Maize is the most common energy source used in poultry feeds, constituting about 40-60% in poultry rations *(*Dayakar-Rao *et al*., 2003*).* This is mainly because their energy source is starch, which is highly digestible and palatable. The metabolizable energy value of maize is generally considered the standard with which other energy sources are compared (Oluyemi and Roberts 2000). The global maize requirement for poultry was estimated at 3.5 million tones at 2003 and was projected to rise to 31 million tons by 2020 (Dayakar-Rao, *et al*, 2003). Where available, other cereals could contribute to provide the seemingly ever increasing demand by the poultry industry.

In Nigeria, Maize production has never been sufficient to meet the needs of the growing human population, because it is a staple food crop for majority of the population (Iken and Amusa, 2004). Thus there is a continuing shortage of maize for use as feed, necessitating the exploration of other energy sources for livestock. To reduce the overdependence on maize, a number of researchers are exploring the use of cereals such as sorghum and millet as alternative energy sources. Sorghum grain is an interesting energy ingredient in poultry diets due to its nutritional composition, which is very similar to corn. (Louis *et al*, 1991).

Sorghum is grown in large quantity in the northern guinea and dry sub humid zones of Nigeria, where it is the second important cereal crop after maize. Its annual production was estimated at 11,700 million metric tons during the 2010 growing season (FAO 2011). The inclusion of sorghum in poultry diets is gaining interest due to favorable nutritional content of the grain. Sorghum can be used in commercial poultry diets to replace maize as an energy source, because they contain similar metabolizable energy (ME) (Kcal/kg) values (3,672 and 3, 667 for yellow and white maize; and 3, 669 and 3, 550 for yellow and red sorghum, respectively) (Tukur, 2011). Previous studies conducted with broiler chickens showed that feeding sorghum yielded similar and sometimes better results in terms of growth performance and carcass characteristics compared to maize (Cramer *et al.*.' 2003; Nyamambi *et al.*, 2007). However, some varieties of sorghum have high tannin content, which lowers palatability and efficiency of feed utilization (Davies *et al., 2003,* Garcia and Dale, 2006*),* thus limiting its use in poultry feeds. Some varieties of sorghum can contain up to 6% tannin (Doka *et al., 2004;* Dicko *et al.,* 2015*),* which binds dietary protein making it unavailable for absorption. Owing to their astringent taste, tannins have negative effects on feed intake, palatability and digestibility of nutrients, with a consequent decrease in weight gain of birds (Hassan *et al.*, 2003; Makkar, 2003; Kim and Miller 2005). The objective of this research is to determine the performance of broiler birds fed with sorghum using different energy levels

MATERIALS AND METHOD

Location of the Study area

The study was conducted at the Poultry Unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma. Dutsin-Ma lies on latitude 12°26'N and longitude 07°29'E (Abaje *et al.*, 2014).

Experimental Materials and Animals

Ninety-six day old broiler chicks were sourced and kept for one week to acclimatize before randomly allotted to four treatment groups of 24 birds each. Each treatment was replicated thrice with 8 birds per replicate in a completely randomized design (CRD) the treatments were as follows: Diet 1 is maize based mash diet with the ME value of 2900 kcal/kg (T1) which is the control. Diet 2 is sorghum based mash diet with 2,900 kcal ME/kg (T2). Diet 3 is also sorghum based diet with 3000 kcal ME/kg (T3), and Diet 4 is sorghum with 3100 kcal ME/kg (T4). Birds in each replicate were weighed at the beginning of the experiment and subsequently on weekly basis to determine the weight gain of bird. Feed intake was also recorded daily. Feed conversion ratio, total feed cost and feed cost per kg gain were determined. Mortality was recorded. Routine management practices such as medication and vaccination were rightly observed. The birds were given feed and water *ad libitum*. The experiment lasted for four weeks. The composition of the experimental diets is shown in table 1 below. Data generated was subjected to analysis of variance in a completely randomized design using several linear program of the stat view statistical package (SAS, 2002).

Table 1: Composition of the starter experimental diet

Ingredients	T1 (2900kcalMe /kg)	T2 (2900kcalMe /kg)	T3 (3000kcalMe /kg)	T4 (3100kcalMe/kg)
Maize	57	-	-	-
Sorghum	-	55	54	53

Limestone	0.5	0.5	0.5	0.5
Bone meal	3	3	3	3
Salt	0.25	0.25	0.25	0.25
Premix	0.25	0.25	0.25	0.25
Methionine	0.2	0.2	0.2	0.2
Palm oil	-	2	3	4
Total	100	100	100	100

RESULTS AND DISCUSSION

The proximate composition of the experimental diets is shown in table 2. Performance of broiler chicks fed with maize and sorghum-based diets containing varying energy levels is shown in table 3. Initial body weight did not differ between the treatments. Final weight and weight gain were similar ($P>0.05$) among the treatment means. Feed intake differ significantly ($P<0.05$) among the treatments with T1 having higher feed intake than T3. T2 and T4 have similar ($P>0.05$) feed intake to both T1 and T3. The feed intake observed in this study (1754.92-2016.39g/bird) was higher than that (1264-1415g/bird) observed by Bako J. M. (2018). Feed Conversion Ratio (FCR) was similar ($P>0.05$) amongst the treatments. (sorghum with the highest energy level have (1.44) compared to the other treatments (1.71, 1.80, and 1.68 for T1,T2 and T3, respectively)). The FCR value recorded for the maize and sorghum diets with the same energy density (T1 and T2) were statistically similar. The FCR recorded in this study is similar to the report of Bako J. M. (2018) because the birds in this research gained higher in body weight.

Table 2: Proximate Composition of the Starter phase of the Experimental Diet

Parameters	T1 (2900kcalMe /kg)	T2 (2900kcalMe /kg)	T3 (3000kcalMe /kg)	T4 (3100kcalMe/kg)
Dry matter (%)	86.17	88.38	87.66	87.12
Ash (%)	7.54	3.24	4.07	4.48
Ether extract (%)	16.41	6.27	8.18	10.16

Crude protein (%)	27.74	30.91	33.11	30.18
Nitrogen free extract (%)	29.25	41.25	37.66	36.85

Table 3: Performance of broiler birds fed with sorghum using different energy levels at the starter phase

Parameters	Maize control (2900Kcal ME)	Sorghum control(2900 Kcal ME)	Sorghum (3000Kcal ME)	Sorghum (3100Kcal ME)	SEM
Initial weight (kg/b)	0.104	0.104	0.104	0.104	0.000
Final weight (kg/b)	1.288	1.150	1.149	1.538	0.161
Total weight gain (kg/b)	1.18	1.046	1.045	1.434	0.161
Total feed intake (kg/b)	2016.39^{a}	1868.38^{ab}	1754.92^{b}	1922.08^{ab}	64.85
Feed conversion ratio	1.713	1.809	1.681	1.444	0.154
Total feed cost (₦/bird)	251.76^{a}	215.71^{bc}	209.37^{c}	236.71^{ab}	7.834
Feed cost per kg gain (₦)	213.91	208.80	200.53	177.89	18.650

Mean with different superscripts along rows are significantly different (p> 0.05) SEM -Standard error of mean

Total cost of feed consumed (₦/bird) differ significantly (p<0.05) with T3 (209.37) having the lowest compared to T1 and T4 (251.76 and 236.71). T2 (215.71) had similar total feed cost to T3 and T4. Cost of feed per kg gain was statistically similar with T4 having (177.89/kg) compared to the other treatments (213.91, 208.80 and 200.53 for T1,T2 and T3 respectively).which make T4 the best and recommended treatment for it is more economical and efficient to farmer.

Conclusion and Recommendation

From the results of this study, feeding sorghum using different energy levels as replacement for maize resulted in similar performance. Sorghum can therefore replace maize in the diet of broiler starter especially with palm oil inclusion.

ABSTRACT

The aim of this study was to assess the growth performance, nutrient digestibility and carcass characteristics of rabbits fed varying levels of groundnut haulm (GH) with concentrate. All together, 54 weaner rabbits of 6-7 weeks of an average initial weight of 735.81g were included in completely randomized design and fed six (6) dietary treatments of: 100% concentrate and 0% groundnut haulms (T_1, control), 80% concentrate and 20% GH (T_2), 60% concentrate and 40% GH (T_3), 40% concentrate and 60% GH (T_4), 20% concentrate and 80% GH (T_5) and 0% concentrate and 100% GH (T_6). In most of the treatments, the total feed intake, the body weight and carcass weight showed no significant ($p>0.05$). There were significant difference ($p<0.05$) in visceral organs and sensory characteristics when rabbits are fed groundnut haulms included diets than concentrate diets.

Keywords: Rabbits, groundnut haulms, concentrate, growth, carcass

INTRODUCTION

Food and Agricultural Organization (2004) reported low per capita animal protein consumption in developing countries particularly in humid tropics which calls for improvement in the production of short-cycle animals like rabbit. If rabbits are judiciously managed, they can kindle about six times in a year with the average of 6-7 kittens per kindling (Adeyemo *et al.,* 2013). This improvement is also essential by the rapid population growth with resultant increase in the demand for protein from animals.Rabbits have been identified to play vital role in the supply of quality protein especially in rural and peri-urban areas within the tropics (Egbo *et al*., 2001) this is because, they mature early and their meat has high protein, low fat, low energy and low cholesterol value (Adeyemo *et al.,* 2013). Rabbits have a short generation interval with high litter size and can be raised at the backyard which is well suited to small holder rabbit producers. It is important to note that, feed supply and quality is the major limiting factor to vibrant rabbit production in Nigeria. To make rabbit rearing more viable as a small-scale business, Makinde *et al*. (2014) had advocated the development of alternative feeding materials that are relatively cheap when compared with commercial feeds or conventional feedstuffs. Rabbits can be raised on high fibre feeds and materials that are not utilized by man and since they do not compete with man for grains, they have the advantage over swine and poultry (Adeyemo *et al.*, 2013). One of the non-conventional feedstuff and under-exploited forage feedstuff for rabbits in Nigeria is groundnut haulms which has high crude protein value.

MATERIALS AND METHODS

The experimental animals were sourced from the Rabbitry Multiplication Unit Minna, of the Niger State Ministry of Livestock and Fisheries. Groundnut haulms was sourced from Animal feed sellers, opposite NEPA office Minna. Concentrate was sourced from Sammy ventures, behind U.K. Bello arts theater, Minna. The study lasted for twelve weeks during which the rabbits were served with concentrate diet in the morning (8:00 am) and groundnut haulms (4:00 pm) of a known weight on a daily basis. Water was also provided *ad libitum*. Left over feeds were recorded to determine the daily feed intake.

RESULT AND DISCUSSION

In **Table 1.0** significant statistical differences between treatment and the parameters measured were noticed ($P < 0.05$). The final body weight (BW) of rabbits irrespective of treatment was all doubled their initial BWs. Nonetheless, very significant statistical difference was observed in feed intake observed between the treatments studied. Studies in rabbits have shown that BW tends to increase correspondingly with increase in feed intake, particularly forage (as seen in T_3) (Houndonougbo *et al.*, 2012; Maidala 2016) in which case feed intake have been positively correlated with level of fibre in rations. In these studies, poor digestion and utilisation of protein were reported to be responsible for the poor growth against the expected growth rate. The growth performance in terms of feed intake, body weight gain, final body weight and feed conversion ratio of rabbits fed only concentrate and those on 40% concentrate plus 60% groundnut haulms were similar. This may be attributed to the fact that forage is considered an important feed for rabbits growth and they are capable of digesting leaf protein effectively (Cheeke and Patton, 1982). This finding agrees with Bamgbose *et al*. (2003) who reported that rabbits can perform well with mixed regimen of forages and concentrates up to 50 % reduction without any adverse effect on growth. Also, lyeghe-Erakpotobor *et al*. (2002) observed significant effect of diets on intake of rabbits offered a combination of concentrate, grass and other forages. Similarly, Shiawoya and Musa (2006) reported that feeding of forage like mango, banana and tridax leaves can successfully support growth when fed with concentrate diets for weaner rabbits.

Table 1.0: Growth performance of rabbits feds varying levels of groundnut haulms and concentrate based diets

Parameters (g)	T1	T2	T3	T4	T5	T6	SEM	P-value
Initial body weight	727.11	728.22	741.22	742.22	742.44	784.55	13.93	0.71
Total feed intake	5754.69^{a}	6263.43^{a}	5320.12^{b}	5450.93^{ab}	4903.93^{c}	5197.71^{b}	24.43	0.00
Body weight gain	1033.30^{a}	1000.01^{a}	1100.12^{a}	1031.04^{a}	986.33^{b}	991.51^{b}	32.59	0.02
Final body weight	1760.41^{ab}	1728.23^{b}	1841.34^{a}	1773.26^{ab}	1728.77^{b}	1740.06^{b}	48.26	0.01
Feed conversion ratio	5.56^{a}	6.26^{a}	4.83^{b}	5.28^{ab}	4.97^{b}	5.24^{ab}	0.84	0.03

abc = means in abc = means in the same row carrying different superscript are significantly ($p<0.05$) difference.

The meat sensory properties of rabbits fed groundnut haulms and concentrate based diets showed beneficent (P<0.05) increase in the appearance, tenderness and overall acceptability of the meat (Table 2.0). While significant statistical difference was recorded in the organoleptic properties of fried rabbit meat in this study between the treatments (P<0.05), other studies obtained contrary results (Raïssa *et al.*, 2018;)

Table 2.0: Sensory characteristics of rabbit meat fed varying levels of groundnut haulms and concentrate based diets

Parameters	T1(keys)	T2( )	T3( )	T4( )	T5( )	T6( )	SEM	P-value
Colour	8.33	7.66	7.66	8.00	7.66	7.33	0.47	0.33
Juiciness	8.66	8.66	8.00	7.66	7.66	7.66	0.66	0.22
Appearance	7.66^{a}	8.00^{a}	7.66^{a}	7.33^{a}	7.66^{a}	6.33^{b}	0.48	0.03
Flavour	8.33	7.33	7.33	7.00	7.66	7.33	0.67	0.28
Tenderness	8.66^{a}	7.00^{a}	6.00^{b}	6.66^{ab}	6.00^{b}	6.33^{b}	0.44	0.00
Aroma	7.33	7.00	7.33	7.00	7.33	6.67	0.47	0.93
Overall acceptability	8.33^{a}	8.33^{a}	7.66^{ab}	7.33^{ab}	7.33^{ab}	7.00^{b}	0.62	0.01

ab = means in the same row carrying different superscript are significantly (p<0.05) differe

Conclusion

1. Feeding rabbits solely on concentrate or inclusion of 60% groundnuts haulms to concentrate have similar feed intake, body weight gain, final body weight and feed conversion ratio.
2. Carcass parameters such as carcass weight, dressing percentage, neck length, cervico-thoracic region weight, tail length, heart weight and spleen weight of animals fed only concentrate and those fed with concentrate along with groundnut haulms up to 80% or solely on groundnut haulms were similar. Improvement was observed in lungs

weight, kidney weight and intestine length the rabbits were fed groundnut haulms included diets than when fed solely on concentrates.

3. Sensory characteristics such as colour, flavor, juiciness and aroma are similar between the treatment diets. Additionally, acceptability of rabbit meat fed only concentrate and those fed concentrate along with up to 80% groundnut haulms are similar.

ABSTRACT

The experiment was conducted to evaluate the nutrients digestibility and carcass characteristics of broiler chickens fed graded levels of baobab (Adansonia digitata) pulp meal (BPSM). Three hundred broiler (Anak) chickens were allotted to five treatments replicated thrice with 20 birds per replicate in a completely randomized design (CRD). The inclusion levels of the BPSM in the diets were 0, 10, 20, 30 and 40% for treatment 1 (Control), 2, 3, 4 and 5 respectively. The experiment lasted for four weeks each for the starter and finisher respectively. Data collected were subjected to analysis of variance and significant differences among treatment means were compared using the Dunnet Test. Nutrient digestibility increased with increasing levels of BPSM in broiler chickens diet up to 20% BPSM and then slightly declined afterward and the significant (P<0.05) increase in carcass characteristic was the total reflection of live weight which was significantly higher in birds fed diets containing BPSM

Keywords: Baobab pulp seed meal, Carcass, Digestibility, Nutrients, Broiler chickens

Introduction

The logical solution in meeting meat scarcity in Nigeria is to increase broiler production (Babatunde, 1990). Isiaka (2006) reported that poultry is strategic in addressing animal protein intake shortage in human nutrition because of its high fecundity, fast growth rate, short generation interval and parallel competence in nutrient transformation to high quality animal protein. The total dependence on cereal as a principal energy source in poultry diets is the major problem militating against the expansion of poultry industry. Medugu *et al.* (2011) reported that the tremendous decrease in poultry production is as a result of high cost of protein and energy feedstuffs especially cereal grains (maize) which form the bulk of energy in poultry feeds and are in short supply as a result of industrial and human needs. This has resulted in competition between human and animals for the available feed resources coupled with constant drought. Hence, the high cost of poultry feed has continued to be the major problem in developing countries as feed cost is about 65 – 75% (Nworgu *et al*., 1999) of the total cost of production compared to about 50 – 60% in developed countries (Tackie and Flenscher, 1995). Therefore, all reasonable and practical options deserve thorough

consideration. This has necessitated the renewal of interest in exploring the feasibility of incorporating neglected or underutilized energy feedstuff. Not much has been done in evaluating the potential feed value of some multipurpose tree products such as baobab *(Adansonia digitata).* Baobab fruit contains 50% more calcium than spinach and high in anti-oxidant (NRC, 1994) hence necessitating this research in a bid to seek for an alternative to the inadequate and expensive conventional feedstuffs.

MATERIALS AND METHODS

Source of Baobab Fruit: Baobab fruits used for this experiment were harvested at mature stage which was indicated by the hard brown colour of the ectoderm from the trees using locally made equipment aroundMamudo, Danchuwa, Alaraba and Mele in Potiskum Local Government area of Yobe State, Nigeria.

Processing: Dried baobab fruits were processed by cracking open the hard shell of the baobab fruits using a small hammer to remove the inner contents (epicarp), and pounded using a mortar and pestle while the seed and pulp were separated using a sieve. The pulp were slightly milled and separated from the unwanted coarse material using a fine mesh.

Experimental design and management: Three hundred (300) broiler chicks (Anak) were purchased from Zarm Farm. The birds were vaccinated against Newcastle disease (intra ocularly) on the day of arrival and brooded together for three days using kerosene stoves and electricity bulbs as sources of heat and light. They were fed a common diet during this period. The birds were subsequently weighed and allotted to five dietary treatments. The birds were housed in a deep litter system in a completely randomized design. The treatments were replicated three times with twenty chicks per replicate. The feeding trial lasted for eight weeks comprising of first four weeks (starter phase) and last four weeks (finisher phase). Both experimental materials and compounded rations were taken to the laboratory for proximate analysis before commencement of the experiment. Birds were vaccinated against Newcastle and Gumboro diseases. Feed and water were provided *adlibitum.*.

Experimental diets: The composition and calculated analysis of the experimental diets are presented in Tables 1 and .2 respectively. The test ingredient was included at 0, 10, 20, 30 and 40% representing 1 (control), 2, 3, 4 and 5 respectively for both the starter and finisher phases respectively. The starter (23% CP; 2900 Kcal/Kg) and finisher (20% CP, 2950 Kcal/Kg) were isonitrogenous and isocaloric and met the recommended crude protein and metabolisable energy requirements as stated by (NRC 1994)

Experimental Site*:* The study was conducted at the Teaching and Research farm (Poultry Unit) of the Department of Animal Science, Faculty of Agriculture, Ahmadu Bello University Zaria. Zaria is located within the Northern Guinea Savannah of Nigeria with an average

annual rainfall, relative humidity and temperature of 1,100 mm, 75% and 24.4^{O} C respectively, on Latitude 11° 12'N and Longitude 7° 33'E on an altitude of 610m above sea level (Ovimap, 2014).

Digestibility trials: At the end of the of the experiment (56th days), 9 birds per treatment of an average weight (3 birds per replicate) were selected from the five treatment groups for digestibility trial and caged individually, after an adjustment period of seven days. The droppings were collected on a daily basis for seven days while feed intake over the period was recorded. The dropping sample was oven dried at a temperature of about 105^{0}C for 18 hours to reduce the moisture content and to bring the faeces to a constant weight. The total daily collections were pooled, weighed and ground and representative samples of the faeces and experimental diets were taken to the laboratory for proximate analysis according to the procedure of AOAC (1990). They were assayed for apparent digestibility of crude protein, ether extract, crude fiber, and nitrogen free extract. The result was used to calculate the digestibility.

Nutrient digestibility = $\frac{Nutrient\ intake - Nutrient\ in\ feaces \times 100}{Nutrient\ intake}$

Carcass measurement: At the end of the experiment (56th days), three birds representing the average weight were selected from each replicate (nine birds per treatment), labeled and then starved overnight but water was provided. The weights of the birds were recorded in the morning before slaughter. Birds were defeathered by dipping into hot water for few minutes to soften the feather for easy removal. The defeathered birds were eviscerated. The parameters measured were carcass weight, dressing percentage, prime cut and organs weighed were expressed as percentages of carcass weight.

Data Analysis: All data collected were subjected to analysis of variance (ANOVA) using the General Linear Model Procedure of SAS 9.2 (2002). Significant differences among treatment means were compared using Dunett multiple ranged in the SAS Package.

The model for this design was as follows:

$X_{ij} = \mu + t_i + e_{ij}$

Where: Xij = any observation made in the experiment,

μ = the population mean,

t_i = Effect due to treatment added or treatment effect,

Eij = Experimental error.

RESULTS AND DISCUSSION

Apparent nutrients digestibility

The nutrients digestibility ranged from 81.53 –88.68%, 77.60 – 84.48%, 68.81 – 80.06%, 80.06 – 86.94%, 70.42 – 77.92% and 88.78 – 92.50% (Table 3) for the Dry matter, Crude protein, Crude fibre, Ether extract, Ash and Nitrogen free extract respectively. Birds fed 20% BPSM was found to significantly ($P<0.05$) different from all treatments groups in the mention parameters except for the dry matter, ether extract and nitrogen free extract digestibility which were found to be similar ($P>0.05$) with treatment 1 (0% BPSM) and 2 (10% BPSM). Treatment 5 (40% BPSM) was significantly ($P<0.05$) lower in most nutrients digestibility than all the treatment groups though found to be insignificantly ($P>0.05$) different from treatment 4(30%BPSM), this implies that nutrient digestibility increased with increasing levels of BPSM in broiler chickens diet up to 20% BPSM and then slightly declined afterward. This result agrees with the report of Rafiu *et al*, (2012) who reported higher nutrient digestion in diets containing BPSM in feeding broiler chicken with baobab seed when compared with the control diet. Similar finding was reported by Sola-Ojo *et al*, (2013) in feeding broiler with BPSM though reported insignificant ($P>0.05$) differences in the digestibility of all the nutrients with slightly higher values was recorded in the diet containing higher levels of BPSM. This result shows that BPSM inclusion up to 40% is possible in the broiler diet without any detrimental effects on nutrient digestibility. These was supported by the work of Proll *et al*. (1998) who found that baobab pulp and seed to have high digestibility, biological value (BV), and net protein utilization (NPU) among unconventional tropical crop. This high digestibility, BV, and NPU of baobab pulp and seed could be attributed to the low levels of trypsin inhibitor phytic acid and tannin and the excellent amino acid profile.

Carcass characteristics

The average live weights were 2000g, 2233.33, 2266.70, 2173.30 and 2000.0g (Table 4) for treatment 1 (0% BPSM) control, 2, 3, 4, and 5 respectively (Table 4). Significant ($P<0.05$) higher slaughter weight 2233.33, 2266.70 and 2173.30g were recorded in birds fed 10% BPSM, 20% BPSM, 30% BPSM respectively while significantly ($P<0.05$) lower values 2000.00g and 2000.00g were recorded in birds fed 0% BPSM and 40% BPSM respectively. Carcass weight, dressing percentage and prime cut followed similar trends as the live weight. This result agrees with the work of Sola-ojo *et al*. (2013) who reported that, live weight differed ($P<0.05$) significantly among varying level of BURBSM in the diet of broiler chickens. The internal organs such as heart, gizzard, liver kidney and gastro intestinal tract

length ranged from 0.58 0.55%, 2.94 - 3.34%, 2.35 - 2.64%, 0.46 - 0.52% and 218.83 – 253.83cm respectively. Significantly (P<0.05) higher heart values 0.54% and 0.55% were recorded in birds fed 10% BPSM and 20% BPSM while significantly (P<0.05) lower values 0.51, 0.50 and 0.50% were recorded in birds fed 0% BPSM, 30% BPSM and 40% BPSM. Significantly (P<0.05) higher gizzard values 3.34, 3.25 and 3.20% were recorded in birds fed 20% BPSM, 30% BPSM and 40% BPSM while significantly (P<0.05) lower values 2.94% and 3.08% were recorded in birds fed 0 and 10% BPSM. Significantly (P<0.05) higher liver values of 2.62 and 2.64% were recorded in birds fed 30 and 40% BPSM while significantly (P<0.05) lower value of 2.35% was recorded in birds fed 0% BPSM. No significant (P<0.05) differences were observed in values of 2.48 and 2.49% recorded in birds fed 0 and 10% BPSM. The values recorded for kidney followed a similar trend as liver while significantly (P<0.05) higher gastro intestinal tract length values of 253.83cm and significantly (P<0.05) lower values of 218.83cm were recorded in birds fed 30 and 0% BPSM respectively. The significant increase in carcass characteristic was the total reflection of live weight which was significantly higher in birds fed diets containing BPSM. This study agrees with the findings of Kutlu and Forbes, (1993) who reported that supplemental ascorbic acid (250/kg) increased performance and yields better carcass quantity and quality in birds reared under heat stress condition and also Sola-ojo *et al,* (2011) who reported a significant increase in carcass components as the DURBSM increased in the broiler chicken diets.

Conclusion

Higher apparent nutrients digestibility and best carcass characteristics were recorded in birds fed 20% BSPM. But It can be included in broiler chicken diets up to 40% without detrimental effects on carcass characteristics of broiler chicken.

ABSTRACT: The experiment was conducted to evaluate the reproductive performance of layer chickens fed dietary levels of kaura sorghum. Five diets (16% CP) were formulated, in which the Kaura Sorghum was included at 0, 25, 50, 75 and 100% levels and the diets designated as treatments T1, T2, T3, T4 and T5 respectively. Kaura sorghum was used to replace maize as a dietary energy source. Three hundred brown pullets were used for the research. They were allotted to five treatments which were replicated four times each with twenty birds per replicate in a completely randomized design (CRD). After flushing for seven days using the experimental diets, initial weights of the birds in each replicate were recorded. Records of feed intake, number of eggs laid and egg mass were taken on daily basis. The result obtained after the research showed that the final body weight and total feed intake were not affected by the dietary treatments. Birds fed diet 4 (75% kaura sorghum) had the highest feed consumption value of 113.33g while the lowest intake was obtained on diet 1(control) with a value of 91.39g. The highest hen-day egg and hen house egg production (72.59% and 70.00%, $P<0.001$) was obtained on diet 5 (100% kaura sorghum). The best feed conversion ratio (1.42) was found on diet 2 while the poorest was obtained on the maize control diet (1.68), even though the value did not differ statistically. It can be concluded that Kaura sorghum in combination with full fat soya bean can completely (100%) replace maize in the diets of laying hens with no deleterious effects on performance parameters.

Key word: Kaura Sorghum

INTRODUCTION

Maize has been the major source of energy in poultry diets. However inadequate production of maize and the intense competition for maize between man and livestock especially in the drier parts of the tropics has made poultry ration to be very expensive. The high cost of commercial diets for poultry due to high cost of maize as the major ingredients, if not addressed will result to lower income to poultry farmers and reduced protein intake among Nigerian populace. One of the major tasks that can be taken to alleviate such a threat is the use of alternative energy sources like kaura sorghum and millet in the drier areas. Researchers like Parthasarathy *et al.,* (2005); and Issa *et al.,* (2007) have reported that sorghum grains can play an important role in poultry feed in the sahelian countries. Other workers, Hancock, (2000), Dawling *et al.,* (2002) and Travis *et al.,* (2006) have shown that sorghum could be a suitable feed stuff in the poultry industry. Sorghum grain is an interesting energy ingredient in poultry diets due to its nutritional composition which is very similar to maize. Layers are raised purposefully for egg production. They are efficient producers of eggs which provide an alternative source of protein and as such

this gives poultry more advantage over other livestock (Ojo, 2000). More so, it was reported that, egg as a product of poultry industry supply about 3.5g of the total 7.2g of animal protein required for individual dietary needs per day (Nicholas, 2014).

MATERIALS AND METHODS

The research was carried out at the Teaching and Research poultry unit of the School of Undergraduate Studies College of Education Azare between the months of February and March 2015. Azare is located in Katagum Local Government Area of Bauchi State. It is located between latitudes 11^0 30'' N and 11^0 10' E. The mean monthly temperature ranges from 20.10 – 22.50^0C in December and January to 30.0 – 32.5^0C in April and May. The temperature of the rainy season remains steady at about 25^0C – 27^0C for the month of June to October. The rainy season in Azare starts in April and lasts upto October with five months of dry season from November to March (Bura, 2000). Five dietary treatments were formulated with kaura sorghum as a replacement for maize using full-fat soyabean as a protein source. Kaura sorghum replaced maize at 0, 25, 50, 75 and 100% in diets 1, 2, 3, 4 and 5 respectively. The full-fat soyabean was mixed with milled kaura sorghum variety and other ingredients to formulate diet with 16% CP. Three hundred (300) brown pullets were used for the research. The birds were allotted to the five dietary treatments which were replicated four times with fifteen (15) birds per replicate in a completely randomized design (CRD). Production performance parameters such as weight change, feed intake, hen day egg production, hen housed egg production and feed conversion ratio were measured. The percent compositions of the various feed ingredients used in formulating the five dietary treatments is presented in Table 1:

Table 1: Ingredients and Percentage Composition of Layer Diets Containing Graded Levels of Kaura Sorghum with Full-Fat Soya Bean as Protein Source

Premix**Vitamin-mineral Premix** contains the following per 2.5 kg: Vitamin A 10,000 IU, Vit. D3 2,000,000IU, Vit E 12,000mg, Vit K3 2,000mg, Vit B1 1,500mg, Vit B2 4,000mg, Vit B6 1,500mg, Niacin 15,000mg, Vit B12 10mcg, Pantothenic acid 5,000mg, Folic acid 500mg, Biotin 20mcg, Cholinechloride 100,000mg, Manganese 75,000mg, Zinc 50,000mg, Iron 20,000mg, Copper 5,000mg, Iodine 1,000mg, Selenium 200mg, Cobalt 5000mg, Antioxidant 125,000mg.

RESULTS AND DISCUSSION

The productive performance of layers fed kaura sorghum replacing maize with full-fat soya bean diets is shown in Table 2. The final body weight and total feed intake were not affected by the dietary treatments. Birds fed diet 4 (75% kaura sorghum) had the highest feed consumption value of 113.33g while the lowest intake was obtained on diet 1(control) with a value of 91.39g. The highest hen-day egg and hen house egg production (72.59% and 70.00%, P<0.001) was obtained on diet 5 (100% kaura sorghum). The best feed conversion ratio (1.42) was found on diet 2 while the poorest was obtained on the maize control diet (1.68), even though the value did not differ statistically. The enhanced hen day and hen house egg production on the kaura sorghum diets could be attributed to the quality of the dietary treatments when compared with maize control diets, (Bawa *et al*., 2003). Also, adequate levels of methionine and lysine have been reported to influence egg production and egg size in laying birds (Bamgbose and Biobaku, 2003).

CONCLUSION AND RECOMMENDATION

From the results obtained in this research it can be concluded that Kaura sorghum in combination with full fat soya bean can completely (100%) replace maize in the diets of laying hens with no deleterious effects on performance parameters. Hence use of Kaura as source of energy in the diets of laying hens is recommended.

ABSTRACT
A study was conducted to evaluate the carcass characteristics and relative organ weights of broiler finisher chickens fed commercial feed (vital feed) supplemented with varying levels of black seed (*Nigella sativa* L.) cake. One hundred unsexed day-old broiler chicks (Arbor Acres strain) were purchased from reputable hatchery and randomly allocated to five dietary treatments of 20 birds per treatment in a completely randomized design experiment and the birds were sub-divided into two replicate each. Five diets were formulated such that diet 1,2,3,4 and 5 were supplemented with black seed cake at 0,1,2,3 and 4g/kg levels respectively. At the end of the experiment two birds were randomly selected,from each replicate, tagged and starved. The birds were slaughtered and data were collected on their carcasses and organs. The result of carcass traits showed that Final live weight, Bled weight, Defeathered weight, Eviscerated weight, Carcass weight and Dressing percentage were not significantly ($P>0.05$) affected. The relative carcass cuts such as Neck, Wings, Breast, Thigh, Shanks, Fat and back were not significantly ($P>0.05$) affect by the dietary treatment except the drumstick which showed significant ($P<0.05$) difference. Significant ($P>0.05$) difference was not indicated in the relatives organs weight of the birds across the treatments except that of kidney which was significantly ($P<0.05$) affected by the dietary treatment. It can be concluded that Black seed cake (BSC) supplementation in diets of broiler chickens at 2g/kg level had no negative effects on the carcass and no deleterious effect was observed on their organs.

Keywords: Carcass and Organs, Broiler, Commercial Feed, Black Seed Cake, Additive

INTRODUCTION
In poultry, feed cost account for up to 80% of the total cost of production and is a very important component in determining the extent of poultry survival and profitability (Olugbemi *et al*, 2010). Success on rearing broiler for maximum weight gain is not only depends upon the strain of the birds and management but also on high quality feed (Nazeer *et al*, 2002). Feed additives are assuming a position of prime importance in poultry nutrition. The use of phytogenics feed additives such as local plant materials in recent time is often aimed at improving animal performance by increasing their growth rate, improving feed efficiency and reducing the incidence of diseases (Zomrawi *et al*., 2013) and serve as alternative for growth promoting antibiotics which has been banned by European union due to their resistance against bacteria which are pathogenic to humans (Majeed *et al*., 2010; Nasir and Grasheorn 2010). Removal of antibiotics from the poultry diets may negatively affect profitability of the animals.
One of the alternatives used as feed additives is black seed. Black seed (*Nigella sativa* L.) is also known as Black cumin and grows in Asian and Mediterranean countries. The seed has been experimented with laboratory rodents and reported to have many biological properties including antibacterial activity (El-Kamali *et al*., 1998), antiviral activity (Salem and Hossain, 2010), antiparasitic (Mahmuod *et al*., 2002). A few studies with broiler chickens showed that black seed has significant effect on carcass and organ of the broiler chickens.

Guler *et al*. (2006) and Toghyani *et al*. (2010) reported an increased carcass yield, liver, abdominal fat, breast, thigh, wings and neck weights in broilers by feeding diet having 1% black cumin. However, non-significant values were obtained regarding heart weight. Controversial results were documented by AL-Beitawi *et al*. (2009) who found no improvement in carcass characteristics by feeding different levels of crushed as well as uncrushed *Nigella sativa* seed in broilers, however, Nasir and Grashorn, (2010) reported an increased in breast percentage. Therefore, there is need to conduct studies on the potential use of black seed cake in the broiler diets. The objective of the study is to evaluate the black seed cake supplementation on the carcass traits and relative organs weight of broiler chickens.

MATERIALS AND METHODS

Experimental Site

The experiment was carried out at the Poultry Unit of the Teaching and Research Farm of Ladoke Akintola University of Technology, Ogbomosho, Oyo State in the derived savanna zone of Nigeria.

Collection of Test Ingredient and preparation of experimental Diets

Black seed cake (BSC) was purchased from a local market in Saki, Oyo State and supplemented in the diets directly without any further processing. Five Experimental diets were formulated using commercial feed concentrate (Vital feed ®), maize and wheat offal. The diets were supplemented with black seed cake (BSC) such that diets 2,3,4 and 5 were supplemented 1, 2, 3 and 4g/kg BSC respectively. Diet 1 served as the control diet with no BSC supplementation.

Experimental animal, Design and management

One hundred (200) unsexed day-old broiler chicks (Arbor acres strain) were purchased from reputable hatchery (AMO farm) in Oyo State. The chicks were weighed individually and randomly allocated to five dietary treatments in a Completely Randomized Design Experiment (CRD). Each treatment was replicated four times with ten birds per replicate. Feed and water were given *ad libitum*. Other management practices and vaccination programs were strictly adhered to.

Data collection

Carcass and Organs Evaluation

The carcass and organs were determined at the end of 6 weeks by selecting randomly, four birds from each replicate in each treatment. The selected birds were tagged and starved overnight. Before slaughtering, the individual weight of the birds was recorded and slaughtered by severing the jugular vein around the neck. The bled weight of an individual bird was recorded. The carcasses were defeathered, eviscerate, and the weights were measured immediately and the weights of the carcass were also recorded. The visceral organs such as liver, pancreas, spleen, kidney, proventiculus, and heart were removed and weighed and expressed in percentage relatives to the carcass weight. The carcasses were cut into various parts (head, neck, back, thigh, breast, shank, drumsticks and wings) and their weights were expressed in percentage relative to the carcass weight. In addition, the dressing percentage was calculated using the formula below.

$$\text{Dressing percentage (DP)} = \frac{\text{Carcass weight}}{\text{Final live weight}} \times 100$$

$$\text{Relative cut parts weight} = \frac{\text{Weight of the cuts}}{\text{Carcass weight}} \times 100$$

$$\text{Relative organ weight} = \frac{\text{Weight of organs}}{\text{Carcass weight}} \times 100$$

Data Analysis

Data generated from the experiment were subjected to one way analysis of variance (ANOVA) using the general linear model of (SAS, 2007) while the significant means among the treatments were separated using Duncan Multiple Range Test of the same statistical package at 5% significant level.

Table 1: Gross composition of experimental diets

Ingredients (Kg)	**Black seed cake supplementation level (g/kg)**

Broiler finisher Concentrate used contains: Fat Max: 8.0%, Calcium: 3.0%, Potein Min: 36.0%, Metabolisable Energy- 2700Kcal/kg.

RESULTS AND DISCUSSION

Results of the carcass traits of broiler finisher chickens fed commercial feed supplemented with varying levels of Black seed cake (BSC) is shown in Table 2. It was observed that Final live weight, Bled weight, Defeathered weight, Eviscerated weight, Carcass weight and Dressing percentage were not significantly ($P>0.05$) affected by the dietary treatments. Despite this, the birds fed diet supplemented with black seed cake at 2g/kg had numerical higher value when compared with other treatment groups. Relative carcass cuts e.g Neck, Wings, Breast, Thigh, Shanks, Fat and back were not significantly ($P>0.05$) affected by the dietary treatment except the drumstick which showed significant ($P<0.05$) difference. Birds fed diets supplemented with black seed cake at 2, 3, and 4g/kg levels respectively compared with the control. Their values were significantly ($p<0.05$) higher than those on 1g/kg black seed cake level. This observation supports the reports of AL-Beitawi *et al*. (2009) who found no improvement in carcass characteristics by feeding different levels of crushed as well as uncrushed Black seed in broilers diets. Although, Al-Beitawi and Goushein, (2008) observed significant improvement in the final live weight of broilers fed diets supplemented with black seed at 1.5% inclusion level. Carcass weight and dressing percentage were improved in birds fed diets supplemented with 1g and 2g/kg Black seed cake respectively and this support findings of Guler *et al*. (2006) and Toghyani *et al*. (2010) who reported an increased carcass yield in broilers by feeding diet having 1% black seed. Improved in cut-up parts weights was observed across the treatments and significant differences was observed in drumstick. This indicated that Black seed cake might have a good effect on enhanced availability of mineral metabolism because black seed contained macro-minerals (mg/100gm) i.e Ca (572), P (540), Mg (264), Na (17.8) and K (810) (Cheikh-Rouhou *et al*., 2007).

The results of relative organ weights of broiler finisher chickens fed commercial feed supplemented with varying levels of Black seed cake (BSC) is shown in Table 3. It was observed that there were not significant (P>0.05) differences in all parameters measured across the treatments except the relative weight of kidney which was significantly (P<0.05) affected by the dietary treatments. Relative weights of proventriculus of the birds fed diets 3, 4 and 5 were similar (P<0.05) and their values fall between 0.61 to 0.71%. Birds fed diet 5 had the highest value of spleen while the birds fed diet 2 had the lowest value. Relative weight of pancreas ranged from 0.44 to 0.54% and the birds fed diet 2 had lowest numerical value (0.44%). However, similarity observed in the relative weights of organs showed that black seed cake have immune-stimulant effects thus maintain broiler chicken in good health. In particular, thymoquinone and dithymoquinone obtained from *Nigella sativa* extract showed important properties against antibacterial, antioxidant, and anti-inflammatory agent (Al-Saleh *et al*., 2006). The disagreement of these studies may be explained in the light of different doses, species and / or age of birds. The highest percentage of supplementation in this study was quite low (0.04%) when compared with previous supplementation levels used by Guler *et al*. (2006) and Toghyani *et al*. (2010) that shows that in this study the choice of 4g/kg could be cost effective when compared with previous studies where higher levels were used.

Lung	0.94	0.91	0.81	0.86	0.94	0.03

[a,b]- means in the same row bearing different superscripts differed significantly (P<0.05). SEM – Standard error of mean.

CONCLUSION

The results obtained from the study revealed that Black seed cake (BSC) supplementation in diets of broiler chicken at 4g/kg level had no deleterious effects on the carcass characteristics and indicate that their organs were in good health state.

PERFORMANCE AND CARCASS CHARACTERISTICS OF GROWER RABBITS FED GRADED LEVELS OF CASSAVA LEAF (*Manihot esculenta*) MEAL

Lalabe, B. C., Wafar, R. J., Mary, S. I., Agyo, A, and Odunze, I. N.
Department of Animal Production and Health, Federal University Wukari.

Abstract
The study was to determine the effect of feeding graded levels of cassava leaf (Manihot esculenta) meal in place of full fat soya bean meal on the performance and carcass characteristics of grower rabbits. Fresh cassava leaves were shade dried to a constant weight and milled. Sample of the cassava leaf meal were subjected to proximate analysis to determine the nutrient composition and the anti-nutrients content. Eighteen grower rabbits were weighed and randomly assigned to 3 dietary treatments (T1, T2 and T3) containing 0, 10 and 20% cassava leaf meal respectively in a 3×6 completely randomized design. Diet T1 served as the control diet with 0% CLM. Diets T2 and T3 contained 10 and 20% CLM. Feed and water were provided ad-libitum for 56 days. The result of the performance revealed no significant difference (P>0.05) in the total weight gain (731.33-743.33g); average daily weight gain (13.06-13.27g); total feed intake (2675.00-2912.00g); average daily feed intake (47.77-52.00g) and the feed conversion ratio (3.75-3.92). There were no significant difference for the cut parts, visceral organs, and small and large intestine length. No adverse effect was observed on the rabbit as a result of the anti-nutrient in the test diets. The result showed high yield of live weight, carcass weight and skin with 10% cassava leaf meal. This study suggests that replacement of soybean meal with up to 20% cassava leaf meal will increase the carcass weight, live weight, skin weight and visceral organs development at a lower cause.

KEYWORDS; Cassava leaf meal, Grower rabbits, Performance, Cut parts, anti-nutrients.

Introduction

Increased competition for available conventional feedstuff and its high cost have led to animal nutritionists, scientists and agriculturists having the need for research into the use of non-conventional feedstuffs that are cheap, readily available and possible substitute for more expensive protein and energy sources (Obun and Adeyemi,2012).

The feeding cost constitutes about 80% of the total cost of intensive production in livestock industry (Tewe et al., 2002). Hence the focus is on alternative feedstuff which could be either substituted directly for cereals or can be included a certain level to attain a comparable production quality with the conventional cereal without deleterious effect on the animal health (Ukachukwu, 2008).Cassava which is widely cultivated in the tropics appears to be one of the possible alternatives for overcoming these chronic high feed cost in livestock industry (Ukachukwu, 2008).

Ravindran and Ravindran (1988) reported that the yield of cassava leaves can be as much as 4.6 tones dry matter per ha taken as a by-product of root harvest. Cassava leaves as a protein source can be combined with low-protein cassava peels and used in rabbit feeding. Both are wastes constituting disposal problems especially where large quantities of cassava plants are harvested and processed.
Cassava leaf contains some anti-nutritional factors like cyanogenicglucosides, tannin, saponins, etc which are toxic to the animals when consumed without reducing the concentration of the toxins. Studies by Ravindran *et al* 1987).has demonstrated the possibility of producing cassava leaf meal with low cyanide levels..
There has been increased awareness of rabbit meat production in developing countries as a means of alleviating animal protein shortages. Although protein can be sourced from plants, the place of animal protein remain unequal, due to its balanced amino acid profile.

Materials and Methods

The research was conducted at the Rabbitry Unit of the Teaching and Research Farm of the Department of Animal Production and Health, Faculty of Agriculture and Life Sciences, Federal University Wukari, Taraba State. Wukari is located at latitude $7^0$51 N orth and Longitude $9^0$47 East (Wikipedia, 2011). Fresh cassava leaves *(Manihot esculenta)* were harvested from the farms around Wukari. The leaves were washed and dried under shade for three days to a constant weight. The dried cassava leaves were milled and put into an airtight container. Sample of the milled cassava leaves was taken for proximate analysis and anti-nutrient content determination. Three diets were formulated using Cassava Leaf Meal (C.L.M.) in replacement for full fat soybean as shown in Table 1. Diet 1 served as a control with 0% CLM, while diet 2 and 3 contained CLM at 10 and 20% inclusion levels respectively.

Eighteen (18) 4-5 weeks old female rabbits of mixed breeds were used in an 8 weeks feeding trial. The animals were randomly assigned to three experimental diets on the basis of equal mean live weight to three treatments groups each with six rabbits in a Completely Randomized Design (CRD). Each group had three replicates with two rabbits per replicate.

The rabbits were housed in a wood-wire hutches equipped with feeders and drinkers. The experimental diets, fresh forages (*Camelina bengalensis*) and water were provided ad-libitum. The rabbits were allowed to acclimatize to their various hutches for one week during which they were de-wormed and given antibiotics.

The data collected were feed intake, body weight, feed cost/kg gain and mortality. Other data collected were Head, heart, lungs, kidney, liver, spleen, stomach, large intestine, small intestine, caecum, and pancrease. Data collected was subjected to statistical analysis using Analysis of Variance (ANOVA). Differences between mean was separated using LSD.

Result and Discussion

The crude protein and energy levels of the formulated diets (Table 1) were 20.17% and 3006.06 Kcal/kg for Diet 1, 18.665% and 2914.59Kcal/kg for Diet 2 and 17.15% and 2814.74Kcal/kg for Diet 3.The respective crude fiber for diets 1, 2 and 3 are 4.79%, 5.09% and 5.25%. The feed cost per kilogram diet progressively decreased from N139.62 (Diet 1) to N126.05 (Diet 2) and N112’47 in Diet 3.

Table 1. Percentage Composition of the Experimental Diet for Grower Rabbits.

Diets Ingredients	T1 control	T2 10% CLM	T3 20% CLM
Maize	36.40	36.40	36.40
Full fat soybean	31.60	28.44	25.28
CLM	-	3.16	6.32
Maize offal	27.70	27.70	27.70
Bone meal	3.00	3.00	3.00
Premix	0.50	0.50	0.50
L- methionine	0.25	0.25	0.25
L- lysine	0.25	0.25	0.25
Salt	0.30	0.30	0.30
Total	100.00	100.00	100.00
CALCULATED CHEMICAL COMPOSITION			
Metabolizable energy (Kg/Kcal)	3006.06	2914.59	2814.74
Crude protein (CP)	20.17	18.66	17.15
Crude fibre (CF)	4.79	5.09	5.25
Feed cost/kg diet (₦)	139.62	126.05	112.47

The result of the performance of rabbits fed graded levels of cassava leaf meal is as shown in Table 2. The result showed no significant difference (P > 0.05) in total weight gain, average daily weight gain, total feed intake, average daily feed intake and feed conversion ratio. The Average Daily Feed Intake of 47.77-52.00g recorded for this study is found to be lower than the value range of 65.00-81.69g (Adeyemi et.al.2014) when he fed graded levels of Unfermented Cassava Leaf: Peel Meal Mix as a replacement for Maize to grower rabbits. The result is however similar to the value range of 45-55g observed by Ozung et.al. (2012) who fed Paw-Paw Peel Meal Based Diets to Weaner Rabbits.

The Average Daily Weight Gain (13.06-13.27g) is lower than that of 20.07-16.92g as reported by Adeyemi et.al. (2014) when he fed graded levels of Unfermented Cassava Leaf: Peel Meal Mix as a replacement for Maize to grower rabbits.

The numerically lower Feed Intake values noticed in the test diets could be attributed to the low palatability in the test diets as a result of the Cassava Leaf Meal portion included in them. The numerically lower Feed Conversion Ratio recorded in Diet 2 revealed that the test diet containing 10% was better utilized than the control Diet and Diet 2.

Feed Conversion Ratio	3.92	3.75	3.87	0.36^{ns}

NS= Not Significantly Different (P>0.05)
S.E.M.= Standard Error Mean

The result of the carcass characterization is presented in Table3. The result indicated no significant difference (P > 0.05) between the test and the control diets in all the parameters considered for carcass characterization.

The result of the carcass characteristics was found to be similar with values reported by Ekpo*et al*.,(2016) who fed graded levels of pumpkin based diet to rabbits. However, the insignificant difference of the carcass characteristics for the different studies mentioned above may be that the fibre content in the diets did not impair nutrient utilization, hence no adverse effect on carcass characterization was observed.

Table 3. Carcass Characteristics of Rabbits Fed Cassava Leaf Based Diets

Parameters % live weight	(0%) CLM	T2 (10%) CLM	T3 (20%) CLM	SEM

Conclusion

The study showed that Cassava Leaf Meal can replace Full Fat Soybean Meal in the diets of grower rabbits up to 20% inclusion level without any adverse effects on their performance, carcass characterization and at a reduced cost.

Abstract

Twenty-five (25) Crossbred grower rabbits were used to assess the effects of Rumen Epithelial Scrapings (RES) inclusion in the diets for rabbits. The five treatment groups consisting of five replicates of one rabbit per replicate in a Completely Randomized Design (CRD). The dietary treatments comprised graded levels of RES at 0, 2.5, 5, 7.5 and 10% in T_1, T_2, T_3, T_4 and T_5 diets respectively. Total feed offered was 100g/rabbit/day. Feed intakes were similar ($P<0.05$) across the dietary treatments, 1, 2, 3, and 4. Daily weight gain and feed to gain ratio were not affected ($P<0.05$) by increasing rumen epithelial scrapings except in T5 (10% RES) that recorded (10.01) and (8.51) respectively. Lower feed cost/kg significantly reduced ($P<0.05$) the cost/kg gain (₦) in diets 2 (₦444.4), 3 (₦447.7) and 4 (₦449.5) compared with the control diet 1(₦450). Conclusively, grower rabbits can utilize up to 7.5% rumen epithelial scrapings based diets without any adverse effect on performance.

Keywords: Grower rabbits, rumen epithelial scrapings, feed to gain ratio, cost/kg gain, inclusion

Introduction

There is an increasing interest in rabbit production in the developing countries, as a means of producing meat from forages and agricultural by-products in the tropics (Babayemi *et al.*, 2014; Adedoyin and Bamimore, 2018). Rabbits are especially well adapted to backyard rearing systems, with little capital and fodder resources which are usually limiting factors in animal production. Rabbits reared according to the techniques appropriate to the environment can do much to improve the family diet of many of the most needy rural families, while at the sametime supplying them with a source of income. With more advance bio-technology rabbit production can also help to supply big City meat markets. It has infact been stated that hindgut digestion which takes place in the rabbit is a superior adaption for dealing with wide varieties of feed staffs (Iyeghe-Erakpotobor and Esiero, 2010). However, to ensure sustainability in livestock production there is a need to optimize usage of the by-products of the abattoir as sources of nutrients for farm animals (Abubakar, 1998). A number of slaughterhouse byproducts are presently being wasted, such as rumen epithelial scrapings, blood, meat scraps, etc. Rumen contents can be prepared as a few material either by sun-drying involves spreading the material on any heat absorbing surface and constantly raking it to facilitate uniform drying. Ensiling involves mixing rumen contents with other ingredients such as molasses and packing the mixture tightly in silos or other suitable containers under anaerobic conditions (Adedoyin *et al.*, 2013). Abubakar (1998) opined that rumen contents are a good source of vitamins, especially the B vitamins. And that the dried material contains 15.43% crude protein, 1.91% ether extract, 39.08% crude fibre, and 31.71 Nitrogen free extract (NFE). Thus, the objectives of this study is to evaluate the nutritional values of rumen epithelial scrapings based diets for grower rabbits.

Materials and Methods

A total of twenty-five, four to five weeks old crossbred rabbits of mixed breeds (New Zealand white and Chinchinlla) and sexes, obtained from I.A.R.T, Ibadan, Oyo State were randomly assigned to treatment
(n = 5 rabbits per treatment). The rabbits of average initial weight of 450g were individually housed and maintained in battery cages in an open sided house. Rumen Epithetical Scrapings (RES) were obtained from Bodija market abattoir, Ibadan. The RES are then dried and grounded separately to a fine powder and replaced with groundnut meal at 0, 2.5, 5, 7.5, and 10% w/w in treatment 1(control), 2, 3, 4 and 5 respectively (Table 2). Body weight and feed intakes were determined weekly while feed to gain ratio was estimated as outlined by Olomu (2011). Feeding was done in the morning at 08:00 hours in earthen flat bottom pots. The concentrate and forage were offered to give a total of 100g feed/rabbit/day. Feed wastage and/left over were measured daily before the morning feeding so as to determined the total feed intake for eight weeks, water was provided ad libitum in plastic drinkers (Iyeghe-Erakpotobor, 2012). Mortality ratio were also calculated as percentage of total Number of rabbits per group. Data collected were subjected to the analysis of variance test, (2007). Means of significant result was compared by Duncan's. Proximate analysis of the rumen epithelial scrapings were analyzed according to the procedures described by AOAC (1990).

RESULTS AND DISCUSSION

Performance of grower rabbits fed different levels of rumen epithelial scrapings (RES) is shown in Table 3. Feed intakes were similar with a slight increase with an increasing levels of Rumen Epithelial Scrapings (RES) from 2.5 to 7.5% in the diets 2, 3, and 4. Similar intakes observed in the diets 2 (78.01), 3 (79.11) and 4 (81.8) for grower rabbits fed 2.5 to 7.5% RES could indicate a threshold of intake which might have been approached as the forage level increased. This could probably also suggests, an inability of the rabbits to further increase their gastrointestinal tract capacity to accommodate any further increase in feed intake as RES level increased from 2.5 to 7.5% level as also suggested (Iyeghe-Evakpotobor *et al.*, 2012). Daily weight gain and feed to gain ratio were not affected (P>0.05) by increasing RES except in T5 (10% RES) that recorded (10.01) and (8.51) respectively. A significant lower weight gains of grower rabbits fed diet 5 (10% RES) in this study compared to others (diets 1, 2, 3, and 4) could be as a result of the depressing effect of increasing rumen epithelial scrapings (RES) in the diet. Also, that possibly an increased level of RES brought about on rich bacteria protein a drastic changes in the biological functions of grower rabbits, poor feed efficiency and utilization, disturbances in metabolism of energy, mineral and vitamin balances, and enzymatic reactions with an impaired fermentative mechanisms in the cecum (NAP, 1991; Nwagu and Iyeghe-Erakpotobor, 2012; Adedoyin *et al.*, 2013) Lower feed cost/kg gain obtained with increasing level of RES up to 7.5% in the diet indicates the potential of reducing cost of producing rabbits by increasing the level of rumen epithelial scrapings in the diet of grower rabbits.

CONCLUSION

It is concluded from this study that grower rabbits can utilize up to 7.5% rumen epithelial scrapings diet based without any adverse effect on performance. Also, that lower feed cost and cost/kg weight gain were obtained.

EFFECT OF DIFFERENT HEAT TREA TMENT OF BAOBAB (*Adansonia digitata*) SEED AS AN ALTERNATIVE PLANT PROTEIN SOURCE ON HAEMATOLOGICAL AND BLOOD CHEMISTRY OF LOCAL TURKEY

L. A. SAULAWA, M. G. GARBA, M. N. SABO AND A. UMAR

DEPARTMENT OF ANIMAL SCIENCE, FEDERAL UNIVERSITY DUTSIN-MA

ABSTRACT

An experiment was conducted to evaluate the effect of boiling time of baobab (*Adansonia digitata*) seed meal as a partial replacement of soya beans meal on anti-nutritional factors, haematological and blood chemistry of local turkey. Raw baobab seeds were boiled for 30, 60, 90 and 120 minutes. The boiled baobab seed meals (BBSM) were used to replace 10% of soya beans meal. Seventy five poults were randomly selected and allocated to treatment diets with 15 poults per treatment and 5 poults per replicate. Proximate analysis of the experimental diets and anti-nutritional factors of the raw and boiled (30, 60, 90 and 120mins) BBSM were carried out. On the 9th week of the feeding trial, blood was collected from the poults for haematological and blood chemistry assays. The results obtained showed there was general reduction in the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) as a result of different boiling time of raw baobab seed. Monocyte count was different ($P<0.05$) among the treatment means with 30 mins BBSM having the highest count. The 30 mins BBSM recorded higher ($P<0.05$) creatinine compared the other treatments. Alkaline phosphate content was higher ($P<0.05$) for the control and 30 mins BBSM compared to 120 mins BBSM. It can be concluded that boiling reduces the content of anti-nutritional factors of raw baobab seeds and assisted the growing turkey in handling the anti-nutritional factors.

Keywords: Baobab, Local Turkey, Haematological, Blood chemistry, turkey

INTRODUCTION

Protein is a global index for measuring well-being of a country (Abdu, 2012). The basic sources of protein in Nigeria are the ruminant and the non-ruminant. The ruminant animals' production is seriously in dangerous stage due to insurgency in the north-east, cattle rustling in the north-west, and seasonal fluctuation of feed which resulted in reducing the supply of protein sources, the next alternative are poultry sources, but poultry is seriously affected by high cost of feed due to high competition between man, industries and poultry. Protein source is the major scarce and expensive ingredient in poultry production there by taking 75-80% of the total cost of production. Hence the need to source for alternative but promising feedstuffs. One of such alternative is baobab (*Adansonia digitata)* seed. Baobab (*Adansonia digitata*), locally called kuka (Hausa) and luru (Yoruba), which is another non-conventional feed stuff that is readily available in Nigeria particularly in the North. The use of legumes as a component of poultry feed has been limited by the content of anti-nutritional factors (ANF). Abdu (2012) and Saulawa *et al* (2014) reported that the inclusion of above 10% raw Baobab seed meal as plant proteins in diets of broilers leads to a significant impairment of growth and other undesirable physiological and biochemical alterations.

The examination of blood gives the opportunity to investigate the presence of several metabolites and other constituents in the body of animals and it plays a vital role in the physiological, nutrition and pathological status of an organism *(*Aderemi, 2004*). According to* Afolabi, *et al,* (2010), changes in haematological parameters are often used to determine various status of the body and to determine stresses due to environmental, nutritional and/or pathological factors. Hence, this study was conducted determine the effect of different time of hot water treatment on proximate composition and anti-nutritional factors of baobab and also its effect as a partial replacement for Soybeans on haematological and blood chemistry parameters of local turkey.

MATERIALS AND METHOD

Experimental Site

The study was conducted at the Poultry Unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma. Dutsin-Ma lies on latitude 12°26'N and longitude 07°29'E (Abaje *et al.*, 2014).

Processing of Baobab Seeds

The raw seeds of baobab were collected from Dutsin-ma market and were divided into five parts and boiled at different time interval. Boiling was carried-out according to the recommendation of Ukachukwu, *(*2000) for *Mucuna cochinchinensis*. The equal quantity seeds were boiled for 30mins, 60mins, 90mins and 120mins using equal vol. of water differently. Thereafter, they were brought down and a basket was used to drain the seeds and allowed them to sun dry.

Experimental Animal, their Management and Data Collection

One hundred (100) day old turkeys were housed and brooded in a deep litter. All routine management practices were strictly adhered to. At the end of the fifth (5) week (brooding period), 75 birds were allotted to five (5) experimental diets and replicated three times in a completely randomized experimental design. Diet was soybeans based (control), while 10% boiled baobab seeds boiled for 30, 60, 90 and 120 minutes were used to quantitatively replace equivalent weight of soya beans meal in diets 2, 3, 4 and 5 respectively. Feed and water were given *ad libitum* throughout the experimental period which lasted for nine (9) weeks.

On the 9th week of the feeding trial, 3 poults were randomly selected from each dietary replicate for blood collection. Blood was collected from the sub-clavicular vein of each poult using a scalp vein needle set. About 5ml of blood was collected into two (2) sets of three sterilized glass tubes/bottles containing Ethylene Diaminetetra-acetic Acid (EDTA) for Haematological studies. Blood samples for serum biochemical studies were collected into plain containers for serum separation.

Haematological parameters measured were red blood cell (RBC), haemoglobin (Hb), white blood cell counts (WBC), packed cell volume (PCV), mean corpuscular haemoglobin concentration (MCHC), mean corpuscular Haemoglobin (MCH) and mean corpuscular Volume (MCV) were all determined. Serum biochemical parameters considered were total serum protein, serum albumin, glucose, cholesterol, creatinine, urea, serum glutamate oxaloacetate transfarase (SGOT), alkaline phosphate (ALP) and serum glutamate phosphate transfarase (SGTP). Data from the experiment are subjected to one way analysis of variance (ANOVA) using SAS software (SAS 1999).

RESULTS AND DISCUSSION

Table 2 shows the result of different anti-nutritional factors obtained in both raw and boiled baobab seeds. There was general reduction in the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) as a result of different boiling time of raw baobab seed though reduction varies in degree with different boiling period. The highest percentage reductions in trypsin is T5 (1.98), tannin T4 (1.08) and in phytate T4 (2.79) were observed when the raw baobab seed were boiled with different boiling period.

The haematology parameters of turkey fed boiled baobab seed meal for different duration is shown in table 3. The result shows that RBC, Hb, PCV, WBC, Neutrophills, Lymphocyte and MCHC were not affected (P<0.05) by the feeding baobab seed meal boiled for various duration a replacement for soyabean meal.

Eosinophil %	0.00 [b]	0.50[ab]	2.00[a]	0.33[ab]	0.67[ab]	0.57
Basophils %	-0.00	0.00	0.00	0.00	0.33	0.15

a,b,c,d means in the same row with different super scripts are significantly (P<0.05) different
SEM – Standard error of means

Monocyte count was different (P<0.05) among the treatment means with 30 mins BBSM having the highest count. 90 mins BBSM recorded the lowest which is statistically lower P<0.05) than the control and the 30mins BBSm but similar (P<0.05) with both 60 and 120 mins BBSM. Eosinophil count of the 60 mins BBSm was significantly higher (P<0.05) than that of the control but similar with the other treatments. The 30, 90, and 120 mins BBSM had similar Eosinophil count with the control. MCV was affected by the feeding of BBSM to growing turkey with 30 and 90 mins BBSM having hiher MCV than 60 mins BBSM.The control and 120 mins BBSM have similar MCV with the 30, 60,

and 90 mins BBSM. Similar to MCV, MCH was higher than the 30 and 90 mins compared to 60 mins BBSM. The control and the 120 mins BBSM have similar MCH with the 30, 60, and 90 mins BBSM.

The result of the serum biochemistry of growing turkey fed BBSM is shown in table 4 all the parameters considered as shown in the table were not affected except for creatinine and alkailine phosphate (ALP). The 30 mins BBSM recorded higher (P<0.05) creatinine compared the other treatments.The control, 60, 90, and 120 mins BBSM had similar (P>0.05) creatinine content. Alkaline phosphate content was higher (P<0.05) for the control and 30 mins BBSM compared to 120 mins BBSM. The 60 and 90mins BBSM had similar (P>0.05) alkaline phosphate with both the control and 30 mins BBSM and the 120 mins BBSM.

Conclusion and Recommendation

From the results of this study it can be concluded that boiling reduces the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) of raw baobab seeds. Boiling of raw baobab seeds for more than 30 mins assisted the growing turkey in handling the anti-nutritional factors. Hence, monocyte count and serum creatinine content decreased with increased boiling time. It is recommended that 10% raw baobab seeds boiled for a minimum of thirty minutes can be used to replace soyabean meal in diets of growing turkey.

Abstract

An experiment was conducted to evaluate the effect of diets containing varying levels of crude protein (20, 22, 24 and 26%) and metabolizable energy (2600, 2800, 3000 and 3200 kcal/kg) on growth performance of growing Japanese quail. A total of 576 two-week old quail chicks were assigned into 16 treatments. Each treatment were replicated three times and each replicate had 12 birds using a 4 by 4 factorial in a completely randomized design. Data on growth performance were recorded during 6 weeks of age. Results of the study showed that both the main and interaction of varying dietary protein and energy levels had no effect on the growth performance of Japanese quails. It could, thus, be recommended that the lowest protein (20 %) and energy (2600 kcal ME/kg) levels be used in the diets of Japanese quails for optimal growth performance since their performance is similar even at the highest protein and energy levels.

Introduction

The world population is growing at an alarming rate. According to PRB (Population Reference Bureau) Projects, Africa's population will be more than double to 2.6 billion by 2050 and will account for about 58 percent of the global population increase by that date (Rosen *et al.*, 2014). With this population and the increased concern over low dietary animal protein supply. There is urgent need to increase the animal protein supply. This has led to search for animal that can supply the needed protein. If there is to be progress in this, effort must be placed on identification of alternative food resources that can meet to pace of the population growth (Rosen *et al*, 2014). The incorporation of game birds has been recommended, particularly for developing countries (Geldenhuys *et al.*, 2013) and one of the game birds that has identified is quail.

Quail has attained economic importance as an agricultural species producing eggs and meat that are enjoyed for their unique flavor. They have low maintenance cost because of their small body size (80-300 g), short generation interval having three to four generations in a year). Quail birds are more resistance to diseases and they have high egg production, thus they are an excellent laboratory animal because of their short generation interval. However, the nutritional requirement of this birds for the tropics have not been well established. Studies has shown that the nutrient of birds varies from species to species and from one location to another. Presently, in Nigeria, the diets fed to quail are mostly based on 24 and 20 % of crude protein for rearing and production, respectively, as recommended by NRC (1999) and there are also variations in the dietary crude protein and energy recommendations for quails.

Woodard *et al*., (1973) reported that quail can be raised on turkey starter diets containing 25 – 28 % crude protein while Lee *et al*. (1977) on the other hand indicated that dietary crude protein level of 24 % is needed in starter diet for quail and the protein content may be reduced to 20 % by 3rd week of age. Nwokedi *et al*. (2010) observed that when four crude protein levels of 20, 22, 24 and 26% were evaluated for Japanese quails, birds on 20 % crude protein level resulted in best performance from 1 to 42 days of age. Murakami *et al*. (1993) discovered that 18% crude protein was adequate at the laying phase this is, however, lower than the 20% recommended by NRC (1994) and 22.42%

recommended by Pinto *et al*. (1998).Report of Reda *et al*. (2015) indicated that Japanese quail fed crude protein and energy levels of 22 % and 2900 kcal ME/kg, respectively, as adequate during the first few weeks of growth. While Jahanian and Edriss (2015) reported that Japanese quail fed CP and energy levels of 26 % and 3000 kcal ME/kg, respectively, for the same period.

For the review above, that there are variations in the Japanese quail requirements for energy and protein. The variation might be attributed to region (climatic), breed of quails, time of rearing among others. This study will therefore, determine the effect of four different energy (2600, 2800, 3000 and 3200 Kcal) and four dietary protein levels of 20, 22, 24 and 26 % on the growth performance of Japanese quail raised under intensive management system in Nigeria (a tropical country).

Materials and Methods

The study was conducted at the teaching and Research Farm of Animal Production Department Federal University of Technology Minna, Niger state. Minna lies between latitude $9^0 15^1$ and $9^0\ 45^1$ N and between longitude $6^0\ 15^1$ and $6^0\ 45^1$ of the equator. The mean annual rainfall is between 1200 and 1300 mm and mean temperature ranges from 38 – 42°C

A total of five hundred and seventy-six (576) two weeks old Japanese quails obtained from the National Veterinary Research Institute, VOM, Nigeria. The two-week old quail chicks were assigned into 16 treatments. Each treatment was replicated thrice and each replicate had 12 birds using a 4 by 4 factorial arrangement in a completely randomized design. The experimental diets were corn-soybean based with 4 levels of protein (20, 22, 24 and 26% CP) at either of 4 levels of energy (2600, 2800, 3000 and 3200 kcal ME/kg diet). The composition of the experimental diets is presented in Table 1. The birds in all the treatments were subjected to similar management practices throughout the six weeks experimental period.

Initial weights were determined at the start of the experiment with the aid of salter weighing scale (SGF 400) balance and thereafter at weekly intervals. The final weight was also taken by weighing the birds in each replicate on the last day of the experiment using the same weighing balance. The weight gain was calculated by subtracting the initial weight from the final weight. In addition, the feed intake was calculated by subtracting the feed remaining from the total feed supplied each day before serving fresh one. The feed conversion ratio was also calculated by dividing feed intake by weight gain.

Data Analysis. All data generated were analyzed using two-way analysis of variance (ANOVA) and where significant differences occurred, the means was separated using Duncan Multiple Range Test as contained in the SAS package (2015), version 15.0.

Results and Discussion

The main effect of dietary protein and energy levels on the growth performance results of Japanese quails is presented in Table 2. All the growth performance parameters measured there were no significant differences observed between the treatment group on the performance value recorded.

The interaction results between protein and energy levels on performance were presented in Table 3. There were similar in the main performance of the Japanese quail in all the parameters. The interaction of protein and energy on all the performance parameters was not significant.

Conclusion

Results of the study showed that both the main and interaction of varying dietary protein and energy levels had no effect on the growth performance. It could be recommended that the lowest protein (20 %) and energy (2600 kcal ME/kg) levels be used in the diets of Japanese quails for optimal performance since their performance is similar even at the highest protein and energy levels. Further study on the digestibility and economic of production can be carried out to ascertain the effect on the quails.

MONETARY COST ANALYSIS OF REPLACEMENT VALUE OF ACHA (*Digitaria exilis* Staph) FOR MAIZE IN BROILER CHICKENS DIETS

Wumnokol, D.P, Latu, M. Y and Magaji, S.T
Department of Animal Health and Production Technology, College of Agriculture, P.M.B 001 Garkawa, Plateau State, Nigeria
Email: satimagaji2009@yahoo.com

ABSTRACT
An experiment was conducted to investigate the cost of replacement value of acha (Digitaria exilis Staph) for maize in broiler diets. Five diets were formulated which unprocessed acha replaced maize at 0, 25, 50, 75 and 100% for the starter and finisher phase. Two hundred and twenty-five unsexed marshal broiler chicks were weighed and randomly allotted to five dietary treatments with three replicates per diet. Treatment 1 had the highest monetary value of ₦240.32 as cost of the feeds as compared to Acha with monetary value of ₦215.29, ₦223.05, ₦232.72 and ₦238.85 in feed 2,3,4 and 5 respectively (25%,50%,75% and 100% Acha); this trend indicated that the diets consisting of Acha had lower feed cost. The money saved from the production of the birds indicated that more money was saved in feed 3 (50% Acha) in the process of production. It can be concluded that unprocessed acha could replace maize especially at 50% level of inclusion in the diets of broilers with concomitant reduction in cost of feed/kgLWG.
Keywords: Acha, replacement, broilers

INTRODUCTION

The state of nutrition of the populace in Nigeria is predominantly marked by inadequate protein intake both in quantity and quality. The shortage has given rise to high price of animal protein (Taiwo *et al*., 2005). The high cost of animal proteins is mainly due to unavailability and high cost of raw material for feed industry especially maize. Abundant animal production also hinges on availability of cheap, available, acceptable and balance feeds. Feed quantity and quality affect how many animals can be raised and how fast they can reach the market weight. Depending on locality feed input is 80-90% the cost of producing eggs, chickens, pigs and rabbits (Aduku, 1992). Therefore, the potential of non-conventional feed resources must be assessed with the objectives of expanding the feed-base for the livestock, and thereby, reducing the cost of feeding farm animals.

The problems of high feeds cost calls for more research in developing new feed resource and upgrading the conventional ones. Preston and Leng (1986) rightly suggested that it is a better objective to make livestock production with available resources. The cost and sometimes scarcity of maize which is the conventional energy source of feedstuff has warranted the need to find alternative sources of energy to meet the demand by feed mill industries. In a bid to find alternative energy sources for broiler diets Agboola (1992) and Ogundipe *et al*. (1990) reported that millet competes favorably with maize in terms of percentage crude protein and percentage ash with no significant adverse effects on the performance of the birds.

Acha (*Digitaria exilis* Staph) is said to be the oldest indigenous West African cereal with cultivation dating back to 500BC but it is not known in a wild state Purseglove (1975). Acha (*Digitaria exilis* Staph) is popularly grown in about six States of Nigeria namely, Plateau, Nassarawa, Bauchi, Kaduna, Kebbi, Niger and the Federal Capital Territory (F.C.T). The crop is the staple food in some of these areas where the very small grain processed into different menus. The greatest diversity of this crop in Nigeria, exist mostly in Plateau State (Kwon-Ndung, 2003). Certain Acha varieties mature so fast that they are ready for harvest long before all other grains, making it to reduce misery, during "hungry times" (Kwon-Ndung, 2003).

In view of the economic value of Acha enjoyed by the rural farmers and its potential for increasing feed supply, the crop has received little attention from national and international scientists. Acha (*Digitaria exilis* Staph) deserves a much greater recognition because it can serve as food crop for the future and a good alternative source of energy for broilers. The objective of this study therefore was to analyze the monetary cost of replacement value of acha (*Digitaria exilis* Staph) for maize in broiler chicken diets.

Materials and Method

Acha (*Digitaria exilis* Staph) was bought in Mushere District of Bokkos Local Government Area of Plateau State. Yellow maize, soyabeans and salt were obtained from local market in Garkawa while bone meal, methionine, lysine, vitamins premixes and drugs were purchased from Jos town. Marshall Broiler chicks numbering 225 were obtained from Zartech Farms, Bukuru in Jos, Plateau State. Feed formulation was done manually and mixing was done in Plateau State College Agriculture, Garkawa feed mill.

The birds were brooded for one week which led to removing of the weak birds and 225 birds were finally used for the experiment. Five diets for the starter was formulated in which Acha replaced maize at 0, 25, 50, 75 and 100% levels designated as diet 1, 2, 3, 4 and 5 respectively. The CP content for starter was 23 crude proteins with maize at 45% in the control diet for the starter. The 225 Marshall birds were randomly assigned to five (5) treatments containing three (3) replications with 15 birds. Tables 1 and 2 showed the percentage composition of broiler starter and finisher.

Data collected were analyzed for cost value of feed per live weight using variance (ANOVA) techniques. Where significant differences were detected, means were separated using the Duncans New Multiple Test (DNMRT).

RESULTS AND DISCUSSIONS

The values of feed cost in naira (₦) per kilograms of feed (Table 3) ranged from 44.15 – 47.03, as the level of Acha (*Digitaria exilis* Staph) increases in the diet, feed cost per kilogram of diet decreases, though not very much due to the low differences in cost price of both ingredients in consideration. The total feed cost for rearing the birds from 1 – 8 weeks was presented in Table 3. The value ranged from ₦215.29 - ₦240.32 from treatment 1, 2, 3, 4 and 5 respectively. Treatment 1 has the highest value of ₦240.32 cost of the feeds; this trend indicated that the diets consisting of Acha had lower feed cost. The money saved from the production of the birds indicated that more money was saved in feed 3 (50% Acha) in the process of production.

It was found that the more the Acha inclusion, the feed intake increases and the less the cost of production. Acha has the advantage in storing ability over maize. The general trend showed that using unprocessed acha grains can reduce the cost of production of broiler chickens which was shown by the fact that least feed cost, high (diet 3) weight gain/kg and more in diet 5 money was saved in diet 3 (₦33.57) and diet 5 (₦31.91). Alabi *et al*. (2014) in a similar research stated that the inclusion of rice husk supplemented with commercial enzymes in the diets of broilers reduced the cost of production and hence increased profit. Similarly, an inclusion of Cassava peels up to 75% showed no adverse effect on the performance of broiler finishers and could lead greater reduction in cost (Abubakar and Ohinege, 2011).

In conclusion, Acha (*Digitaria exilis* Staph) could completely replace maize in broiler diet. Feed cost per kg body weight gain decreases with increases levels of Acha (*Digitaria exilis* Staph) in broiler diets and it was more profitable to produce broilers at 50% level of inclusion.

Based on the results, it was recommended that Acha (*Digitaria exilis* Staph) is a suitable substitute and also an alternative energy source to conventional maize for broiler production, particularly if purchased during the harvesting period.

ABSTRACT
The study was designed to investigate the performance attributes of chickens fed different levels of red sorghum variety as replacement for maize. Two hundred and twenty five (225) unsexed day old broiler chicks were allotted to five treatments containing red sorghum replacing maize at 0,25,50,75 and 100% levels of inclusion designated as diets 1,2,3,4 and 5 respectively in a completely randomized design (CRD). The results obtained after the research did not show any significant difference across the five diets. It is concluded that red sorghum variety can completely (100%) replace maize without compromising productive performance. Red sorghum variety is recommended as a suitable alternative to maize as dietary energy source in broiler chickens production.

INTRODUCTION

Livestock consumes more than a third of all the world's grains particularly maize (Omale and Igwe, 2006). Maize has remained the chief source of dietary energy in compound feeds and constitutes about 50-60% in most poultry diets. Despites its worldwide production, a stiff competition for the usage of maize by humans, livestock and industries persists. This is simply because, maize is high in energy and forms the standard (100) against which other cereal grains is compared (Atteh, 2002). Sorghum (*sorghum bicolor*) is a drought tolerant crop able to withstand a wide range of environmental conditions and has limited industrial uses in Nigeria.This high demand for maize by man and consequently the high prices has made the use of other alternative energy sources like Red sorghum imperative. Sorghum grain has proven to be a suitable feedstuff for use in animal diets (Hancock, 2000; Dowling *et al.*, 2002; Cramer *et al.*, 2003; Travis *et al.*, 2006; Medugu *et al.*, 2010). One major constraint to the use of sorghum in poultry feeding is its tannin content which exerts anti-nutritive on birds.

MATERIALS AND METHODS

Experimental site:

The experiment was conducted at the poultry unit of the Teaching and Research Farm of the College of Agriculture and Animal Science, Mando-Kaduna Division of Agricultural Colleges, Ahmadu Bello University, Zaria. Kaduna State is located within the North-West Geo-Political Zone of Nigeria. Kaduna State is found in the Northern Guinea Savannah Zone of Nigeria (COMPASS, 2009). The state has two main seasons; dry and rainy seasons. The rainy season covers the month of April-October and the dry season covers November-March. The mean annual rainfall is 700-900 mm for the Northern Zone, 690-1031 mm for the Central Zone and 900-1300 mm for the Southern Zone (KADP, 2003). The temperature ranges from 24.4^{o}C to 30.4^{o}C, with the hottest months being March and April while the coldest months are December and January. August use to record the highest relative humidity (99%) and February has the lowest (57%) (KADP, 2003).

Experimental Diets

Five experimental diets of 23% CP were formulated in which red sorghum variety replaced maize at 0, 25, 50, 75 and 100% levels coded as diets 1,2,3,4 and 5 respectively. Yellow maize was replaced by red sorghum as the source of energy while the major sources of protein in the diets were roasted full-fat soya beans (FFSB) and fish meal. The percent and proximate compositionsof the experimental diets are presented in Table

Experimental Birds:
Two hundred and twenty-five (225) Armor breed of broiler chickens were used for the research. They were allotted to the five treatments in three replicates with fifteen birds per replicate in a completely randomized design (CRD).

RESULTS

The performance of broiler chickens fed dietary levels of red sorghum variety is presented on Table 2. All the performance parameters (Daily feed intake, Daily weight gain and Feed conversion ratio) were not affected by the dietary treatments. This finding is in conformity with the reports of Nyannor *et al.* (2007) who stated that the growth performance of broiler chickens was equally supported by maize and sorghum, since sorghum grains compares quite favorably with maize in terms of nutritional quality. It is also similar to the reports of Kawu (2010), who stated that low tannin sorghum is similar to maize in its nutritional value and gives response equivalent to that observed in maize diets.

Table 2: Performance of Broiler Chickens Fed Red Sorghum Variety Replacing Maize at the Starter Phase (1-4 weeks)

Parameters	Diets					
	T1(0%)	T2(25%)	T3(50%)	T4(75%)	T5(100%)	SEM
Daily feed intake (g)	66.54	67.66	71.35	69.04	67.87	1.42 NS
Daily weight gain (g)	21.17	23.78	24.44	23.09	22.05	1.44 NS
Feed conversion ratio	3.20	2.85	2.94	3.01	3.10	0.19 NS
Mortality (Number)	3	2	0	0	3	-

SEM= Standard Error of Mean, NS= Not Significant

DISCUSSION

The productive performance of broiler chickens fed red sorghum based diets showed no significant differences in the starter. This indicates that red sorghum variety can substitute maize weight for weight in the diets of broiler chickens without compromising the performance of broiler birds.

CONCLUSION AND RECOMMENDATION

It is concluded that red sorghum variety can completely (100%) replace maize without compromising productive performance. Red sorghum variety is recommended as a suitable alternative to maize as dietary energy source in broiler chickens production.

ABSTRACT

This study evaluated the biochemical and haematological indices of weaner rabbits fed sorghum brewer's dried grain (SBDG). Forty mixed breeds of rabbits (4-8weeks) were allotted into four experimental treatments in a completely randomized design. Four concentrate diets were compounded by replacement of maize with the inclusion of SBDG at 0, 20, 30 and 40%. The diets were fed to the rabbits at 5% of their body weight respectively. The diets containing SBDG (20%, 30% and 40%) had similar ($p>0.05$) value of glucose, total protein, globulin, albumin, AST and ALP. Animal fed diet 20%SBDG (85.63) had significantly highest ($p<0.05$) ALT compared to 0%SBDG (69.58), 30%SDBG (63.13) and 40%SBDG (58.99). The bilirubin total was significantly higher ($p<0.05$) than diets 0%SBDG and 30%SBDG.Rabbits fed diet 30%SBDG had significantly highest PCV value (36.65), followed by 40%SBDG (34.75), 20%SBDG (34.59) and 0%SBDG (35.55). The RBC was significant higher ($P>0.05$) in rabbits fed diets 30%SBDG (6.49) and 20%SBDG (6.14) than 0%SBDG (4.83) and 40%SBDG (4.20) whereas, the WBC count was significantly higher ($P>0.05$) in rabbits on diet 40%SBDG and 0%SBDG than 30%SBDG and 20%SBDG. It could be concluded that the total replacement of maize with SBDG in the diet of rabbits had no deleterious effect on the biochemical and haematological indices.

INTRODUCTION

Feed cost among other cost of production accounts for over 50% of intensively reared rabbit in the tropics (Ogunsipe *et al*., 2011). This can be attributed to high cost of conventional feed sources in formulated concentrate diets (Olomu, 2011). Their seasonality as well as competing demand by man as food and industrial raw material has not helped in this regard. Several studies have revealed that the development and utilization of unconventional feedstuffs can greatly reduce the overdependence on conventional feed sources and subsequently reducing the cost of production of livestock. A characteristic of such alternative feedstuff should be its non-competitive usage with man, brewery by-products fall into this category (Dowling *et al*., 2003). These alternative feed sources have been utilized successfully by several animal nutritionists in the formulation of feed which include the use of cassava peel meal in rabbits (Adegbola and Oduozo, 1992). Therefore of sorghum brewers waste (SBW) is derived from sorghum used solely. It is relatively cheap as large quantity is produced in local gin production (Awika *et al.*, 2001). It does not require much of additional processing such as grinding before being incorporated into livestock diets. The examination of blood provides the opportunity to clinically investigate the presence of several metabolites and other constituents in the body and it plays a vital role in the physiological, nutritional and pathological status of the animal (Aderemi, 2004). Hence, this study evaluates the biochemical and serum of rabbits fed sorghum brewers dried grain.

MATERIALS AND METHODS

Forty weaners rabbits of mixed sexes aged 4 - 6 weeks were used for the experiment. The rabbits were raised in hutches fitted with feeders and drinkers at The Oke-Ogun Polytechnic Saki, Teaching and Research Farm. There was two-week adaptation period during which the rabbits were treated against parasitic infestation with ivermectin subcutaneous and multivitamin added to their water. The forty rabbits were randomly allotted into four treatments (10 per treatment) in a completely randomized design. Fresh and wet local sorghum brewers waste was sourced from reputable local brewery in Saki metropolis, oven-dried for three days and store in polythene bags for subsequent use. Four concentrate mash diets were compounded by replacing of maize with LSBDG at 0%, 20%, 30% and 40% levels respectively. The diets were fed to rabbits at 5% of their body weight. On the last day of the experiment, blood samples were taken from the goats using 5 ml syringe. One ml blood sample was

collected into labelled sterile bottles containing anticoagulant free bottles, allowed to coagulate at room temperature and centrifuged at 3000 rpm for 10 minutes. The serum concentration of cholesterol, aspartate aminotransferase (AST), alkaline phosphate (ALP) and albumin were determined using commercial laboratory kit (Randox Laboratories Ltd, U.K). The red blood cell (RBC), white blood cell (WBC) and the packed cell volume (PCV) were determined using the method of Adedapo *et al*. (2007). Data collected were subjected to one-way analysis of variance procedure of the general linear model (SAS, 2008). The mean was separated using the Duncan Multiple Range Test.

Table 1: Table 1: Gross composition of the experimental diets

Ingredients	0%SBDG	20%SBDG	30%SBDG	40%SBDG

Blood is an important index of physiological, pathological and nutritional status in the organism (Olorode *et al*., 2007). The glucose values in this study were relatively similar to 111.13 – 124.93 reported by Terzungwe *et al.* (2013) for rabbits fed *Moringa oleifera* leaves. The total protein content reported in this study were slightly higher than the range (4.81- 5.48g/dl) reported by Odetola *et al.* (2012). The glubolin concentrations were lower than the values (2.55 – 2.77) reported by Olabanji *et al.* (2007). The albumin was similar to value recorded by Ayandiran *et al.* (2019) for rabbits fed bread waste and Moringa based diet. Mean values of ALT for rabbit fed SBDG were close to the normal range of (48.5-78.9) reported by Mutruka and Rawnsley (1997). The serum enzyme activities above the normal range are abnormal and are an indication that the animal might have suffered liver and/or kidney damage. The PCV in this study were lower than 43.30-46.77 (Federick, 2010) but higher than 32.25-34.78 reported by Ayandiran (2019). The RBC values (4.20-6.49) obtained in this study were close to the normal ranges of 5.0-8.0 as reported by (Ahamefule *et al*., 2008). The WBC values were slightly higher than 5.13-5.60 (Yakubu *et al*., 2008). Furthermore, the MCV values were close to the reference values of (60.00-69.00) reported for apparently healthy rabbits (Madirabbit, 2011); but higher than 32.75-34.00 reported by Bitto *et al*. (2006). The MCH values reported in this study was relatively low compared to the values reported (19.85-20.06) by Togun *et al*. (2007) while Njidda *et al*. (2006) posited that MCV, MCH and MCHC are used in diagnosing anaemic conditions. The lymphocyte values obtained were however above the stipulated values obtained were however above 41.0-53.5 reported by Aderemi *et al.* (2014) for rabbits fed Soybean with *Tephrosia linearis* meals.

CONCLUSION

It could be concluded that the total replacement of maize with SBDG in the diet of rabbits had no deleterious effect on the biochemical and haematological indices.

ABSTRACT
A feeding trial was conducted at the Aminu Saleh College of Education Azare Teaching and Research Farm, Bauchi State to evaluate the dietary response of broiler birds fed sorghum in place of maize at various inclusion levels. A total of one hundred and five day old chicks were used for the study. Five experimental diets were formulated and designated as T_1 (control), T_2, T_3, T_4 and T_5. The birds were randomly allotted to five experimental treatments of twenty one birds per treatment while each treatment was replicated three times (seven birds per replicate) in a completely randomized design (CRD). The result of growth performance revealed that average daily weight gain were significantly ($p<0.05$) influenced by the dietary treatments. Birds fed 25% sorghum had superior weight gain compared with other treatments. Daily fed intake was however not influenced ($p>0.05$) by the dietary treatments. There were significant ($p<0.05$) difference in the cut parts measured except the weight of chest and wings. Birds fed 75% sorghum had lowest values in wing weight while birds fed 100% sorghum had lowest values in chest weight. Carcass weight were significantly ($p<0.05$) different across dietary treatments. Organs weight and length were not significantly ($p>0.05$) different across dietary groups except in small intestine length. It was concluded that 25% sorghum can be included in the diet of broilers without adverse effect on growth performance of broilers. However, T2 with 25% sorghum is recommended, since birds on this diet had the best performance and carcass characteristics.

INTRODUCTION
Due to increasing meat consumption and a growing population, animal production is increasing in the world (Food and Agriculture Organization of the United Nations FAO, 2016). This increase is realized through fewer, but larger farms (large animal units and high stocking densities and with large numbers of animals per farm) in upper middle-income countries and high income countries (Lowder *et al.,* 2016). Commercialization in the poultry industry and generally in the agriculture sector has increasingly become popular in East Africa, mainly as an entrepreneurial response to income growth in the region (Katongole *et al.,* 2013). According to FAO (2013), chicken meat production in Africa between 2006 and 2013 increased steadily by almost 5% per year. With regard to number of animals, poultry production (with broilers being the most commonly reared poultry species) is one of the largest livestock sectors in the world (Silvera, 2017). Broiler production is one of the livestock industries that offers the highest turnover rate and quicker returns on investment either in small, medium or large scale production (Afolayan *et al.,* 2014). Poultry birds especially broilers play a significant role in the provision of animal protein required by man to meet his daily protein intake (Maidala and Istifanus, 2012). The increased demand of poultry meat has directed breeding focus towards a fast growing broiler with increased feed efficiency and greater final weights (Petracci and Cavani, 2012). Within the age of six weeks, female birds gain weight up to 175-200g and the males weigh between 125-150g (Akintunde *et al.,* 2017). Female births start laying eggs at 5-6 weeks of age and continue up to twenty two weeks of which the egg weighs about 9-10g (Akintunde *et al.,* 2017). There are also essential in poultry production being fundamental attributes for assessing growth and feed efficiency as well as important yardstick in management and economic decision making (Assan, 2015). This study was carried out to determine the effect of sorghum replacement for maize on the performance and carcass characteristics of broilers.

MATERIALS AND METHODS
Experimental site
The study was conducted at the poultry unit of the Department of Agricultural Science Education Teaching and Research Farm, Aminu Saleh College of Education Azare, Bauchi state.

Experimental birds and management

One hundred and five day-old broilers chicks purchased from Amo farm, Kano state were used for the seven weeks experiment. The chicks were brooded conventionally in a deep litter system using electric bulb (200wattt) as a source of heat and light. The chicks were brooded for fourteen days. Medications, vaccinations and other routine management practices as described by Abdo *et al.* (2015) were strictly followed. The birds were weighed on commencement of the experiment to obtain the initial weight and 21 birds were randomly selected and allotted to each of the five treatments of 3 replicates each (7 birds per replicate) making a total of 105 birds. The birds were fed diets containing 0, 25, 50, 75 and 100% graded levels of red sorghum, both at starter and finisher phases.

Experimental diets

The sorghum and maize used for the experiment was bought from a local market in Azare, Katagum L.G.A of Bauchi state. The dried feed ingredients were grounded using hammer mill and mixed together to homogenized, packed in a sack and stored at room temperature (Wafar and Tarimbuka, 2016). Diets were formulated by using Pearson square method. Two basic diets comprising of the starter and finisher diets were formulated. The diets were formulated in order to meet the broilers nutritional requirements, based at nutritional program recommendation by Rostagno *et al.* (2011). The nutritional and energy levels, as well as the feed composition of the diets involved in all treatments were based on the four nutritional stages (pre-starter, starter, grower and finisher). Five experimental diets were formulated using sorghum as energy source and as replacement for maize. Maize was replaced with sorghum at dietary inclusion levels of 0, 25, 50, 75 and 100% designated as T_1 (control), T_2, T_3, T_4 and T_5 respectively.

Chemical analysis

Samples of each diet fed to the birds (starter and finisher) were analyzed to determine the dry matter, crude protein, crude fibre and ether extract according to the method of AOAC (2006). The analysis was conducted at Central Laboratory Services Unit, National Animal Production Research Institute, Ahmadu Bello University, Shika-Zaria.

Data Collection

Data were collected on weekly weight changes was determined by weighing the birds on weekly basis and weight gain was calculated by subtracting the weight of the previous week from that of the current week. The feed intake was determined by subtracting the left-over feed from the feed offered, while feed conversion ratio was calculated as average feed intake divided by average /weight gain. The mortality was recorded daily and the weights of all the dead birds were taken in order to minimize an error in feed conversion ratio. It was expressed as percentage mortality at the end of the experiment for corresponding treatment group.

Statistical Analysis

The experimental design was completely randomized design. The data obtained from the study were subjected to analysis of variance (ANOVA) procedure (Steel and Torrie, 1980). Significant means were separated using Duncan's Multiple Range Tests (Duncan, 1955). All statistical analyses were carried out using SPSS (2012) package (statistical package for social sciences) procedure.

RESULTS AND DISCUSSION

The percentage composition of broiler starter and finisher's diet are shown in table 1 and 2. The result of cut parts of broilers chicken fed with sorghum as replacement for maize (1-7 weeks) is presented in table 3. The cut parts revealed significant difference ($p<0.05$) in pectoral muscle (8.94-12.01%), back (3.62-6.44%) and thigh (11.45-14.95%). Table 4 revealed the result of carcass and offal characteristics of broiler chickens fed with sorghum to replace maize (1-7 weeks). The result unveiled that the live weight gain ranged from 1600- 2150g which was significant ($p<0.05$) and the result is comparable (1925-2200.0g) reported by Adamu *et al.* (2012). The values recorded for dressed weight ranged from 50.04-58.38% which was significant ($p<0.05$) across dietary treatment. The dressed weight is lower than (66.20-71.11%) recorded by Bakoshi *et al.* (2014). This could be attributed to the source of the chicks used for the experiment. The plucked weight ranged between 1466-1900g and were found to be statistically significant ($p<0.05$) this result is comparable (1750.0-2025.0g) reported (Adamu *et al.* (2012). The result agreed with the work of Bakoshi *et al.* (2014) but contradicts that of Medugu *et al.* (2010a) who observed no significance ($p<0.05$) in carcass yield of broilers fed sorghum

compared with maize. Similarly, the organs weight (%) has no significant difference (p>0.05) on the two energy sources in the heart and legs (3.82-6.75%), gizzard (1.19-1.40%), heart (0.17-0.29%), lungs (0.29-0.35%), pancrease (0.8-0.12%), liver (1.33-1.79%), small intestine (0.65-1.01%), large intestine (1.47-2.38%), caecum (0.31-0.46%) and proventriculus (0.24-0.33%). This result agreed with the work of other authors (Medugu *et al.*, 2010b; Mohammed *et al.*, 2013). The values recorded for the organs weight in the proventriculus, lungs, small intestine, large intestine and liver are higher than the values recorded by Ibitoye *et al.* (2012) in a similar experiment elsewhere.

CONCLUSION

The complementary nature of maize for sorghum as energy sources in feeding broilers in Nigeria can be encouraged as it does not affect most of the growth and carcass characteristics, this will reduce the cost and diversify the feed ingredients used as energy feedstuff.

ABSTRACT

The experiment was conducted to evaluate the effect of nitrogen fertilizer on forage yield and quality of *Pennisetum pediacellatum* under rainfed in Gashua, Yobe State. The experiment was laid out in Randomized Complete Block Design, with plot divided into three main plots and replicated three times measuring 3 x 2 m^2. The three fertilizer rates are 100kg, 125kg and 150 kg per hectare, respectively. Forage yield and percentage of proximate compositions were significantly ($P < 0.05$) affected by the fertilizer rates. The highest fresh (29,444kg/ha) and dry (3,828 kg/ha) matter yield were recorded in 150kg N/ha fertilizer rates. Similarly, the highest crude protein (19.94%) and ash contents were observed with plots receiving 150kg N/ha rate whereas 100kg N/h fertilizer level had higher values for Crude fibre (32.11%) and ether extract (1.15%). The experiment reveals that among all fertilizer rates, 150kg N/ha had the best forage yield and proximate composition than the other fertilizer rates. It is therefore, recommended that 150kg N/ha fertilizer rate be used for enhanced forage productivity and better animal performance in Gashua, Yobe State.

keywords: *Pennisetum pediacellatum, fertilizer rates, forage yield, proximate composition*

INTRODUCTION

In most of the tropical regions of the world, strategic provision of feed to meet up with the nutrient requirement of livestock animals have been a major problem faced by ruminant animal keepers, especially during the dry season. In the small farmers' perspective, this requirement is provided through the basal supply of natural pasture grasses (Odedire and Babayemi, 2016) which are characterized by poor nutrients and low yield as they grow on infertile and erosion degraded soils (Babayemi and Bamikole, 2006). Since the forages on the rangelands in these areas provide feed which are not adequate for the ruminant animals, the Fulani herdsmen migrate to other places where feed is in abundance. The movement of these Fulani herdsmen on many occasions has resulted in clashes with farmers (Nweze *et al*., 2012).

Tropical grasses have the ability for high yield and the nutrients are simultaneously enhanced when treated with organic or inorganic fertilizers or established with nitrogen-fixing shrubs or tree legumes (Abdullahi *et al.,* 2018). Unfertilized grasses had been described to be less nutritive as forage for ruminant animals (Bamikole *et al*. 2004). Nitrogen (N) fertilisers application has been shown to increase DM yield, herbage metabolisable energy (ME) and crude protein (CP) and decrease water-soluble carbohydrate (WSC) content (Coblentz *et al*., 2017)). Such effects may be advantageous for the production of higher DM yields for silage, while improving, or at least maintaining herbage nutritive quality.

Pennisetum pedicellatum (Trin.) belongs to the *Poaceae* family and tribe *Paniceae*. It is annual and commonly known as *Kyasuwa* grass. It is also indigenous and occurs naturally in tropical and subtropical Africa (Bogdan, 1977). The grass is palatable and could be fed fresh, as silage or directly grazed on the field (Woodard *et al*., 1991). Information on the yield and nutritive value of this grass as influenced by nitrogen level are not available or scarce in the study area, hence this study was designed to evaluate the effect of nitrogen levels on forage yield and quality of *Pennisetum pedicellatum* (Trin.) in Gashua, Yobe state Nigeria.

MATERIALS AND METHODS

Experimental site

The experiment was conducted during the 2019 rainy season at the Teaching and Research Farm of the Department of Animal Science, Federal University Gashua, Yobe. The major vegetation type of the area is the Sahel savannah, it consists of open thorny savannah with short trees and grasses. It is located between longitudes 10° 02' and 11° 11'E and latitudes 12° 48' and 12° 88' N. The climate is characterized by high temperature and seasonal rainfall and the mean minimum temperature ranges between 10 -12°C in December/January, while the mean maximum is about 34-40°C in March-May. The mean rainfall is between 300-500 mm per annum and is unimodal and lasts mostly from June to September while the dry season starts from October to May (NEAZDP, 2015). The soil characteristic in the study area was sandy loam, very low in organic carbon (1.344 g/kg) an nitrogen (0.21 g/kg), moderate in available phosphorus (9.81 g/kg) and high in exchangeable potassium (1.71 cmol/kg)

Land Preparation, Experimental Layout and Treatments

A land area of 12m x 9m was used for the experiment. The field was cleared, ploughed and harrowed to provide a clean seedbed for the ease of planting and germination. The plot was divided into three main plots and replicated three times measuring 3m x 2m and 1m in-between the plots in a Randomized Complete Block Design (RCBD).

Biomass yield (kg DM/ha)

Plants within 0.5 m^2 quadrant in the plots were cut at 10 cm above the ground level with a sickle to determine the forage yield at eight weeks after sowing. The cut forages were immediately weighed to determine fresh weight after which they were oven-dried at a temperature of 65^oC for 48 h to determine the forage dry matter yields. Forage dry matter yields were calculated using the formula reported by Akpensuen *et al*. (2019) as stated below:

Forage dry matter yield (kg DM ha-1) = Fresh weight (kg) x Oven dried weight (DM%) × 40,000
There are 40,000 quardrat (0.5m-2) per hectare

Chemical analysis

Forage was collected, processed and analysed for dry matter by oven drying at 60^oC for 48hours. Nitrogen Free Extract (NFE) was determined by calculation [NFE = 100 - (%CP + %CF + %EE + %Ash)]. Nitrogen was analyzed by the Kjeldahl method (AOAC, 2005) and crude protein calculated as %CP = %N *6.25, ash by burning in a furnace at 550^oC for 3 hours and crude fat by soxhlet extraction according to A.O.A.C. (2005) method.

Statistical analysis

The results obtained were subjected to analysis of variance using General Linear Model Procedure (Proc. GLM) of SAS (2005). Significant ($P<0.05$) differences among treatment means were compared by using Duncan Multiple Range Test (Duncan, 1955) of the SAS package.

RESULTS AND DISCUSSION

The forage yield of Kyasuwa (*Pennisetum pedicellatum* Trin.) was affected by the application of nitrogen fertilizer (Table 1). Application of 150kg N/ha rate increased ($P<0.05$) forage yield which was 27.17 % higher than with 100kg N/ha. The increase in forage yield with increased nitrogen level could be attributed to the production of taller plants with maximum photosynthetic areas (Mbahi and Gende, 2016; Subrahmanya *et al*., 2017). Kumar *et al*. (2015) reported that fertility level of 150kg N/ha should be used to obtain maximum fodder yield. This agrees with the report of Shahin *et al*. (2013) who recorded increase in fresh and dry forage yield with increasing levels of nitrogen fertilizer application. Similar results were also obtained by Bhilare *et al*. (2010) and Ayub *et al.* (2017). The mean (3408.16 kg/ha) dry matter yield observed in this study was higher than the value (3010kg /ha cut at 8weeks after sowing) reported by Mbahi and Gende (2016).

The crude protein (CP) content increased ($P<0.05$) with increasing level of nitrogen fertilizer with the highest CP value observed (19.94%) in treatment receiving 150kg N/ha (Table 1). It implies that as the level of nitrogen increases the CP content increases, this is because nitrogen promote rapid

growth, chlorophyll formation and protein synthesis. The result corroborates with that reported by Meena *et al.* (2017) who reported that the crude protein content of grasses significantly increases with the addition of urea fertilizer. Crude protein content obtained in this study was higher than the one (7.81%) reported by Mbahi and Gende, (2016).

There was significant (P<0.05) increase in ash concentration as the levels of nutrient increase up to 150kg N/ha. The maximum level of ash (17.54%) was recorded at 150kg N/ha fertility rate. The crude fibre, ether extract and nitrogen free extract concentration within the forage were affected negatively by nitrogen fertilization. The least values for CF (27.58%) and NFE (22.87%) were recorded in plots fertilized with 150kg N/ha. This might be due to higher crude protein content of *Pennisetum pediacellatum* at higher nutrient levels and protein content is negatively correlated with crude fibre. This agrees with reports of VanSoest (1982) and Coblentz *et al*. (2017) that nitrogen fertilizer results in increased concentration of CP with concomitant reductions in water-soluble carbohydrates and crude fibre.

Table 1. Effect of Nitrogen Levels on Forage Yield and Quality

Parameters	**Nitrogen level**			
Forage yield (kg /ha)	**100kg N/ha**	**125kg**	**150kg**	**SEM**
Fresh forage yield	21,444.00^{c}	25,778.00^{b}	29,444.00^{a}	2,276.00*
Dry forage yield	2,788.00^{c}	3,609.00^{b}	3,828.00^{a}	308.84.00*
Proximate compositions (%)				
Dry matter	18.30^{c}	20.17^{b}	21.02^{a}	0.40*
Crude protein	17.19^{b}	17.20^{b}	19.94^{a}	0.34*
Crude Fibre	32.11^{a}	29.91^{b}	27.58^{c}	0.66*
Ether extract	1.15^{a}	1.09^{b}	1.07^{c}	0.01*
Ash content	15.16^{c}	16.96^{b}	17.54^{a}	0.26*
Nitrogen free extract	34.06^{a}	34.84^{a}	22.87^{b}	7.54*

Means followed by similar letters within a row are not significantly different

CONCLUSION AND RECOMMENDATION

The result of this study indicated that application of 150kg N/ha gave highest fresh (29,444kg/ha) and dry (3,827.8kg/ha) weights, crude protein (19.94%) and ash (17.4%) contents whereas 100kg N/ha fertility level had relatively higher crude fibre (32.11%) and nitrogen free extract (34.06%). It is therefore, recommended that 150kg N/ha fertilizer rate be used for enhanced forage productivity and better animal performance in Gashua, Yobe State.

ABSTRACT
The present study evaluated the *in vitro* gas production and post-incubation parameters of concentrate diets containing varying levels of *Gliricidia sepium* leaves (GS) (0%, 10%, 20% and 25%). The experiment was set up in a completely randomized design.Gas production was measured at 3, 6, 9, 12, 15, 18 and 24 hours of incubation and the methane was estimated at the end of the 24th hour of incubation, volatile fatty acid profile was measured and post incubation calculations was carried out. Data obtained were analysed using one way analysis of variance. The result obtained showed that the crude protein content of diets increased as the inclusion of GS increased ($P<0.05$) from 0 to 25% (10.90% to 14.71%) while NDF values reduced ($P<0.05$) as the reduced as the inclusion increased (49.94% to 42.69%). Total gas and methane production at 24 hours were not affected ($P>0.05$) by inclusion of GS. Also, DMD and OMD values were not affected ($P>0.05$) by the inclusion of GS in the diets. This study concludes that when *Gliricidia sepium* is used at inclusion level of 10% or more, it has potential to modify the rumen thereby reducing gas production during fermentation resulting in higher post-ruminal nutrient utilization.
Keywords: Gliricidia, *in vitro*, methane, digestibility, diets.

INTRODUCTION
Ruminant livestock raised in the tropics tend to exhibit cyclical variation in the quantity and quality of the available forages (Bamikole and Babayemi, 2008). This is so because, during the dry season, ruminant feeding systems depend on poor quality tropical foliage Poor nutrition results in low production performance, slow growth rate, loss of body condition and increased susceptibility to diseases and parasites. These poor quality forages are usually augmented with crop residues or agro-industrial by-products (Oni *et al*., 2012) and a number of browse plants worldwide serve as alternative feedstuffs for livestock (Rinehart, 2008; Fayemi *et al*., 2011). As a result, animals under semi-intensive and free-range systems have been observed feeding on them (Isah *et al.,* 2007). Proteinaceous legumes like *Gliricidia sepium* are abundantly found in the tropics and considered as high quality leguminous forage due to its high protein content with good amino acid profile. The incorporation of such resources into concentrate diets for ruminant feeding in combination with other crop residues and agro-industrial by-products will help combat both the challenge of dry season low feed quality and might also lead to a reduction in the cost of protein ingredients used in formulating ruminant diets.The *in vitro* method of feed evaluation for ruminants has gained wider acceptance due to its ease of adoption, repeatability, minimized use of animals and the decrease in funding of the in vitro evaluation of feeds (Getachew *et al.,* 2005).The objective of this study was to evaluate the chemical composition, *in vitro* total gas and methane production of concentrate diets containing *Gliricidia sepium* leaves.

Materials and Methods
The experiment was carried out at Animal Nutrition Department Laboratory, Federal University of Agriculture Abeokuta, Ogun state, Nigeria. The experimental design was a completely randomized design (CRD) with four concentrate diets formulated through the use of *Gliricidia sepium* leaves (GS) at varying levels (0%, 10%, 20% and 25%) along with cassava peel, cassava leaves, palm kernel cake, rice bran, wheat offal, salt, oyster shell and sulphur. Rumen fluid was collected using the method of collection described by Babayemi *et al* . (2006). Rumen liquor was collected from cattle into warm insulated flasks and used as the source of inoculums The *in vitro* gas production procedure by Menke and Steingass (1988) was employed for the experiment. A sensitive scale was used to measure 200mg of substrate, replicated five times and were placed into 50ml calibrated plastic syringes fitted with

plungers. The rumen fluid (inoculum) was filtered through layers of cheesecloth and mixed with buffer at a ratio of 1:2 (v/v), and resazurin dye was added to sustain the activities of microbes. Fifteen millilitres of the buffered inoculums was then added to each syringe containing the milled samples and the gas released was read directly on the graduated syringe. The syringes were placed in an incubator kept at 40°C along with blank syringes containing only 15ml of the buffered inoculums. The syringes were shaken at regular intervals to simulate rumen motility. Gas production was recorded for 24 hours of incubation at 3-hour intervals. The volume of methane gas from each sample was determined by dispensing 2mls of 0.4 sodium hydroxide (NaOH) in to the sample at the end of 24 hours of incubation (Fievez *et al* ., 2005). Analysis of chemical composition was done according to the methods of AOAC (2000).

Data obtained from this experiment were analysed using one-way analysis of variance option of the SPSS (IBM SPSS Statistics 23) software. Treatment means were statistically compared using Duncan's Multiple Range Test to identify differences between means and significant differences were declared if $p<0.05$.

Results and Discussion

Chemical composition of concentrate diets containing varying levels of *Gliricidia sepium* leaves is presented in Table 1. The result shows that there were significant ($P<0.05$) variations across the various levels of inclusion. Dry matter (91.19%), NDF (49.94%) and ether extract (4.39%) and metabolizable energy (8.19 MJ/kg) values were higher ($P<0.05$) in the control diet (0% GS) while the highest ($P<0.05$) crude protein value (14.71%) in the diet containing 25% GS. It is observed that the dry matter values reduced with increase in the level of GS while the NDF values also followed the same trend. The lowest ($P<0.05$) DM and NDF values were obtained in diets containing 25% GS (89.15% and 42.69%).

Table 1: Chemical composition of concentrate diets containing varying levels of *Gliricidia sepium* leaves

Parameters	0%	10%	20%	25%	SEM	P-value
Dry matter (%)	91.19^{a}	89.74^{b}	89.38^{c}	89.15^{c}	0.243	0.00
Crude protein	11.25^{d}	10.90^{c}	13.70^{b}	14.71^{a}	0.487	0.00
NDF	49.94^{a}	47.47^{b}	43.46^{c}	42.69^{d}	0.897	0.00

The effect of inclusion of *Gliricidia sepium* at various levels on in vitro gas volume is presented in Table 2. Volume of gas produced at 6th and 12th incubation hour is significantly different ($P<0.05$) with 0% Gliricidia having the highest value in both period. At other time of incubation, volume of gas produce is not significantly ($P>0.05$) affected by the inclusion levels of *Gliricidia sepium*. The highest gas volume at 24th hour of incubation is (20.67ml) obtained from the control diet.

Table 2: Effects of inclusion of *Gliricidia sepium* on *in vitro* gas production

Incubation time	0%	10%	20%	25%	SEM	P-value
3	0	0	0	0	0.000	-
6	1.33^{a}	0.67^{ab}	0.00^{b}	0.00^{b}	0.195	0.01
12	10.67^{a}	8.33^{ab}	5.67^{b}	5.33^{b}	0.830	0.04

OMD (%)	39.12	35.96	36.49	36.00	0.961	0.67

SEM: Standard error of mean

Dry matter (DM) values obtained in this study are similar to the range of 85.70 to 95.86 % reported by (Asaolu*et al.,* 2012) for fodder, with the lowest at 25% Gliricidia. The CP content range between 10.9 and 4.71% which is above the minimum level for maintenance of 7.70 % for goats (NRC, 1981), with the highest obtained at 25% Gliricidia (14.71%) and low at 10% Gliricidia (10.9). The CP is in agreement with the minimum of 8 % CP observed by (Norton 1994) to provide the ammonia levels required by rumen microbes for optimum activity. The CP (10.90-14.71%) and the in vitro digestibility (81.67-91.00%) is not in agreement with the range of (18-30 %CP) and (60-65% DMD) reported by Cook *et al*. (2005). Organic matter digestibility value was observed to be the highest at 0% Gliricidia. Feedstuffs that are inherent with certain anti-nutritive factor had been reported to be low in organic matter digestibility (Aregheore and Abdulrazak, 2005).

This study result is in accordance with report given by Gillespie (1998) that NDF is inversely related to the plants' digestibility. The higher the NDF (49.94) the lower the plant's digestibility (81.67) and vice versa. The values obtained for the various Gliricidia levels may imply a moderately high cell wall contents with all having different effects on the various level of Gliricidia and expressed on Dry matter (DM) basis.

The inclusion of *Gliricidia sepium* at various level does not affect the gas production with the lowest value of methane at 20% inclusion of *Gliricidia sepium*. Changes in methane production with increasing inclusion levels of *Gliricidia sepium* can be attributed to the tannin content which was also reported by Jayanegara *et al.* (2011). It has also been observed that a decrease in CH_4 production occurs with the inclusion of *Gliricidia sepium* in ruminant diets (Sebata *et al*., 2011). In addition, it was reported that with an increase in tannin concentration in browse species, a reduction effect on methane production was found (Sultan *et al*., 2012). The impact of tannins on methane production varies with tannin chemical structure (plant origin) as well as with its concentration.

CONCLUSION AND RECOMMENDATIONS

From the results of this study, it can be concluded that the chemical composition of diets were improved by inclusion of *Gliricidia sepium* leaves. It was also noted that gas production reduced as the inclusion increased. It is recommended that *Gliricidia sepium* leaves can be included in concentrate diets for ruminants at values above 10% of the total feed. Further studies are therefore recommended to investigate the response of animals in a feeding trial to these diets.

ABSTRACT

Methane (CH_4) production and fermentation of a maize stover-based substrate in response to inclusions of cinnamon powder (CNP) were evaluated using the *in vitro* gas technique. Substrate (200 mg) consisting of maize stover and concentrate in ratio 6: 4 was incorporated with CNP at levels of 0, 15 and 30 mg/g dry matter (DM) to make three different treatments. These were incubated *in vitro* in 100 ml glass syringes at 39℃ for 48 h with total gas and CH_4 production measured. Dry matter degradability (DMD), partitioning factor, microbial biomass and volatile fatty acids were also determined. Results showed that CNP reduced ($P < 0.05$) total gas volume, CH_4 production and DMD s with the least reduction at 30 mg/g DM inclusion. The partitioning factor increased ($P < 0.05$) with inclusion of CNP at both levels of inclusion. It was concluded that, inclusion of cinnamon powder at 15 and 30 mg/g DM has potentials to reduce CH_4 production in maize-stover based diet. The higher fermentation efficiency implied that cinnamon powder reduced the amount of gas produced per gram of substrate degraded which implied better rumen fermentation efficiency.

Keywords: Maize stover, *in vitro*, fermentation, methane, cinnamon.

INTRODUCTION

Maize stover is one of the abundant crop residues for ruminant feeding, particularly during the dry seasons (Methu *et al*., 2001; Tang *et al*., 2011). Limitations to feeding these fibrous carbohydrates to ruminants include low digestibility and CH_4-shifted digestion (Gemeda and Hassan, 2015). Ruminants fed crop residues produce more CH_4 than those fed high quality forages (Berhanu *et al*., 2019). Rumen CH_4 asides from posing a threat to the environment via increase in greenhouse gas emissions, also reduces feed energy utilization by ruminants. It accounts for up to 12% loss of dietary gross energy intake (Chaudhry and Khan, 2012) or up to 15% depending on the diet (Patra *et al*., 2010). With the value of crop residues as feed resource for ruminants, it is beneficial to optimize their utilization by reducing CH_4 emission attributed to their digestion within the rumen. Spices are recognized as potential agents to reduce enteric CH_4 emission due to the presence of plant secondary metabolites which exert antimicrobial activities (Patra *et al*., 2006; Khan and Chaudhry, 2010; Chaudhry and Khan, 2012). According to Khan and Chaudhry (2010), they can be used to enhance the utilization of low quality forages and reduce nutrient wastages by ruminants. This study therefore, evaluated the effect of cinnamon powder on CH_4 production and rumen fermentation of maize stover-based diets for ruminants.

MATERIALS AND METHODS

Experimental site

The experiment was conducted at the Animal Nutrition laboratory of the Federal University of Agriculture, Abeokuta. The area is located in the South-western zone of Nigeria and falls within Latitude 7°13'23.8" N and Longitude 3°26'25.4" E (Google map, 2018).

Preparation of cinnamon powder

Cinnamon sticks were sourced from a local market within Abeokuta and was ground to pass through 1 mm sieve. Ground samples were stored at room temperature in air-tight glass container for subsequent use for chemical analysis and for *in vitro* study.

Experimental diets used as substrate

The substrate degraded consisted of 60% Maize stover and 40% concentrate (DM basis). Cinnamon powder was included in the substrate as feed additive at varying levels of 0, 15 and 30 mg/g DM to make three different experimental treatments. The maize stover used was collected from a maize field after the harvesting of maize grains. Samples (n=3) of the maize stover were chopped, weighed and

oven-dried at 60℃ until constant weight for DM determination and subsequently milled through 1 mm sieve. The compounded concentrate consisted of 44% wheat offal, 38% rice bran, 15% brewers' dried grain, 2% bone meal and 1% salt. Concentrate samples (n=3) of known weight were similarly oven-dried for DM determination.

In vitro total gas and CH_4 production measurement

The *in vitro* total gas production was measured using the *in vitro* gas technique (Menke and Steingass, 1988). Approximately 200 mg of substrate was weighed into 100 ml glass syringes using ten syringes per treatment. Each of the syringes were filled with 30 ml inoculum. The inoculum was a mixture of a medium solution and rumen liquor at ratio 2: 1. The tip of the syringes were fitted and sealed with a rubber tube to prevent escape of gas. The syringes were incubated at 39℃ for 48 h with gas readings recorded at three hours interval from 0 to 48 h. The incubation procedure was handled under continuous anaerobic conditions. Four blanks were included in the run to correct for gas production not arising from feed degradation. Methane was determined (n=4 per treatment) at 48 h incubation according to Fievez *et al.* (2005).

Determination of dry matter degraded and fermentation parameters

At 48 h incubation, contents of each syringe (n=6 per treatment) were filtered through Whatman filter paper (grade 1, 11µm pore size). The supernatants were collected into tubes and used for total volatile fatty acids determination following the titration method of Barnett and Reid (1957). The filtered residues were oven-dried at 105℃ overnight to determine DM degraded. The DM degradability (mg/g DM) was then calculated as difference between dry matter content of substrate incubated and that of its residue. Partitioning factor and microbial biomass production were estimated according to Blummel *et al*. (1997).

Chemical analysis

Dried samples of maize stover, concentrate, and CNP were analyzed for proximate and fibre composition following the procedure of AOAC (2000) and Van Soest *et al*. (1991), respectively. Metabolizable energy was estimated according to De Boever *et al.* (1997). Samples of cinnamon powder were further analyzed for phytochemical constituents such as tannin, saponin, flavonoids, oxalate, alkaloids and total phenol following standard procedures.

Experimental design and statistical analysis

The experiment was laid out as a completely randomized design. All data were subjected to one-way analysis of variance (SAS, 2002). Significant differences were accepted at $P \leq 0.05$. Significant means were separated using Duncan multiple range test (SAS, 2002).

RESULTS AND DISCUSSION

Chemical composition of diets used as substrate is presented in Table 1. Maize stover had a high neutral detergent fibre, acid detergent fibre and low crude protein which is typical of maize stover as previously reported (Fon *et al*., 2012). The concentrate with a higher crude protein content served as an additional source of protein. Phytochemicals in CNP is shown in Table 2. Cinnamon powder contained a high flavonoids content followed by saponin and tannin. These phytochemicals are plant secondary metabolites (PSM) described as naturally occurring biochemical compounds in plants and considered to serve as defense mechanism for plants survival (Bodas *et al*., 2012).

Table 1. Chemical composition (%) of experimental maize stover and concentrate

Parameters	Maize stover	Concentrate
Dry matter[1]	38.12	95.43
Crude protein	5.27	15.04
Organic matter	92.20	93.64
Neutral detergent fibre	68.75	51.32
Acid detergent fibre	37.28	23.70
Acid detergent lignin	11.53	8.86
Metabolizable energy (MJ/kg DM)[2]	12.32	12.68

[1]On as-received basis; [2]Estimated according to De Boever *et al*. (1997)

Table 2. Phytochemical composition (g/kg) of cinnamon powder

Parameters	Concentration
Tannin	56.36
Flavonoids	72.08
Total phenolic acid	44.10
Saponin	60.21
Oxalate	1.45
Alkaloids	32.32

Total gas volume, CH_4 production and DM degradability reduced ($P < 0.05$) with CNP inclusion in maize stover-based substrate at both 15 and 30 mg/g DM inclusion levels while total volatile fatty acids and microbial biomass were unaltered ($P > 0.05$) compared to the control (Table 3). The reduction effect suggested inhibition of microbial activity to ferment substrate since gas production in the rumen is a direct product of substrate fermentation by rumen microbes. Similar reduction effect of cinnamon on CH_4 and DM degradability from wheat-based substrate was reported by Chaudhry and Khan (2010). The observed reduction effect of CNP was attributed to the antimicrobial properties of phytochemicals in CNP. Condensed tannins have been reported to reduce methanogenesis through direct toxic effect on methanogenic archaea (Bodas *et al*., 2012). Saponin reduction effect on methanogenesis was linked to inhibition of protozoa activity (Bodas *et al*., 2012). Antimicrobial effect of flavonoids on dry matter degradation and methane production *in vitro* has similarly been reported (Oskoueian, 2013). A higher ($P < 0.05$) partitioning factor was observed with increasing levels of cinnamon powder. Partitioning factor is a measure of fermentation efficiency (Jimenez-Peralta *et al*., 2011). This implied that less gas was produced per unit of substrate degraded suggesting better utilization of organic matter in substrate.

Table 3. *In vitro* methane production and fermentation of maize stover-based substrate containing varying levels of cinnamon powder

	Levels of CNP in substrate degraded				
Parameters	**0**	**15**	**30**	**SEM**	***P*-value**
In vitro dry matter degraded, mg/g	345.0[a]	249.2[b]	236.7[b]	18.30	0.019
In vitro total gas production, ml/g DM	162.5[a]	136.7[b]	124.2[b]	5.52	0.006
CH_4 production, ml/g DM	57.5[a]	29.6[b]	28.1[b]	3.63	<0.001
Partitioning factor	3.3[b]	4.1[a]	4.5[a]	0.16	0.034
Microbial biomass production (mg/g DM)	218	184	175	13.42	0.399
Total volatile fatty acids (mM/100 ml)	12.19	11.41	10.95	0.37	0.394

[a,b]Means along the same row with different superscripts are significantly different ($P < 0.05$); CNP: cinnamon powder

CONCLUSION AND RECOMMENDATION

From this study, 15 and 30 mg of cinnamon powder per gram of maize stover-based substrate reduced CH_4 production and dry matter degradation similarly, with no change in total volatile fatty acids and microbial biomass *in vitro*. Inclusion level of 15 mg/g DM can therefore be recommended for mitigating methane production in ruminant diets based on maize stover. However, studies *in vivo* are required to confirm the effects of these reductions on animal performance.

ABSTRACT

The leaves and seeds of *Clitoria ternatea* were evaluated for the proximate, mineral and anti-nutritional composition. Atomic absorption spectrometry were used in determination of the seeds and leaves for Phosphorus (P%), Potassium (K%), Magnesium (Mg%), and Calcium (Ca%) were also determined using appropriate technique. The result of proximate analysis indicate that leaves and seed have high crude protein (26.75% and 48.30%), dry matter (93.82% and 90.50%), Ash (6.90% and 7.50%), crude fiber for both leaves (11.70%) and seed (8.10%) while the ether extract for leave (5.31%) and seed (7.90%). Mineral analysis indicate the *Clitoris ternatea* leave and seeds contained some essential mineral such as %P (0.40%) leave and (0.35%) seeds, %K (1.13%, 0.78%), % Mg (0.30%, 0.26%) and %Ca (0.37%, 0.34%)for leave and seeds for *Clitoris ternatea*. The overall result suggested that *Clitoria ternatea* leaves and seed is of high nutritionally quality due to high protein and mineral contents.

Keywords: *Clitoris ternatea*. Proximate, Mineral Composition, leaves and seeds

Description of Problem

Livestock usually derive most of their dietary nutrient from plant materials. However, as a result of high temperature region in the tropics, it stimulates the growth and aging of the plants with a consequent fall in nutrients and digestibility. This changes in nutritional quality results in very irregular growth and marked fluctuation in seasonal weights gains of the animals (Smith *et al.,*1989). A large number of leguminous leaves and seeds are able to meet the nutrient requirements of small ruminants for production (Akinlade *et al.,*2004). The *Clitoria ternatea* is a high – quality protein-rich legume, a tropical "alfalfa" often referred to as a protein bank that can be grown at low cost (Cook *et al.,*2005). *Clitoria ternatea* is palatable and has high nutritive value, with a higher leaf nitrogen percentage and lower acid digestible fibre than most other tropical legumes. As a result of poor nutrition which is major constraint to livestock production, especially during the dry season when available feed quantity is low and quality extremely poor (Alhassan, 1987). There is need to mitigate the problem with the use of sown and purposely managed pastures. The shortage of feed for ruminants can be solved through cultivation of forage crops with better nutritional values than the existing feed resources. This can be achieved with the establishment of leguminous forage (Poppi and McLennan, 1995). Furthermore, to improve livestock productivity in Nigeria, sustainable solutions to essential deficiencies in feed availability and quality are required. A number of pasture legumes such as *Centrosema, Desmodium, Canavalia* and *Glycine* have been tried in Nigeria, but the minor information is on *C. ternatea* compared with those legumes mentioned above. The objective of the study was to assess the nutritional contents of *C. ternatea* leaves and seed.

Materials and Methods

Experimental Site

The experiment was conducted at Teaching and Research Farm of Oyo State College of Agriculture and Technology, Igboora in the derived Savannah zone of Nigeria. The College is located within $7^0$15'North and $3^0$30' East of the equator with an average annual rainfall of 1278mm and average annual temperature of 27^0C (Sanusi, 2011).

Collection of Plant Materials
The leaves and seeds of *Clitoria ternatea* were all obtained from pasture demonstrated unit, Teaching and Research Farm. The seeds were then separated from their shells, dried appropriately, milled with blender and stored in air-tight containers until required for analysis.

Proximate Analysis and Mineral Analysis
The leaves and seeds were analyzed for moisture content, ash, crude fat, crude protein and crude fiber were determined in accordance with the Standard Methods of the AOAC, (1990).
The minerals such as K, P, Mg, Ca, Fe and Zn were determined by the atomic absorption spectrophotometric method. Phosphorus was determined spectrophotometrically using the vendates solution (Sekine, *et al.* 1965).

Statistical Analysis
The data collected were subjected to Student T test of SAS package.

RESULTS AND DISCUSSIONS
Proximate composition
The proximate composition of both leaves and seed of *Clitoria ternatea* is shown in Table 1. The high dry matter content obtained on both seeds and leaves of *Clitoria ternatea*. The percentage ranged (90.50 – 93.82%), indicating high shelf – life of the leave and seed hence long storage would not lead to much spoilage due to its susceptibility to microbial attack especially of drying. The percentage Crude Protein of leaves (26.95%) and seeds (48.30%) were above 17.5% recorded for *Stylosanthes hamata* leaves (Akinlade, *et al*., 2007). The higher crude protein recorded for both seed and leaves of *Clitoria ternatea* in the present study above 7% CP requirement for ruminant animal which will provide ammonia requirement by the rumen microorganism to support optimum microbial activity. The Ash content value of *C. ternatea* leave (6.90%) and seed (7.50%) were observed to be higher than value (0.11%) reported for *Mucuna utilis* leaves by Ujowundu *et al*., (2010), The ash values for both seed and leaves obtained for the present study fell within the range of 3.0 – 9.65% (Okoli, *et al*., 2001). Ash content useful in assessing the quality grading of mineral element present in the *C. ternatea* leave and seeds. Ether extract content of *C. ternatea* seed (7.90%) and leaves (5.31%) which were higher than (1.89%) reported for *Canavalia ensiformis* leaves (Akinlade, *et al*., 2007). Also higher than the 1.9% Ether extract for lablab seed (Osman, 2007).The Crude Fiber content of *C. ternatea* leave (11.70%) and seeds (8.10%) were lower compared with (14.80%) of *Mucuna utilis* leaves reported by Ujowundu, *et al* (2010) and 23.80% for *Stylosanthes hamata* (Akinlade, 2004). Arukwe *et al,* (2012) reported that 3.10% obtained for *Persea ameneansn* seed but lower than 8.10% recorded for *C. ternatea* seed. The crude fiber content of both seed and leaves samples did not fall within the range of 15 – 20% recommended for improved intake and production in finishing ruminant (Buxton, 1996).

Table 1: Proximate contents of seed and leaves of *Clitoria ternatea*

Proximate (%)	Leaves (%)	Seeds (%)
Dry matter	93.82	90.50
Crude protein	26.95	48.30
Ash	6.90	7.50
Ether extract	5.31	7.90
Crude Fibre	11.70	8.10

Mineral composition
The mineral analysis of both leaves and seeds of *Clitoriaternatea* indicated their richness in Phosphorus, Potassium, Magnesium, Calcium and Iron in Table 2.The mineral analysis of a plant gives the idea of possibility either the plant should be used for any feeding trial purpose. The phosphorus content for leave (0.40%) and seed (0.35%) were higher compared to the NRC recommended value of 0.15% for Phosphorus (NRC. 1985). The level of Phosphorus in both the seed and the leaves of *C. ternatea* was consistently above the 0.2% level which would satisfy livestock

dietary maintenance requirement (NRC. 1985). The value of Potassium (%K) in both seed (0.78%) and leave (1.13%) were higher than (0.46%K) for *Canavalia ensiformis* leaves by (Akinlade, *et al.*, 2007) and for seed of *Brachystegia eurycoma* harms (0.25%) in the present investigation the level of %K in *C. ternatea* leaves was over 0.18% recommended for grazing animals (McDowell, 1985). Potassium help to maintain body weight and regulate water and electrolyte balance in the blood and tissue (NRC, 1985). Magnesium (Mg) content for leave (0.30%) and seeds (0.27%) both were higher than value 0.20% reported for *Canavalia ensiformis* leave by (Akinlade, *et al.*, 2007). The higher forage and seed Mg level found in this present study were above 0.12 – 0.20% of requirement of ruminants diet suggested by NRC, (1985).The Calcium (Ca) content of both seed (0.34%) and leave (0.27%) were higher than (0.09%) observed in *Canavalia ensiformis* leave by (Akinlade, *et al.*, 2007). The leaves and seed Ca values found in this study were considered adequate for the optimum performance of ruminants. The values of both leaves (0.37%) and seed (0.34%) of %Ca for *Clitoria ternatea* would meet the theoretical Ca requirement of 0.30% %Ca diet needed for all forms of production in ruminants (ARC, 1980).

Table 2: Mineral composition of seed and leaves of *Clitoria ternatea*

Mineral Content	Leaves	Seeds
Phosphorus (%)	0.40	0.35
Potassium (%)	1.13	0.78
Magnesium (%)	0.30	0.27
Calcium (%)	0.37	0.34

CONCLUSION AND RECOMMENDATION

It can be concluded from the results from this study that the *Clitoria ternatea* leaves and seed appeared to have the potential as feed supplements. Higher content of protein and minerals contents would make them good protein supplements to poor quality roughages especially during the dry season of the derived savannah zone of Nigeria.

ABSTRACT

An experiment was conducted to evaluate the forage yield of Lablab (*Lablab purpureus L*) during the 2018 cropping season at the Teaching and research farm of the College of Agriculture and Animal Science, Ahmadu Bello University, Mando Road, Kaduna. Treatments consisted of three phosphorus fertilizer rates (0, 20, and 30 kg/ha) and three plant spacing (20cm x 30cm, 25cm x 30cm, and 30cm x 30cm), laid out in a 3x3 factorial arrangement in a randomized complete block design with three replications. The results of the experiment showed that phosphorus fertilizer rates significantly ($p<0.05$) affected plant height, number of leaves/plant and dry forage yield at 6 and 9 weeks after sowing. However, number of leaves was not affected by phosphorus fertilizer application rates across the sampling periods. Plant spacing at (25cm x 30cm and 30cm x 30cm) have significantly increased ($p<0.05$) plant height and total dry forage yield. It can be concluded that 30kg /ha of phosphorus fertilizer application rate and plant inter-row spacing at 30cm x 30cm, produced the highest dry forage yield of Lablab. Famers in Northern ecological zone of Nigeria can adopt the application of phosphorus fertilizer at 30kg/ha and using wider spacing of 30cm x 30cm for better yield of Lablab, thereby increasing farm output and animal performance.

Key words: Lablab, phosphorus rates, plant spacing, forage, yield

INTRODUCTION

In Nigeria, Lablab (*Lablab purpureus* L.) as forage crop is grown mostly in research and experimental farms. Despite the importance of *Lablab* in our diet and as feed for livestock, the yield obtained by farmers in Nigeria is low, because of the problem of neglecting good cultural practices such as fertilizer application and plant spacing. To achieve maximum yield of *Lablab*, agronomic factors must be at their optimum, such as phosphorus fertilizer application rates and plant spacing (Karachi, 1997). Phosphorus fertilizer plays significant roles in increasing the plant height, number of leaves and dry forage yield of *Lablab*. Similarly, management of *Lablab* using intra-row spacing has been used to increase its productivity (Pandita and Randhawa, 1994). The objectives of the study were to determine the effect of phosphorus fertilizer rates (0kg/ha, 25kg/ha, and 30kg/ha) and inter-row spacing at different level (20cm x 30cm, 25cm x 30cm and 30cm x 30cm) on growth components and yield of *Lablab*.

MATERIALS AND METHODS

The study was conducted at the pasture and range unit of teaching and research farm, College of Agriculture and Animal Science, Ahmadu Bello University, Mando Road- Kaduna. The farm is located at an elevation of 676m and latitude of 10°35'N and longitude of 7°25' E (GPS, 2018). The experiment was laid out in a 3 x 3 factorial arrangement in a randomized complete block design (RCBD) with three replications. There were three phosphorus rates (0kg/ha, 20kg/ha, and 30kg/ha) and three plant inter-row spacing (20cm x 30cm, 25cm x 30cm, and 30cm x 30cm). The Seeds of *Lablab purpureus* were planted at about 2 cm depth using a seed rate of 10 kg/ha. Planting took place when rain was established in July 2018. First and second weeding were carried out manually with hoe at 3 and 6 weeks after sowing, respectively. There was a total of 27 plots inform of basins measuring $4m^2$ with 1m inter-row path way. The growth components and yield parameters measured were as follows:

a) Plant height; the height of 5 tagged plants in each plot will be measured from the ground level to the tip of the plant using a meter rule at 6 and 9 weeks after sowing.
b) Number of leaves per plant; these will be obtained by counting and recording the average of 5 tagged plants in each plot.
c) Dry forage yield: Total fresh weight (TFW) of the material cut will be weighed immediately using

a hanging scale to determine the fresh forage yield. A sample of 150–200g fresh material (FWss) will be weighed, oven dried at 65°C for 48hrs and reweighed (DWss) to give an estimate of the dry-matter production during this period using the formula below by Tarawali *et al*., 1995.

Dry matter (kg/ha) = TFW x (DWss / FWss) x 10

Where: TFW = total fresh weight from 1 m^2 in g

FWss = fresh weight of the subsample in g

DWss = dry weight of the subsample in g

Data on plant height, number of leaves and dry forage yield were collected and subjected to analysis of variance by using procedure of Statistical Analysis System (SAS, 2003).

RESULTS AND DISCUSSION

Table 1 shows that, at 6 WAS application of phosphorus (30kg/ha) produced the tallest plants than the other rates, but at 9 WAS application of 20kg/ha and 30kg/ha of phosphorus fertilizer significantly ($p<0.05$) produced the longest lablab plants than the control. The effect of spacing on plant height shows that at 6 and 9 WAS, plant spacing of 30cm x 30cm produced the longest lablab plant, but statistically at par with application of phosphorus at 25cm x 30cm. The highest number of leaves of lablab was produced at 30kg/ha, but was statistically similar with application of 20kg/ha of phosphorous. Similarly, at 6 WAS, phosphorus fertilizer application rates at 30kg/ha statistically produced the higher dry forage yield of lablab, than at 0kg/ha and 20kg/ha. At 6 and 9 WAS, plant inter-row spacing of 20cm x 30cm produced the lowest dry matter yield of lablab plant. The results showed that plant height, number of leaves and dry mater yield significantly produced better results using phosphorus fertilizer rates at 20kg/ha and 30kg/ha. This might be related to plants having access to greater share of available nutrients (response to phosphorus) in the soil which resulted in improved growth performance. This is in consonance with the findings of Tanko *et al*., (2013) in which they reported that plant height and dry matter yield of lablab was better at 30kg/ha phosphorus fertilizer rate. Plant inter-row spacing significantly affected the performance of lablab. Plant inter-row spacing of 30cm x 30cm from the research, significantly gave tallest plant, higher number of leaves and dry mater yield of lablab. This is in line with the findings of Ahmed *et al.* (1988) who stated that wider plant spacing in lablab, recorded the highest plant height.

Table 1: Effect of phosphorus fertilizer rates and inter-row spacing on plant height and number of leaves of Lablab at 3, 6 and 9 weeks after sowing

	Plant height (cm)		Number of leaves		Dry forage yield (kg/ha)	
Treatment	6 WAS	9 WAS	6 WAS	9 WAS	6 WAS	9 WAS
SSP kg/ha						
0	29.93^{b}	36.29^{b}	13.20^{b}	16.60^{b}	59.33^{b}	89.02^{c}
20	33.42^{b}	42.89^{a}	15.53^{ab}	17.53^{ab}	104.46^{ab}	156.72^{b}
30	37.32^{a}	43.79^{a}	16.60^{a}	18.93^{a}	163.06^{a}	244.60^{a}
SEM	3.88	5.58	3.01	9.00	72.87	12.63
Spacing (cm)						
20 x 30	28.27^{b}	34.72^{b}	14.80	16.67^{b}	39.95^{c}	59.93^{c}
25 x 30	32.74^{ab}	41.84^{ab}	14.30	18.27^{ab}	65.24^{b}	97.87^{b}
30 x 30	35.10^{a}	42.91^{a}	14.33	26.00^{a}	82.78^{a}	135.62^{a}
SEM	3.88	5.58	3.01	9.00	72.87	12.63

Means within a column of any set of treatment group with unlike latters are significantly different at ($p<0.05$), SEM = Standard Error of Mean, WAS = Weeks after sowing.

CONCLUSION

Based on the findings of the study, famers could plant lablab using 30kg/ha phosphorus fertilizer application rate at wider inter-row plant spacing of (30cm x 30cm) for better growth components and forage yield.

ABSTRACT
The aim of determining the proximate analysis of red finger millet/*Tamba* (*Eleusine coracana*) was to ascertain its nutritional composition and its ability to be used as feed ingredient. Proximate analysis of red finger millet was carried out at the biochemistry laboratory of the department of Animal Science, Ahmadu Bello University, Zaria. The result of the analysis revealed that it contained Dry Matter-88.48; Crude Protein (CP)-13.98; Ether Extract (EE)-3.70; Crude Fiber (CF)-6.67; Ash-4.90; Nitrogen Free Extract (NFE)-59.22. Therefore, it can be concluded that finger millet is a nutritious feed resource and can be incorporated into animal feed. It is recommended for farmers to use it by incorporating it into livestock feed because of the prospects it has shown in the proximate analysis result.

Key words: Finger millet, Proximate, Feed resource, Analysis, Nutrients

INTRODUCTION
The term millet is derived from the French word "mille'' which means thousand, with a handful of millet containing up to 1000 grains (Shahidi and Chandrasekara, 2013). *Eleusine coracana* is called *kpana* by the Beroms, *tamba* in Hausa (Fernandez *et al.,* 2003). Millet belongs to the group of small seeded species of cereal crops or grains which are annual plants (Shiihii *et al*., 2011). The grain belongs to the family Poaceae which originated in Ethiopia and the sub-family *Chloridodeae* (Pradeep&Sreerama, 2015; Sood *et al*., 2016; Ramashia *et al*., 2018). The brown cultivar is utilized for brewing traditional opaque beer in Southern Africa (Sood *et al*., 2017). The grain is a semi-arid region crop cultivated in dry areas with limited rainfall and can adapt to various agro-climatic conditions (Gull *et al*., 2014). Hence, it is important to look at ways of how to economically and effectively substitute some of the conventional feed resources since they are becoming scarce and beyond the reach of the small and medium entrepreneur farmers. Hence, the proximate analysis to find out the nutritional contents of red/brown finger millet so that farmers can be encouraged to adopt its usage.

MATERIALS AND METHOD
Source of finger millet
The grain which is popularly called finger millet or *tamba* locally was purchased from Ganawuri local market located in Riyom local Government Area of Plateau State and Manchok in Kaduna State.

Determination of finger millet proximate composition
The proximate composition of finger millet was carried out at the biochemistry laboratory of the department of Animal Science, Ahmadu Bello University, Zaria, Kaduna State, Nigeria. The analysis was carried out according to the standard method of (AOAC, 2005).

RESULTS AND DISCUSSION
The proximate analysis results obtained for red finger millet revealed that it had a crude protein of 13.98%, The value obtained here is higher than 9.1g/100g recorded byRavishankar *et al*., (2003); D'Andrea *et al.* (1999) who reported 7.3%; Chethan and Malleshi, (2007) 5-8%, Gull *et al.,* (2015), Gupta *et al.,* (2011) 7.5 – 9.56, brown/red 8.7 g /100 g (Rao, 1994) for other members of the millet family, such as foxtail millet (10.29%), burnyard millet 6.93% (Verma *et al*., 2014), These differences could be due to the variations experienced in geographical locations and soils where the finger millet was planted or the amount of rainfall in those areas. Therefore, this high CP of red finger millet makes it a very nutritionally important ingredient for animal feed, since protein is very vital for normal functioning of the entire body system. Proteins are essential components of the diet needed for survival of animals and humans; their basic function in nutrition is to supply adequate amount of

required amino acids (Pugalenthi *et al*., 2004).

The ether extract or crude fat obtained from the analysis of red finger millet revealed that it had 3.70%. This is higher than what was reported by Ravishankar *et al*., (2003) 1.2g/100g, David *et al*., (2014) 0.83%, 1-2% (Chethan and Malleshi, 2007), 1.3-1.8% (Bhatt *et al*., 2003; Lupien, 1990). However, it is comparable to what was obtained 2.1% (Anthony *et al*., 1996).The differences and variations seen may be as a result of different methods of laboratory analysis by different laboratory personnel that carried out the analysis. High fat ingredients are suggested for inclusion in weight gaining diets because of the energy embedded in them. Leeson, (1997) reported that fats are widely used energy sources in addition to improving the consistency and palatability of mash feed.

The result of the proximate analysis revealed Ash content of 4.90% for red finger millet, this is higher than what was reported by David *et al*., (2014) 2.37%; 1.7% (Rao, 1994). The differences recorded may be due to the different types of fertilizer used and the methods of application found in those areas. This suggests that red finger millet has more content of inorganic or mineral in it. This result agrees with what was reported by Singh and Raghuvanshi, (2012) that the Ash content in finger millet is higher than what was obtained in the commonly used cereal grains.

The result of crude fiber showed that Red finger millet had 6.67%, This is higher than what was reported in foxtail millet 4.25% and burnyard millet 2.98% (Verma *et al*., 2014); 72% obtained by D'Andrea *et al* (1999). These wide variations could be as a result of using different cultivars on different soils with various rainfalls ranges, probably the stage of maturity at which the crop was harvested. Crude fiber is nutritionally important as it aids the absorption of trace elements in the gut and elimination of undigested waste through the bowel (Abolaji *et al*., 2007).

The nitrogen free extract (NFE) obtained from the result revealed that red finger millet had 59.22% which is lower than 72% obtained by D'Andrea *et al* (1999); 77.9g/100g (Ravishankar *et al*., 2003). These wide variations could be as a result of using different cultivars on different soils with various rainfalls.

Table 1: Proximate composition Finger millet (*Eleusinecoracana)*(%)

Parameter	**Composition**	
	Red colour	**Black colour**
Dry matter	88.48	87.55
Crude protein	13.98	13.14
`Ether extract	3.70	3.10
Crude fiber	6.67	7.02
Ash	4.90	4.36
Nitrogen Free Extract	59.22	59.84

ABSTRACT
A laboratory experiment was conducted to access the effect of immersion period in hot water and sulphuric acid pre-treatments on total germination of *Leucaena leucocephala* seeds. The experiment was arranged in a factorial combination of three (3) immersion time (for 2, 4 and 6 minutes) and pre-treatment methods (hot water at 80°C and diluted sulphuric acid at 10%) in a Completely Randomized Design with four (4) replicates. Results shows that immersing *Leucaena* seeds in hot water for 6 minutes recorded higher seed germination percentage (82.5%) followed by immersing seeds for 4 minutes (65%). The least seed germination percentage (35%) was recorded at 2 minutes. Total germination values increased as increasing immersion time up to 6 minutes. However among the immersion periods of the acid treatments, the highest germination percentage was recorded when seeds were soaked for 2 minutes (50%) followed by soaking in 4 minutes (25%) and 6 minutes (25%). It is therefore concluded that immersion of Immersing *Leucaena* seeds in hot water for 6 minutes was the best option to obtain rapid germination.
Keywords: *Leucaena,* germination, seeds, immersion

INTRODUCTION
Certain crops produce seeds with a characteristic thick wax layer covering the seed coat, thus preventing the easy penetration of moisture into the cotyledons, and hence inhibit germination, a phenomenon called seed dormancy. Seed dormancy refers to a state in which the viable seeds fail to germinate when provided with conditions normally favorable to germination such as adequate moisture, appropriate temperature regimes and light (Schmidt, 2000). Seeds of legumes such as *Leucaena leucocephala* are generally considered to have physical dormancy (Jayasuriya *et al.*, 2013). *Leucaena* is fast growing multi-purpose drought resistance tree species that is widely cultivated around the world for its highest wood production and wide ranges of uses which includes ruminants feed (Yige *et al*., 2012). Supplementing animal fed with dried *Leucaena* leaves will lead to higher weight gain (Rubanza *et al*., 2007). Notwithstanding, the planting and successful adoption of this drought tolerant forage is limited to some extent by water impermeability of the seed coat or 'hardseededness', caused by one or more water-impermeable layers of palisade cells in the seed or fruit coat (Baskin *et al.,* 2000). In nature, this seed coat dormancy may be overcome by abrasion, fire, drying, freezing/thawing, high or widely fluctuating soil temperatures and microbial activity (Baskin and Baskin, 1998). Thus several techniques to reduce the hard seed coat of forage seeds have been investigated over the years but little information is available on the immersion time to various seed treatment methods. Therefore, this study was conducted to evaluate the effect of hot water and sulphuric acid pre-treatment on total germination and germination period of *Leucaena leucocephala* seeds at different immersion time in Mando-Kaduna State.

MATERIALS AND METHOD
The laboratory trial was conducted in 2019 at the Entomology Laboratory of the College of Agric and Animal Science, Mando, Kaduna. Mature seeds of *Leucaena* were harvested from the The experiment was arranged in a factorial combinations of three (3) immersion time (for 2, 4 and 6 minutes) and pre-treatment methods (hot water at 80°C and diluted sulphuric acid at 10%) in a Completely Randomized Design with four (4) replicates. Ten seeds of *Leucaena* were placed in each petri dish (9cm diameter) lined with one layer of filter paper. The filter papers were moistened with addition of distilled water throughout the experimental period. The petri dishes were kept on laboratory table at room temperature of (30-36°C) and covered with lid to prevent moisture loss by evaporation. The seeds under hot water and sulfuric acid scarification were gently stirred periodically during the treatments,

then the seeds were washed repeatedly in running tap water until they were considered safe to handle. After that, the seeds were spread in a thin layer for shade drying. Total germination was measured as:

$$\text{Germination percentage} = \frac{\text{Number of germinated seeds}}{\text{Total number of seeds in petri dish}} \times 100$$

Data collected on were analysed using simple percentages.

RESULTS AND DISCUSSION

Immersing *Leucaena* seeds in hot water for 6 minutes recorded higher seed germination percentage (82.5%) followed by immersing seeds for 4 minutes (65%). The least seed germination percentage (35%) was recorded at 2 minutes. Total germination values increased as increasing immersion time up to 6 minutes. The unappreciable effects of immersing the seeds for lesser periods like the 2 and 4 minutes compared to the 6 minutes might be due to the low permeability or imbibitions of water and oxygen caused by short time exposure to hot water (Rincon *et al.*, 2003). However among the immersion periods of the acid treatments, the highest germination percentage was recorded when seeds were soaked for 2 minutes (50%) followed by soaking in 4 minutes (25%) and 6 minutes (25%). This indicates that immersion of seeds in sulphuric acid for 2 minutes quickly ruptured the seed coats, thereby resulted in high total germination (Bala, 2019). The author reported that, the harmful effect of immersing sulfuric acid for 4 and 6 minutes indicates that prolonged immersion of the seeds was injurious to seeds as the acid may damage the vital parts of the embryo.

Table 1. Effect of hot water and sulphuric acid pre-treatment on total germination and germination period of *Leucaena leucocephala* seeds at different immersion time

Immersion period	Immersion in 80°C H_2O	Immersion in 10% H_2SO_4
	Total germination (%)	Total germination (%)
2 minutes	35.00	50.00
4 minutes	65.00	25.00
6 minutes	82.50	25.00

C= Centigrade, H_2O=Warer, H_2SO_4= Hydrogen tetraoxosulphate (vi) acid

CONCLUSION

From the results obtained in this study, it was concluded that immersion of *Leucaena* seeds in hot water for 6 minutes was the best option to obtain rapid germination. It is therefore recommended that farmers should use hot water scarification to break the hard seed coat of *Leucaena* most especially where there is need for bulk pre-treatment.

CHEMICAL COMPOSITION OF MILLET PANICLE WASTE ENSILED WITH POULTRY MANURE AT GRADED LEVELS

N. kadi[2], Muftau, M. A[1]
Department of animal science, KSUSTA, Kebbi State

ABSTRACT
Millet panicle waste was ensiled with poultry dropping at graded levels; 90:10, 80:20, 70:30, 60:40 (millet panicle waste/poultry dropping) representing B, C, D and E respectively, and 100:00 (control) treatment A. The material ensiled were put in polythene bags replicated three times, the sample were sealed and allow fermentation to take place for a period of 21 days. The resultant silage was analyzed for pH, Crude protein (CP), Crude fiber (CF), Either Extract (EE), ash and Nitrogen Free Extract (NFE). There were significant differences ($p<0.05$) in all the parameters measured except that of Dry matter (DM). Ensiling millet panicle waste increased pH, CP, ash, EE, and NFE, but reduced CF with increased proportion of poultry dropping. Treatment C has the highest CP (4.38) and DM (93.50), with lower CF (1652) compared with control treatment with (33.73). The result suggested that ensiling millet panicle waste with poultry dropping improve its feeding value.

INTRODUCTION
Proper nutrition is necessary for optimum livestock production; unfortunately, there is shortage of forage supply during dry season for ruminant animal especially in the northern part of Nigeria. (Ruthender, 1980). There are many agricultural crop residues with great potential for ruminant feeding. One of such is millet by product known as millet panicle waste.

Presently, the consumption of millet is becoming more pronounced in the most of the northern region especially in villages and semi urban areas where there is availability of millet panicle waste especially during dry season in northern part of Nigeria when people engage in processing of millet. The panicle waste are thrown everywhere during this period of processing. Millet panicle waste is obtainable from processing of millet which is not use for any purpose. The waste are dumped in the water ways causing environmental havoc by blocking drainages or burnt by local people which causes additional environmental pollution by increasing the global warming effect.

Silage making is considered as a technology that increase livestock productivity and minimizes resource degradation and viable option for conserving succulent feeds (Muhammad et *al.,* 2008).
In view of this, the utilization of millet panicle waste as feed for ruminants will drastically reduce the above mentioned problems as well as solving the problem of feed scarcity especially in the dry season. The aim of this study is to find out the chemical composition of millet panicle waste ensiled with poultry droppings at different graded levels

MATERIALS AND METHODS
The experiment was conducted within the Animal Science laboratory of Kebbi State University of science and Technology.

Collection and preparation of experimental materials
Millet panicle waste was collected from processing points identified within and around Aliero LGA. All foreign materials (stones, irons, polythene) were removed. Poultry manure was obtained from Labana poultry farm Aliero. The collected millet panicle waste and poultry manure were sun dried to a constant weight by spreading on a concrete floor.

Ensiling procedure
The dried millet panicle waste used for silage was packed in a polythene bags to make compaction easier. (Ogunlolu *et al*; (2010). Millet panicle waste was ensiled with poultry manure in proportions, 100:00, 90:10, 80:20, 70:30 and 60:40, representing treatment A, C, D, and E respectively. Fifteen Polythene bags were used as laboratory silos (Ogunlolu *et al*; 2010). The samples were ensiled for 21 days in triplicates; masking tape was used to further seal the polythene bags after filling with weighed materials and compressed.

At the expiration of the ensiling period, the polythene bags were opened and top most materials was scooped off to avoid contamination with partially ensiled materials. The samples were taken using forceps from each ensiled polythene bag for pH determination and chemical analysis.

Experimental design and Data Analysis
A complete Randomized design (CRD) was used as outlined by Steel and Torrie (1980). There were five treatments designated as A, B, C, D and E with three replicates each.

Proximate analysis
Crude protein (CP) where measured using kjeldhl method (Nx6.25) while other proximate constituents, Either extract (EE), Ash, Crude fiber (CF) and Nitrogen Free Extract (NFE) were measured according to procedure described by AOAC (2005).

Data analysis
Data were analyzed using the general linear model procedures of the (SPSS 2007), and mean separation was done using Duncan multiple range test (DMRT) at 5% probability level.

RESULTS AND DISCUSSION

Table 1: pH properties of ensiled millet panicle waste

Treatments		**pH**
A	100:00	5.45^{c}
B	90:10	5.71^{c}
C	80:20	6.11^{bc}
D	70:30	7.69^{ab}
E	60:40	8.45^{a}
SEM		9.39

abc: means on the same row with different super scripts are significantly ($p<0.05$) different

Table 1: present the pH reading of the silage. Significant differences ($p<0.05$) were observed among the treatments. The highest pH was recorded in treatment E(8.45) with the least in treatment in treatment A. (4.45). This is in accordance with the findings of Rasool *et el*. (1998) Who reported an increase in initial and subsequent pH in sudax grass ensiled with 30% broiler litter and 9%molasses.

Table 2: Proximate analysis millet panicle waste

	Treatments					
Parameters	A (0%)	B (10 %)	C (20 %)	D (30%)	E (40%)	SEM
DM	94.00	92.50	93.50	92.00	91.75	12.27
CP	3.15^{d}	3.68^{c}	4.38^{a}	3.99^{b}	3.98^{b}	0.069
CF	33.73^{d}	22.46^{c}	19.30^{b}	21.06^{bc}	16.52^{a}	7.89
EE	4.25^{ab}	4.05^{ab}	4.95^{ab}	3.25^{c}	5.51^{a}	7.89
ASH	4.25^{d}	6.75c	8.25^{b}	12.25a	11.75a	8.74
NFE	20.47^{d}	75.32^{b}	77.63^{a}	972.02^{c}	72.77^{c}	10.39

abcd: means on the same row with different superscripts are significant ($p<0.05$) different.

Table 2: shows the proximate composition of millet panicle waste. There is no significant ($p<0.05$) difference in the dry matter among the treatments. However, the highest value was obtained in treatment A (94:00) and the least was recorded in treatment E (91.75). This contradicts with Al Rokayan *et al*. (1998) who reported an increase in the dry matter when broiler litter was ensiled with sorghum forage in the proportions of 0:100, 25:75, 35:65, and 45:55.

The values of CP of the resultant silage was observed to have increased ($p<0.05$) with increase proportion of poultry droppings. The CP was highest in treatment C (4.38) than B, D, and E although

the increase was not steady across the treatments. This is in line with Ngele *et al*. (2006) who reported an increase in the CP when rice straw was treated with broiler litter at different ratios.

There was significant difference ($p<0.05$) in CF composition of the silage among the treatments. CF of all treatments is lower than the control, the CF was observed to decrease with increased proportion of poultry dropping from (22.46) in treatment B to (16.52) in treatment E. This is in accordance with the findings of Rasool *et al*, (1998) who observed decreased in CF when sudax grass was with broiler litter and molasses.

The EE components of the treatments were significantly ($p<0.05$) affected, the highest EE was recorded in treatment E (5.51) and the least was recorded in treatment D (3.25). The result of this study agreed with that of Mthiyan *et al*. (2001) who observed an increase in EE composition of sugar cane top ensiled with broiler litter and that of Ngele *et al* (2006).

Ensiling millet panicle waste with poultry dropping increases ($p<0.05$) ash content of the resultant silage. Treatment D has highest value (12.25) compared with treatment E, C, B and the control which has least value of (4.25). This is in agreement with the findings of Al Rokayan *et al*. (1998) and that of flachowsky and Hennig (1990) who observed a linear increase in ash content with increased proportion of broiler litter.

Nitrogen Free Extract of the millet panicle waste ensiled with poultry dropping increases ($p<0.05$) with the increase in the level of poultry dropping with treatment C having the highest value (77.63) and the least was recorded in treatment A (20.47). This observation agreed with the findings of Baba *et al*. (2010).

CONCLUSION

Poultry dropping improved the nutritive value by increasing the CP and lowering the CF of the waste.

INTERCROPPING MULTIPURPOSE TREES (MORINGA, ALBIZIA AND LEUCAENA) WITH MAIZE AND ITS UTILIZATION AS DRY SEASON FEEDS FOR RUMINANTS IN SOUTHERN GUINEA SAVANNAH, NIGERIA

D.O Ogunbosoye[1,*] & Afe A.I[2]

*[1]Department of Animal Production, Fisheries and Aquaculture, Kwara State University, Malate Nigeria: [2]Department of Crop Production, Kwara State University, Malete, Nigeria; *Corresponding author (olufunflory@gmail.com); Phone No. +2348038262722*

ABSTRACT

A field trial was carried out to investigate the suitable cropping pattern in browse trees (Moringa, Albizia, and Leucanea)/maize system and their utilization as dry season fodders. Full population of browse trees were intercropped with full population and fifty percent population of maize in a 2x3 factorial in split plot arrangement and replicated four times. Cropping pattern involving combinations of full population of browse trees and maize recorded higher plant height than those involving intercropping combination of 50% full population. Sole maize significantly had longer cobs than those at the intercrops. There was no significant difference in maize cob length between the three cropping patterns. Number of seed/cob of maize at combination of 50% full maize with browse trees were higher than when full population of maize was intercropped. Intercropping involving maize at full population produced higher grain yield than 50% full population. The highest grain yield (2.33t/ha) at the intercrop was obtained at combination of full population of maize with Albizia. Sole maize significantly performed better than the intercrop in grain yield. All the browse species evaluated at the intercrops were high in crude protein concentration with moderate value of Neutral Detergent Fiber (NDF), Acid Detergent Fibre (ADF) and Acid Detergent Lignin (ADL). The three browse plant species were accepted by the goats toward the end of the experiment indicating the browse species intercropped with maize to be a suitable feed for ruminants to ameliorate dry season feed deficit and enhances food security through the production of maize.

Key words: browse trees, cropping pattern, dry season, feed scarcity, goats

INTRODUCTION

Ruminants play a significant role in the lives of rural farmers, providing milk, meat, animal traction, manure for crop production, cash from sales of animal products and a safety net of capital assets against misfortune in harsh weather. However, poor nutrition has been the main factor limiting ruminant production in the tropic due to unavailability of feed all year round.

The use of multipurpose trees such as Moringa, Albizia and Leucaena in livestock production in Nigeria cannot be over emphasized in solving feed shortage. Composition of feed given to animals has a very significant influence on animal performance such as reproduction, milk production, quality and growth performance. Adegbola (2002) observed that poor performance of ruminants during dry season was as a result of poor quality roughages fed to these animals without supplementation with concentrates or quality forages. The conventional feed resources (grains) available during the lean period are very expensive to feed ruminants because of the competition with man for sustainability (Akinmuti 2004). This situation has indeed necessitated the search for cheap, readily available feed materials that can meet the nutritional requirements of farm animals and less competitive. Most of the multipurpose trees (MPTS) have hitherto not been systematically exploited for strategic year round livestock production; especially during dry season to boast an improved productivity. The MPTS are considered to be repository of quality nutrients under good management and both palatability and digestibility will be enhanced.

Voluntary intake of tropical grasses can be a major constraint to ruminant performance in the tropics. The solution to this problem may be through the incorporation of tree fodders as feed supplements to improve the rumen environment, which can lead to increased forage intake. A lot of studies have been carried out on few of the browse trees, and the most prominent ones are *Leucaena leucocephala. Gliricidia sepium, Albizia odoratissima* (Ogunbosoye and Babayemi 2010). However, in ruminant

production practices, a common practice is to offer a variety of tree fodders as supplements, either separately or with grasses (Sandoval-Castro *et al.*2005). Therefore, to obtain sufficient and good quality feed for the ruminant, a strategy has to be developed to assess the value of these parameters as predictors of forage preference, and their values in designing feed for effective management of the available browse plants. Preference assessment or otherwise called acceptability is a fast and cheaper means of assessing fodder plants in a short period of time (Sandoval-Castro *et al*. 2005). Therefore, this research was focused on the establishment and utilization of browse trees intercropped with maize by ruminants.

MATERIALS AND METHODS

Establishment at the permanent site

The experiment was laid out in a 2x3 factorial in split plot arrangement and replicated four times. The treatment consisted of Moringa, Abizia and Leuceana as the main block while various population of maize constituted the sub-plot. Poultry manure was applied at the rate of 7.5t/ha at 2weeks before transplanting. Seedlings were transplanted at four weeks old to the main field at a spacing of 4.0m x 4.0m. Maize was introduced to the browse trees at one week after transplanting.

Chemical composition of browse trees

Crude protein, crude fibre, ether extract and ash contents of the browse plants were determined (AOAC 2000), acid detergent fibre (ADF), neutral detergent fibre (NDF), and acid detergent lignin (ADL)were assessed using the method proposed by Van Soest et al. (1991)

Acceptability study

The study was carried out at the sheep and goat unit of Teaching and Research farm, College of Agriculture, Kwara State University. Nine adult female red Sokoto goats were used in a cafetarian feed preference study which lasted for 14 days with 7 days of adaptation. The initial weight of the animals were between 15-17 kg at10-12 months old. They were housed in groups in well ventilated open pens capable of accommodating animals with the feeders and drinkers. The forages were harvested fresh and 3 kg of each was introduced to the animals in different containers. Each plant replicated thrice in order to have access to the plants. The positioning of the plants in the pens were changed daily to avoid conditioning and learning effects by the animals sticking to the same feed in the particular position. The feeding of the animals was monitored for 2 hours (0800-1000) daily. Average daily intake was calculated. Coefficient of preference (COP) was determined as the ratio of individual intake of the forage and the average intake. Forage with COP less than unity is considered not accepted, while COP greater than unity is well accepted (Babayemi 2007; Ogunbosoye and Otukoya, 2014)

Data collection and statistical analysis

The following data were collected for analysis; plant height of browse trees were taken at 6 and 8 weeks after transplanting (WAT), stem girth at 8 WAT. Maize data collected were plant height and stem girth at 6WAT, number of cobs per plant, cob length, number of grains per cob weight of 1000 grains and grain yield. On acceptability study, intake and COP of browse plants records were taken. Data were subjected to analysis of variance using SAS (2010) package and treatment means compared using Duncan's Multiple Range Test of the same statistical package. This was done where results were significant at 5% level of probability.

RESULTS

The significant interaction effect of cropping pattern and population density on plant height, stem girth and days to 50% flowering of maize intercropping is presented in Table 1. Generally, cropping pattern involving combinations of full population of browse trees and maize recorded higher plant height than those involving intercropping combination of 50% full population. The significant interaction effect of cropping pattern and population density on cob length, cob circumference, number of seeds per cob weight of 1000 grains and grain yield in moringa, albizia and leucaena maize intercropping is presented in Table 2. Sole maize had longer cobs than those at the intercrops. Irrespective of the population density, there was no significant difference in maize cob length between

the trees cropping patterns. Number of seed/cob at combination of 50% full maize with browse trees were higher than when full population of maize was intercropped. Intercropping involving maize at full population produced higher grain yield than 50% full population. The highest grain yield (2.33t/ha) at the intercrop was obtained at combination of full population of maize with Albizia.
The chemical composition of the browse foliage is shown in Table 3. The dry matter content of the browse plants ranged between 29.8% in*Moringa oleifera* and 44.00% in *Leucaena leucocephala.* The value obtained in these plants was lower in moringa when compared with others. The crude protein (CP) contents of *Albizia odoratissima, Leucaena leucocephala* and *Moringa oleifera* are 16.3%, 21.03%, and 28.75%, respectively. The highest CP value was obtained from moringa, a non-leguminous plant while the other two are legumes. The crude fibre values were from 10.16% in moringa to 15.87% in albizia and leucaena had 14.34%. Plant materials contain a group of substances, insoluble in water and organic compounds like ether. These are referred to as lipids and act as stores of energy. The highest value of ether extract was obtained in moringa (8.20%) which is an indication of high energy feed. Ether extract is the lipid component and the energy derived from it is utilized by the animal for body maintenance and production and the least value was obtained in *Leucaena leucacephala* (3.44%). The ash contents of browse plants range from (6.50% to 16.55%). The ash content of any feed is a measure of mineral level. The values of ash content was lowest in *leucaena leucocephala*, a legume but higher value was obtained in moringa, a non-leguminous plant.

The fibre fraction of the foliage of browse species shows that *Moringa oleifera* leaves had the highest neutral detergent fibre (NDF) value of 28.85% while the least (25.3%) was recorded for Albizia odoratissima. Acid detergent fibre (ADF) ranged from (13.34% to 22.0%) *M. olivera* and *A. odoratissima* respectively. Acid detergent lignin ranged between 7.55 to 11.0% with the *Albizia odoratissima* having the highest value and leucaena the least value.

The daily free choice intake of browse plants is presented in Table 4. The animals consumed more moringa from the inception of the study far above other fodders. As the day progressed, intake of other browse trees was improving. Similar trend was observed in the coefficient of preference (COP) values. In this study, *Albizia odoratissima* and *Leucaena leucocephala* were not initially consumed as expected. But looking at the coefficient of preference (COP) which is the ratio of individual intake and the average intake of individual forages, the COP was getting better till the end of the study.

DISCUSSION

The complementary effects as observed in this study were an indication of high potential of low-cost approach to sustain agricultural production and reduce environmental degradation. The intercropping advantage as observed in this study is consistent with the works of earlier researchers on intercropping involving maize and arable crops such as: cowpea/ maize (Afe, and Olofintoye, 2013), maize/sesame (Mkamilo, 2004). According to Nair (2007), the system is based on the premise that land use systems that are structurally and functionally more complex than either crop or tree monocultures result in greater efficiency of resource capture and utilization (nutrients, light, and water), and greater structural diversity that entails a tighter coupling of nutrient cycles. The significant difference observed among the browse trees in this study could be attributed to differences in their growth habits. Naturally, moringa is a fast growing plant compared to albizia and leucaenea and was able to compete for natural resources particularly light interception better than the other browse trees. This is evident in the taller maize height in maize/moringa intercrop.

The CP levels of the browse species agreed with the report of Ogunbosoye and Babayemi (2012). This result, however, falls within the minimum and maximum protein requirement for ruminants in the tropics (Minson 1990). The ash values were high, suggesting substantial mineral deposited in the browse plants. In earlier studies, Ogunbosoye and Babayemi (2012) obtained similar enhanced ash contents in browse plants. Values obtained for NDF, ADF and ADL corroborate those reported for some browse species in Nigeria (Larbi *et al*. 1996).

The observed marked preference towards *Moringa oleifera* during the two hours preference study may be due to its high crude protein with low crude fibre. Moreover, Bamikole *et al*. (2004) observed

that when five species of ficus were introduced to goats in a cafeteria feed preference study; the animals were able to make their choice among the ficus trees as a result of preferential taste by the goats. It is therefore concluded that the three browse plant species can be successfully established and intercropped with arable crops like maize to alleviate dry season feed scarcity being encountered by ruminant animal farmers and the arable crop (maize) could serve as additional food to the farmers.

ABSTRACT:
The phytochemical and proximate compositions of *Spondias mombin* leaves were determined using standard methods. The results of the phytochemical analyses showed the presence of phytate (1.01mg), oxalate (0.47mg), tannin (0.38mg) and saponin (2.70mg).The results of proximate compositions shows that the leaves were rich in nutrients such as dry matter was 94.57%,Crude protein 13.36%,crude fibre 10.34%, ash 9.86%, ether extract 2.95%, Nitrogen free extract 67.87% and organic matter 84.71%. The findings indicate that *S. mombin* leaves is a potential source of highly nutritious feed stuff and phytomedicine. They are of nutritional, clinical and veterinary relevance considering the diverse ethnopharmacological uses of the plant in different parts of the world. In conclusion, this study shows that leaves of *S. mombin* are potential source of pharmacologically active phytochemicals. It has also revealed that the leaves are important source of nutrients for domestic animals.

Keywords: *Spondias mombin*, phytochemical and proximate composition.

INTRODUCTION
Spondias mombin is a deciduous tree, usually 20 meters high, its bark is greenish-brown, thick, rough, often deeply grooved, with blunt, spine-like projection. The trunk branches 2-10m above ground level to form a spreading crown up to 15m in diameter. They are dull light orange to yellow or brown in colour, but turn yellow on ripening and contain 3-6 small seeds. The leaves are alternate, once pinnate with an odd terminal leaflet and stipules are absent but have rachis of 30-70cm long. Leaflets are up to 5-10 pairs, apex long acuminate, asymmetric and truncate with entire margins and glabrous leaves (FAO, 1982).The tree thrives under conditions with altitude ranging from 0-587m in a very dry soil, gravelly loam, sandy, or partly clay, throughout much of sub-tropical. Mean annual rainfall suitable for growth is over 1500mm. The bark is used as a purgative and in local application is used for leprosy (Kerharo and Bouquet, 1950). The bark decoction is used for severe cough, causing relief through vomiting. The dry pulverized bark is applied as a dressing to the circumcision wound. The bark contains a certain amount of tannin. A decoction of the mashed leaves is used by the Igbo (Nigeria) for washing a swollen face. The leaves, ground with sugar, are rubbed on the mouth and gums. A leaf infusion is a common cough remedy or used as a laxative for fever with constipation. A leaf decoction is used for gonorrhea. They are also used for leprosy and when crushed with lemon, they are effective on worms among children. A decoction of pounded leaves is used as an eye lotion and the juice pressed from young, warm leaves is given to children for stomach troubles. Hog plum (*Spondias mombin*) is a small deciduous tree plant occurring in a great variety of humid tropical climates. Its fruits, bark, leaves and roots are of great importance agriculturally and otherwise (Oladele, 2008). The leaves are more readily available and cheap especially during the dry seasons when most other forages are in short supply (Aregheore *et al*., 2003).

MATERIALS AND METHODS
Sample Collection and Preparation
The Hog plum *(Spondias mombin*) fresh leaves were collected from Bakori, Bakori Local Government Area, Katsina State. The fresh leaves were spread under the shade and allowed to dry for ten (10) days. All foreign materials such as branches and dead leaves were removed from the sample. The dried leaves were ground into a fine powder using a mechanical grinder, packaged in glass jars and stored at 4^0C until analysis (Ojiako and Akubugwo, 1997).

Quantitative phytochemical Analysis

Prior to quantitative phytochemical analysis, phytochemical screening was carried out on the plant's leaf extract using standard methods as described by Sofowora (1982) and A.O.A.C. (2005). The percentage compositions of saponins, tannins and phytate were determined accordingly to the methods of Harborne (1973) and Treas and Evans (1989). Oxalate content was determined by Spectrophotometric methods of Hang and Lantzsch (1983).

Proximate Analysis:
The hog plum dry leaves were analyzed for ether extract (EE) by soxhlet for 8 hours at 60^0C and crude protein (CP) was determine using micro khedjahl method. The dry matter (DM), crude fibre (CF), ash and nitrogen free extract (NFE) were also analyzed according to standard method of A.O.A.C (2005). The analysis was conducted in the Biochemistry Laboratory, Department of Animal Science, Faculty of Agriculture, Ahmadu Bello University, Zaria.

Results
The results of phytochemical analysis revealed the presence of phytate, oxalate, tannin and saponin, with their quantitative estimations in every 100g of *Spondias mombin* powdered dry leaves, phytate (1.01mg), oxalate (0.47mg), tannin (0.38mg) and saponin (2.70mg) (Table 1) The quantitative estimations (in percentages) of the proximate compositions are shown in Table 2. The dry matter 94.57%, Crude protein 13.36%, crude fibre 10.34%, ash 9.86%, ether extract 2.95%, Nitrogen free extract 67.87% and organic matter 84.71% were obtained

DISCUSSION
Basically, the leaves of *S. mombin* make an excellent fodder for goats, sheep cattle especially during the dry seasons and drought, the leaves are more readily available and cheap especially during the dry seasons when most other forages are in short supply and dried leaves can be stored for long periods of time (Aregheore *et al*., 2003).The results of anti-nutritional factors of *S. mombin* leaf shows that there was low content of phytate (1.01mg), oxalate (0.47mg), tannin (0.38mg) and saponin (2.70mg), which is highly tolerable by ruminants (Kumar 1991), who observed that sheep ingesting up to 0.9mg hydrolysable tannins per kilogram body weight showed no toxicity. These phytochemicals exhibit various pharmacological and biochemical actions when ingested by animals. Saponin is a known anti-nutritional factor that can reduce the uptake of certain nutrients including cholesterol and glucose at the gut through intra-lumenal physicochemical interaction or other yet unidentified activity (Price *et al.,* 1987).The nutritional compositions of *S. mombin* leaves were found to be rich in dry matter (94.57%), Crude protein (13.36%), crude fibre (10.34%), ash (9.86%), ether extract (2.95%),Nitrogen free extract (67.87%) and organic matter (84.71%),the good distribution of nutrients in the leaves may explain its use as one of the forage feed given to domestic animals. Findings have established it as a potential source of highly nutritious feed stuff, medicine and phytomedicine, (Ayoka *et al*., 2006; Njoku and Akumefula, 2007; Ayoka *et al*., 2008; Arif and Fareed, 2010; Igwe *et al*., 2010). The *S. mombin* leaves are also of great nutritional value (Oladele, 2008).In conclusion, this study shows that leaves of *S. mombin* are potential source of pharmacologically active phytochemicals. It has also revealed that the leaves are important source of nutrients for domestic animals.

ABSTRACT
The study was conducted to evaluate the effect of watering volume and planting density on the fodder yield of selected tropical cereals in hydroponic fodder production. Guinea corn (*Sorghum bicolor*), Millet (*Pennisetum glaucum*) and Wheat (*Triticum aestivum*) were used for the study. The experiment was laid out in a 3x3x3 factorial design with grain type, planting densities and watering volume as the three factors. The cereals were employed in hydroponic fodder production and data obtained were subjected to factorial analysis of variance and significantly ($P<0.05$) different means were separated using Duncan multiple range test of SAS (2003). Results indicated Guinea corn had the highest ($P<0.05$) mat depth and fodder yield with 3.65cm and 145.02% respectively, while wheat recorded the least values.Planting density also improved ($P<0.05$) mat depth and fodder yield, while Watering volume only impacted ($P<0.05$) on the cereals mat depth and fodder yield up till 500ml.The study concluded that cereal type, planting density and watering volume influenced mat depth and fodder yield in hydroponic forages.

Keywords: Hydroponic forages, guinea corn, millet, wheat,Mat depth, Fodder yield

INTRODUCTION
Human population increase is putting pressures on the available land for grazing and farming activities. This has resulted in recurrent clashes between cattle herders and settled crop farmers when competing for the available limited resources. There is therefore the need for a sustainable approach to ameliorate this recurrent clashes (Odedire, 2018). One of such approach is the use of hydroponic technology to grow forages for cattle and other grazing livestock, especially during the period of feed scarcity that is more crisis - prone. The potential of hydroponic fodder as a feed resource for livestock feeding is big, due to its high yielding ability and improved nutritive values of grains employed in the production system (Odedire *et al*, 2019). This study aimed to evaluate the effect of watering volume and planting densities on some selected cereal grains in the tropics.

MATERIALS AND METHODS
The experiment was conducted at the Animal Ecology Laboratory of the Department of Animal Sciences, Obafemi Awolowo University, Ile-Ife. A locally adapted hydroponic chamber (Odedire, 2018) was employed for this experiment which lasted 21 days.The experiment was laid out in a 3x3x3 factorial design, where the factors were the selected cereal grains (Wheat, Millet and Guinea corn); Planting density (0.56, 0.83 and 1.11 kg/m^2); and watering volume (250, 500 and 750ml) giving a total of 27 treatments which were replicated thrice.The grains were procured from a local market in Ile-Ife. The grains were sorted, washed, disinfected with hypochlorite and the disinfected grains were spread out in a 60cm×30cm×6cm perforated galvanized sheet tray and covered with aluminium foil for 24 hours. The trays were then placed in the hydroponic chamber and watering was done thrice daily for the 7 days after which the hydroponic forages were harvested. Daily weight changes were recorded and Fodder yield was calculated according to the method of Fazaeli *et al.*, (2011) where:

$$\text{ForageYield}(\%) = \frac{\text{Weight at harvest (kg)} - \text{Weight at planting (kg)}}{\text{Weight at Harvest (kg)}} \times 100$$

Mat depth (clustered and intertwined roots) of the hydroponic fodder was measured with the aid of a graduated ruler. All data collected were subjected to analysis of variance and significantly ($P<0.05$) different means were separated using Duncan multiple range test of SAS (2003).

RESULTS AND DISCUSSION

Table 1 shows the mat depth and fodder yield of the selected grains' hydroponic fodders.There were significant differences (P<0.05) among the means of the mat depth and fodder yield.Mat depth ranged from 1.23cm (millet) to 3.65cm (guinea corn). Highest fodder yield was obtained for guinea corn (145.02%) and the least (26.54%) obtained for wheat.The result showed that guinea corn performed better than millet and wheat in this study. Millet and wheat have been reported to be highly susceptible to mould infestation (Myers, 1974). The cereals employed in this study were sourced from the open market which might have affected seed purity and germination capacity. The fodder yield recorded in this study were lower than reported values (Sneath and McIntosh, 2003; Naik *et al.*, 2013)but higher than the values reported by Odedire *et al.*, (2019). Variation in the hydroponic forage yield may be attributed to the purity of seed and degree of mould infestation.The fodder yield for wheat was the lowest as wheat has been reported to be highly susceptible to *Fusarium spp*. (Saharan and Neaf, 2008).

Table 1: Fodder yield and mat depth of the selected cereals used in hydroponic trials

Cereal type	Mat depth (cm)	Fodder yield (kg)	Fodder yield (%)
Guinea corn	3.65^{a}	3.51^{a}	145.02^{a}
Millet	1.23^{c}	2.85^{b}	88.62^{b}
Wheat	3.19^{b}	1.87^{c}	26.54^{c}
P value	0.017	0.01	0.01

^{abc,} Means within Column with different superscript are significantly different (p<0.05)

Table 2: Effect of planting density on mat depth and fodder yield

Planting Density (kg/m^2)	Mat depth (cm)	Fodder yield (kg)	Fodder yield (%)
0.56	2.39^{c}	2.03^{c}	69.77^{c}
0.83	3.23^{b}	2.81^{b}	87.05^{b}
1.11	4.64^{a}	3.39^{a}	103.35^{a}
P value	0.001	0.0001	0.0001

^{abc,} Means within Column with different superscript are significantly different (P<0.05)

Table 3: Fodder yield and mat depth as affected by watering volume

Watering volume(ml)	Mat depth (cm)	Fodder yield (kg)	Fodder yield (%)
750	3.50^{a}	2.93^{a}	95.68^{a}
500	3.43^{ab}	2.78^{a}	86.95^{ab}
250	3.33^{a}	2.53^{b}	77.55^{b}
P value	0.0342	0.0219	0.0126

^{abc,} Means within Column with different superscript are significantly different (P<0.05)

Table 4: Effect of factors and their interaction on the fodder yield parameters

Parameters	Cereal type (P Value)	Planting Densities (P Value)	Watering Volume (P Value)	CT*PD (P value)	CT*WV (P value)	WV*PD (P value)	CT*PD*WV (P value)
Mat Depth(cm)	0.017	<.0001	0.37	<.0001	0.1423	0.012	0.0349
Folder yield (kg)	0.01	<.0001	0.002	<.0001	<.0001	0.001	0.0001
Percentage Increase in sprouted folder yield (%)	0.01	<.0001	0.013	<.0001	<.0001	<.0001	<.0001

*CT*PD: Cereal type * Planting Densities; CT*WV: Cereal type* Watering Volume; WV*PD: Watering Volume* Planting Densities; CT*PD*WV: Cereal type * Planting Densities*Watering Volume*

Table 2 shows the effect of the Planting density on the Mat depth and Yield of the hydroponic fodder. There were significant differences ($P<0.05$) among the means of mat depth and fodder yield, as the values of both the mat depth and fodder yield nearly doubled when planting density was increased from 0.56 to 1.11kg/m^2. Increasing the watering volume from 250ml to 500ml improved ($P<0.05$) the mat depth and the fodder yield of the cereals but the results of 500 and 750 ml were similar ($P>0.05$). The implication is that watering volume beyond 500ml will create a water logging effect if the tray has no facility for drainage which would eventually result in seed degeneration. The result obtained for the optimum watering volume contrasts Al-Karaki, (2010)who reported that about 1.5-2 litre is required to produce 1 kg of green fodder hydroponically, but agrees with the submission of the author that hydroponically grown fodder requires less amount of water to produce 1 kg green fodder in comparison to 73, 85 and 160 litres to produce 1 kg of green fodder of barley, alfalfa, and Rhodes grass under field conditions respectively.Table 4 shows the interaction effect of the factors on the mat depth and fodder yield. All the factors (watering volume, planting density and cereal types) significantly affect hydroponic fodder yield and mat depth production.

CONCLUSION

It was concluded from this study that Mat depth and Fodder yield are influenced by Watering volume, Planting densities and Cereal type. Guinea corn (*Sorghum bicolor*) gave the best performance among the cereals studied and Planting density of 1.11kg/m^2 with Watering volume of 500ml is recommended for optimum performance.

EFFECT OF ORGANIC AND INORGANIC MANURE ON CHEMICAL COMPOSITION AND *IN SACCO* DEGRADABILITY OF GAMBA GRASS (*ANDROPOGAN GAYANUS*) HARVESTED AT FOUR WEEKS

[1]ONWIH, E.E & [2]MILLAM, J.J

[1]Department of Animal Science, University of Abuja.[2]Department of Animal Science Adamawa State University Mubi.

Corresponding author: orokstar@gmail.com

ABSTRACT

This study was aimed at assessing the long time effect of organic and inorganic manure (control, pig waste, poultry litter, cow dung and NPK fertilizer) on the nutritive value and digestibility using the nylon bag technique. The experiment was carried out at the teaching and research farm University of Ibadan between March and September 2014. Seedlings of *A. gayanus* were planted on a total land area of 1382.5m^2 which was cleared and subdivided into 30 sub plots of 4m x 4m with 1m within and between plots respectively. The experiment was laid out in a completely randomized design of five manure treatments i.e cow dung, pig waste, poultry litter, NPK 15:15:15 and control. The Manure type affected ($p<0.05$) CF, ASH ADF and NDF but had no ($p>0.05$) effect on CP, DM and NFE and potential degradability. It was recommended from this study that farmers should adopt the use of organic manure of animal origin such as pig waste, cow dung and poultry litter respectively as a viable alternative for ease of establishment of this grass species as livestock feeds in order to remove competition with humans on conventional feed stuff.

Keyword: *Andropogan gayanus*, manure, digestibility.

INTRODUCTION.

It is the portion of the digestive tract known as the rumen and its distinctive population of microorganism that provides ruminants with the genetic potential to derive energy from widely varying fibrous feeds. The nutritional values of forage species are low in the dry seasons compared to the wet season Buxton, (1996). Concentrations of nutrients according to McDowell *et al.,* (1983) in forage plants are dependent upon the interaction of a number of factors. Such as plant species, soil type, plant age, pasture management and climate. Most soil used to grow plants, including ornamentals, grass and vegetables, needs its basic nutrients replenished over time. Fertilizers boost the soil's reserves of elements essential to the healthy growth and development of plants. Although conventional and organic fertilizers both add needed nutrients to the soil, organic fertilizer differs because it is derived from natural sources as opposed to being synthetically manufactured. Although organic and synthetic fertilizers add the same nutrients to the soil, organic fertilizers work in a different way. Organic fertilizers work double duty by providing required nutrients to growing plants while also feeding the soil. In Nigeria, forage species still serve as source of essential elements for grazing animals. However, little information is available on the nutrient status of grazing animals and of the forages upon which they subsist. Onyeonagu *et al*., (2013) It therefore becomes essential to replenish the soil with the nutrient elements to increase the forage production, improve nutrient quality of forage and to enhance establishment of range land. Farmers mostly use inorganic fertilizer but the usual unavailability of these fertilizers alongside it high price and potential pollution effect on the environment makes organic manure a veritable alternative.

MATERIALS AND METHOD

The experiment was carried out at the teaching and research farm of the University of Ibadan. An area of 1382.5m^2 was mapped out ploughed and allowed to rest for a period of two weeks before harrowing. The area was divided into two blocks and each block was subdivided into 60 sub plots of 4m x 4m with 1m within and between plots respectively. The grass seedlings were planted at a depth of 2cmwith a spacing of 1m x1m within and between rows with a total of 16 planting spots per plot. The grasses were planted in the month of March and were cut back to a height of 15cm for data collection in the month of July. Basal application of manures (treatment) was done three weeks after the emergence of the grass.

The experiment was laid out in a completely randomized design CRD Weed control was done manually with the use of a hoe throughout the experimental period.

Chemical composition: Crude protein, crude fibre, ash and ether extract were determined according to the method of AOAC (1990) and fibre analysis was carried out using the method of Van Soest *et al.* (1991).

Determination of Degradability

In determining the degradability of the experimental grass, the rumen degradability study of the grass were carried out at the intensive care unit of the Department of Animal Science University of Maiduguri using two fistulated bulls fitted with a stable cannulae.

Procedure

3g of the milled sample were weighed into a nylon bag each measuring 5x10cm with a pore size of 50microns. The nylon bags with the samples were inserted in to the rumen via the cannulae with the use of a sample holder. The sample holder was perforated to allow the movement of rumen microbes in and out of the sample holder as well as coming in contact with the feed sample but not the sample bags out of the holder. The sample holder serves as a confinement for the nylon bags for easier evacuation /removal of the bags from the rumen after incubation. The nylon bag with the sample is incubated for a period of 6, 12, 18,24,36,48 and 72 hours respectively to be incubated (digested) then evacuated. After evacuation of the nylon bag from the rumen of the bull, the cannulae and area surrounding it was cleared of rumen content, spillage and disinfected with the use of a disinfectant (dettol) the nylon bag with the sample was rinsed under tap water immediately to stop further fermentation. The residue was the oven dried at 60°c for 24 hours and weighed. The degradability was calculated as the difference in weight between the initial weight of the sample and the final weight of the sample before and after incubation respectively (McDonald 1995). Dry matter disappearance was determined as

$$\% \text{ DMD} = \frac{A - B}{A} \times 100$$

Where A= initial weight before incubation, B= final weight after incubation.

3.3 Statistical Analysis

Data obtained were subjected to Analysis of Variance (ANOVA) using SAS (2010) and means were separated using Duncarn multiple range test of the same package.

RESULTS AND DISCUSSION

Chemical composition of *ANDROPOGON GAYANUS*

,b,c: means on the same column with different super superscript are significantly different($p<0.05$).
CD= cow dung, PW= pig waste, PL= poultry litter, NPK fertilizer, SEM= Standard error of mean.

The neutral detergent fibre (NDF) which is a measure of the plant cell wall content is the chemical component of the feed that determines its rate of digestibility. NDF is inversely related to plant digestibility (Mc Donald *et al*.1995; Gillespie 1998.) NDF in grasses results in longer retention time and reduces feed intake by ruminants. The higher the NDF the lower the plant digestible energy. The NDF value observed in this study was lower than 75% reported by Babayemi and Odedire (2008). The highest value of 58 .966 % was recorded at poultry litter treated A. gayanus was lower than 60%

reported by Babayemi and Odedire (2008) for A gayanus.. ADF value ranges between 49.80- 51.08% This variation may be due to the fact that the complete plant at harvesting period was chopped and milled together for this analysis. Bamikole and Babayemi *et al.,(*2006) also reported that stages of harvesting , storage, fertilizer application, soil fertility, climate and region could affect chemical composition. The dry matter content ranges between 39.38.- 40.36%. The crude protein content of the grasses were significantly different ($p<0.05$) the crude protein value obtained in this study ranges between 7.89- 8.78% .The variation in CP with that of the cited authors could be as a result of change in climate as well as the nitrogen content of the soil. Bamikole and Babayemi (2006) observed that Cp of grasses intercropped with legumes increases as a result of nitrogen fixation in to the soil by legumes. The crude fiber content varies significantly ($p<0.05$) which ranges between 23.52-24.48%.The value was lower than that reported by Mohammed *et al* .,(2002) who reported 31% CF in hay of A gayanus. Crude fiber content tends to increase as the plant matures Waziri *et al.*,(2013) reported that CF increases as plant matures this makes the plant tensile, strong, erect for exposure to needed sunlight , maturation of seeds and easy harvesting. The ether extract varies significantly ($p<0.05$) across the treatments with respect to harvesting stage (maturity). The value obtained in this study ranges between 6.24-6.63% The value obtained was lower than 9.20 repoted by Waziri *et al*.,(2013) Ether extract found mainly on the leaves of plants assists in the formation of protective layers constituent of many membrane and major source of stored energy. The ash content value ranges from 4.71-5.16%. The value obtained was lower than 10.50 reported by Babayemi and Odedfire(2008) and also lower than the range of 7- 12% as observed by AFRIS (1980) and Duke (1983) although there was no specification on the stage of maturity for the determination of their ash values. The difference could be due to high absorptive capacity of mineral elements from the soil by the plant and its perennial nature. These study observe that the ash value tends to increase as the plant matures since the organic matter content of plants are determined by the difference in ash content in percentage from 100. It's a clear indication that the lower the ash content the higher the organic matter.

Dry Matter Disappearance

Table 2 Main effect of manure type and age at harvesting on Percentage disappearance of *Andropogon gayanus Kunt(% ml/200mg)*

TREATMENT	6HRS	12HRS	18HRS	24HRS	36HRS	48HRS	72HRS
CONTROL	47.767[a]	49.875[a]	55.484[a]	61.323[a]	70.946[a]	77.731[a]	79.032[a]
NPK	49.122[a]	52.161[a]	57.173[a]	63.402[a]	74.032[a]	80.731[a]	82.321[a]
CD	49.475[a]	52.846[a]	57.769[a]	64.020[a]	74.643[a]	81.354[a]	82.961[a]
PL	48.898[a]	52.156[a]	56.906[a]	62.971[a]	72.280[a]	78.926[a]	80.427[a]
PW	49.170[a]	52.479[a]	57.510[a]	64.489[a]	74.336[a]	81.174[a]	82.651[a]

The dry matter disappearance observed in these study was within the range of 79.032- 82.961% The 72hr period of incubation was the period in which grasses were expected to reach their potential degradability as reported by Orskov and Mc Donald (1979).

Effective Dry Matter Degradability

Rumen turnover rate which is the sum of passage rate and degradation rate in the rumen are not only influenced by intrinsic plant characteristics but also by extrinsic factors with in the rumen environment such as rumen pH, rumination, absorption and stimulation of microbial population At 72hrs incubation periods the cow dung treated forages had higher dry matter degradability value than the control. The digestibility of a feed stuff is defined by the potential degradability of the material, the rate of degradation of this potential degradable fraction and its residence time in the rumen (Orskov *et al., 1980*).

CONCLUSION

These study shows that *A.gayanus* can be cultivated in south western Nigeria with the use of organic manure to obtain a high quality yield that can meet the nutrient needs of grazing animals at a lower cost and higher yield compare to the use of inorganic manure which has high cost and low long time effect on the soil. These study shows that *A.gayanus* responds well to organic manure and yields high nutritional content and digestibility. This was observed in the rate of disappearance from the nylon bag with respect to incubation period with organic manure treated forages showing the highest rate of potential degradability.

ABSTRACT

An experiment was conducted to determine the nutrient composition and *in vitro* gas production from six (6) cereal stovers hays in Teaching and Research Farm of Federal University, Wukari, Taraba State, Nigeria. Fresh stovers of maize, sorghum, pearl millet, finger millet, rice and acha were harvested, chopped and air-dried in late October and early November, 2018. The experimental design was Completely Randomised Design (CRD) and each treatment (each stover) was replicated three times. The *in vitro* gas production was carried out in laboratory using standard technique. The results showed that DM, CP, CF, NFE, EE, Ash, OM, CHO and fibre fractions (NDF, ADF, ADL),cellulose and hemicellulose of the selected cereal stovers hay were significantly ($P < 0.05$) different from each other except for ether extract (EE) that was similar across the treatments. Sorghum stover hay (T_3) had the highest DM value of 92.69% while T_1 had the highest CP contents of 11.78% CP. However, T6 had the highest CF value (34.00%) of all the selected cereal stovers. The *in vitro* gas production parameters such as CH_4, TGV, FE, OMD, (DMD, SCFA and ME varied significantly ($P < 0.05$) across the treatments. The TGV was highest (24.67ml) in T_2 (finger millet stover) and least (16.67ml) in T_3 (sorghum stover). The results of this study indicated that T_1 (rice stover hay) had over all best nutrient composition and *in vitro* gas production assessment.

Keywords: Cereal stovers, chemical composition, hay, *in vitro* gas production, ruminants

INTRODUCTION

In feeding livestock, the aim is to provide the animals with a balanced ration throughout the year with sufficient nutrients to meet the animal's nutrient requirements for maintenance and production. The major constraint to livestock production is feed both in quality and quantity. In Nigeria, forage and fodder supply during the dry season and drought periods is a very important factor limiting livestock productivity. Shortage of feed resources often imposed major constraints on the development of animal production in the tropics and sub-tropics. Considerable quantities of crop residues are generated every year in most developing countries in the tropics and sub-tropics which are suitable for feeding livestock. An intensive feeding system based on locally available agro-industrial by-products and crop residues is an alternative promising feeding system to rear ruminants economically. Ruminants because of their rumen physiological adaptation can utilise inexpensive agro-industrial by-products and crop residues to meet their feed requirements for maintenance, growth, and production. Agro industrial byproducts and crop residues in the diets of ruminants support growth, lactation and result in the production of human edible food. Although most have low nitrogen content, more fibre as well as low nutrient density, effective processing can raise their nutritive value (Areghore, 1994). Little information is available on the extent to which small holder farmer in Nigeria use crop residues as livestock feed. It is very likely, however, that these resources are under-utilised. Even when they are utilised, farmers may not be able to incorporate them efficiently into their year-round livestock feeding programmes because they lack suitable storage facilities and technical know-how on treatment and processing methods and on formulating feed ration. The selected cereal stovers hay (maize, sorghum, pearl millet, finger millet, rice and acha) are major food crops cultivated in northeast Nigeria. Most of these cereal stovers are left on the field to waste after harvesting the main crops.

Consequently, there is need to examine their potential feed value for ruminant animals production. Thus, a study was carried out to determine the chemical composition and evaluate nutritive value of selected cereal stover hay using *in vitro* fermentation technique.

MATERIALS AND METHODS

Experimental Site

The study was carried out at Teaching and Research Farm of the Federal University Wukari Taraba State, North-East Nigeria. Wukari is located on Latitude 7^0 51^1 North and Longitude $9^{tl}47^1$ East. Wukari is situated at elevation 189 metres above the sea level and has a mean annual rainfall of 1300mm. The maximum annual temperature ranges between 30^0C and 39.4^0C while the minimum annual temperature is between 15^0 and 23^0C (Oyatayo *et al*., 2015).

Harvesting and Hay Making

Freshly harvested green cereal stovers (maize, sorghum, pearl millet, finger millet, rice and acha) were collected from Crop Production Teaching and Research Farm of Federal University Wukari and processed into hay. The harvesting was done in the month of October and November 2018 and the samples were collected in batches. Harvested cereal stovers were chopped with cutlass into 3-5cm size (for easy drying). Thereafter, the chopped materials were air-dried under shed for two weeks on concrete. The chopped cereals stover were constantly turned-over to ensure uniform drying and prevent mouldness and loss of nutrients. The chopped cereal stovers were then weighed and divided into equal portions (1kg) and each of the cereal stover serve as experimental treatment making six treatments. Treatment A = Maize Stover (MS); Treatment B = Sorghum Stover (SS); Treatment C = Pearl Millet Stover (PMS); Treatment D = Finger Millet Stover (FS); E = Rice Stover (RS) and F = Acha Stover (AS). All were replicated three times in a completely randomized design. However, the samples for laboratory analysis were oven dried at 65^oC and milled by 'MG 123' grinder. The samples were ground in the laboratory with hammer mill of 1mm sieve and subjected to chemical analysis for determination of dry matter (DM), organic matter (OM), crude protein (CP), crude fibre and nitrogen free extract as described by AOAC (2002). Neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL) were assayed by the method of Van Soest *et al,* (1991). Hemicellulose was calculated as the difference between NDF and ADF and cellulose as the difference between ADL and ADF.

In vitro study

The rumen fluid was collected through the suction method by means of the hose from three West African Dwarf (WAD) goats under the same feeding regime. The animals were fed with 40% concentrate feed (40% corn, 10% wheat offal, 10% palm kernel cake, 20% groundnut cake, 5% soybean meal, 10% dried brewers grain, 1% common salt, 3.75% oyster shell and 0.25% fish meal) and 60% Guinea grass. The rumen fluid was collected into a thermos flask that had been pre-warmed to a temperature of 39^0C before morning feeding and taken to the laboratory. It was filtered through a four-layered cheese cloth into a warm flask, flushed with carbon dioxide (CO2) gas, and stirred using an automatic stirrer. Incubation was done as reported by (Menke and Steingass, (1988) using 120ml calibrated syringes in three batch incubation at 39^0C into 200mg sample in the syringe was introduced using 30ml inoculums containing strained rumen liquor and buffer ratio (1: 4 v/v) under continuous flushing with CO2. The gas production was measured at 3, 6, 9, 12, 15, 18, 21 and 24hr. At post incubation period 4ml of NaOH (10 M) was introduce to estimate methane production as reported by Fievez et al., (2005). The volume of the gas produced at intervals was recorded. Metabolisable energy (ME) was calculated as ME = 2.20 + 0.136 GV + 0.057CP + 0.0029CF (Menke and Steingass, 1988). Organic matter digestibility (OMD) = 14.88 + 0.889 GV + 0.45 CP + 0.651 XA. Short chain fatty acids (SCFA) as 0.0239GV - 0.0601(Getachew et al., (1998) was also obtained, where GV, CP, CF and XA are total gas volume (ml/200mg DM), crude protein, crude fibre and ash, respectively. Data collected were subjected to Analysis of Variance (ANOVA) using statistical package for social sciences(SPSS) version 23 and significant means were separated by the use of Duncan' Multiple Range Test.

RESULTS AND DISCUSSION

Chemical composition of selected cereal stovers hay

Table 1 showed the chemical composition of selected cereal stovers hay (Rice, Finger millet, Sorghum, Maize, Pearl millet and Acha). The T_1 (rice stover hay) ($p<0.05$) was significantly higher both in crude protein (11.78%) and ash content (14.40) while T_4 (Maize stover hay) was significantly $P<0.05$) higher (34.00%) in CF compare to other cereal stover hays. Similarly, T_3 (sorghum stover hay) was significantly ($P<0.05$) higher in DM (92.69%), OM (91.65%) and CHO (80.73%) respectively. The crude protein contents which was the major nutrient of the selected cereal stovers hay ranged (8.90 -11.78%) was higher than the critical value of 7.0% recommended by National Research Council (NRC 1981) and also higher than the minimum CP level of 7% required for optimum rumen function (Van Soest, 1994).

Tab le 1: Chemical composition (g/100g DM) of selected cereal stovers hay

Treatments

Parameters	T_1	T_2	T_3	T_4	T_5	T_6	SEM
Dry Matter	92.56^{ab}	91.69^{c}	92.69^{a}	92.10^{bc}	92.14^{bc}	91.91^{c}	0.30
Crude Protein	11.78^{a}	11.70^{a}	9.60^{b}	8.90^{b}	9.35^{b}	9.05^{b}	0.92
Crude Fibre	31.62^{a}	32.00^{a}	31.05^{b}	31.55^{b}	31.53^{b}	34.00^{a}	1.67
Nitrogen Free Extract	40.52^{c}	43.55^{b}	48.42^{a}	48.15^{a}	43.71^{bc}	44.95^{ab}	2.33
Ash	14.40^{a}	11.50^{b}	8.35^{c}	10.75^{b}	14.20^{a}	10.80^{b}	0.72
Ether Extract	1.15	1.25	1.20	1.15	1.20	1.20	0.11

Fibre fraction of selected cereal stovers hay

Presented in Table 2 is the fibre fractions (NDF, ADF, NDS, ADL, Cellulose and Hemicellulose) of selected cereal stovers. There were significant ($P<0.05$) differences among treatments, except for ADF which was similar across the treatments. Fibre fractions (NDF, ADF, ADL) and cellulose were significantly ($P<0.05$) higher in T_5 (Pearl millet stover hay) compare to other cereal stovers hay. The fibre fractions, cellulose and hemicellulose of the selected cereal stovers hay are relatively low, therefore ruminants can digest them.

In vitro fermentation parameter of selected cereal stovers hay

Table 3 showed the *in vitro* gas fermentation parameter of selected cereal stovers hay. The parameters observed differs significantly ($P<0.05$) across the treatments. The *in vitro* gas fermentation technique

provided a useful basis from which metabolisable energy (ME), organic matter digestibility (OMD), short chain fatty acid (SCFA) and methane (CH_4) production of feeds samples be measured. The values of ME (5.14-6.23) obtained among the treatments were significant. The *in vitro* fermentation technique has been widely used to evaluate the energy value of several classes of feed (Getachew *et al.,* 1998).The OMD is said to be a measure of degradability potentials of the microbes on the substrate in the presence of sufficient ammonia nitrogen (NH_3-N) that has influence on bacteria fermentation. The values (45.54-52.58%) obtained were higher than ranged values (35.45 - 46.0%) reported by Falola *et al.,* (2015) for vetiver grass *(Chrysopogon zizanioides L., Roberty)* and 36.45 - 45.93%) reported by Alasa *et al.,* (2010) for *Panicum maximum* intercropped with two cultivars of *Lablab purpureus.* Similarly, SCFA ranged values (0.36 - 0.53ml) obtained in this study were higher than the ranged values (0.31 - 0.36ml) reported by Alasa *et al.,* (2010) but relatively inclined to range values (0.42 - 0.68ml) reported by Falola *et al.,* (2015).The ranged values of OMD, DMD, ME, SCFA and TGV indicated that the cereal stovers are degradable, digestible and could provide energy to ruminants animals.

Table 3: *In vitro gas* fermentation parameters of selected cereal stovers hay

Parameters	Treatments						
	T_1	T_2	T_3	T_4	T_5	t_6	SEM
TGV (ml)	18.67^{b}	24.67^{a}	16.67^{b}	18.00^{b}	18.67^{b}	17.33^{b}	5.94

DMD (%)	74.67^{a}	69.80^{ab}	66.77^{ab}	69.67^{ab}	70.93^{a}	61.40^{b}	7.60
ME (MJ/Kg DM)	5.42^{ab}	6.23^{a}	5.14^{ab}	5.78^{a}	5.42^{ab}	5.24^{ab}	0.89
SCFA (^ml)	0.39^{b}	0.53^{a}	0.34^{c}	0.45^{ab}	0.39^{b}	0.36^{b}	0.16

a,b,c= means on the same row with different superscripts are significantly ($P<0.05$) different.

T_1 = Rice stover, T_2 = Finger millet stover, T_3 = Sorghum stover, T_4 = Maize stover, T_5 = Pearl millet stover, T_6 = Acha stover, TGV =Total Gas Volume, CH_4 = Methane, FE = Fermentation Efficiency, OMD = Organic Matter Digestibility, DMD = Dry Matter Degradability, ME = Metabolisable Energy, SCFA = Short Chain Fatty Acid, SEM = Standard Error of Mean

CONCLUSION

It was concluded from this study that rice stover hay (T_1) was higher in nutrient (crude protein), dry matter and DMD as revealed by chemical composition and *in vitro* gas production compare to other stover hays.

ABSTRACT

The proximate, anti-nutrient and amino acid concentrations of *Luffa aegyptica* and *Cucumis sativus* decorticated seed meals were determined using methods described by Benitez (1989); Anhwange *et al*. (2004) and AOAC (2006). Results of the investigation revealed the moisture content 3.75-4.43%, protein (32.18-33.92%), crude fibre (6.01-7.42%), crude fat (29.38-34.37%), ash (4.55-4.89%) and NFE (15.3-23.79%) respectively. The anti-nutrient components for *C. sativus* are low for oxalate (0.05%), alkaloid (1.38%),phytate (0.05%) and tannin(15.38%) except for saponin (1.29%) compare with values of 0.08% oxalate, 2.98% alkaloid, 0.07% phytate, 24.64% tannins and 0.33% saponin) obtained for *L.aegyptica seed meal.* The amino acid compositions of *C.sativus* and *L.aegyptica* seed meals were comparable with arginine (6.54-7.37g/100g) and leucine (6.60-6.89g/100g) the most concentrated essential amino acids while the glutamic acid (12.57-13.47g/100g) was the most concentrated non-essential amino acid. The study shows that *C.sativus* and *L aegyptica* seed contain sufficient amount of nutrients and minimal constituents of anti-nutrients. These seeds are potential sources of food and feed for human and livestock.

Keywords: Proximate composition, Anti-nutrients, Amino Acid, *Luffa aegyptica, Cucumis sativus seed*

INTRODUCTION

The family *Cucurbitaceae* consists of members commonly known as melons and gourds that include cucumbers, squashes, luffa and melons (Azzez, *et al*., 2013), consisting of climbing and scrambling herbs with either simple or branched tendrils. *Luffa aegyptica* grows well in a well-drained soil that is rich in organic waste. The leaves are oval, simple, deeply five to seven lobed- dentate, dark green and frequently hairy. The fruits are smooth and cylindrical shaped with white flesh. The mature fruits are the source of the spongy reticulated material used for sponges and filters and for stuffing pillows, saddles and slippers, for bathing and cleaning dishware (Oboh and Aluyor, 2009). Several studies on the nutrient and anti-nutrients have been reported in *Luffa aegyptica* seed meal (Dairo, 2008; Abitogun *et al*. (2010). The *Cucurbita pepo'L* (commonly known as Cucumber fruit*s)* has been essential crop in the Andes since the pre-columbian era. It is a seasonal crop used as human food, the fruit is eaten fresh, processed in different ways as dried, frozen, fried, candied or pickled (Teotia, 1992) while the seeds are utilized directly for human consumption as snacks after salting and roasting in Arabian countries (Al khalifa, 1996). Studies have shown that fruits and vegetables contain among other vital nutrients, an appreciable quantity of carbohydrate, proteins, fats, fibers, and phytochemicals (Kubola *et al*., 2011). Despite the numerous nutritional benefits from fruits only a small portion of plant material is utilized directly for human consumption (El-Adawy *et.al*.1999), the remainder part may be converted into nutrient for either food or feed or into fertilizer. However, there is paucity of information on the amino acid and anti-nutrients of the luffa seeds grown in the study area. Hence this study was designed to determine the proximate, amino acids and the anti-nutrient contents of luffa and cucumber seed meals to encourage the utilization by human and as animal feed to reduce large quantity of waste seeds.

MATERIALS AND METHODS

Luffa aegyptica fruits were collected from experimental plots of department of Forestry and Wildlife management and its environs while *cucumber* fruits were collected from the Department of Crop Protection both in Federal University Wukari, Taraba State. The fruits were opened and seeds removed, washed with water and sun-dried before decorticated manually and grounded into powdered form. The powdered seeds were kept in an air-tight container and stored in a refrigerator prior to the analysis. The decorticated sponge gourd and cucumber seeds were analyzed in duplicate for proximate composition of moisture, crude protein, crude fibre, ash, ether extract and nitrogen free extract using

AOAC (2006) methods. The anti-nutritional factors for saponin, Phytate, Oxalate, alkaloids, and tannins were determined using methods described by Anhwange *et al*.(2004).The Amino Acid profile of decorticated seed meals were determined using methods described by Benitez (1989) and AOAC (2006).

RESULTS AND DISCUSSION

The results in Table 1 shows that cucumber moisture content of 4.44%, 34.37% (fat), (33.92% (crude protein) and 7.42% (crude fibre) are higher compared with *L.aegyptica* seed values of 3.75% moisture, 29.38% ash, 32.18% CP and 6.01% CF. *L aegyptica* result is similar to earlier reports by Amoo *et al.* (2008) and Dairo *et al*. (2013) except for ether extract which is above these authors. The analyzed cucumber seed results are in agreement with those reported by Uruah *et al.* (2011) and Niyi *et al.* (2019) but disagreement with lower values reported by Abulude *et al.* (2007).The analyzed results of *C.sativus* and *L.aegyptica* seed meal were higher than those reported for water melon by Fila *et al.* (2013).

Table 1: Proximate composition of decorticated Cucumber and Sponge gourd seed meals (% DM)

Seed meal	Moisture	Protein	Crude Fibre	Ether exyract	Ash	NFE
Cucumber	4.43	33.92	7.42	34.37	4.55	15.31
Sponge gourd	3.75	32.18	6.01	29.38	4.89	23.79

Table 2 shows the anti-nutrients in dehulled cucumber and sponge gourd seed meals. The results revealed that *L. aegyptica* seed has higher values of oxalate (0.08%), alkaloids (2.96%), phytic acid (0.07%) and tannins (24.64%) compared with cucumber seed with values of 0.05% oxalate, 1.38% alkaloids, 0.05% phytic acid and 15.38% tannins. The saponin concentration in cucumber (1.29%) seed was higher compared with L.aegyptica (0.33%) seed meal. The anti-nutrients in *C.sativus* is similar to previous study by Gomathi *et al*. (2016) and Johnson *et al.* (2012) for water melon seeds

Table 2: Anti-nutritional factor of decorticated Cucumber and Sponge gourd seed meals (% Dm)

Seed meal	Oxalate	Saponin	Alkaloids	Phytic acid	Tannins
Cucumber	0.05	1.29	1.38	0.05	15.38
Sponge gourd	0.08	0.33	2.96	0.07	24.64

Table 3 shows the amino acid profile of *L. aegyptica and C. sativus* seed meals. The most concentrated non-essential amino acid in the seed meals was glutamic acid with values of 13.47g/100g for *C. sativus* and 12.57g/100g for *L. aegyptica* while arginine and leucine (7.57 and 6.60 g/100g for *C. sativus* and 12.57 and 6.84 g/100g for *L.aegyptica}* were the most concentrated essential amino acid. Aremu *et al*. (2008) and Oyetayo *et al.* (2012) made a similar observations in *L. cylindrica* seed kernel. The methionine content in the samples of 1.28 to 1.44g/100g is found to be higher than that of soyabean (0.9g/100g) (Akintayo *et al.*, 2002) while the lysine content (3.24 - 3.61g/100g) is higher than that reported by Aremu *et al*.(2008) for *L. cylindrica* seed kernel (2.9g/100g).

Table 3: Essential and non-essential amino acids composition of decorticated Cucumber and Sponge gourd seed meals

S/N	Parameters	DCSM	DSSM
1.	Leucine	6.60	6.89
2.	Lysine	3.61	3.24
3.	Isoleucine	3.21	3.27
4.	Phenylalanine	3.90	4.08

6	Serine	3.56	4.11
7	Aspartic acid	8.31	8.00

DCSM = Dehulled cucumber seed meal
DSSM = Dehulled Sponge gourd seed meal

CONCLUSION AND RECOMMENDATIONS

The results obtained from this study have shown that the cucumber and luffa seeds are sources of fat, crude protein, crude fibre and ash contents. The seeds contain a relatively low amount of saponin, alkaloid, phytate and oxalate except for tannin. The seed meals are rich sources of essential and non-essential amino acids .Hence the seeds could be used to encourage the developing countries like Nigeria to shift from cultural practice of sticking to the known food sources for human and livestock and embrace other food materials especially sponge gourd.

ABSTRACT

This study was carried out to evaluate the proximate composition of plant parts of *Pennisetum purpureum* harvested at selected locations in South-west Nigeria. The experiment was laid out in a 6 × 2 factorial design comprising of six (6) locations (Ewekoro, Odeda, Ibarapa, Ido, Oriade and Ejigbo) and two (2) plant parts (stem and leaf) replicated three times. The dry matter (DM) value ranges from 83.83% in *P. pupureum* harvested at Ibarapa to 93.00% in *P. purpureum* harvested at Ejigbo and *P. purpureum* harvested at Ido had the highest (10.71%) crude protein (CP) content with the lowest value (9.68%) observed in *P. purpureum* harvested at Odeda. Meanwhile, *P. purpureum* harvested at Oriade had the highest (7.33%) ether extract (EE) content with the lowest value (5.17%) observed in *P. purpureum* harvested at Ewekoro. The leaf fraction of the harvested *P. purpureum* recorded the highest value (88.16% and 11.74%) for DM and CP content respectively with the lowest value (5.67%) for EE content and the leaf fraction also had the highest value (15.00% and 13.60%) for Ash and NFC content respectively. The leaf fraction of *P. purpureum* harvested at Ejigbo recorded the highest value (94.33%) DM content with the lowest value (81.00%) observed in stem fraction of *P. purpureum* harvested at Ibarapa and the CP content range from 7.83% in stem fraction of *P. purpureum* harvested at Odeda to 12.38% in leaf fraction of *P. purpureum* harvested at Ido. While the leaf fraction of *P. purpureum* harvested at Ewekoro and Ejigbo had the lowest value (4.67%) of EE content with the highest value (8.00%) observed in stem fraction of *P. purpureum* harvested at Ibarapa, Ido and Oriade. It is therefore concluded that there were variations in the nutrient of *P. purpureum* harvested at the selected locations with different plant parts.
(Keywords: natural pasture, *Pennisetum purpureum*, plant parts, location)

INTRODUCTION

The ever-increasing human population and their high demand for animal protein, especially from meat and milk will depend on better utilization of available feed resources by the ruminant livestock for improving household food security and income (Kabi and Bareeba, 2008). Among feed resources, forage crops, especially grasses have shown unique characteristics in different agricultural systems. They can be grown in harsh environments, utilized as functional components in providing environmental services in soil erosion control and greenhouse gas emission mitigation efforts (Beard and Green, 1994) and income generation as basic animal feed (Wright and Turhollow, 2010). Currently, there is increasing demand for ruminant animal products owing to the growing population and improved livelihoods (Dastagiri, 2004). Ruminants rely more essentially on pasture for their nutrient requirement than any other feed resources and inadequate feed supply is a major constraint of livestock production in sub-Saharan African countries (Arigbede *et al.*, 2011). Forage is important to livestock production since it is a major source of ruminant feed and nutrition for sustainable animal protein and ruminant is the largest source of animal protein. Forage crops make up a significant part of the total agricultural land in Africa and provide a critical food supply for the livestock industry. Grasses are the most abundant flowering plants that are useful to man. They are one of the most important sources of nutrients for domesticated ruminants during a large part of the year (Taweel *et al.*, 2005). The nutritive value of forage, as related to ruminants, may be regarded as the product of the intake of the forage and its digestibility, with intake being the more important of the two parameters (Mott, and Moore, 1969).

MATERIALS AND METHODS

The research was carried out at the Laboratory of Pasture and Range Management Department of the Federal University of Agriculture, Abeokuta. The grass was harvested from natural pastures from selected locations across south-west Nigeria. The plant were separated into two (2) parts (stem and

leaf) and oven dried for laboratory analysis. The study was laid out in 6 × 2 factorial design comprising of six (6) locations (Ewekoro, Odeda, Ibarapa, Ido, Oriade and Ejigbo) and two (2) plant parts (stem and leaf) and data collected were subjected to a Two-way analysis of variance and the treatment means were separated using Duncan's Multiple Range Test using SAS (1999) package. The dry matter, crude protein, ether extract and ash contents of the milled grass sample was determined according to procedure of A.O.A.C. (2000) and NDF was determined according to Van Soest *et al,* (1991). Non-fibre carbohydrate was calculated as NFC = 100 - (CP+Ash+EE+NDF)**.**

RESULTS AND DISCUSSION

There was significantly ($p<0.05$) difference on the proximate composition of plant parts of *Pennisetum purpureum* harvested at different location in South-west (Table 1). It is quite evident that there were variations in the proximate composition of the *Pennisetum purpureum* across locations as revealed in the study and these variations could be affected by various factors, in which seasonality and species specific feed resources were known to be the major factors in affecting the nutritive value of native grasses (Subhalakshmi *et al.*, 2011). It was also reported by Kavana *et al.* (2007) that bimodal distribution of rainfall, uneven seasonal growth and availability of pasture had been considered as the major limitations to constant supply of forage for ruminant animals. The dry matter (DM) value ranged from 83.83% in *P. pupureum* harvested at Ibarapa to 93.00% in *P. purpureum* harvested at Ejigbo and the leaf fraction of the harvested *P. purpureum* recorded the highest value of 88.16% for DM content. The increase in the DM value of the leaf proportions as the *Pennisetum purpureum* advance in age conforms to the submission of McDonald *et al*. (1995) who reported that dry matter content increases with advancing maturity which reflects decrease in cell content. *P. purpureum* harvested at Ido had the highest (10.71%) crude protein (CP) content with the lowest value (9.68%) observed in *P. purpureum* harvested at Odeda while the leaf fraction of the harvested *P. purpureum* had the highest value of 11.74% for CP content (Table 1). There was significantly ($p<0.05$) difference on interaction effect of location and plant parts on the proximate composition of harvested *P. purpureum*. The leaf fraction of *P. purpureum* harvested at Ejigbo recorded the highest value (94.33%) DM content with the lowest value (81.00%) observed in stem fraction of *P. purpureum* harvested at Ibarapa and the CP content range from 7.83% in stem fraction of *P. purpureum* harvested at Odeda to 12.38% in leaf fraction of *P. purpureum* harvested at Ido (Table 2). The crude protein content of the *P. purpureum* was considerably influenced by location. There were variations in CP contents of the *P. purpureum* with the different location and this was in comformity with the report of Da Silva *et al*. (2011) in which similar reports was also obtained from previous findings of Teka *et al.* (2012). The variation in the crude protein of *Pennisetum purpureum* might also be attributed to site potential in terms of differences in edaphic factors and temperature condition.

P. purpureum harvested at Oriade had the highest (7.33%) ether extract (EE) content with the lowest value (5.17%) observed in *P. purpureum* harvested at Ewekoro while the leaf fraction had the lowest value (5.67%) for EE content (Table 1). While the leaf fraction of *P. purpureum* harvested at Ewekoro and Ejigbo had the lowest value (4.67%) of EE content with the highest value (8.00%) observed in stem fraction of *P. purpureum* harvested at Ibarapa, Ido and Oriade (Table 2). The ash content range from 13.00% in stem fraction of *P. purpureum* harvested at Odeda to 15.33% in leaf fraction of *P. purpureum* harvested at Ibarapa, Ido , Ejigbo and Oriade. Meanwhile, the leaf fraction of *P. purpureum* harvested at Odeda recorded the highest value (14.47%) of NFC content and stem fraction of *P. purpureum* harvested at Ewekoro had the highest value (63.67%) for NDF with the lowest value (52.33%) observed in leaf fraction of *P. purpureum* harvested at Oriade (Table 2). The higher fibre levels of the grasses in this study might be a demerit in facilitating the colonization of ingesta by rumen microorganisms, which in turn might induce higher fermentation rates, hence digestibility, intake and animal performance might be impaired.

ABSTRACT
This study was aimed at determining the effect of substituting maize grain with maize cobs treated with 25% urea plus 75% wood ash (WA) on intake, digestibility, nitrogen utilization, rumen NH_3, pH and performance of Tswana breed of sheep. Tswana sheep were fed experimental diet whose maize grain was substituted with graded levels of 25U75WA in the dietary ingredients and the treatments were: 100M = 100% maize grain, 66M34C = 66% maize grain plus 34% treated maize cobs, 34M66C = 34% maize grain plus 66% treated maize cobs and 100C = 100% treated maize cobs in a 4×4 Latin Square Design. Treatment 34M66C had CPI, DMI,OMI and NDFI of 0.1334, 0.9500, 0.8921 and 0.4800 kg/d respectively while the CPD, DMD, OMD and NDFD were 79.57, 68.02, 66.26, and 57.8% respectively. All the treatments had similar rumen NH_3 ranging from 23.55 – 24.00 mg/ml while pH were different and ranged from 6.117 – 6.937. Treatment 100M had the lowest pH. Treatment 100M and 34M66C had ADG of 0.1150 and 0.1417 kg/d respectively however treatment 100M had the lowest FCR of 5.217 compared to 7.059 for 34M66C. It was concluded that treatment 34M66C had better nutrient intake, digestibility and performance compared to diet with 100% maize grain and that the substitution could also reduce cost of feed at the same time supplying minerals present in ash to the fed animals.

Key word: Maize grain, maize cob, urea, wood ash, Tswana sheep

INTRODUCTION

Crop residues such as maize cobs are increasingly becoming popular as livestock feed due to feed shortage occasioned by drought and depletion of the rangelands. Other reasons why crop residues are becoming popular could also be attributed to the high cost of grains as a result of competition between man and livestock. However, crop residues are poor nutritionally and needed to be supplemented with other sources of nutrients. According to Wanapat and Rowlinson (2007), maize cobs can be used as source of energy in ruminant feeds. Maize cobs when used as source of non-forage fibre, increase milk fat concentration and also reduce time of rumination when fed in combination with alfalfa in dairy cattle (Depies and Armentos, 1995). Peyton and Conrad (1982) reported that ground maize cob has been used as energy source for dairy cows in concentrate mixture. Ground maize cobs have also been reported by Wanapat *et al.* (2012) as potential replacement for cassava chips as source of energy in swamp buffalo. This study was aimed at determining the effect of substituting maize grain with maize cobs treated with 25% urea plus 75% WA on intake, digestibility, nitrogen utilization, rumen NH_3, pH and performance of Tswana breed of sheep.

MATERIALS AND METHODS

EXPERIMENTAL INGREDIENTS AND LOCATION OF STUDY

The study was conducted at the Botswana University of Agriculture and Natural Resources, Content Farm located 10 Km north of Gaborone in South Eastern Botswana. Maize cobs were sourced from Molepolole village, 70km from Gaborone and milled (4 mm sieve) at the school farm feed mill in Notwane before mixing with the rest of the ingredients.

IN VIVO STUDY

Four Tswana male sheep sourced from the school farm (18 months old, 32±1 kg) were used in a 4×4 Latin Square Design and housed in metabolism cages suitable for collection of urine and faeces separately. Prior to commencement of the trial, sheep were weighed, vaccinated against

Enterotoxaemia Pasteurella followed by deworming with Ecomectin 14 days later. The trial lasted for forty eight days with 7 days of adaptation and 5 days for collection (12 days/period). Each period was restricted to 12 days due to insufficiency of maize cobs to substitute maize grain as a result of the drought experienced in Botswana during the experimental period.

DATA COLLECTION AND CHEMICAL ANALYSIS

Feed offered and refused were recorded daily throughout the experimental period. Feed were offered twice daily (500g at 8am and 500g at 4pm) while samples of the experimental diets including refusals and faeces (5% samples) were collected daily in the morning before feeding during the 5 days collection period. Samples of concentrate mixture and faeces for each treatment group were then composited and stored at -20°C for later chemical analysis. The samples were divided into two parts, first part for dry matter (DM) analysis, while the second part was kept and pooled for analysis of ash, crude protein (CP), neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL). Feeds, refusals and faecal DM (DM, ID number 930.15) for all samples were determined by drying in forced air oven at 60° C for 24 hr. Organic matter (OM) (OM, ID number 942.05) and ash were obtained by difference in weight after ignition at 550° C in a muffle furnace (Muffle Furnace Size 3, Gallenkamp, UK). The NDF, ADF and ADL were determined with ANKOM fiber analyzer (Ankom Technology Corporation, Fairport, NY, USA) according to the procedure of Van Soest *et al.* (1991). In the analysis of NDF, sodium sulphite and alpha amylase were also added. Nitrogen was determined by a Kjeldahl method (ID number 955.04) according to AOAC (1999) and CP determined as N*6.25 (ID number 954.01).

Daily collection of urine for each treatment before feeding was acidified with 50% H_2SO_4 to prevent ammonia volatilization, stored and then mixed at the end of the trial. The urine samples were then analyzed for N according to AOAC (1999). Rumen liquor was collected 3 hours post feeding after every period in the morning using a mechanical suction pump. The rumen fluid was then measured for pH using digital pH meter and the fluid sample was then strained through four layers of cheesecloth. Forty five ml of the rumen fluid was kept in a plastic bottle to which 5 ml of 1M H_2SO_4 was added to stop fermentation. About 20 to 30 ml of supernatant was collected and analyzed for NH_3- N according to AOAC (1999).

STATISTICAL ANALYSIS

Data generated from various *in vivo* parameters were analyzed using a 4×4 Latin Square Design with GLM procedure of SAS (2002) and means separated with Duncan's Multiple Range Test (Steel and Torrie, 1984).

RESULTS

Nutrient intake and digestibility of experimental diets (Table 1) are shown in Table 2. Effect of treatments was observed on CPI, DMI, OMI and NDFI. Effect of treatments was observed on crude CPD, DMD, OMD and NDFD. Nitrogen utilization of sheep fed experimental diets is shown in Table 3. Effect of treatments was also observed on NI, FN, UN and NB.

Rumen ammonia and pH of sheep fed experimental diets are shown in Table 4. Effect of treatments was not observed on rumen ammonia while it was observed on rumen pH. Treatment 100M had the lowest pH (6.12) while 100C had the highest (6.94). Treatments 66M34C and 34M66C had similar pH of 6.77 and 6.74 respectively. Performance characteristics of sheep fed experimental diets are shown in table 5. Effect of treatments was observed on FI, FW, WG, ADG and FCR.

DISCUSSION

Despite the fact that the maize grain-based diet (100M) had low NDF, ADF and ADL, it was characterized by low intake and digestibility. All animals on this treatment had diarrhea and not willing to eat much probably because they initially selected the more palatable grains that were rapidly fermented. The reason for the low intake and digestibility may be attributed to the rapid fermentation of the grain leading to a drop in the rumen pH, hence the inability of the microbes to digest fibre (Nocek and Tamminga, 1991). According to Oba and Allen (2000) when forages that are more fermentable are fed, rumen pH could be lowered leading to low NDF digestibility.

Low intake and digestibility also observed on treatment 100C may be attributed to its high NDF, ADF and ADL compared to the rest of the treatments since more fibrous feed reside longer in the rumen thereby reducing passage rate and hence low intake. Allen and Mertens (1988) reported that NDF digestibility is determined by the fraction of NDF that is potentially digestible, the rate of NDF degradability in the rumen and the rate of passage from the rumen.

The reason why treatments 66M34C and 34M66C lost more nitrogen in faeces and urine may be attributed to their higher intakes of nitrogen compared to treatments 100M and 100C. Van Soest (1994) reported that excess nitrogen derived from microbial nitrogen and proteins that are not part of microbial proteins is normally secreted in milk or lost in faeces and urine of ruminants. Groff and Wu (2005) also reported that when CP in diets is increased there is a general increase in intake and this leads to increased losses of nitrogen into milk, urine and faeces. Even though all the treatment groups had positive nitrogen balance, treatment 100M had the highest because its nitrogen losses to faeces and urine were minimal compared to the rest of the treatments.

The rumen ammonia concentrations in all treatments were similar. The range of NH_3-N concentration was 23.55 to 24.00 mg/100ml. This observation was similar to the figures reported by Hamad *et al*. (2010) who reported values of 22.87 to 23.64 mg/100 ml in lambs fed maize cob-based diet measured 6 hrs post feeding. Khan *et al*. (2006) reported 20.6 to 25.3 mg/100 ml concentration after 6 hours in buffalo bulls fed restricted diets containing urea treated maize cobs ensiled with or without different additives. The result of the rumen pH showed that it ranged from 6.117 to 6.937. Orskov and Ryle (1990) reported that cellulolytic bacteria require pH of 6.2 – 7 while Wanapat and Pimpa (1999) also reported that optimum level of pH in the rumen should be 6.5 to 7.0 which were optimal for microbial growth when animals feed mostly on roughages. The normal rumen pH implied that volatile fatty acids (VFA's) which are by-products of fermentation rapidly diffused through the rumen wall instead of accumulating within the rumen. Accumulation of VFA's could lead to drop in pH because of increased acidic environment hence resulting in decreased DM digestibility. The low pH recorded for the 100% maize grain-based diet might have led to the low intake and digestibility observed as a result of the rapid fermentation of the maize grain in the rumen.

The higher feed intake and digestibility recorded for treatment 34M66C had also translated into higher WG and ADG as compared to the rest of the treatments. However, treatment 100M had lower feed consumption to gain ratio which was as a result of the lower feed intake. Various authors have also reported improvement in intake and digestibility of ruminants fed urea treated maize cobs (Khan *et al*., 2006; Hamad *et al*., 2010; Wanapat *et al*., 2012).

CONCLUSION

It was concluded that maize cobs treated with a combination of urea and wood ash could replace 66% maize grain in sheep diet with added advantage of reducing cost of feed at the same time supplying minerals present in wood ash to the animal.

ABSTRACT

An experiment was conducted to evaluate the physicochemical characteristics of two grain sorghum varieties as influenced by planting date in Shika-Zaria. A laboratory trial of representative samples of silages using the two varieties (Samsorg-16 and Samsorg-17) and three planting dates (15th June, 30th June and 14th July) in a 2 x 3 factorial arrangement denoted as A, B, C, D, E and F was made in glass jars from chopped forage material harvested at booting stage. The forage was ensiled for 21 days in glass jar. There was no significant (P>0.05) effect of variety on temperature and pH of ensiled grain sorghum (Table 1). The temperature for both varieties was 22.93°C while pH observed ranged between 3.82 and 3.83 for Samsorg-16 and Samsorg-17 varieties, respectively. Variety had effect on dry matter, crude protein, neutral detergent fibre, acid detergent fibre, calcium and phosphorus composition of ensiled grain sorghum. Planting date had significant (P<0.05) effect on all the parameters measured in which silage made from sorghum planted on 15th June recorded higher temperature, dry matter, crude protein, neutral detergent fibre and acid detergent fibre. It is therefore recommended that for good quality silage, Samsorg-17 variety should be planted on 15th June.

Key words: Silage, sorghum, variety, physicochemical and planting date.

INTRODUCTION

The adaptive nature of sorghum, it's potential to produce higher tonnage of green forage and its diverse uses make it a valued tool and one of the best choices for forage growers and dairy farmers demanding high quality feed stocks (Iqbal and Bethune, 2015). Genotype or variety and planting date plays an important role in determining yield and quality of sorghum hence, its silage physicochemical composition (Diawara, 2012). Silage is made to conserve the grass or other herbage with a minimum loss of nutritive value by fermentation of soluble carbohydrates in an anaerobic environment into organic acids, preferably lactic acid, which reduce pH inhibiting normal aerobic bacterial action (Saarisalo *et al*., 2007). Water soluble carbohydrates (WSC) in ensiled crops are a source of energy for bacteria to produce lactic acid and lower pH to <4.2 for good silage quality (McDonald *et al*., 1991). Although excellent silages can be made from sorghums but crude protein (CP) concentrations decrease with increase in stage of maturity (Pholsen and Higgs 2005). Sorghum silage has the potential to bridge the gap between animal feed supply and demand particularly during drier months (Oliver *et al*., 2004). Hence, the experiment was conceived to determine the physicochemical characteristics of two grain sorghum varieties silage as influenced by planting date in Shika, Zaria, Nigeria.

MATERIALS AND METHODS

SILAGE PREPARATION AND SAMPLING

In 2018 growing season at National Animal Production Research Insitute (NAPRI), Shika, five (5) seeds of Samsorg-16 and Samsorg-17 grain sorghum were planted on ridges at 2 cm depth at plant spacing of 15 x 85 cm using the planting dates and later thinned to two (2) plants/ stand after twelve (12) days so as to have a uniform plant population of (13,333 stands/ha). A uniform dose of 120 kg/ha NPK (20:10:10) was applied to sorghum seedlings at 2 and 5 weeks after sowing as first and second doses, respectively. Forage material was harvested at 14 weeks after sowing (booting stage), then chopped to 2 cm with a forage chopper. The chopped forage material was ensiled in glass jars. A laboratory trial of representative samples of silages using the two varieties and three planting dates denoted as A, B, C, D, E and F was made in glass jars. The temperature and pH of the silage was measured with thermometer and pH meter. Proximate and detergent analyses were determined using the method of AOAC, (2005) and van-Soest *et al.* (1991), respectively in the Central Laboratory of NAPRI, Shika, Zaria. While mineral analysis was determined by AOAC (2005) methods using the Atomic Absorption Spectrophotometer.

STATISTICAL ANALYSIS

Data generated were subjected to ANOVA using General Linear Model Procedure of SAS (2005). Significant means will be compared using the Duncan's Multiple Range Test (Duncan, 1955).

RESULTS AND DISCUSSIONS

There was no significant ($P>0.05$) effect of variety on temperature and pH of ensiled grain sorghum (Table 1). The temperature for both varieties was 22.93^{o}C while pH observed ranged between 3.82 and 3.83 for Samsorg-16 and Samsorg-17 varieties, respectively. There was significant ($P<0.05$) effect of variety on DM, CP, NDF, ADF, Ca and P composition (Table 1) of ensiled grain sorghum. Dry matter, crude protein and calcium were 4.86%, 34.93% and 25.00% higher in Samsorg-17 than Samsorg-16 sorghum silages, respectively. Neutral detergent fibre, acid detergent fibre and phosphorus were 13.98%, 14.83% and 33.33% higher in Samsorg-16 silage than Samsorg-17 silage, respectively. The variation observed may be attributed to the varietal difference in which the yellow colour of Samsorg-17 sorghum grains could be responsible for the high crude protein. The DM and ADF obtained in this study was higher than the values reported by Kumari *et al*. (2013) for chopped sweet sorghum silage. Significant ($P<0.05$) planting date effect was observed for temperature, pH, DM, CP, NDF and ADF (Table 1) of ensiled grain sorghum. The pH obtained in this study is within 4.2 and below reported by Iqbal and Bethune (2015) that must be attained for a good quality silage. Mineral elements play special roles in the proper functioning of the rumen microorganisms especially those which digest plant cellulose, utilization of energy, protein and metabolism among other functions (McDowell *et al*., 1993). The P content was lower than (0.4-0.9g/day) required for growing goats (Fjell *et al.,* 1991). The Ca concentration was within the daily requirement for goats (0.4-1.1g/ca/day) reported by (Ishiaku *et al.*, 2016). There was significant ($P<0.05$) interaction effect between variety and planting date on parameters measured except pH.

Table 1: Physicochemical composition of ensiled grain sorghum as influenced by variety and planting date and their interaction

	Chemical composition (%)							
	T°C	pH	DM	CP	NDF	ADF	Ca	P
Variety								
Samsorg-16	22.93	3.83	71.70[b]	6.78[b]	62.79[a]	47.34[a]	0.42[b]	0.06[a]

P-value	<0.001	<0.001	0.092	<0.001	<0.001	<0.001	<0.001	<0.001
Interaction								
V x P	<0.001	0.230	0.009	<0.001	<0.001	0.015	<0.001	<0.001

[abc]Means with different superscripts within column differed significantly, SEM = standard error of mean, DM = dry matter, CP = crude protein, NDF = neutral detergent fibre, ADF = acid detergent fibre, Ca = calcium, P = phosphorus

CONCLUSION

It can be concluded that silage made from Samsorg-17 sorghum give the highest DM, CP and Ca while higher NDF and ADF were obtained in Samsorg-16 sorghum silage whereas sorghum planted on 15th June recorded the highest DM, CP, NDF and ADF. It is therefore recommended that for good quality silage Samsorg-17 should be planted on 15th June.

ABSTRACT
An experiment was conducted to evaluate the effect of breed on carcass characteristics of some Nigerian breeds of sheep. A total of nine (9) mature rams of 12 months of age (25 Kg) managed on the same system were used. The animals were kept for 24 hours where only water was provided to clear the gut content before slaughter. The result indicated that there was significant (P<0.05) effect of breed on carcass characteristics in which Balami breed of sheep had higher value for live weight (39.90 kg), slaughter weight (36.7 kg) and dressed carcass weight (21.0 kg), followed by Uda and Yankasa. Dressing percentage was not significantly (P>0.05) different among breeds. Breed significantly (P<0.05) affected the visceral components in which Balami recorded higher value followed by Uda and Yankasa. The result of prime cut revealed significant (P<0.05) breed effect in which the rack (6.00 kg), rib (2.67 kg), loin (3.10 kg), thigh (3.77 kg), flank (3.19 kg) and breast (2.27 kg) were higher for Balami, followed by Uda and Yankasa. It was concluded that Balami breed of sheep was superior to Uda and Yankasa breeds in terms of carcass characteristics, visceral components and prime cuts. It was therefore recommended that Balami should be used when one is interested in carcass characteristics, visceral components and prime cuts.

Keywords: Breed, carcass and sheep

INTRODUCTION
Sheep contributes about 50% of the total domestically produced meat in Nigeria (Bourn *et al.,* 1994). There are four main breeds of sheep native to Nigeria and these are Balami, Uda, Yankasa and West African Dwarf. Balami and Uda are kept in the semi-arid regions; West African Dwarf sheep in the south and Yankasa throughout the country (Bourn *et al.,* 1994). These four breeds differ considerably in size, coat colour and other characteristics (Adu and Ngere, 1971).

A carcass is made up of various proportions of muscle, bone and fat. The ideal carcass can be described as one that has a minimum amount of bone, a maximum amount of muscle and an optimum amount of fat (Marinova *et al*., 1992; Ameha, 2006). Market requirements differ in size of carcass and level of fatness acceptable. A certain proportion of fat is desirable to reduce drying out of the carcass. On the other hand, too much fat is undesirable. Water makes up 74% of the total muscle weight. The remainder of the muscle is protein, lipid, minerals and some vitamins. Bone provides the rigid support to which the muscles are attached. The hard, calcified cells give bone the strength needed to support the weight of the animal (Marinova *et al*., 1992; Ameha, 2006).

An understanding of carcass characteristics and meat quality traits of these sheep breeds has been over time neglected due to the focus on beef quality, butcher`s expectation and consumer demand for superior quality meat with optimum food value as well as the importance of protein in human diet has however made mutton quality important (Osuhor *et al.,* 2009). Hence, the need to evaluate the carcass characteristics of some Nigerian breeds of sheep.

MATERIALS AND METHODS

Experimental site

The study was conducted at the Animal Products Laboratory of the Department of Animal Science, Ahmadu Bello University, Zaria.

Experimental design and management of animals

The experiment was carried out in a Complete Randomized Design using three breeds of sheep (Balami, Uda and Yankasa). A total of nine (9) matured rams of twelve (12) months of age with an average body weight of 25 kg raised on the same diets and the same system of management were used. The animals were sorted according to the three breed (Balami, Uda and Yankasa) groups comprising of three (3) rams per group. The animals were inspected for diseases and disabilities. The animals were fasted for 24 hours without feed but water was made available before slaughtering.

SLAUGHTER AND CARCASS DISSECTION

The animals were slaughtered according to the *Halal* standard procedure by severing the jugular vein and carotid arteries. The hair was removed by flaying as described by Fasae and Adelegan (2011). The internal organs (kidney, liver, heart and spleen) were carefully excise and weighed. The carcass was cut into primal cuts (shoulder, rack, loin, breast shank and flank) and each part was weighed. The dressing percentage was calculated as the ratio of dressed carcass weight to live weight in percentage.

STATISTICAL ANALYSIS

Data generated were subjected to ANOVA using General Linear Model Procedure of SAS (2005). Significant means will be compared using the Duncan's Multiple Range Test (Duncan, 1955).

RESULTS AND DISCUSSIONS

Carcass Characteristic of Nigerian Breeds of Sheep

There was significant ($P<0.05$) effect of breed on carcass characteristics of sheep (Table 1). The higher values obtained in Balami breed for live weight, slaughter weight and dressed carcass weight might be attributed to the large body size of Balami over Uda and Yankasa. The dressing percentage obtained in this study was lower than the values reported by Osuhor *et al*. (2009) for Yankasa rams fed dried poultry litter plus maize offal supplement. Carcass weight is the main factor affecting the composition of the carcass and is closely related to age at slaughter. As animals mature, they normally gain weight resulting in a heavier carcass. Much of the weight gain of a mature animal is fat rather than muscle. Thus, at heavier live weight, an animal's carcass will have lower proportions of muscle and bone and a higher proportion of fat.

Table 1: Carcass characteristic of Nigerian breeds of sheep

	Breed			
Component	Balami	Uda	Yankasa	SEM
Live weight (kg)	39.90[a]	30.00[b]	27.00[b]	2.22
Slaughter weight (kg)	36.70[a]	27.60[b]	24.84[b]	4.45
Dressed carcass weight (kg)	21.00[a]	16.00[b]	15.00[b]	1.70
Dressing %	52.60	53.00	55.00	3.00

[abc] means within rows having different superscripts differed significantly (P<0.05), SEM = Standard error of mean

Edible and Non-edible By-products Components of Nigerian Breeds of Sheep

Breed significantly (P<0.05) affected the edible and inedible by-products components (Table 2). The lower values obtained in Yankasa, followed by Uda for the edible and inedible by-product components might be due to the small size of Yankasa followed by Uda compared to the higher values obtained in Balami breed. Some breeds mature earlier than others and the main breed differences may be related to the rate of fat deposition during the later stages of growth (Marinova *et al*., 1992; Ameha, 2006). To achieve a similar level of fatness with breeds of different maturity types, it is necessary to market earlier maturing lambs at lighter weights than later maturing lambs.

Table 2: Edible and non-edible by-products components of Nigerian breeds of sheep

	Breed			
Component (kg)	Balami	Uda	Yankasa	SEM
Head	2.40[a]	2.10[b]	1.85[c]	0.03

[abc] means within rows having different superscripts differed significantly (P<0.05), SEM = Standard error of mean

Prime Cuts of Nigerian Breeds of Sheep

The results revealed significant (P<0.05) breed effect on the prime cuts (Table 3). The conformation of a carcass refers to its shape. Carcasses that are short in the leg and plump or 'blocky' in appearance are said to have 'good' conformation (Marinova *et al*., 1992; Ameha, 2006). Carcasses with a longer 'leggy' appearance are said to be of 'poor' conformation. Carcasses having good conformation generally contain more fat and less protein than those of poor conformation (Marinova *et al*., 1992; Ameha, 2006). The higher values obtained in Balami over Uda may be due to breed difference. The effect of nutrition on carcass composition is not a simple one as it involves the interactions among

level of intake, the composition of the feed, and nutrient needs of the animal. As more food energy is required to produce a kilogram of fat than a kilogram of muscle, one has to be conscious of the type of market targeted during the feeding operation (Marinova *et al*., 1992; Ameha, 2006).

Table 3: Prime cuts of Nigerian breeds of sheep

Component (kg)	Breed			SEM
	Balami	Uda	Yankasa	
Rack	6.00[a]	5.00[b]	4.70[b]	0.25
Rib	2.67[a]	2.02[b]	2.00[b]	0.14
Loin	3.10[a]	2.53[b]	2.15[b]	0.22
Round/ thigh	3.77[a]	2.47[b]	2.33[b]	0.15
Flank	3.19[a]	2.43[b]	2.37[b]	0.06
Breast	2.27[a]	1.55[b]	1.50[b]	0.06

[abc] means within rows having different superscripts differed significantly (P<0.05), SEM = Standard error of mean

CONCLUSION

It was concluded that Balami breed of sheep was superior to Uda and Yankasa breeds in terms of carcass characteristics, visceral components and prime cuts. It was therefore recommended that Balami should be used for better carcass characteristics, visceral components and prime cuts.

ABSTRACT

This study was conducted to evaluate the dry matter yield and proximate composition of irrigated Brachiaria ruziziensis as influenced by different rates of goat manure application during the dry season. Five treatments comprising of Brachiaria ruziziensis fertilized with 5, 10, 15, 20 t/ha dry matter (DM) goat manure (GM) and the control were arranged in a randomized complete block design with five replicates. The grass was cut back to 15 cm stubble height at the commencement of the study followed by harvesting of three random quadrat samples of 45-days regrowth for determination of yield and nutrient composition. The dry matter yield ranged from 1.88 to 5.26 t/ha and was highest for plots fertilized with 20 t/ha DM GM and least for control. The crude protein content of B. ruziziensis increased significantly (P < 0.05) with increased manure application rates. Plot fertilized with 20 t/ha DM GM had the highest value (9.28 %) while the control had the least value (7.59%). It can be concluded that goat manure application rate of 20 t/ha DM had the better potential to increase dry matter yield and proximate composition of irrigated B. ruziziensis during the dry season.

Keywords: Goat manure, forage yield, proximate composition, *B. ruzuziensis* and ruminant

INTRODUCTION

Natural grasslands constitute the major feed resources of ruminants, either by grazing or as conserved forages. However in the tropics, the inadequacies of feed and its low nutritive quality during the dry season are major limitation to successful ruminant production (Fasae *et al*., 2019). Most of the animals suffer from seasonal nutritional stress, resulting in weight loss, reproductive inefficiency and even death (Yohanna *et al*., 2015). This seasonal shortage can be mitigated by the use of sown forage of better nutritional value and purposely managed. High quality grass forage like *Brachiaria ruziziensis* have been reported as perennial tropical forage which is easy to establish and respond well to nitrogen fertilization (Skerman and Riveros, 1990). However to maintain the quality and year round production, there is need for water and nutrient to be supplied especially during the dry season to enable continuous production. Thus providing quality forage for ruminant to enhance their growth and provide maximum profit for farmers throughout the year. In Nigeria despite government interventions, inorganic fertilizers still remain expensive, in lieu of this researchers have shifted attention to examine the performance of crops with organic manure which is cheap, readily available, biodegradable and environmentally friendly. Organic manure has been discovered to be rich in nutrients which increase crop growth rate, yield, quality, and the ability to tolerate stressful conditions (Nweke *et al*., 2013). This study was designed to evaluate the effect of different goat manure rate on yield and nutrient composition of irrigated *Brachiaria ruziziensis* as potential dry season forage for ruminants.

MATERIALS AND METHODS

The experiment was conducted at the Kalahari Red goat unit of the Institute of Food Security, Environment Resource and Agricultural Research Farms of the Federal University of Agriculture, Abeokuta, Nigeria, situated in the humid tropics. *B. ruziziensis* was established by planting the seeds using a drill method in June 2015. Prior to manure application, soil samples were randomly collected

from the plots, air−dried, sieved with a 2 mm mesh sieve and analyzed for physical and chemical properties through methods reported by Osayande *et al.* (2015) while goat manure (GM) was also collected from the goat unit of the experimental site for analyses. Necessary manure rates were applied before the commencement of the experiment by making a small farrow about 4−8 cm from the base of the plant then manure applied and farrow closed back and irrigation of the plots to fill capacity started 7 days before the commencement of the experiment at three-day interval. The experiment was laid out in randomized complete block design with five treatments comprised of *B. ruziziensis* fertilized with 5, 10, 15, 20 t/ha dry matter (DM) GM and the unfertilized plot. Each treatment was replicated five times. The plants were undefoliated before the initial cut−back to a stubble height of 15 cm at the start of the experiment in December 2015. Each plot measure 4 m by 4 m with an inter plot space of 0.5 m. Dry matter yield was estimated after 45−day regrowth by throwing a 1.0 × 0.5 m^2 quadrant frame thrice in each plot and the entire sward falling inside it harvested manually using a sickle to stubble height of 15 cm and weighed fresh, sub samples were taken and oven dried at 65^oC till constant weight for determination of dry matter yield. The dry matter, crude protein, ash and ether extract were determined according to AOAC (2005) and data obtained were subjected to analysis of variance using the statistical package SAS (2003) and means were separated using least significant difference (LSD) of the package.

RESULTS AND DISCUSSION

The soil and goat manure composition are shown in Table 1. The composition of goat manure (GM) observed in this study was lower in total nitrogen, organic matter, phosphorus and potassium values reported by Awodun *et al.* (2007) but higher than that reported by Odedina *et al.* (2011). The differences in nutrient content of GM could be related to the nutritional management of goats.

Table 1: Chemical analysis of soil and goat manure sample

Parameters	Soil	Parameters	Goat manure
pH in water	8.15	pH in water	8.07
% Total nitrogen	0.14	Total nitrogen (%)	1.55
% Organic carbon	0.60	Organic carbon (%)	13.07
% Organic matter	1.03	Organic matter (%)	45.41
Av. phosphorus (mg/kg)	16.10	Phosphorus (%)	0.22
K^+ (Cmol/kg)	0.84	Potassium (%)	0.87
Na^+ (Cmol/kg)	0.71	Sodium (%)	0.28
Ca^{2+} (Cmol/kg)	3.13	Calcium (%)	1.27
Mg^{2+} (Cmo/lkg)	1.46	Magnesium (%)	1.36
Exch. acidity ($Cmolkg^{-1}$)	2.70		
% Sand	76.90		
% Clay	17.80		
% Silt	5.30		

Goat manure application rates was found to have significant effect ($P<0.05$) on the dry matter yield of *B. ruziziensis* (Figure 1). The highest DMY of 5.26 t/ha was recorded for treatments fertilized with 20

t/ha DM GM while the least DMY of 1.88 t/ha was recorded for control. The results of this study revealed that DMY of *B. ruziziensis* increased with increased rate of goat manure application. This agrees with the finding of Maleko *et al*. (2015) who observed that dry matter yield of *B. ruziziensis* increased significantly from 9.31 to 13.70 t/ha as cow manure application rate increased from 0 to 15 t/ha DM. This increase in DMY with increased manure application could be attributed to increasing large amount of goat manure added to the soil and slow nutrient release from the manure particularly nitrogen (N) which is known to plays a major role in leaf growth. The DMY in this study was higher than the yield (1.87 t/ha) reported by Panchaban *et al*. (2005) but lower than that reported (21.5 t/ha) by Naveh and Anderson (1967) and (17.6 t/ha per year at 800 kgN/ha per year application) by Skerman and Riveros (1990). The observed variations in yield of *B. ruziziensis* under these studies compared to others might be due to time of data collection, age at cut, season variation, type and rate of fertilizer/manure applied and soil fertility.

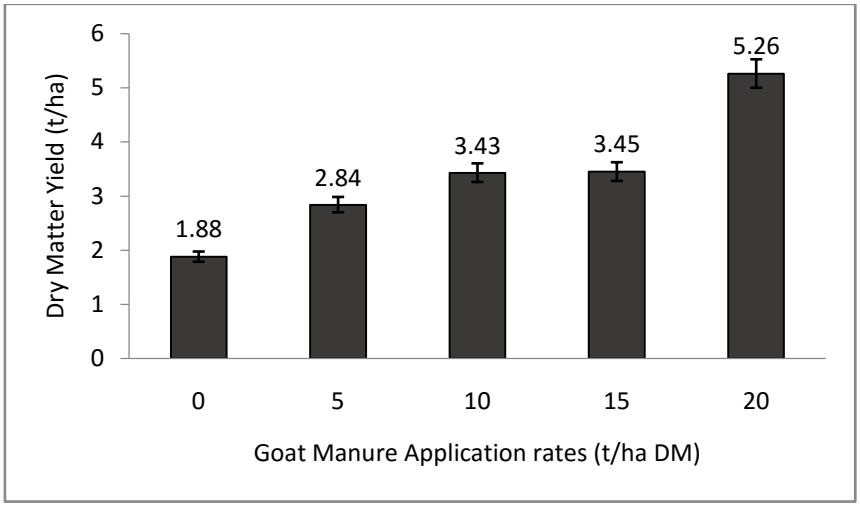

Figure 1: Effect of goat manure application rates on dry matter yield (t/ha) of *B. ruziziensis*

Dry matter (DM) and ash content were not significantly influence by the manure application rates (Table 2). Olanite *et al*. (2014) reported similar DM value for grasses in their experiment. The crude protein (CP) content and ether extract (EE) content were significantly influenced ($P<0.05$) by the manure rates (Table 2). The EE content ranged from 4.49 % in the control to 5.73 % in treatment fertilized with 20 t/ha goat manure. Crude protein content ranged from 7.59 in unfertilized plots to 9.28 % in plots fertilized with 20 t/ha DM goat manure. Also plots fertilized with 10, 15 and 20 t/ha goat manure was observed to be significantly higher than the control. Despite these variations, the forage generally had adequate amount of protein to meet ruminant requirement. The CP contents of *B. ruziziensis* in this experiment were consistently above the critical limit required for maintenance by ruminants. According to Minson (1990), if the CP content of a feed is lower than 7%, animal performance could decline due to low voluntary intake, lower rate of digestibility and negative nitrogen balance. The highest CP values were recorded for *B. ruziziensis* fertilized with 20 t/ha DM goat manure is an indication of a more positive effect of increased goat manure rate on the grass during the experiment. This might be attributed to more organic matter decomposition, and quicker release of nutrients, in the form of nitrogen and phosphorous for plant uptake because of the higher quantity added.

Table 2: Proximate composition (%) of *Brachiaria ruziziensis* using different goat manure application rates

Treatments (t/ha DM)	Dry Matter	Crude Protein	Ether Extract	Ash
Control	37.15	7.59[d]	4.49[ab]	8.37
5	40.86	8.10[cd]	4.65[ab]	8.42
10	39.50	8.17[bc]	3.75[b]	8.51
15	41.84	8.69[b]	5.32[a]	8.77
20	42.70	9.28[a]	5.73[a]	9.33
SEM	0.96	0.17	0.26	0.27

[abcd] Means on the same column having different superscripts were significantly different (P<0.05)

SEM, Standard Error of Mean

CONCLUSION

The study showed that dry matter yield and proximate composition of irrigated *Brachiaria ruziziensis* fertilized with 20 t/ha DM goat manure produced the best quality forage. This could facilitate year-round production of forage and a safer environment with sensible and efficient use of goat manure.

ACKNOWLEDGEMENT

The authors would like to appreciate the World Bank through the Centre of Excellence in Agricultural Development and Sustainable Environment, Federal University of Agriculture, Abeokuta, Nigeria for the financial support in carrying out this research.

ABSTRACT

An experiment was conducted to determine the nutrient composition and in vitro gas production from six (6) cereal stovers hays in Teaching and Research Farm of Federal University, Wukari, Taraba State, Nigeria. Fresh stovers of maize, sorghum, pearl millet, finger millet, rice and acha were harvested, chopped and air-dried in late October and early November, 2018. The experimental design was Completely Randomised Design (CRD) and each treatment (each stover) was replicated three times. The in vitro gas production was carried out in laboratory using standard technique. The results showed that DM, CP, CF, NFE, EE, Ash, OM, CHO and fibre fractions (NDF, ADF, ADL), cellulose and hemicellulose of the selected cereal stovers hay were significantly (P < 0.05) different from each other except for ether extract (EE) that was similar across the treatments. Sorghum stover hay (T_3) had the highest DM value of 92.69% while T_1 had the highest CP contents of 11.78% CP. However, T6 had the highest CF value (34.00%) of all the selected cereal stovers. The in vitro *gas production parameters such as CH_4, TGV, FE, OMD, (DMD, SCFA and ME varied significantly (P < 0.05) across the treatments. The TGV was highest (24.67ml) in T_2 (finger millet stover) and least (16.67ml) in T_3 (sorghum stover). The results of this study indicated that T_1 (rice stover hay) had over all best nutrient composition and in vitro gas production assessment*.

Keywords: Cereal stovers, chemical composition, hay, *in vitro* gas production, ruminants

INTRODUCTION

In feeding livestock, the aim is to provide the animals with a balanced ration throughout the year with sufficient nutrients to meet the animal's nutrient requirements for maintenance and production. The major constraint to livestock production is feed both in quality and quantity. In Nigeria, forage and fodder supply during the dry season and drought periods is a very important factor limiting livestock productivity. Shortage of feed resources often imposed major constraints on the development of animal production in the tropics and sub-tropics. Considerable quantities of crop residues are generated every year in most developing countries in the tropics and sub-tropics which are suitable for feeding livestock. An intensive feeding system based on locally available agro-industrial by-products and crop residues is an alternative promising feeding system to rear ruminants economically. Ruminants because of their rumen physiological adaptation can utilise inexpensive agro-industrial by-products and crop residues to meet their feed requirements for maintenance, growth, and production. Agro industrial byproducts and crop residues in the diets of ruminants support growth, lactation and result in the production of human edible food. Although most have low nitrogen content, more fibre as well as low nutrient density, effective processing can raise their nutritive value (Areghore, 1994). Little information is available on the extent to which small holder farmer in Nigeria use crop residues as livestock feed. It is very likely, however, that these resources are under-utilised. Even when they are utilised, farmers may not be able to incorporate them efficiently into their year-round livestock feeding programmes because they lack suitable storage facilities and technical know-how on treatment and processing methods and on formulating feed ration. The selected cereal stovers hay (maize, sorghum, pearl millet, finger millet, rice and acha) are major food crops cultivated in north-east Nigeria. Most of these cereal stovers are left on the field to waste after harvesting the main crops.

Consequently, there is need to examine their potential feed value for ruminant animals' production. Thus, a study was carried out to determine the chemical composition and evaluate nutritive value of selected cereal stover hay using *in vitro* fermentation technique.

MATERIALS AND METHODS

EXPERIMENTAL SITE

The study was carried out at Teaching and Research Farm of the Federal University Wukari Taraba State, North-East Nigeria. Wukari is located on Latitude 7^0 51^1 North and Longitude $9^{tl}47^1$ East. Wukari is situated at elevation 189 metres above the sea level and has a mean annual rainfall of 1300mm. The maximum annual temperature ranges between 30^0C and 39.4^0C while the minimum annual temperature is between 15^0 and 23^0C (Oyatayo *et al*., 2015).

HARVESTING AND HAY MAKING

Freshly harvested green cereal stovers (maize, sorghum, pearl millet, finger millet, rice and acha) were collected from Crop Production Teaching and Research Farm of Federal University Wukari and processed into hay. The harvesting was done in the month of October and November 2018 and the samples were collected in batches. Harvested cereal stovers were chopped with cutlass into 3-5cm size (for easy drying). Thereafter, the chopped materials were air-dried under shed for two weeks on concrete. The chopped cereals stover were constantly turned-over to ensure uniform drying and prevent mouldness and loss of nutrients. The chopped cereal stovers were then weighed and divided into equal portions (1kg) and each of the cereal stover serve as experimental treatment making six treatments. Treatment A = Maize Stover (MS); Treatment B = Sorghum Stover (SS); Treatment C = Pearl Millet Stover (PMS); Treatment D = Finger Millet Stover (FS); E = Rice Stover (RS) and F = Acha Stover (AS). All were replicated three times in a completely randomized design. However, the samples for laboratory analysis were oven dried at 65^oC and milled by 'MG 123' grinder. The samples were ground in the laboratory with hammer mill of 1mm sieve and subjected to chemical analysis for determination of dry matter (DM), organic matter (OM), crude protein (CP), crude fibre and nitrogen free extract as described by AOAC (2002). Neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL) were assayed by the method of Van Soest *et al,* (1991). Hemicellulose was calculated as the difference between NDF and ADF and cellulose as the difference between ADL and ADF.

IN VITRO STUDY

The rumen fluid was collected through the suction method by means of the hose from three West African Dwarf (WAD) goats under the same feeding regime. The animals were fed with 40% concentrate feed (40% corn, 10% wheat offal, 10% palm kernel cake, 20% groundnut cake, 5% soybean meal, 10% dried brewers grain, 1% common salt, 3.75% oyster shell and 0.25% fish meal) and 60% Guinea grass. The rumen fluid was collected into a thermos flask that had been pre-warmed to a temperature of 39^0C before morning feeding and taken to the laboratory. It was filtered through a four-layered cheese cloth into a warm flask, flushed with carbon dioxide (CO2) gas, and stirred using an automatic stirrer. Incubation was done as reported by (Menke and Steingass, (1988) using 120ml calibrated syringes in three batch incubation at 39^0C into 200mg sample in the syringe was introduced using 30ml inoculums containing strained rumen liquor and buffer ratio (1: 4 v/v) under continuous flushing with CO2. The gas production was measured at 3, 6, 9, 12, 15, 18, 21 and 24hr. At post incubation period 4ml of NaOH (10 M) was introduce to estimate methane production as reported by Fievez et al., (2005). The volume of the gas produced at intervals was recorded. Metabolisable energy (ME) was calculated as ME = 2.20 + 0.136 GV + 0.057CP + 0.0029CF (Menke and Steingass, 1988). Organic matter digestibility (OMD) = 14.88 + 0.889 GV + 0.45 CP + 0.651 XA. Short chain fatty acids (SCFA) as 0.0239GV - 0.0601(Getachew et al., (1998) was also obtained, where GV, CP, CF

and XA are total gas volume (ml/200mg DM), crude protein, crude fibre and ash, respectively. Data collected were subjected to Analysis of Variance (ANOVA) using statistical package for social sciences(SPSS) version 23 and significant means were separated by the use of Duncan' Multiple Range Test.

RESULTS AND DISCUSSION

CHEMICAL COMPOSITION OF SELECTED CEREAL STOVERS HAY

Table 1 showed the chemical composition of selected cereal stovers hay (Rice, Finger millet, Sorghum, Maize, Pearl millet and Acha). The T_1 (rice stover hay) ($p<0.05$) was significantly higher both in crude protein (11.78%) and ash content (14.40) while T_4 (Maize stover hay) was significantly $P<0.05$) higher (34.00%) in CF compare to other cereal stover hays. Similarly, T_3 (sorghum stover hay) was significantly ($P<0.05$) higher in DM (92.69%), OM (91.65%) and CHO (80.73%) respectively. The crude protein contents which was the major nutrient of the selected cereal stovers hay ranged (8.90 -11.78%) was higher than the critical value of 7.0% recommended by National Research Council (NRC 1981) and also higher than the minimum CP level of 7% required for optimum rumen function (Van Soest, 1994).

Table 1: Chemical composition (g/100g DM) of selected cereal stovers hay

	Treatments

T_6 = Acha stover, SEM = Standard Error of Mean

FIBRE FRACTION OF SELECTED CEREAL STOVERS HAY

Presented in Table 2 is the fibre fractions (NDF, ADF, NDS, ADL, Cellulose and Hemicellulose) of selected cereal stovers. There were significant ($P<0.05$) differences among treatments, except for ADF which was similar across the treatments. Fibre fractions (NDF, ADF, ADL) and cellulose were significantly ($P<0.05$) higher in T_5 (Pearl millet stover hay) compare to other cereal stovers hay. The fibre fractions, cellulose and hemicellulose of the selected cereal stovers hay are relatively low, therefore ruminants can digest them.

Table 2: Fibre fractions (g/100g DM) of selected cereal stovers hay

In vitro fermentation parameter of selected cereal stovers hay

Table 3 showed the *in vitro* gas fermentation parameter of selected cereal stovers hay. The parameters observed differs significantly (P<0.05) across the treatments. The *in vitro* gas fermentation technique provided a useful basis from which metabolisable energy (ME), organic matter digestibility (OMD), short chain fatty acid (SCFA) and methane (CH_4) production of feeds samples be measured. The values of ME (5.14-6.23) obtained among the treatments were significant. The *in vitro* fermentation technique has been widely used to evaluate the energy value of several classes of feed (Getachew *et al.,* 1998).The OMD is said to be a measure of degradability potentials of the microbes on the substrate in the presence of sufficient ammonia nitrogen (NH_3-N) that has influence on bacteria fermentation. The values (45.54-52.58%) obtained were higher than ranged values (35.45 - 46.0%) reported by Falola *et al.,* (2015) for vetiver grass *(Chrysopogon zizanioides L., Roberty)* and 36.45 - 45.93%) reported by Alasa *et al.,* (2010) for *Panicum maximum* intercropped with two cultivars of *Lablab purpureus.* Similarly, SCFA ranged values (0.36 - 0.53ml) obtained in this study were higher than the ranged values (0.31 - 0.36ml) reported by Alasa *et al.,* (2010) but relatively inclined to range values (0.42 - 0.68ml) reported by Falola *et al.,* (2015). The ranged values of OMD, DMD, ME, SCFA and TGV indicated that the cereal stovers are degradable, digestible and could provide energy to ruminants animals.

Table 3: *In vitro gas* fermentation parameters of selected cereal stovers hay

Parameters	Treatments						
	T_1	T_2	T_3	T_4	T_5	t_6	SEM
TGV (ml)	18.67^{b}	24.67^{a}	16.67^{b}	18.00^{b}	18.67^{b}	17.33^{b}	5.94
CH_4 (%)	13.33^{b}	17.33^{a}	9.33^{c}	10.67^{c}	11.33^{c}	12.00^{b}	5.14

SCFA (^ml)	0.39^{b}	0.53^{a}	0.34^{c}	0.45^{ab}	0.39^{b}	0.36^{b}	0.16

a,b,c= means on the same row with different superscripts are significantly (P<0.05) different.
T_1 = Rice stover, T_2 = Finger millet stover, T_3 = Sorghum stover, T_4 = Maize stover, T_5 = Pearl millet

stover, T_6 = Acha stover, TGV =Total Gas Volume, CH_4 = Methane, FE = Fermentation Efficiency, OMD = Organic Matter Digestibility, DMD = Dry Matter Degradability, ME = Metabolisable Energy, SCFA = Short Chain Fatty Acid, SEM = Standard Error of Mean

CONCLUSION

It was concluded from this study that rice stover hay (T_1) was higher in nutrient (crude protein), dry matter and DMD as revealed by chemical composition and *in vitro* gas production compare to other stover hays.

ABSTRACT
Twenty-four West African dwarf (WAD) goats were subjected to four dietary treatments containing Vernonia amygdalina (VA) at varying inclusion levels (0, 5, 10 and 15g/ kg DM) to assess its effect on nutrient intake and digestibility. Panicum maximum was fed as a basal diet and concentrate diet as supplement in a ratio of 60:40.The experiment was laid out in a completely randomized design and it lasted for 112 days. Results showed that VA inclusion increased (p<0.05) total dry matter (DM), crude protein (CP), crude fibre (CF) and acid detergent fibre (ADF) intakes. Goats on diets containing VA also had the highest (p<0.05) CF, ADF and acid detergent lignin (ADL) digestibility. It was therefore concluded that for increased nutrient intake and fibre fibre digestibility, VA can be included in the diet of WAD goats up to 15g/kg DM.

INTRODUCTION
Phytogenic feed additives are substances derived from plants; they are also referred to as phytobiotics or botanicals. They include herbs and spices and their extracts which can be added to animal feed to promote growth and improve the health status of the animals. Their usefulness lies in some chemical substances that produce definite physiological actions in the body of the animals (Oko and Agiang 2009). Some of the useful herbs and spices are indigenous to Africa and include ginger (*Zingiber officinale*), garlic (*Allium sativium*), scent leaf (*Ocimum gratissimum*) and bitter leaf (*Vernomnia amygdalina)* (Muhammad et al. 2009). *Vernonia amygdalina* is a valuable medicinal plant that is widespread in West Africa, it is known as bitter leaf due to its characteristic bitter taste and flavor, and can be used as an active anticancer, antibacterial, anti malarial and anti parasitic agent (Udochukwu *et al*., 2015). The bitter leaf plant contains *vernonine, vernodalin* and *venomygdin*. It is known to be endowed with valuable biochemical properties, fixed oil, alkaloids, saponins, tannins and other glycosides (Bonsi *et al*., 1995).It is a unique plant, so unique that every part of it has an economic importance. Its leaves are macerated and used in cooking soup, while the extracts are used as tonic for prevention of certain illness. *Vernonia amygdalina* have been shown to be valuable nutritionally. It contains significant quantities of lipids (Ejoh *et al.* 2007), proteins with essential amino acids (Igile *et al.* 1994). It also contains carbohydrates (Eleyinmi *et al.* 2008) and carotenoids, though not in large quantities (Udensi *et al.* 2002). Also contained in this plant are essential elements such as calcium, iron, protein, potassium, phosphorus, manganese, copper and cobalt (Bonsi *et al.* 1995). The study therefore aims at determining the effect of diets containing bitter leaf on nutrient intake and digestibity in West African dwarf goats.

MATERIALS AND METHODS
The study was carried out at the Animal Nutrition laboratory of the Federal University of Agriculture, Abeokuta, Ogun State, Nigeria. Ogun State is in the rainforest zone of South West Nigeria. The area has an annual mean temperature of 34.7°C, a relative humidity of 82% and an annual mean rainfall of 1,037 mm. It is about 70 m above sea level and lies on latitude 7°5'-7°8'N and longitude 3°11.2'E.

PROCESSING OF TEST MATERIALS AND FORMULATION OF DIETS

The leaves of bitter leaf were harvested, air-dried and ground to pass through 1mm sieve. This was used to formulate four concentrate diets which contain bitter leaf at 0, 5, 10 and 15g/kg DM (Table 1).

The diets; basal and concentrate supplement were offered to the animals at 5% of their body weight in a ratio of 60:40 respectively.

Table 1: Ingredient composition of experimental concentrate diet (%)

Ingredients	T1	T2	T3	T4
Cassava peel	40	40	40	40
Maize cob	20	20	20	20
Dried brewer's grain	20	20	20	20
Wheat offal	17	17	17	17
Bone meal	2	2	2	2
Salt	1	1	1	1
Bitter leaf	-	+	++	+++
Total	100	100	100	100
Determined analysis (%)				
Crude protein	11.88	11.88	11.88	11.88
Crude fibre	13.84	13.84	13.84	13.84

-, +, ++, +++ means 0g, 5g, 10g, and 15g of bitter leaf/kg of concentrate feed..

Experimental animals and management

Twenty- four (24) West African dwarf goats with an average live weight of 6.5 - 9kg were used for the experiment. Pens were cleaned and disinfected with Izal solution prior to the arrival of the animals. The goats were kept in the quarantine section for two weeks for proper prophylactic treatment which consisted of intramuscular application of oxytetracycline LA and vitamin B complex at the dosage of 1 mL/10 kg body weight of the animal. The animals were maintained on *Panicum maximum* grass and concentrate and clean water was supplied *ad libitum.* They were thereafter divided into four treatment groups of five animals each on weight equalization basis and housed in individual pens. The study comprises 14 days of adaptation followed by 12 weeks feeding trial and 2 weeks' nutrient digestibility study. The diets were offered at 8:00am in the morning and 12.00pm in the afternoon. The concentrate diets were offered first and then the basal diet in separate feeding trough. Left over of the feed offered was weighed and recorded every morning to compute feed intake on dry matter basis. Initial weights of the animals were taken on the first day of the experiment and thereafter fortnightly throughout the experiment. The nutrients intake was calculated as follows:

Dry matter intake =% dry matter of feed x daily feed intake

Crude protein intake =% crude protein of feed x daily feed intake etc.

NUTRIENT DIGESTIBILITY STUDY

After 12 weeks feeding trial, four goats from each treatments were transferred into clean metabolic cages for separate collection of faeces and urine. There was a 7-day acclimatization followed by 7 days' collection of faeces. Aliquots of collected faeces were dried in the oven at 65^0 C till constant weight.

CHEMICAL ANALYSES

Oven dried feed and faecal samples were analyzed for their proximate compositions: crude protein, crude fibre, ether extract and ash according to AOAC (2000). Neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL) were determined by the methods of Van Soest *et al.* (1991).

STATISTICAL ANALYSIS

All data collected were subjected to one-way analysis of variance in a completely randomized design using version 9.1 of SAS software (SAS, 2001)

RESULTS AND DISCUSSION

Vernonia amygdalina (VA) is rich in crude protein, ether extract and ash (Table 2). The CP and ash content obtained in this study are however lower than the range (17 to 33g/100g DW and 10 to13g/100g DW respectively) reported by Alabi (2005). However, ether extract content falls within the range of 2 to 15g/100gDW reported by same author. Presented in table 3 is the nutrient intake of goats fed experimental diets. *Vernonia amygdalina* inclusion increased ($p<0.05$) total dry matter, CP, CF ADF intakes. This is indicative of better degradability and hence increased intake. According to Olafadehan *et al*. (2017) feed intake is a function of availability, palatability, fibre digestion and digesta flow rate. Fajemisin *et al*. (2010) also reported increased nutrient intake when graded levels of VA leaf meal was included in the diets of West African dwarf ewes. The diets have significant ($p<0.05$) effect on CF, ADF and ADL digestibility (Table 4). Crude fibre, ADF and ADL digestibility were highest in diets containing VA while the least values were obtained in the control diet. This implies that the secondary metabolites in VA did not interfere with the digestion process in the rumen.

Table 2: Chemical composition (%) of Bitter leaf *(Vernonia amygdalina)*

CONCLUSION AND RECOMMENDATION

Based on the findings of this work, VA improved nutrient intake and fibre digestibility up to 15g/kg DM. It can therefore be included in the concentrate supplement for West African dwarf goats at 15g/kg DM

ABSTRACT

An experiment was carried out to investigate the growth performance of growing West African Dwarf Rams fed diets containing varying inclusion levels of Cajanuscajan leaf meal (CCLM) and Panicum maximum for 56 days in a feeding trial carried out at the Teaching and Research Farm of Oyo State College of Agriculture and Technology Igbo-ora, Nigeria. A total of sixteen (16) growing WAD rams between 6 - 9 months of age with an average body weight of 9.00 -12.00kg were randomly allocated to 4 treatments with 4 animals per treatment, while 2 animals served as replicate. The experimental diet was fed at 3% body weight of individual animals whileCajanuscajan leaf meal was supplemented in total mixed rations at varied inclusion levels (0%, 5%, 10% and 15%) with Panicum maximum. There were significant (P<0.05) difference in all parameters determined across the dietary treatments. The results revealed that rams fed diet T_2(5% CCLM) recorded the least daily weight gain (8.04g/d) while the highest daily weight gain (15.36g/d) was recorded in diet T_4 that contained 15% inclusion level of CCLM. The weekly weight gain of rams was significantly different across all treatments (P<0.05). The feed conversion ratio (FCR) range between 22.03 – 41.16 and showed significantly different (P<0.05) across all treatments. Hence, rams fed diet T_4 that contained 15% inclusion levels of CCLM in total mixed rations recorded the best feed utilization value of 22.03. It is therefore recommended that supplementation of CCLM in diets of growing rams up to 15% enhance the growth performance of the animals.

INTRODUCTION

Forages such as grasses and legumes are the main source of feed for ruminants to meet their nutritional requirements, either for maintenance or production. However, in the tropics, inadequate nutrition is a great challenge contributing to production losses in ruminants (Ibhaze, 2016) due to unavailability of forages throughout the year. This unpleasant situation has necessitated the search for alternative feed resources rich in energy and protein that are readily available and relatively cheap. Several indigenous and exotic browse species have been investigated and evaluated for inclusion in ruminant feeding systems in Nigeria (Fajemisin, 2015). The shortage in feed supply due to high cost and seasonality has caused ruminant livestock farmers to search for alternative feed resources that are inexpensive and readily available and which are not directly required as a component of human dietaries and can economically supplement the feed ingredients in rations without adverse effects on the rumen microbial fermentation and performance of the animals (Okoruwa*et al.,* 2013). Tropical browse plants such as *Cajanuscajan* is multipurpose nitrogen fixing crop that provides the seed as human food and poultry feed, the leaves and young stems as animal fodder for the subsistence farmers (Lorgyer, 2009). *Panicum maximum* also called guinea grass (FAO, 2003) is a highly productive, palatable, persistent and acceptable grass by ruminants. It can be fed to livestock solely or with concentrates or legumes. This study was therefore designed to evaluate the effect of *Cajanuscajan*leaf meal in total mixed rations on the growth performance of West African dwarf growing rams fed *Panicum maximum*.

MATERIALS AND METHODS

EXPERIMENTAL SITE AND ANIMALS

The experiment was carried out at the Sheep and Goat Unit, Teaching and Research Farm, Oyo State College of Agriculture and Technology, Igboora. Sixteen (16) growing West African Dwarf rams weighing between 9.00-12.00kg and of 6 – 9 months of age were used. The animals were acclimatized for two weeks and treated against ectoparasites and endoparasites prior to the commencement of the experiment.

HARVESTING, PROCESSING AND PREPARATION OF EXPERIMENTAL DIETS

The forages were harvested from pasture demonstration plot of the college farm. *Cajanuscajan* leaves and *Panicum maximum* were cut at a height of 30cm above the ground level at 50% flowering stage to allow for good re-growth. *Cajanuscajan* leaves including twigs and petioles were harvested and air-dried to constant weight at room temperature while retaining their greenish colouration. The forage was then milled to pass through 2mm sieve. The CCLM were stored at room temperature in jute bags until needed for inclusion in the commercial supplement. Four experimental diets were formulated by replacing corn bran with *Cajanuscajan*leaf meal (CCLM).

EXPERIMENTAL LAYOUT, DESIGN AND FEEDING METHOD

The animals were allocated by weight into four treatments of four rams per treatment and two animals as a replicate in a Completely Randomized Design (CRD). The treatments consisted of four total mixed diets containing CCLM at 0, 5, 10 and 15% inclusion levels. The rams were fed on a basal diet of *Panicum maximum* in the morning (0800hr), while the experimental supplements were offered in the afternoon (1500hr). Each group of animals was assigned to an experimental diet and fresh clean water was made available.

DATA COLLECTION AND ANALYSIS

Adjustment period of one week was allowed before data collection commenced. At the beginning of the experiment, the rams were weighed and subsequently on a weekly basis prior to feeding in the morning. The initial live weight was subtracted from the final live weight to determine the weight gained by the animals. Feed offered and reminant (left over) were weighed daily to determine the feed intake of the animals. Both values were used to determine Feed conversion ratio, Dry Matter Intake (DMI), the mean initial body weight and weekly body weightwere calculated. All growth performance data obtained were subjected to one-way analysis of variance (SAS, 1999). Mean value variance showing significant ($P<0.05$) difference were separated using Duncan's multiple range test (Duncan 1955).

$^{a\,b\,c\,d}$*Means on the same row with different superscript are significantly different (P< 0.05*).

RESULTS AND DISCUSSION

The growth performance summary of the experimental rams was shown in Table 3. There were significant differences (P<0.05) among the treatments in all the parameters measured. The mean dry matter intake (DMI) values were between 313.61 – 338.43g/day, and these values were similar, meaning that the presence of the CCLM in the diets did not depress feed intake and that the diets containing the test ingredients were all accepted by the rams. Observed values were comparable with 334.94 – 365.97g/day reported by Sanwo*et al.* (2011) for goats fed melon husk and palm oil slurry at 30% inclusion level, but lower than 525.14 – 546.26g/day reported by (Oloche*et al.*, 2013) for WAD goats fed diets containing graded levels of sweet orange peel meal. There were significant (P<0.05) differences in the mean daily weight gain and the feed conversion ratio which ranged from 8.04 –

15.36g/day and 22.03 – 41.16 respectively. The mean daily weight gain of the rams seemed to be slightly increases from $T_2 – T_4$ as the level of CCLM increased. Differences in the mean daily weights of the animals implies that the treatment diets with CCLM also provided adequate nutrients for the growth of the animals and these diets can be used for fattening of rams. Animals on T_4 diet (15% inclusion) had the highest average daily weight gain (15.36g/day) and the least (22.03) feed conversion ratio followed by the rams fed T_1 diet (0% inclusion) with the value (10.89g/day) of average daily weight gain which could be due to the environmental factors and animal factors which can influence the feed intake in animals, such as age and level of exercise. These values are lower than the range of 35.72 – 64.29g/day reported by Ogunbosoye*et al.* (2016) for West African dwarf goats fed graded levels of shea nut (*Vitellariaparadoxa*) cake based rations. FCR seemed to improve from $T_I – T_4$ as the level of CCLM increased in the diets. This showed that inclusion of test ingredients (CCLM) in the diets of the experimental animals had a positive impact on the feed conversion ratio. Observed values were higher than those values of Sanwo*et al.* (2011) who reported 11.59 – 17.24 for goats fed melon husk and palm oil slurry at 30% inclusion level.

CONCLUSION

From the result of the study,*Cajanuscajan* leaf meal at 15% inclusion level had the best performance for WAD rams, it can be concluded that *Cajanuscajan* leaf meal possesses adequate nutritive value to support good growth of growing West African Dwarf rams, especially during the period of drought and the forage can effectively serve as alternative feed ingredient in West African Dwarf growing rams diet.

RECOMMENDATION

Based on the result of this research, it could be recommended that *Cajanuscajan* leaf meal could be incorporated into the diet of WAD rams with inclusion level of up to 15% without any deleterious effect. Further research should be carried out using *Cajanuscajan* leaf meal at higher levels of inclusion in the diets of sheep and other livestock to substantiate its suitability and utilization by the animals.

INTRODUCTION

Forages such as grasses and legumes are the main source of feed for ruminants to meet their nutritional requirements, either for maintenance or production. However, in the tropics, inadequate nutrition is a great challenge contributing to production losses in ruminants (Ibhaze, 2016) due to unavailability of forages throughout the year. This unpleasant situation has necessitated the search for alternative feed resources rich in energy and protein that are readily available and relatively cheap. Several indigenous and exotic browse species have been investigated and evaluated for inclusion in ruminant feeding systems in Nigeria (Fajemisin, 2015). The shortage in feed supply due to high cost and seasonality has caused ruminant livestock farmers to search for alternative feed resources that are inexpensive and readily available and which are not directly required as a component of human dietaries and can economically supplement the feed ingredients in rations without adverse effects on the rumen microbial fermentation and performance of the animals (Okoruwa *et al.*, 2013). Tropical browse plants such as *Cajanus cajan* is multipurpose nitrogen fixing crop that provides the seed as human food and poultry feed, the leaves and young stems as animal fodder for the subsistence farmers (Lorgyer, 2009). *Panicum maximum* also called guinea grass (FAO, 2003) is a highly productive, palatable, persistent and acceptable grass by ruminants. It can be fed to livestock solely or with concentrates or legumes. This study was therefore designed to evaluate the effect of *Cajanus cajan* leaf meal in total mixed rations on the growth performance of West African dwarf growing rams fed *Panicum maximum*.

MATERIALS AND METHODS

EXPERIMENTAL SITE AND ANIMALS

The experiment was carried out at the Sheep and Goat Unit, Teaching and Research Farm, Oyo State College of Agriculture and Technology, Igboora. Sixteen (16) growing West African Dwarf rams weighing between 9.00 - 12.00kg and of 6 – 9 months of age were used. The animals were acclimatized for two weeks and treated against ectoparasites and endoparasites prior to the commencement of the experiment.

HARVESTING, PROCESSING AND PREPARATION OF EXPERIMENTAL DIETS

The forages were harvested from pasture demonstration plot of the college farm. *Cajanus cajan* leaves and *Panicum maximum* were cut at a height of 30cm above the ground level at 50% flowering stage to allow for good re-growth. *Cajanus cajan* leaves including twigs and petioles were harvested and air-dried to constant weight at room temperature while retaining their greenish colouration. The forage was then milled to pass through 2mm sieve. The CCLM were stored at room temperature in jute bags until needed for inclusion in the commercial supplement. Four experimental supplements were formulated by replacing a conventional supplement palm kernel cake (PKC), wheat offal, corn bran, bone meal, sheep premix and salt) with *Cajanus cajan* leaf meal (CCLM).

EXPERIMENTAL LAYOUT, DESIGN AND FEEDING METHOD

The animals were allocated by weight into four treatments of four rams per treatment and two animals as a replicate in a completely randomized design (CRD). The treatments consisted of four total mixed diets containing CCLM at 0, 5, 10 and 15% inclusion levels. The rams were fed on a basal diet of *Panicum maximum* in the morning (0800hr), while the experimental supplements were offered in the afternoon (1500hr). Each group of animals was assigned to an experimental diet and fresh clean water was made available.

DATA COLLECTION AND ANALYSIS

Adjustment period of one week was allowed before data collection commenced. At the beginning of the experiment, the rams were weighed and subsequently on a weekly basis prior to feeding in the morning. The initial live weight was subtracted from the final live weight to determine the weight gained by the animals. Feed offered and reminant (left over) were weighed daily to determine the feed intake of the animals. Both values were used to determine Feed conversion ratio, Dry Matter Intake (DMI), the mean initial body weight and weekly body weight were calculated. All growth performance data obtained were subjected to one-way analysis of variance (SAS 1999) mean value variance showing significant ($P<0.05$) difference were separated using Duncan's multiple range test (Duncan 1955).

Parameters	T_1	T_2	T_3	T_4	SEM
Average initial weight (kg)	10.91^{d}	11.46^{b}	11.55^{c}	11.64^{a}	0.14
Average final weight (kg)	11.52^{d}	11.91^{c}	12.12^{b}	12.50^{a}	0.12
Average weight gain (kg)	0.61^{b}	0.45^{d}	0.57^{c}	0.86^{a}	0.07
Daily weight gain (g/day)	10.89^{b}	8.04^{d}	10.18^{c}	15.36^{a}	1.33
Weekly weight gain (g/wk)	87.14^{b}	64.29^{d}	81.43^{c}	122.86^{a}	10.66
Concentrate Intake (g/day)	204.82^{b}	196.24^{c}	185.76^{d}	208.65^{a}	4.40
Panicum max. Intake (g/d)	130.91^{b}	134.68^{a}	127.85^{d}	129.78^{c}	1.25
Total DMI (g/head/d)	335.73^{b}	330.92^{c}	313.61^{d}	338.43^{a}	4.83
Feed Conversion Ratio	30.83^{b}	41.16^{a}	30.81^{c}	22.03^{d}	3.91

$^{a\,b\,c\,d}$*Means on the same row with different superscript are significantly different (P< 0.05*).

RESULTS AND DISCUSSION

The growth performance summary of the experimental rams was shown in Table 3. There were significant differences (P<0.05) among the treatments in any of the parameters measured. The mean dry matter intake (DMI) values were between 313.61 – 338.43g/day, and these values were similar, meaning that the presence of the CCLM in the diets did not depress feed intake and that the diets containing the test ingredients were all accepted by the rams. Observed values were comparable with 334.94 – 365.97g/day reported by Sanwo *et al.* (2011) for goats fed melon husk and palm oil slurry at 30% inclusion level, but lower than 525.14 – 546.26g/day reported by (Oloche *et al.*, 2013) for WAD goats fed diets containing graded levels of sweet orange peel meal. There were significant (P<0.05) differences in the mean daily weight gain and the feed conversion ratio which ranged from 8.04 – 15.36g/day and 22.03 – 41.16 respectively. The mean daily weight gain of the rams seemed to be slightly increases from $T_2 – T_4$ as the level of CCLM increased. Differences in the mean daily weights of the animals implies that the treatment diets with CCLM also provided adequate nutrients for the growth of the animals and these diets can be used for fattening of rams. Animals on T_4 diet (15% inclusion) had the highest average daily weight gain (15.36g/day) and the least (22.03) feed conversion ratio. These values are lower than the range of 35.72 – 64.29g/day reported by Ogunbosoye *et al.* (2016) for West African dwarf goats fed graded levels of shea nut (*Vitellaria paradoxa*) cake based rations. FCR seemed to improve from $T_I – T_4$ as the level of CCLM increased in the diets. This showed that inclusion of test ingredients (CCLM) in the diets of the experimental animals had a positive impact on the feed conversion ratio. Observed values were higher than those values of Sanwo *et al.* (2011) who reported 11.59 – 17.24 for goats fed melon husk and palm oil slurry at 30% inclusion level.

CONCLUSION

From the result of the study, it can be concluded that *Cajanus cajan* leaf meal possesses adequate nutritive value to support good growth of West African Dwarf growing rams, especially during the period of drought and the forage can effectively serve as alternative feed ingredient in West African Dwarf growing rams diet.

RECOMMENDATION

Based on the result of this research, it could be recommended that *Cajanus cajan* leaf meal could be incorporated into the diet of WAD rams with inclusion level of up to 15% without any deleterious effect. Further research should be carried out using *Cajanus cajan* leaf meal at higher levels of inclusion in the diets of sheep and other livestock to substantiate its suitability and utilization by the animals.

ABSTRACT
This experiment was carried out to examine the effect of sugarcane top treated with different nitrogen sources on rumen fermentation parameters and microbial profiles of West African dwarf (WAD) sheep. Four different silages were prepared such that sugarcane tops were ensiled alone (control) or with 2% urea (USCT silage), 45% boiler litter (BLSCT silage) and 1% urea plus 22.5% broiler litter (UBLSCT) for 42 days. Each silage treatment contains 2% molasses. Twenty-four female WAD sheep weighing 14.58±1.16kgwere randomly assigned to the four silage treatments in a completely randomised design with six animals per treatment for 84 days. Effect of silages on rumen fermentation parameters and microbial profiles at 4 hours post-feeding were evaluated. Results revealed that the rumen pH was highest in animal fed control silage (6.85) and lowest in those fed BLSCT silage (6.56). Highest ammonia nitrogen, total volatile fatty acid, acetate and propionate concentration were recorded in animals fed BLSCT silage. Total viable bacteria, fungi zoopores, cellulolytic bacteria, and proteolytic bacteria counts were higher ($P < 0.05$) in animals fed BLSCT and UBLSCT followed by animals fed USCT while those fed control silage recorded the lowest counts. It can be concluded that feeding of all treated sugarcane top silages especially BLSCT and UBLSCT resulted in improved rumen ecology in terms of microbial biomass, volatile fatty acids production and ruminal pH compared with the control silage.

INTRODUCTION

The most critical constraint hindering livestock productivity in developing countries is irregular and insufficient supply of quality forage (Sarwar *et al*., 2002). In Nigeria, small scale farmers cannot afford the cost of establishing improved pasture, and feeding nutritious supplemental feed such as concentrate to ruminant is expensive. Natural forage crops of good quality are not available all the year round, it is therefore becomes imperative for ruminant nutritionists to investigate more on the use of alternative feedstuffs that are less or not useful to man in order to avoid the problem of feed shortage experienced during the dry season. Ruminant animals have ability to cope with poor quality feeds due to the presence of microorganisms in their rumen which encourage pre-gastric fermentative digestion of feed. Sugarcane top is a crop residues derived after harvesting of the cane and is readily accepted by ruminant either fresh, dried or ensiled (Bhatti and Khan, 1996). Sugarcane top is low in protein, poor in mineral and had low digestibility of nutrients (Patil *et al*., 1999) therefore, there is a need to improve its nutritive value by treating with non-protein nitrogen substances for better utilization by animals since rumen micro-organisms depend on dietary protein for proper growth and optimum activity. Information on the influence of sugarcane top treated with urea and poultry litter on rumen fermentation characteristics and microbial profile of ruminant is limited. The study therefore aimed at determining the effect of sugarcane top treated with urea and poultry litter on the rumen fermentation characteristics and microbial profile of West African dwarf sheep.

MATERIALS AND METHODS

Fresh sugarcane tops were allowed to wilt overnight, chopped into small pieces (about 2-4cm) for ease of loading at ensiling. Four silage treatments were prepared with sugarcane tops ensiled alone (control silage) or with 2% urea (USCT silage), 45% boiler litter (BLSCT silage) and 1% urea plus

22.5% broiler litter (UBLSCT silage). Each silage treatment contained 2% molasses and stored under a shed for a period of 42 days.

Twenty-four female West African dwarf sheep weighing 14.58±1.16kg were randomly allotted to four experimental diets (six animals per treatment) in a completely randomised design. The animals were housed in individual pens and had free access to clean water. Each animal was offered their respective silage on *ad-libitum* basis at 7.00 am in the morning and concentrates feed (at 1.5% body weight) as supplement at 4.00 pm in the evening for a period of 84 days. On the last day of the study, about 60mL of rumen fluid was collected from each animal at 4-hour post-feeding via the oesophagus through the use of suction tube for fermentative and microbial analysis. The fluid was immediately measured for pH and temperature using portable pH meter and was filtered through four layers of cheese cloth, and stored at -20^{0}C pending analyses. Ammonia-nitrogen and volatile fatty acid analyses were analysed (AOAC, 2005; Kayol and Borilek, 1995 respectively). Total direct count of bacteria, protozoa and fungal zoospore was done (Baker and Breech, 1986). Total viable bacteria, cellulolytic, proteolytic and amylolytic bacteria counts were also carried out according to Hungate (1969).

All data collected were subjected to Analysis of Variance (ANOVA) while significant differences among means were compared using Duncan's Multiple Range F-test (SAS, 1999). The mathematical model of the experiment: $Y_{ij} = \mu + T_i + \Sigma_{ij}$, where Y_{ij} = observed value of the dependent variables,μ = Population mean, T_i = Effect of the different silages (treatment effect),Σ_{ij}=Random residual error

RESULTS AND DISCUSSION

The rumen fermentation parameters and microbial profiles of West African dwarf sheep fed sugarcane top silage are presented in Table 2. The rumen pH taken was significantly affected ($P < 0.05$) by the diets with sheep fed control silage having the highest value (6.85) while those fed BLSCT silage recorded the least (6.56). The rumen temperature range across the treatment is compared favourably with 39°C which was necessary for the optimum growth of rumen bacteria (Kamra, 2005). The rumen pH recorded for all treatments fell within the range (6.0-7.0) reported by Aduku (1993) as suitable pH for growth and normal activities of rumen bacteria. Rumen bacteria are very sensitive to pH change and none of the three predominant fibrolytic bacteria can grow at pH less than 6.0 (Shi and Weimer, 1992). Fibre digestion is also reduced when ruminal pH reached values below 6.0 (Wanapat *et al*., 2000). Ruminal ammonia nitrogen concentration recorded was significantly ($p<0.05$) different across the treatments with sheep fed USCT, BLSCT and UBLSCT silages having higher concentration compared to control silage. It means that addition of nitrogen sources (urea and broiler litter) had increased ammonia nitrogen concentration with ammonia being the main nitrogen source for the growth and protein synthesis by ruminal bacteria to achieve maximum fermentation (Hoover, 1986). Nguyen *et al.* (2005) had also stated that rumen ammonia concentration reflected the CP levels in the diets and was associated with higher number of bacteria. Ammonia nitrogen concentrations recorded in sheep fed USCT, BLSCT and UBLSCT silages were within the optimal range of ruminal ammonia nitrogen (15 – 30mg %) (Perdok and Leng, 1990) needed for increasing microbial protein synthesis, feed digestibility and voluntary feed intake.

There were significant variations ($P < 0.05$) in the total volatile fatty acid (TVFAs), acetate, propionate and butyrate concentration across the treatments. Total viable bacteria, cellulolytic and proteolytic bacteria counts also differ statistically ($P < 0.05$). It could be observed from this study that the TVFAs, acetate, propionate and butyrate concentrations increased with addition of nitrogen sources. Results obtained is consistent with the rumen pH data which means that the more acid is being produced, the lower the pH. The highest value obtained for acetic acid in sheep fed BLSCT was higher than the value (66.6 mmol/l) reported by Azizi-Shotorkhoft *et al*. (2012). Variation observed

might be due to differences in the proportion of poultry litter included in the ration. The range of cellulolytic and proteolytic bacteria count observed was similar to the range reported by Chanjula *et al*. (2004).

CONCLUSION

It could be concluded from this study that all treated sugarcane top silages especially BLSCT and UBLSCT improved rumen ecology in terms of microbial biomass production, volatile fatty acids concentration and ruminal pH. Sugarcane tops treated with broiler litter and urea is recommended for feeding ruminants especially during the dry season when forages are scarce and of low nutritive value

PHYSICO-CHEMICAL, PHYTOCHEMICAL AND ANTI-OXIDANT PROPERTIES OF BOTANICAL GALACTOGOGUES USED IN RUMINANT FEEDING

***B.N. Umar and **Y. Garba**
**Department of Animal Science, Bayero University, Kano.*
***Centre for Dryland Agriculture, Bayero University, Kano.*

ABSTRACT
Botanical galactogogues contained in Guiera senegalensis (Guiera), Tamarindus indica (Tamarind), Ficus thonningii (Blume) and Anogeissus leiocarpus (African birch) were evaluated for their physico-chemical, phytochemical and antioxidant properties. The samples were shade dried, ground to powder, stored and analyzed for the above-mentioned properties in the laboratory. The treatments were laid in a completely randomized design replicated thrice. The antioxidant properties were evaluated using the diphenyl-2-picryl-hydrazyl (DPPH) radical scavenging activity and ferric reducing antioxidant power (FRAP). Data collected were analyzed using SAS (2000) and Tukey's test was used to separate means (P<0.05). Physico-chemical analysis of the browse plants showed that there was a significant (P<0.05) difference in their contents of moisture, ash, acid insoluble ash, water insoluble ash, sulphated ash, acid soluble extractive and water soluble extractive. Result further revealed that the extracts of G. senegalensis, T. indica, Ficus thonningii and A. leiocarpus possessed varied degree of free radical scavenging and antioxidant activities in a concentration-dependent manner. The values ranged from (0.220- 0.570) µg/ml for DPPH and (0.4715- 0.7185) µg/ml for FRAP. The extract of G. senegalensis was observed to be the most effective radical scavenger and antioxidant (5.124 µg/ml) and was closely followed by A. leiocarpus extract (1.841 µg/ml). Their high radical scavenging and antioxidant activity can be attributed to their high flavonoid and phenolic contents. It was concluded that G. senegalensis had the highest antioxidant property while F. thonningii had the highest ferric reducing antioxidant property. These findings supported the ethno-veterinary uses of these plants to produce effective intervention for free radical mediated diseases. It is thus reommended that antioxidant profile in milk of ruminants fed botanical galactogogues be further studied.

Keywords: galactogogues, antioxidant, physico-chemical, phytochemical

INTRODUCTION

Galactagogues are substances that boost established lactation, whereas the term galactopoietic is used independently to describe the hormone preparations which enhance milk production in an animal already in lactation (Asimov and Krouze, 1991). Phytochemical screening of plants extracts either with organic or aqueous solvents has revealed the presence of numerous active components including ascorbic acid, domperidone, metoclopramide, saponins, glycosides, essential oils, isoflavones, etc. which contribute to galactopoietic effect (Bharti *et al.,* 2012). Majority of these herbal preparations have however not been scientifically, systematically and thoroughly evaluated, but their traditional use suggests some safety and efficacy. The objectives of the study were to determine the physico-chemical, phytochemical and anti-oxidant properties of *Guiera senegalensis* (sabara), *Tamarindus indica* (tsamiya), *Ficus thonningii* (chediya) and *Anogeissus leiocarpus* (marke).

MATERIALS AND METHODS

The experiment was conducted at the Department of Biochemistry, Faculty of Science, Bayero University Kano, Nigeria.

Samples Collection and Preparation

Leaves of *Anogeissus leiocarpus* was collected at Tsohuwar Zara, *Ficus thonningii* at Tarauni, *Guiera senegalensis* at Dirbindai and *Tamarindus indica* at Magadawa in Kano State, Nigeria.

The leaves were air dried at room temperature and ground separately to powdered form. The extraction method used for dried samples involved adding 150 ml of methanol to 20g of the dried

sample. The mixture was then refluxed in a water bath at 50^0C for 1 hour and was then filtered and placed in fridge (Charalampos *et al*., 2013).

LABORATORY ANALYSIS

The total flavonoids content of each plant extract was assessed by a method employed by Zhishen *et al*., (1999). Each sample (0.5 mL) was mixed with 2 mL of distilled water and subsequently with 0.15 mL of a $NaNO_2$ solution (15%).

The total phenol content (TPC) was measured using Folin-Ciocalteu assay (Kähkönen *et al*., 1999). A volume of 0.2 mL of the extract was introduced into test tubes followed by 0.5 mL Folin-Ciocalteu's reagent (diluted 10 times with water). Antioxidant activity of the extracts was evaluated using Phosphomolybdenum according to the procedure of Prieto *et al*., (1999). Then 0.3 ml of plant extract was combined with 3 ml of reagent solution (0.6 M sulfuric acid, 28 mM sodium phosphate and 4 mM ammonium molybdate).

The antioxidant potential was measured using the stable radical DPPH. The experiments were carried out using Blois method (Blois, 1958).

$$\text{DPPH radical scavenging activity (\%)} = \frac{\text{(Absorbance of control–Absorbance of sample)}}{\text{Absorbance of control}} \times 100$$

A modified method of Benzie and Strain (1996) was used for the determination of total antioxidant activity (FRAP assay). The stock solutions included 300 mM acetate buffer (3.1 g $C_2H_3NaO_2 \cdot 3H_2O$ and 16 ml $C_2H_4O_2$), pH 3.6, 10 mM 2, 4, 6-tripyridyl-s-triazine (TPTZ) solution in 40 mM HCl, and 20 mM $FeCl_3 \cdot 6H_2O$ solution.

The Physicochemical analysis of United States Pharmacopoeia-National Formulary (2003) method was adopted for studying physicochemical properties which include;

Two grams of the powdered plant material was weighed in a tared china-dish and oven dried for 30 minutes at 105°C. The china-dish was put in desiccator to cool. It was then weighed on digital balance and the weight of empty dish was subtracted to get dried material. Two grams of powdered plant material was weighed in a tared china-dish and incinerated in furnace at a temperature of 675 ± 25°C for the duration of 48 hours, until the ash got free from carbon. After getting the desired form of ash, the china-dish content was cooled. At the end, the ash contents were weighed and the percentage of the total ash was calculated with reference to the sample weight.

The total ash contents were boiled in 25 mL dilute HCl for 5 minutes. It was then filtered through an ash less filter paper. The filter paper was then dried and ignited in tared china-dish until the ash got free from carbon and later cooled. The ash contents were weighed and the percentage of acid insoluble ash was calculated.

The total ash contents obtained from 2g of powdered plant material were boiled in 25 mL distilled water for 5 minutes and filtered through an ash less filter paper. The filter paper was then dried and ignited in tared china-dish until the ash got free from carbon and then cooled. The ash contents were weighed and the percentage of water insoluble ash was calculated with reference to weight of the total ash used in the test.

Sulphuric acid was mixed with 2g of the powdered plant material in a tared china-dish to make a paste like material. The china-dish was ignited and it was then cooled in a desiccator. The ash contents were

weighed and the percentage of sulphated ash was calculated with reference to the weight of the dried powdered plant material used in the test.

Five grams of powdered plant material was put in a tared flask. Ethanol 95% (100 mL) was poured on it and then macerated in a closed flask for 24 hours. The contents were filtered and 25 mL filtrate was evaporated to dryness in a china dish and the residue was dried in an oven at 105°C and weighed. The percentage of alcohol soluble extractives was calculated with reference to the weight of the sample. One gram of air-dried sample, coarsely powdered was macerated with 100 mL of distilled water in a closed flask for 24 hours shaking frequently. Solution was then filtered and 25 mL of filtrate was evaporated, further dried at 1000^0C and weighted. The percentage of water soluble extractive was calculated with reference to the air-dried samples (Momin and Kadam, 2012).

PHYTOCHEMICAL ANALYSIS

The powdered plant samples (50 g/250 mL) were extracted with petroleum ether, chloroform, ethyl acetate, methanol and water using Soxhlet apparatus at 55-85 °C for 8-10 hours to remove the polar and non- polar compounds (Elgorashi and Van Staden, 2004). The extracts were air dried and then used. The solvents of the respective extracts were condensed and then stored at 4 °C for further use. A small portion of sample was added to 5mL of 1% aqueous HCl in a beaker. The mixture was then stirred, filtered and the volume was reduced to one quarter using a water bath. Few drops of Dragendorff's reagent was added to the filtrate. An orange-red precipitate results which shows the presence of alkaloids (Sofowara, 1993).

Total phenolic content was estimated using Folin-Ciocalteau reagent by the method of Sidduraju and Becker (2003). Twenty (20µg) of leaf extracts were taken separately and it was made up to 1 mL with distilled water. Then, 500 µL of diluted Folins-phenol reagent (1:1 ratio with water) and 2.5 mL of sodium carbonate Na_2CO_3 (20%) were added. The mixture was shaken and incubated in a dark condition for 40 minutes and the absorbance was measured at 725 nm. A calibration curve of gallic acid was constructed and linearity was obtained in the range of 10-50 µg/mL. The total phenolics content in the plant extracts were expressed as mg of gallic acid equivalent (mg GAE/g extract) by using the standard curve.

The total flavonoids content was estimated using the procedure described by Jia *et al*., (1999). A total of 1 mL of the plant extracts were diluted with 200 µL of distilled water separately followed by the addition of 150 µL of sodium nitrite (5%) solution. It was incubated for 5 minutes and 150 µL of aluminium chloride (10%) solution was added. Then, 2 mL of sodium hydroxide (4%) solution was added and made up to 5 mL with distilled water. The mixture was well shaken and the absorbance was measured at 510 nm. Appearance of a pink color showed the presence of flavonoids content. The total flavonoids content was expressed as rutin equivalent mg RE/g extract on a dry weight basis using the standard curve.

Tannins content was estimated by the method described by Siddhuraj and Manian, (2007). 0.5g of the extracts and 10mL of distilled water was mixed, stirred and filtered. Few drops of 1% ferric chloride solution was added to 2mL of the filtrate. Results showing blue-black, green, blue-green precipitate is positive (Trease and Evens, 2002).

Estimation of total saponins content was determined by the method described by Sofowara (1993). One gram of the plant extract was added with 5mL of distilled water. The mixture was then boiled and filtered. The filtrate and 3mL of distilled water was vigorously shaken for 5 minutes. Results showing persisting frothing on warming is positive.

STATISTICAL ANALYSIS

The experiment was laid in a completely randomized design (CRD) with three replicates in each treatment. Analysis of Variance (ANOVA) of the SAS (2000) package was the tool of analysis and the means were separated using the Tukey test ($p<0.05$).

RESULTS AND DISCUSSION

The antioxidant activity of evaluated samples revealed a significant ($P<0.05$) difference. Results obtained ranged from 1.329-5.124(µg/ml) with *Guiera senegalensis* having the most while *Ficus thonningii* had the least. Table 2 presents the antioxidant activity of the botanical galactogogues using the DPPH method at different concentrations. However, *Ficus thonningii* (0.360- 0.570µg/ml) had the highest antioxidant activity while *Guiera senegalensis* (0.255-0.320µg/ml) and *Anogeissus leiocarpus* (0.255-0.305µg/ml) had the least among all the plants samples evaluated. Table 3 presents the antioxidant activity of the samples using the FRAP method at 0.2, 0.4, 0.6, 0.8, and 1mg/ml concentrations. At 0.2mg/ml, the result showed that the antioxidant concentration of the plant samples were the same and ranged from (0.4715-0.5420µg/ml). Result reveals that at 0.4mg/ml, 0.6mg/ml, 0.8mg/ml and 1.0mg/ml concentration, the values ranged from (0.4875-0.6580µg/ml), (0.4860-0.6915µg/ml), (0.4830- 0.6995µg/ml), (0.4820-0.7185µg/ml) respectively with *Ficus thonningii* having the highest while *Guiera senegalensis* had the least. Table 4 presents the result of physico-chemical characteristics of the plant samples evaluated. Moisture content was found to be highest in *Ficus thonningii* (11.30%) and lowest in *Anogeissus leiocarpus* (8.15%). Ash was also found to be highest in *Ficus thonningii* (34.85%) and lowest in *Tamarindus indica* (10.85%). Results of Acid insoluble ash and water insoluble ash revealed that *Ficus thonningii* had the highest (6.15/11.60%) while *Guiera senegalensis* had the least (2.55/4.55%) respectively. Sulphated Ash ranged from (23.94-51.35%) with *Guiera senegalensis* having the highest (51.35%) while *Anogeissus leiocarpus* had the least. Acid Soluble Extractive result showed that *Anogeissus leiocarpus* had the highest (13.73%) while *Ficus thonningii* had the least (3.97%). Water Soluble Extractive was also found highest in *Anogeissus leiocarpus* (4.17%) and lowest in *Guiera senegalensis* (2.63%). Table 5 shows the Phytochemical Concentration of the plant samples. Tannins content was found to be highest in *Anogeissus leiocarpus* (6.91%) and least in *Guiera senegalensis* (4.55%). *Anogeissus leiocarpus* and *Guiera senegalensis* were found to have the same saponin content which ranged from (3.47-3.64%). Result of flavonoids content was found to be highest in *Guiera senegalensis* (3.44%) and lowest in *Anogeissus leiocarpus* (2.28%). Alkaloids content reveals that *Anogeissus leiocarpus* has the highest (27.90%) while *Guiera senegalensis* had the least (8.53%). The Total phenolics content of the botanical galactogogues revealed that *Anogeissus leiocarpus* has the highest phenolics content (190.18%) while *Guiera senegalensis* has the least (159.68%).

CONCLUSION

The radical scavenging ability and antioxidant properties of these plants has been found to be adequate for enhancing milk production in lactating animals. Their high radical scavenging and antioxidant activity can be attributed to their high flavonoid and phenolic contents. Without any reservation, the plants extracts evaluated in the present study possess antioxidant properties which provides effective intervention for free radical mediated diseases that may affect lactation in mammals.

ABSTRACT

The study evaluated the effects of supplementation of legume pellets on the rumen fermentation parameters of West African dwarf (WAD) sheep fed Panicum maximum. Twenty WAD rams with average body weight of 12.43 ± 0.5 kg were allocated to four dietary treatments: sole Panicum maximum, P. maximum supplemented with Lablab purpureus pellets, P. maximum supplemented with Calopogonium mucunoides pellets *and P. maximum supplemented with Mucuna pruriens pellets arranged in a Completely Randomized Design. Panicum maximum was offered to the animals ad libitum and legume pellets were fed at 5 % of their body weight. The feeding trial lasted 12 weeks. Rumen pH, ammonia nitrogen (NH_3-N) and total volatile fatty acid were determined, and analyzed using one-way analysis of variance. At 6 hours post feeding, NH_3-N concentration in rams supplemented with* C. mucunoides *pellets were significantly ($P<0.05$) lower than others. Rams supplemented with L. purpureus pellets had the lowest ($P<0.05$) rumen pH (6.99) at 0 hour and at 6 hours post feeding (6.54). Moreso, supplementing rams with L. purpureus pellets increased the NH_3-N and reduced the rumen pH which can improve the activity of micro-organisms in the rumen. As such, supplementation with forage pellets during dry season, will serve as reliable source of feed for ruminants.*

Keywords: Ammonia, legume pellets, *Panicum maximum*, rumen pH, volatile fatty acids

INTRODUCTION

The forage plants decline rapidly in quantity and quality during dry season (Ajayi, 2007). During this period, the animals are faced with reduced feed intake, loss of weight and this led to their poor performance. To alleviate this problem, it becomes imperative to conserve and process forages during period of abundance for use during the period of scarcity. They can be stored as hay or silage and fed to animals as conserved feed. The rumen which is an essential fermentation vat in ruminants, is capable of preparing end products particularly volatile fatty acids and microbial proteins as major energy and protein for ruminants hosts. It also provides an anaerobic environment, constant temperature and pH to the microorganisms for digestion (Yusuf, *et al* 2008). The products of microbial fermentation, mainly volatile fatty acids (VFA) and microbial protein, are available for absorption in the small intestine while the gases (carbon dioxide and methane) are eructated (Bayat and Shingfield, 2012). Tropical forages are rich in fibre and lignin which reduces the fermentation rate, microbial mass and production of VFA in the rumen of the animals (Ebtehag *et al*., 2016). The fibre contents can be reduced by processing forages into pellets (Oyaniran *et al*., 2018) and this will increase the fermentation rate. Hence, this study investigated the rumen pH, ammonia nitrogen and VFA of West African dwarf sheep fed *Panicum maximum* supplemented with legume pellets.

MATERIALS AND METHODS

The experiment was carried out at the Directorate of University Farms, Federal University of Agriculture, Abeokuta (FUNAAB), Nigeria on latitude 7° 13’ 49.46" N and longitude 3° 25’ 11.98" E. *Lablab purpureus*, *Calopogonium mucunoides* and *Mucuna pruriens* leaves were harvested at 12 weeks and dried. The dried legumes were milled and pelletized using a 6 mm die size to produce pelletized legume forages of average length of 40 mm. Cassava flour was used as binder (proportion of 1 kg of cassava flour to 100 kg of the milled sample) with addition of water to moisten. The pellets

were warm and moist, when they came out of the mill. They were then air dried to harden up so as to hold their forms. The experimental diets were Sole *Panicum maximum*, *P. maximum* supplemented with *L. purpureus* pellets, *P. maximum* supplemented with *C. mucunoides* pellets, *P. maximum* supplemented with *M. pruriens* pellets. A total number of twenty (20) West African dwarf (WAD) rams with average body weight of 12.43 ± 0.5 kg were used for the experiment. The animals were weighed and randomized into four treatment groups of five animals per treatment each balancing for body weight. A basal diet

of fresh *Panicum maximum* grass was fed daily to the animals. The grass was harvested at 6 weeks of re-growth, wilted, chopped and offered to the animal's *ad libitum* daily. The legume pellets were fed as supplements to the animals at 5 % of their body weight. At the end of feeding trial, ruminal fluid samples were collected before morning feeding and six hours post feeding using oesophageal tube for the determination of rumen pH, ammonia nitrogen and volatile fatty acids. Sub- samples of the grass and legume pellets were oven dried at 65 ^{o}C to constant weight. Proximate composition were determined according to AOAC (2000). Fibre fractions: neutral detergent fibre (NDF), acid detergent fibre (ADF), acid detergent lignin (ADL) were analysed according to the procedure of Van Soest *et al.* (1991). Tannin contents were determined using the Vanillin-HCl method as described by Price and Butler (1977). Saponin contents were determined according to the method of Obdoni and Ochuko (2001). The pH of the rumen fluids were measured immediately after collection with the use of pH meter (Hanna instruments, pH 211, microprocessor pH meter, K012818, Portugal). Thirty (30) ml of rumen fluid was taken and filtered through four layers of cheese cloth for the determination of rumen ammonia nitrogen (Lanyansunya *et al*., 2007) and volatile fatty acids were determined according to the procedure of Siedlecka *et al*. (2008). All data obtained were arranged in a completely randomized design and subjected to one-way analysis of variance (ANOVA). Significant means were separated using Duncan's Multiple Range Test of SAS (2000).

RESULT AND DISCUSSION

Table 1 shows the chemical composition of *P. maximum* and herbaceous forage legume pellets. The crude protein content in this study ranged from 94.5 gkg^{-1} in *P. maximum* to 126.0 g kg^{-1} in *Mucuna puriens* pellets. The crude protein content of the legume pellets was higher than the minimum recommended range of 7.0 - 8.0 % for efficient functioning of rumen microorganisms (Van Soest, 1994). *Calopogonium mucunoides* pellets had the highest (P<0.05) NDF content while *L. purpureus* pellet had the least value. The fibre contents of samples in this study were below 60-65 % suggested as the critical limit above which efficiency of utilization of tropical forages by ruminants would be impaired (Muia, 2000). Tannin content was highest (P<0.05) in *Mucuna pruriens* pellets (0.0042 %) while *C. mucunoides* pellet (0.0018 %) had the lowest (P<0.05) value. Tannin content recorded in this study were lower than 2-5 % sheep and cattle can tolerate (Diagayete and Hugg, 1981). Babayemi *et al*. (2004) reported that higher level of saponin in feed is known to deter the activities of bacteria in the rumen.

Table 1: Chemical composition (g kg^{-1}) of *P. maximum* and herbaceous forage legume pellets

	Treatment					
Parameters (g kg^{-1})	*Panicum maximum*	*Lablab purpureus*	*Calopogonium mucunoides*	*Mucuna pruriens*	SEM	P-value

Tannin (%)	ND	0.0025[b]	0.0018[c]	0.0042[a]	3.51	<.0001
Saponin (%)	ND	5.00[c]	5.50[b]	6.00[a]	0.15	0.0002

[a, b, c] means on the same row with different superscripts are significantly different (P<0.05). ND: Not determined. SEM: Standard error of mean

Table 2 shows the rumen parameters of West African dwarf rams fed *P. maximum* supplemented with herbaceous forage legume pellets. Rams supplement with *M. pruriens* pellets had the highest (P<0.05) rumen pH (6.91) while rams that were supplemented with *L. purpureus* pellets (6.51) had the lowest (P<0.05) rumen pH. The high ruminal pH in rams before feeding could be due to effect of low soluble carbohydrate in the rumen of the animals at that time. However, the rumen pH of the animals was reduced at 6 hours post feeding and this could be as a result of high VFA and rapid fermentation at 6 hours post feeding. Highest ruminal pH in rams fed *M. pruriens* pellet supplemented diet at 6 hours post feeding could be the effect of high tannin content which increases saliva and it serves as buffering capacity in the rumen (Yusuf *et al*., 2017). Volatile fatty acids usually accumulate in the rumen if its rate of production exceeds the clearance rate which may lower the rumen pH and cause the metabolic disturbance (Yusuf *et al*., 2013). Low VFA in the rumen of rams supplemented with *C. mucunoides* pellets, could be attributed to high fibre in the feed. At 6 hours post feeding, the VFA in the animals was higher compared before feeding except for rams supplemented with *M. pruriens* pellet. This could be due to high tannin content in the feed and this in line with the reports of Getachew and Makkar (2002) that lower production of VFAs could be due to the elevated content of tannin. The rumen pH of the rams after feeding fell within the range 6.00-7.00 required for optimal microbial digestion of fibre and protein in the rumen (Firkins, 1996). Low NH_3-N in rams supplemented with *C. mucunoides* pellets could be due to low crude protein content and VFA because metabolism of the ammonia requires a considerable and commensurate amount of energy (Oba and Allen, 2003). The concentration of NH_3-N in the rumen depends on the protein content in the feeds fed to the animals (Ranjah, 1980). The ruminal NH_3-N concentration of the rams were sufficient for maximizing rumen microbial synthesis since it lies within the range of 2 and 5 mg/100ml reported as minimum rumen fluid.

Table 2: Rumen Parameters of West African dwarf rams fed *P. maximum* supplemented with herbaceous forage legume pellets

Parameters %	Dietary treatment				SEM	P-value
	P. Maximum	*Lablab purpureus* + *P. maximum*	*Calopogonium mucunoides* + *P. maximum*	*Mucuna pruriens* + *P. maximum*

CONCLUSIONS

From the results of this study, it can be concluded that rams supplemented *Lablab purpureus* pellets had highest ruminal ammonia nitrogen and the lowest rumen pH. The rumen pH of the rams were reduced at 6 hours post feeding.

ABSTRACT
The challenge of inadequate nutrition and inability to meet the energy-protein requirement of cattle especially during the dry season has limited their productivity. In Nigeria, Cassava and Gliricidia are valuable feed resources that can fill the gap in feed supply if adequately harnessed, and this is dependent on methods of processing and preservation. This could be through pelleting of feedstuffs. This study was carried out to assess the effect of pellet mill and binder on quality characteristics of Cassava-Gliricidia pellets and its acceptability by cattle. Two flat die pellet mills (vertical and horizontal designs) at 2 levels of starch inclusion (0 and 5%) were adopted for the pellet feed production. Four Zebu cows were used for the preference assessment in a cafeteria study which lasted for 30min daily and a total period of eight days. The effect of pellet mill and starch level was significant on the assessed quality parameters. The crude protein content of pellets ranged from 17.65 to 19.45%. Physical quality was measured in terms of durability. Pellet Durability Index values show that pellets compressed by vertical design flat die mill with 5% starch are the most durable. Pellet preference considered in terms of intake rate showed that Zebu cows preferred Cassava-Gliricidia pellets compressed by vertical design flat die mill without starch (0%) to other pellets used in this study. It is concluded that cassava root meal and gliricidia leaves possess the potential of solving the problem of limiting feed resources of ruminant animals in Nigeria.

Keywords: *Cassava; Gliricidia; pellet mill; Zebu cows; PDI: Pellet Durability Index*

INTRODUCTION

The trends in livestock production in developing countries as well as in the world show a more rapid growth in production of pig and poultry meat in comparison with that of ruminant (Upton, 2004). The unavailability of sufficient pasture forage during the dry season in tropical and subtropical regions is a major problem in ruminant livestock production (Olorunnisomo, 2011). During this period, grazing ruminants lose weight and in extreme cases some deaths do occur. The feeding of supplemental protein diets is one of the means of minimizing weight loss during this period. Thus a sustainable strategy will entail developing means capable of optimizing the use of our common feed resources such as cassava and gliricidia. In Nigeria, cassava production is well-developed as an organized agricultural crop. It has well-established multiplication and processing techniques for food products and cattle feed. Cassava production in other African countries appears small in comparison to Nigeria's substantial output (FAO, 2004a). Ruminants can be fed on cassava tuberous root, foliage, peel and residue obtained after processing cassava. Also as part of global efforts to improve animal nutrition during the dry period of the year, attention is being shifted to the evaluation of indigenous multi-purpose tree (MPT) species. These indigenous MPT are well distributed and adapted to the hot tropical climate (Anele *et al*., 2006). Among the MPT is Gliricidia which is a browse tree of nutritional importance in ruminant feeding system. One of the means of preserving excess forage to ensure a steady supply of quality feeds for livestock during the dry season is to make the leaf meal into pellets. These pellets can be improved nutritionally by mixing leaf meal with other feed ingredients such as wheat bran, cassava tubers, palm kernel cake, brewers' dry grain, and etc. The voluntary intake of feed is a major determinant of feed quality and is quite well accepted as an indicator of potential animal performance (Coleman and Moore, 2003). Furthermore, the utilization of any feed resource is influenced by the preference and acceptability of the feed, which is related to the animal's behavioral pattern (Mtenga *et al*., 1992; Kalio *et al*., 2006).

MATERIALS AND METHODS

The experiment was conducted at the Dairy Unit of the Teaching and Research Farm (TRF), University of Ibadan, Ibadan, Nigeria (3º45´E, 7º27´N; at 220m above sea level).

FORAGE MATERIALS

Gliricidia leaves were harvested from the existing plantations at the TRF. The leaves were seperated and air dried to a constant moisture level and thereafter bagged. It was then ground into the meal form at the feedmill of the Teaching and Research farm. Cassava roots was purchased from Ikire in Osun state. It was washed and crushed. It was thereafter pressed, dried and finally milled into flour. Other ingredients were purchased from the feedmill.

PELLET MILL

Two different pellet mills were used in pelleting the feed ingredients. Treatments 1 and 2 were pelletised by a flat die pellet mill while treatments 3 and 4 were pelletised on a locally fabricated ring die pellet mill.

PREFERENCE AND ACCEPTABILITY TRIAL

Four Zebu cows were used for the acceptability study. The method used is the cafeteria method of feeding as described by Larbi *et al.* (1993). Large feeders were used to enable the four (4) cattle feed simultaneously in a convenient situation. Each animal had free access to each of the alternative feed resources in the feeding troughs. The order of placement of the test feed in the parlor was randomized every day to avoid adaptation of the animal to a particular diet. The animals were served 2kg each of the treatments and were replicated twice. Feeding was allowed for a period of 30 minutes daily and the trial was carried out for eight days. The feed consumed was determined by deducting the feed refusal from the quantity offered.

PROXIMATE ANALYSIS

Feed sample (Pellets) were analysed for Dry Matter (DM) and Crude Protein (CP) according to AOAC (2005). Neutral detergent fibre (NDF) and acid detergent fibre (ADF) were determined according to the procedure of Goering and Van Soest (1985).

DURABILITY MEASUREMENT

The durability of the pellets was evaluated by using a durability tester. 100g of each sample was placed in a tumbling box having 60 rpm (revolution per minute) and was allowed to run for 5 minutes. The samples were recovered and the fines were separated from the pellets.

EXPERIMENTAL DESIGN AND STATISTICAL ANALYSIS

A 2 x 2 factorial arrangement in a completely randomized design consisting of 2 pellet mills (a flat die pellet mill and a locally fabricated ring die mill) and 2 levels of starch (0 and 5%) of starch inclusion in the diets was adopted for the pellet feed production.

The data collected were subjected to analysis of variance (ANOVA) using the General Linear Model (GLM) procedure of MINITAB (2002-2003). Significant differences among means were separated using the Duncan's Multiple Range Test (DMRT) of the same software.

RESULTS AND DISCUSSION

Table 1: Proximate Composition (%) of Pellets

	DM	CP	EE	ASH	CF	NFE	NDF	ADF	ADL
T1	85.72	19.45^{a}	0.75^{a}	8.25^{c}	20.55^{d}	39.45^{a}	46.00^{b}	20.50^{b}	11.50^{b}
T2	85.42	18.85^{b}	0.85^{a}	8.35^{c}	21.25^{c}	38.65^{b}	41.50^{c}	17.00^{c}	10.25^{bc}
T3	85.46	18.35^{c}	0.85^{a}	9.75^{a}	21.85^{b}	36.85^{c}	49.50^{a}	27.50^{a}	14.50^{a}
T4	85.53	17.65^{d}	0.75^{a}	9.25^{b}	22.05^{a}	38.45^{b}	45.50^{b}	15.50^{c}	9.25^{c}
SEM	0.13	0.05	0.05	0.05	0.05	0.09	0.66	0.66	0.395

$^{a-d}$ Means in the same row with different superscripts are significantly different ($p < 0.05$)

T1: Pellets compressed by flat die mill + 0% starch; T2: Pellets compressed by flat die mill + 5% binder

T3: Pellets compressed by ring die mill + 0% binder; T4: Pellets compressed ring die mill + 5% binder

The CP content of pellets ranged from 17.65 to 19.45%. All these values are well above 8% suggested by Norton (1994) for effective ruminal function. This is an indication that pellets of this composition can serve as a protein supplements for cattle, especially during the period of drought.

PELLET DURABILITY INDEX

Table 2: Effect of pellet mill and starch on PDI of cassava-gliricidia pellets

Pellet mill	
M1	93.75^{a}
M2	89.25^{b}

$^{a-b}$ Means in the same column with different superscripts are significantly different ($p < 0.05$)

M1: Flat die pellet mill; M2: Locally fabricated ring die pellet mill

Table 3: Effect of Starch Inclusion on Durability Index

Starch level	
0%	90.25^{b}
5%	92.75^{a}

The effect of pellet mill on the PDI value was pronounced with pellets compressed by flat die having lesser fines after agitation compared to pellets from ring die. The difference may be due to the quantity of steam generated by the individual pellet mill. Skoch *et al*. (1981) indicated that steam

conditioning improved pellet durability. The addition of starch binder (5%) made the pellets to be more durable. PDI values for pellets having binder were significantly ($P < 0.05$) higher than pellet without binder. This emphasised the importance of binder in the production of durable pellets. Pellets without binder compressed by flat die mill were more durable than pellets from ring die mill irrespective of binder inclusion. Sonthi and Nitipong (2013) studied the potential of cassava root to serve as pellet fuel and found out that all pellets had little amount of fines. This result agrees with the above assertions and show that pellets of cassava roots are of good durability. In addition, the durability of such pellets can be influenced by pellet mill.

ACCEPTABILITY

Starch level	
0%	1.09[a]
5%	0.91[b]

[a-b] Means in the same row with different superscripts are significantly different ($p < 0.05$)

STARCH: CASSAVA STARCH

The Coefficient of Preference is a measure of acceptability of forages by ruminants and is determined as the ratio of individual forage intake to the mean intake of all the forages. The results are presented in Tables 4 & 5. Based on this, the effect of machine was significant on the acceptability of pellets by cattle. Pellets compressed by flat die mill are considered to be acceptable while pellets from the ring die mill are not acceptable. West (1998) reported that a major factor which could enhance intake of forages by cattle is to simply lower the cell wall content. Thus, result of statistical analysis of pellets' chemical quality showed that pellets compressed by flat die mill had comparatively lower NDF content than pellets from ring die mill. This could be one of the reasons that made pellets compressed by flat die mill acceptable to the cattle. The effect of starch binder inclusion in the diet is also noticeable in the preference of cattle for pellets made by either mill. The result revealed that the addition of starch binder (at 5%) to the diet reduced the intake of pellets by the animals. According to Matthews (1983), palatability of a feed is interchangeable with preference for the feed. It is determined by the taste, smell, appearance, temperature and texture of the feed. It could then be argued that the inclusion of pregelatinised starch as binder in the production of pellets has a way of altering those dietary characteristics that stimulates a selective response by the animals.

CONCLUSION AND RECOMMENDATION

It is concluded that pellets made from cassava root meal and gliricidia leaves possess the potential of solving the problem of limiting feed resources in Nigeria. However, the efficiency of pellet mill must be carefully considered for optimum maximization of these resources. It is recommended that binder inclusion in cassava-gliricidia pellets should not exceed 5% of the feed.

ABSTRACT
The aim of this experiment was to determine the effect of feeding varying levels of brewers dried grain on feed intake, body weight gain, milk yield and composition of Yankasa ewes. Five treatment diets designated D1, D2, D3, D4 and D5 were formulated with maize component substituted with BDG at 0 %, 10 %, 20 %, 30 % and 40 % respectively. The experimental animals were randomly allotted to the five treatments groups in four replicates, each comprising one lamb per replicate in a completely randomized design. The animals were sourced from Biotechnology Department of the National Animal Production Research Institute (NAPRI), Shika Zaria, with properly recorded dates of birth and weight at birth. The lambs were used for the experiment at twelve week. The animals were intensively managed given the experimental diets in the morning and supplemented with forage (Digitaria smutti) afterward. The oestrus of ewes was synchronized using a synthetic prostaglandin named Estrumate® administer through intramuscular injection to have a uniform gestation and parturition. The parameters measured were feed intake, body weight gain, milk yield and milk composition. One way ANOVA using SAS (2000) statistical package was used for analysis. A non-significant (P>0.05) difference was observed among the treatment groups in respect of feed intake with weight gain having a significant difference. However D5 had a better result (4.75 Kg, 22.08) in respect to weight gain and feed conversion ratio respectively. Milk composition and showed a significant (P<0.05) difference with D5, D4 and D3 (7.39%, 7.25 % and 6.63 % respectively. Milk yield showed a significant (P<0.05) difference at week two among the dietary treatment with treatment two (D2) having the best result ((0.11 Kg). It was concluded and recommended that maize can be replaced with BDG up to 40 %.

INTRODUCTION

BACKGROUND TO THE STUDY

Low protein intake, coupled with rapid human population growth, constitute a major problem facing developing countries. Animal protein consumption is among the most important components of human diet and varies from country to country (Okai *et al*., 2005). Rapid human population and low productivity of livestock has led to low protein intake of animal origin in developing countries like Nigeria (Okai *et al*., 2005). This has resulted to demand of this animal protein to exceed supply. To solve this problem, the need to improve animals and animal products production by putting a lot of effort in the production of highly reproductive animals becomes very paramount (Ani and Adiegwu, 2005). The feeding cost constitutes about 65-75 % total production expenses under intensive animal production system. This scenario is attributed to the struggle for foodstuff by livestock and man for some common and normal feed and foodstuff. This situation is so serious in third world countries such as Nigeria thereby necessitating the sourcing for cheaply available unconventional feedstuff that can meet the growth and reproductive requirements of the animals. In Nigeria, there abound untapped potentials for unconventional feed ingredients which can be utilized to feed sheep and other small ruminants. Among these, is brewers' dried grain (BDG) which is a major by-product of brewing industries. The primary purpose of sheep production is to supply wool, meat and milk. The need to increase the supply of milk and mutton is worrisome as seen in most cities in Nigeria. The high demand for milk and mutton could be as a result of its potential over other milk and meat. Low productivity level of production is due to nutritional constraints characterize Sheep production in Nigeria (Tolera *et al*., 2000). The aim of this work is to evaluate the effect of brewers dried grain on growth and lactation performance on Yankasa sheep in guinea savannah.

MATERIALS AND METHODS

EXPERIMENTAL LOCATION

This experiment was conducted at the Biotechnology department farm of the National Animal Production Research Institute (NAPRI), Ahmadu Bello University, Shika - Zaria. Shika lies between Latitudes 11° and 12° N, and between Longitude 7° and 8°E and is located in the sub-humid zone of the Northern Guinea Savannah at the elevation of 640 meters above sea level. Shika experience an average annual rainfall of 1100mm from May to October. The peak of rainfall is witnessed between July and September record the peak of the rainfall Shika also has an average daily temperature of about 25°C with mean relative humidity of about 75 %. The wet period (rainy season) is preceded by dry season (dry period) that starts November to April, having an average daily temperatures ranging from 14 to 36°C and an average relative humidity of between 20 and 37 % (IAR, Meteorological report, 2009).

DESIGN AND MANAGEMENT OF THE EXPERIMENTAL ANIMALS

The experimental design used for the study was complete randomized design (CRD). Twenty Yankasa ewes aged between 5 and 6 months raised at the Biotechnology department farm of the National Animal Production Research Institute (NAPRI), Ahmadu Bello University, Zaria, Shika station were used. The experimental animals were treated with ivomec to control the internal parasites and vaccinated against Pestes des Petite Ruminate (PPR), before allotting them to dietary treatments. The weights of experimental animals were taken on the farm and allowed a 14-day adjustment period and subsequently on a weekly basis. The experimental animals were fed at 1.5 % body weight. The experimental animals were allotted to five dietary treatments, D1 (control 0 % Brewers' Dried grains BDG), D2 (10 % BDG), D3 (20 % BDG), D4 (30 % BDG) and D5 (40 %) with each treatment having four animals and each animal constituting a replicate. The animals were managed intensively. Water and forage were given *ad libitum*. This experiment lasted for 90 days.

FEED COMPOSITION

Five different experimental feeds were compounded for the five treatments which were designated as D1, D2, D3, D4 and D5. Diet1 served as control containing 0 % BDG replacing maize, while D2, D3, D4 and D5 had 10 %, 20 %, 30 % and 40 % respectively of BDG replacing maize. The composition of the experimental diets is presented in table 1

BREEDING PROCEDURE AND OESTRUS SYNCHRONIZATION

Oestrus synchronization was done on all the twenty experimental animals during the feeding trial. This was aimed at having a uniform gestation and parturition period using Estrumate®; a synthetic Prostaglandin $F_{2\alpha}$ analogue (Coopers Animal Health Ltd, Berkhamsted, England) containing 263µg of Cloprostenol Sodium (Vet), equivalent to 250 µg Cloprostenol, and 0.1 % w/v Chlorocresol (BP). Intramuscular injection of 2 ml of the $PGF_{2\alpha}$ was administered to each animal. Following intramuscular injection of experimental animals with $PGF_{2\alpha}$, they were observed for oestrus continuously for 7 days (Voh Jr. 2004). Ninety nine (99 %) percent of the animals that came into oestrus during the first $PGF_{2\alpha}$ treatment were mated using rams of proven performance at the rate of one ram to 10 ewes (1:10) The experimental animals were twice daily (at 0700 and 1800 hours), observed for oestrus visually by trained inseminators. Pregnancy was determined through the use of Ultra sound Technology

COLLECTION OF DATA

FEED INTAKE

Data on intake of feed was taken on daily basis. Feed that was offered to the experimental animals were weighed and unconsumed feed was collected and weighed in the morning of the preceding day. Feed intake was obtained by subtracting the leftover from the amount of feed offered in each treatment.

BODY WEIGHT GAIN

Body weight was taken at the beginning of the experiment *using CAMRY Scale of 150 Kg capacity made in China* Model NS-(100kg-150kg). Body weight gain for each week was determined by differences between the body weight of the present week and the preceding week.

MILK SAMPLES COLLECTION

Milking was done once daily using partial milking method. This was done by separating the lambs from their dams in the night and their weight taken in the morning before they are taken to their dams between the hours of 7-8 am. At noon their weight is taken again. The difference between the weight taken before they are taken to their dams and weight after they stay with their dams represent yield of milk. .

MILK COMPOSITION DETERMINATION

100 ml milk samples were taken weekly from each animal by hand milking and preserved with potassium chromate tablets and were used for the determination of milk protein - using the AOAC (2006) procedures.

Milk Fat content was determined using the Gerber Milk test procedure, while Total solid was calculated using the formular: TS = Lc/4 + (1.22 x % Fat) + 0.72,

Where Lc = lactometer reading. Solid non-Fat was determined by subtracting % fat from Total solids.

Ash content was determined by oven drying the samples at 550°C for 2 days.

DATA ANALYSIS

Data collected were subjected to analysis of variance (ANOVA) using SAS. The separation of means and others are contained in the package.

Growth and Lactation Performance of Yankasa ewes fed varying levels of Brewers Dried Grains diet

Growth performance of Yankasa ewes fed varying levels of BDG diet is presented in Table 2. No significance (P>0.05) difference among the treatments with regard to feed intake, total feed intake and final body weight gain was observed. However a trend was observed, animals fed diet having 10 % BDG (D2) had the highest (28.70) value for final body weight, and animals fed diet having 30 % BDG (D4) had the lowest value (25.00 %). Body weight gain was highest (4.75 Kg) in treatment five where the animals were fed 40 % BDG. Animals fed diet containing 40 % BDG (D5) had the highest value (0.86 Kg) and D4 which contains 30 % BDG had the lowest value (0.75 Kg) for daily feed intake. As for total feed intake, D5 containing 40 % BDG has the highest value (78.49 %) while D4 which contain 30 % BDG had the lowest Value (68.25 %).

Weekly milk Yield samples from Yankasa ewes fed varying levels of Brewers Dried Grain diet.

Table 4.8 shows the weekly milk yield from Yankasa ewes fed varying levels of BDG from Nigerian brewery Kaduna. There was no significant differences (P>0.05) within the diet groups except in week two where there was significant differences among the diet groups. D2 which contain 10 % BDG had the highest value (0.11 Kg) diet D5 which contain 40 % BDG had the lowest value (0.03 Kg).

Total milk yield was highest (0.40 Kg) in animals fed 10 % BDG (D2) and lowest (0.29 Kg) in D5 which contains 40 % BDG.

Composition of milk of Yankasa ewes fed varying level of Brewers Dried Grain obtained from Nigerian Brewery

Table 4 shows the composition of milk from Yankasa ewes fed varying levels of brewers dried grains. Milk Protein values of D3, D4 and D5 showed significant difference between D1 and D2. Milk protein is observed to have increased as the level of BDG increases. Total solids decreases from 20 % inclusion level as inclusion level increases. However, D1 and D3 differ significantly from D4 and D5 in total solids Milk fat, moisture and energy values showed no significant difference among the diet groups. Non- fat- solids values of D3 and D1 (control) are significantly different from those of D4 and D5 but are statistically similar to D2. Moisture is significantly higher in D3, D5 and D2 but is statistically similar with other diet groups. Ash values in D2 are significantly lower than other diet groups. Calcium and phosphorus values of animals fed D5 are significantly higher than those fed D1. It is also observed that Calcium and Phosphorus increases in the milk as the inclusion levels of BDG increases in the diet. Sodium values are significantly higher in D2, D3, D4 and D5 over D1 (control). Sodium is seen to have increased in the milk up to 30 % BDG inclusion in the diet. Potassium values of milk from animal fed D4, D3, D1 (control) and D2 were significantly higher than those of D5. The milk protein result shows that as the inclusion levels increases, the milk protein, fat, calcium and phosphorus also increase. This means that there is a correlation between milk protein increase and milk fat, calcium and phosphorus increase. This is supported by the work of Cunningham *et al*. (1996) who reported that milk protein is positively correlated with milk fat. The authors believe that that the behavior of the milk protein is influence by milk fat content.

Also the result agrees with the work of Duncan (1998) who reported that calcium and phosphorus in milk are known to be bounded to casein which is a major component of milk protein. The protein content of the milk increased with an increase in milk fat and decreases as milk fat content declined.

This might probably explain the pattern of behavior of calcium and phosphorus content in milk. The general composition of mineral composition in milk is connected to mineral content of the test ingredient (BDG) used. Pyne (1990) reported that nutrition has a major effect on milk composition.

ABSTRACT
The study was carried out at Akinyele international Cattle Market, Ibadan. A period of 15 days was used to monitor the inflow of grass brought to feed cattle by direct observation using checklist. Relevant information on source of grass, types of grass and quantity supplied were gathered. The study revealed that grass was brought from 30 different locations within Oyo state. The location with highest contribution of grass forages supplied was Fiditi (103±68.71) while the lowest is from Sogunro (11.00±0.00) and Oloosa-oko (11.00±0.00) respectively. Five different grass species were brought to feed cattle at the study area with the highest being Pennisetum purpureum (59%) and the least Pennisetum pedicellatum (10%). The largest quantity of grass was brought on Fridays while the smallest was on Tuesdays. The study revealed that there is consistent inflow of different species of grass to the study area from various locations.

INTRODUCTION
In Nigeria, the uneven distribution of rainfall poses serious forage management and animal feeding difficulties during the dry season. Thus, available forage materials can no longer provide the minimum protein and energy requirements to grazing animals (Obioha and Ndukwe, 1976). However, in the rainy season, there is an abundance of grazeable forages. Ruminants suffers a lot from the unavailability of quality feed during the dry season, as there is usually a total absence of succulent and high quality nutrition feed for grazing. Seasonal fluctuation in nutritive values of forages are the constraints to livestock production during the dry season (Abbator *et al.,* 2000).

Akinyele international cattle market presents an interesting situation as it is one of the largest cattle market in South-west Nigeria and at any point in time, up to a thousand cattle are available for sale. The cattle are fed maintenance ration to keep them healthy prior to when they are sold. This ration consists majorly of grass forage as it is the cheapest feed source available. However, due to the amount of cattle units present in the market, the availability of grass forages and the source of these grass forages that cattle traders in Akinyele International cattle market use to meet the maintenance ration requirement of their cattle prior to its sale needs to be assessed.

Therefore, the study was carried out to assess the inflow of grass forage fed to cattle at Akinyele International cattle market, IbadanMaterials and methods

The study was carried out at Akinyele International cattle market, Ibadan for a period of fifteen days from 7am-7pm every day of the week. Direct observation with the aid of checklist and weighing balance was used to obtain relevant data on the source of grasses, type of grasses, quantity of grass offloaded daily. Data obtained were analysed using descriptive statistics with Excel 2016 and SPSS statistical package (version 21).

RESULTS AND DISCUSSION

Presented in Figure 1 is the species of grass forage supplied to Akinyele International Cattle Market. It was observed that four different species of grass were constantly supplied which are *Pennisetum purpureum, Andropogon gayanus, Panicum maximum, Pennisetum pedicellatum, at 59%, 18%, 13% and 10% respectively*. The most frequently supplied specie of grass *is Pennisetum purpureum while the least is Pennisetum pedicellatum.* The high supply of *Pennisetum purpureum* may be due to the fact that it is one of the highest yielding tropical grasses. It is a very versatile species that can be grown under a wide range of conditions and systems: dry or wet conditions. It is a valuable forage and very popular throughout the tropics, notably in cut-and-carry systems (Mannetje, 1992; FAO, 2015). While the least supplied grass forage found in Akinyele international cattle market was *Pennisetum pedicellatum*. The reduced quantity supplied might be that animals in the study area has less preference for the specie of forage. It could also be that available *pennisetum pedicellatum* at that season of the year might be lignified with minimal quantity available for cut and carry. Babayemi *et al.*, (2005) reported that the dry season is characterized by insufficient feed.

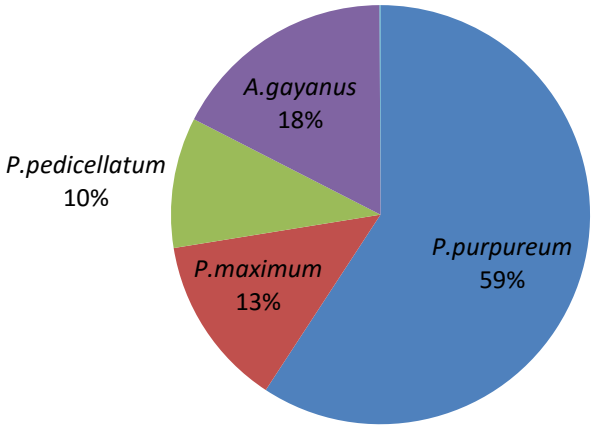

Figure 1: Species of Grass Forage Supplied to Akinyele International Cattle Market

Shown in Figure 1 is the average daily grass of forage supplied to Akinyele International cattle market. The study showed that, grasses are consistently supplied to the study area on a daily basis all through the period of the study. It was observed that the frequency of supply and quantity was highest on Fridays (16 tonnes) and the least on Tuesdays (2.7 tonnes). The quantity of grass inflow at the other days are Wednesday, Sunday, Monday, Saturday and Thursday follows at 15981kg, 12551kg, 9163kg, 3895.3kg, and 3816kg respectively. The highest frequency of supply and quantity on Fridays might be due to the fact that most farmers will want to purchase more grass on Friday as most sellers may not be around during the weekend while the least supply on Tuesday could be as a result of suppliers trying to decongest available grasses in relation to weekend preparation.

According to information gathered on the field, grass sellers source for grass at alternate days. They source today and rest tomorrow. They do this so that grass will not be in abundant

without them being able to sell off. Since the shelf life of cut and carry grass is small before chlorination and depreciation sets in. This is as justified from figure 2 below.

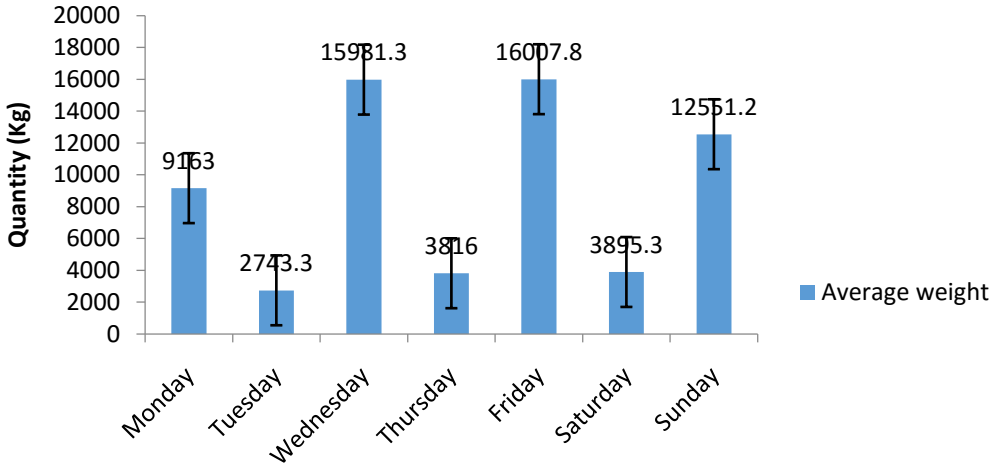

Figure 2: Average Daily Grass Forage Supplied to Akinyele International Cattle Market

Presented in Table 1 are the locations of grass forages supplied to Akinyele International cattle market Ibadan. It was observed that grass species were brought from 30 different locations within Oyo state. The location with the highest frequency of supply was Fiditi (103±68.71) with the lowest from Sogunro (11.00±0.00) and Oloosa-oko (11.00±0.00) respectively. Fiditi had the highest population of all the grass species supplied (*Pennisetum purpureum (698), Panicum maximum (142), Pennisetum pedicellatum (113)*) except for *Andropogon gayanus (215)* which is highest in Ajibode. The highest frequency of grass supplied from Fiditi could be due to the fact that Fiditi is a location at the outschet of Ibadan but relatively closer to the study area. It is an area with a land mass not occupied by buildings when compared with other source within Ibadan thus encouraging the growth of forages. Kallah (2014) reported that rain forest and mangrove swamp encourages very high yielding grass. Exploration of forages by individuals within Ibadan metropolis might be as a result of proximity.

CONCLUSION

The study showed that grasses are always supplied daily to Akinyele International Cattle Market Ibadan. Four different species of grass were offloaded with *Pennisetum purpureum* most frequently supplied. The quantity of grass supplied was more on Friday. Fiditi was recorded to be the location from which most of the grass species were mostly brought to the study area.

NUTRIENT INTAKE, NITROGEN METABOLISM AND FEED GAIN RATIO OF WEST AFRICAN DWARF GOATS FED CASSAVA PEEL BASED DIETS SUPPLEMENTED WITH GRADED LEVEL OF *SACCHAROMYCES CEREVISIAE*

***Fajemisin, A. N., Omotoso, O. B., Ajayi, H. J. and Alokan J. A.**

ABSTRACT
*A-90 day study was conducted to evaluate the nutrient intake, nitrogen metabolism and feed gain ratio of West African Dwarf (WAD) goats fed cassava peel based diets supplemented with graded level of saccharomyces cerevisiae. Five concentrate diets were formulated such that yeast (***S. cerevisiae)** *were supplemented at diet A (control), diet B (0.25g), diet C (0.375g), diet D (0.50g) and diet E (0.625g) respectively. Fifteen WAD goats with an average live weight of 8.30±2.5kg were randomly allotted to the five dietary treatments, of three goats per replicate in a completely randomized design experiment. Parameters assessed included; nutrient composition, feed intake, nutrient digestibility, nitrogen utilization and weight gain. Results showed that inclusion of Saccharomyces cerevisiae significantly (P<0.05) influenced the dietary treatments. Dry matter (DM) contents ranged from 77.03±0.86% (Diet B) to 82.56±0.46% (Diet A). Crude protein (CP) content of the diets increased progressively with increased supplementation of Saccharomyces cerevisiae in the diets. Diet E of 0.625g level of S. cerevisiae had the highest CP content of 16.75±1.52%. The DMI was higher in the WAD goats fed the control diet (422.87±10.81) while the CPI was higher in the diet D of 0.5g level of Saccharomyces cerevisiae (78.19±6.95g/day). Highest nitrogen intake (10.70±0.12g/day) and highest nitrogen retained (72.47±2.16%) were obtained in WAD goats fed Diet A (control). However, yeast supplementation caused a better ruminal digestion, improved nitrogen balance and nutrient utilization; and at supplementation level up to 0.625g, no significant improvement was noticed on the weight gain.*

Key words: Ruminant farmers, goats, yeast, weight gain.

INTRODUCTION

Cassava peel is a rich source of energy and fibre in ruminant feeding (Baah *et al*., 1999) and it is readily acceptable by goats especially when fermented or dried to reduce its moisture and primarily hydrocyanic acid (HCN) content. Feeding concentrates to ruminants has proven to enact the activities of the rumen microbes for better feed utilization. To ensure continuous supply of adequate nutrients required by these animals, both in-season and off-season, the efficient use of alternative feed resources has earlier been and persistently be advocated (Adegbola, 2002). Although, most alternative feed materials are highly lignified and of low protein value, thereby limiting their intake and utilization by animals, this could possibly be surmounted by their combinations with feed materials of higher nutritive value as supplement. However, the yeast (***Saccharomyces cerevisiae***) has the potentials to improve the nutritional quality of fibrous feeds through fermentation and thus, enhance feed/nutrient intake by the animal. Thus, this study was conducted to assess the effect of feeding cassava peel-based concentrate diets supplemented with graded levels of ***Saccharomyces cerevisiae***.

MATERIALS AND METHODS

The experiment was conducted at the Ruminant Unit of the Teaching & Research Farm, Federal University of Technology, Akure, Ondo state, Nigeria. The concentrate diet (Table 1) was prepared using floor mixing method, and yeast (***S. cerevisiae)*** were supplemented at graded levels such that; diet A (control), diet B (0.25g), diet C (0.375g), diet D (0.50g) and

diet E (0.625g) respectively. Nutrients composition, nutrient intakes, weekly weight change week were evaluated. Ten percent of feaces collected each day were oven dried at 105^0C. The oven dried feed and feacal samples were milled and stored in air tight to containers until required for analysis. Daily urine samples from each goat was collected in sample bottles containing 10mls of 10% concentrated sulphuric acid to prevent loss of nitrogen and refrigerated until required for analysis. The experiment spanned for 90days. Nitrogen balance by the goats was calculated as the difference between nitrogen intake and nitrogen excreted from feaces and urine while nitrogen retention was computed from nitrogen balance expressed as a percentage of nitrogen intake. The air-dried samples of feed and faeces collected were analysed for proximate composition while the urine samples collected were analysed for nitrogen according to AOAC (2002) procedures while all data collected were subjected to statistical analysis using SAS (2008).

Table 1. Gross composition of experimental diets fed to the WAD goats

Ingredients	Diet 1 (0)	Diet 2 (0.25)	Diet 3 (0.375)	Diet 4 (0.50)	Diet 5 (0.625)

0g, 0.25g, 0.375g, 0.50g and 0.625g are levels of yeast supplementation in the diets

RESULTS AND DISCUSSION

The results revealed that all parameters observed were significantly ($P<0.05$) influenced by the dietary treatment. The dry matter intake (DMI) ranged from 312.08±39.42g/day (goats fed diet E) to 422.87±10.81g/day (goats fed diet A). This implies that yeast supplementation does not affect the dry matter intake of the animals which was according to Hasunuma ***et al.*** (2016) who discovered that DMI was not affected by yeast supplementation to dairy cattle. Also, Whitley ***et al***. (2009) reported that DMI was not impacted by yeast supplementation due to the limited involvement of yeast with ruminal microbes, which is required for improving ruminal fermentation and increasing intake. This study negates the result of Mutsvangwa *et al*. (1992) and Salama *et al*. (2002) who observed that supplementation of yeast in the diet of bulls and dairy goats improved dry matter intake. The crude protein intake (CPI) increases as the level of yeast supplementation increases (Table 2). This might be attributed to the stabilization of ruminal fermentation and activity (Jouany and Morgavi, 2007). More so, age and status of the goats could also be a factor for increased protein intake. The highest nitrogen intake (10.98g/day) was obtained in animals fed diet B. The nitrogen intake observed in this study was slightly higher than 8.75g/day obtained by Ibhaze and

Fajemisin (2015) for WAD goats fed naturally fermented maize cob-based diets. The result suggests that the diets were able to meet the animals' requirements for nitrogen. This could also be attributed to the protein concentration in the diet as well as the nitrogen intake by the animal. The observed live weight gains by the goats were statistically (P>0.05) similar. This affirm the report of several authors that yeast culture supplementation has no effect on growth but reported an increased digestibility of nutrients (Kawas *et al*., 2007; Titti *et al*., 2008). But all these negates the observation of Haddad and Goussous (2004), who reported improved weight gain after supplementing yeast to finishing sheep diets. However, it is evident that yeast can have beneficial effects on the general performance under some circumstances, but there seems to be a considerable unexplained variability in response this could be due to factors such as basal diet, viable cell numbers, the amount of yeast supplemented, type of forage fed and feeding strategy.

Table 2: Response of WAD goat to the test diets

Parameters	A	B	C	D	E

abc - Means bearing different superscripts along the same row are significantly different (P < 0.05).

CONCLUSION AND RECOMMENDATION

Yeast supplementation caused a better ruminal digestion, improved nitrogen balance and nutrient utilization. However, at supplementation up to 0.625g, no significant improvement was noticed on the weight gain.

ABSTRACT
The study was conducted to evaluate the carcass by-products and visceral organs of fattened Yankasa rams fed complete diets containing rice straw. Twelve (12) Yankasa sheep (rams) were used for the experiment. The animals were randomly distributed to 4 treatments with 3 animals per treatment, each ram served as a replicate and an adjustment period of a week was allowed for the animals before data collection commenced. The feeding trial lasted for a period of 70 days. A Completely Randomized Design (CRD) was used. Data collected was analyzed using Analysis of Variance (ANOVA). Results of this experiment suggests that nutrients in all diets impacted positively and similarly on carcass characteristics and visceral organs of fattened rams with the utilization of available nutrient to rams fed varying levels of rice straw. In this study, it was observed that 8.75% rice straw increased carcass weight compared with rams fed other diets. The improved carcass weight could be attributed to the effect of the laxative action of rice straw in the gut and fibre content of rice straw which supports increased carcass weight. From the study, it can be concluded that rice straw fed had no adverse effect on the carcass by-products and visceral organs characteristics of fattened rams. Therefore, it is recommended that rice straw up to 26.26 % could be included in the fattened rams' diet.

Key words: yankasa rams, carcass by-products, visceral organs, diets, rice straw.

INTRODUCTION

In Nigeria fattened rams play an important role in socio-cultural activities as they are of great use during cultural, religious and other festivities in Nigeria. Sheep production is one of the best ways of enhancing meat supply and also generates income to small holder farmers. Livestock contributes 6-8% of agricultural gross domestic product in Nigeria with estimates of 41.3 million sheep's population in the country (PTNP, 2017). These estimates highlight the important contribution of livestock to sustainable agricultural development. Sheep and other ruminants are essential to the livelihoods of millions of farmers and critical to human health, global food and nutritional security (FAO, 2016). There are four major breeds of sheep in Nigeria, namely: Uda, Balami, Yankasa and West African Dwarf (WAD). However, ram in Nigeria are use for fattening mostly by small holder farmers both in rural and urban areas especially by women and children as a source of investment, without some basic fattening feeding principles and the utilization of agro-industrial by-products in achieving this objective.

Rice is the second most cultivated cereal worldwide (FAO, 2013). Rice straw, a by-product of the rice grain industry, is a potential alternative feed for ruminants. Rice straw producers have generally considered straw as waste product and as such are either left on the farm or baled at their convenience after harvest. Though, several factors determine how much straw can be used in ration, including; quality of rice straw, nutritional needs of the animal, environmental conditions during feeding such as temperature, rain, snow, mud, as well as the condition of the animal and expected performance. Rice straw remain a potential alternative feed for ruminant that needs to be explore for fattening ram, hence the reason for this study.

MATERIAL AND METHODS

EXPERIMENTAL LOCATION

This study was conducted at the Department of Agricultural Education Teaching and Research Farm, Federal College of Education (Technical) Bichi. The farm is located within the campus of the College at about 40 km North of Kano Metropolis in Bichi Local Government Area of Kano State, Nigeria. Kano is situated in the Sahelian geographic region, South of the Sahara in the North-Western Nigeria, 481 metres (1,578 feet) above sea level within longitude: 8°31′00″ E and latitude: 12°00′00″ N (Wikipedia, 2018; Dateandtime.info, 2018).

EXPERIMENTAL RAMS AND THEIR MANAGEMENT

Twelve (12) Yankasa sheep (rams) were used in this experiment and were purchased from Badume market, Dawakin Tofa local government area of Kano State. The animals were randomly distributed to 4 treatment groups of 3 animals per treatment. Each ram served as a replicate and an adjustment period of a week was allowed for the animals before data collection commenced. The feeding trial lasted for a period of 70 days. Water and salt lick were also offered *ad libitum.* The animals were quarantine in the College Farm, for two weeks, and given prophylactic treatment with Avomec® against *endo* and *exto* parasites and also treated with oxytetracycline HCl (a broad spectrum antibiotic). Prior to the experiment, the animals were managed intensively and group-fed with groundnut haulm and wheat offal.

Table 1: Composition of the Rice straw Meal Based Diets fed to Fattening *Yankasa* Rams

	Experimental Treatments			
Ingredients	A	B	C	D
Rice straw	0	8.75	17.5	26.25
Wheat offal	35	26.25	17.5	8.75

Ether extract	6.59	6.80	7.20	6.77
Ash	10.64	8.58	10.21	12.80

STATISTICAL ANALYSIS

In this study the data generated were subjected to Analysis of Variance (ANOVA) using Completely Randomized Design (CRD). The treatment means were separated and compared using standard error of the mean (SEM), and Duncan's Multiple Range Test (DMRT) as contained in SPSS (2013) for window 32, version 24.

RESULTS AND DISCUSSION

As shown in Table 3, the pre-slaughter live weight of rams fed 0% rice straw was significantly ($p<0.05$) higher compared with those fed other diets, while those fed 17. 5% rice straw had the lowest pre-slaughter weight. However, the rams fed 8.75% had the highest carcass weight which was significantly ($p<0.05$) higher compared with those fed the control and 26.25% rice straw was significantly lower. In this study, it was observed that 8.75% rice straw increased carcass weight compared with rams fed other diets. The improved carcass weight could be attributed to the effect of the laxative action of rice straw in the gut and fibre content of rice straw which supports increased carcass weight. The rams fed 17.5% rice straw had significantly ($p<0.05$) higher dressing percentage than those fed 8.75% rice straw, while those fed the control diet (0%) and 26.25% rice straw were significantly ($p>0.05$) similar. Dressing percentage at 17.5% level of inclusion of rice straw was highest compared with rams fed other diets. The percentage ribs and loins of rams fed 8.75% had significant differences ($p<0.05$) which was higher than those fed the control, 17.5% and 26.25% respectively. The results of the present study which showed that rice straw resulted in better ribs and loins. It is known that the ram is known to be especially sensitive to dietary fibre concentration. The rams fed 17.5% rice straw had significantly ($p<0.05$) higher back percent than those fed 8.75% rice straw, while those fed diet the control diet (0%) and 26.25% rice straw were significantly ($p>0.05$) similar. The values for the shoulder of rams fed 17.5% and 26.25% were significantly ($p<0.05$) higher than those fed 8.75% rice straw (diet B), which was higher than those fed the control diet (0%). The neck percent of the rams fed 8.75% rice straw and the control diet (0%) were significantly ($p<0.05$) higher than those fed 17.5% rice straw, which was higher than those fed 26.25%. However, percent thigh were highest with rams fed 17.5% and 26.25% rice straw compared with rams fed the control diet (0%) and 8.75% rice straw which were similar ($p>0.05$).

Table 3: Effect of Feeding Complete Diets Containing Rice Straw on Carcass Characteristics of fattened Yankasa Rams

Parameters	Treatments				
	A	B	C	D	SEM
Pre-slaughter Live weight (Kg)	34.10^{a}	32.20^{b}	27.10^{d}	28.10^{c}	0.08
Carcass Weight (Kg)	13.90^{b}	14.10^{a}	13.30^{c}	11.50^{d}	0.08
Dressing Percentage (%)	40.51^{c}	43.70^{b}	45.57^{a}	40.97^{c}	0.21
Ribs (%)	7.33^{b}	8.07^{a}	7.04^{c}	6.64^{d}	0.08
Loin (%)	3.22^{b}	3.73^{a}	2.96^{c}	2.54^{d}	0.07
Back (%)	3.83^{c}	4.35^{b}	5.93^{a}	3.77^{c}	0.08
Shoulder (%)	8.31^{c}	9.01^{b}	10.00^{a}	9.86^{a}	0.08
Neck (%)	4.99^{ab}	5.28^{a}	4.81^{b}	2.72^{c}	0.14

Testes	0.90[d]	1.32[a]	1.09[c]	1.17[b]	0.24
Full Gut	23.53[b]	9.94[d]	15.56[c]	24.42[a]	0.05
Empty Gut	2.94[b]	1.82[d]	2.90[c]	3.00[a]	0.08
Skin	5.88[c]	8.70[a]	6.67[b]	5.77[d]	0.02

SEM: standard error of mean [a.b, c] Means on the row with different superscripts are significantly ($p<0.05$) different.

The visceral organs of the carcass of fattened Yankasa ram fed complete diet containing rice straw are presented in Table 4. The values for the heads of rams fed 8.75% rice straw was significantly ($p<0.05$) higher compared with those fed the control diet and those fed 17.5% rice straw, while those fed 26.25% rice straw had the lowest. The values for the legs were ($p<0.05$) higher in rams fed 26.25% rice straw compared with those fed the control diet and those fed 17.5% rice straw, while those fed 8.75% rice straw had the lowest. Hearts of the rams were not significantly ($p>0.05$) affected across the dietary treatments. The values for the lungs were ($p<0.05$) higher in rams fed 26.25% rice straw compared with those fed the control diet and those fed 17.5% rice straw, while those fed 8.75% rice straw had the lowest. The liver and kidney of the rams were not significantly ($p>0.05$) affected across the dietary treatments. Spleen was higher ($p<0.05$) for rams fed 8.75% compared with those fed the control diet, while those fed 17.5% and 26.25% were ($p>0.05$) similar. Lower values for testes was recorded in rams fed the control diet and higher in rams fed 8.75% rice straw. The full gut and empty gut were significantly ($p<0.05$) higher in rams fed 26.25% rice straw than those fed other diets. It is however lowest in rams fed 8.75% rice straw. Skin from the rams fed 8.75% rice straw were higher compared with those fed 17.5% rice straw, which was higher than those fed the control diet, while it is lowest in those fed 26.25% rice straw. The result of the present study is not consistent with those of Nader (1999; 2000) who reported poorer performance of rams when fed rice straw as a complete or only feed.

CONCLUSION

From the present study, it can be concluded that rice straw fed had no adverse effect on the carcass by-products and visceral organs characteristics of fattening rams studied. Therefore, on the basis of the results obtained from this study, it is recommended that rice straw up to 26.26 % could be included in the fattened rams' diet.

ABSTRACT:
Hydroponics fodder is a method of growing cereal grains to produce fresh green grass leaves within 6 to 8 days. The leaves are very nutritious and with high crude protein and is very economical feed for all grazing animals including horses, cattle, hogs, sheep, goats, rabbit and zebra. The major challenges of hydroponics fodder production are loses in total dry matter because a lot of studies reported that sprouting resulted in 7 to 47 % loss in dry matter from the original seed. Also high temperature in green house slows down the growth of hydroponics fodder similarly high humidity lead production and the light used to create energy for Biochemical activity in the plant. to the infestation of mold. In managing the production of hydroponics fodder it is recommended to disinfect the planting materials using chlorine solution and also maintain correct moisture, pH and temperature in green house. Lighting is the one the most important aspect of hydroponics fodder

Key words: Hydroponics fodder, challenges, production

INTRODUCTION

Hydroponics is a method of growing plants without soil. Hydroponics fodder systems are usually used to sprout cereal grains such as barley, oats, wheat, sorghum, and corn or legumes such as alfafa, clover or cowpea Al-Karaki and Al-Hashimi, (2012). It is a well-known technique for high fodder yield, year round production and least water consumption. This technology may be especially important in the regions where forage production is limited Fazaeli *et al.* (2012). Sprouting is a simple technique to germinate the seeds for the improvement of their nutritive value. Germination eliminates the effect of phytic acid by the production of phytase enzyme and increases the plant enzyme contents Shipard, (2005). Fresh green grass sprout fodder (6 to 8 day old) is a very nutritious and economical feed for all grazing animals including horses, cattle, hogs, sheep, goats, rabbits, zebras Hydroponics Farming, (2013). From time to time, hydroponics growers may face challenges with their hydroponic systems and fodder. Some challenges can easily be resolved without causing too much stress. The most common issues in hydroponics production usually involve high cost initial startup, mold and control of temperature and humidity.

MAJOR CHALLENGES OF HYDROPONICS, FODDER PRODUCTION

LOSS IN TOTAL DRY MATTER

A number of studies reported that sprouting resulted in 7 to 47 % loss in Dry Matter from the original seed after sprouting for a period of 6 to 7 days of growth, mainly due to respiration during the sprouting process Putnam *et al,* (2013). Seed soaking activates enzymes that convert starch stored in endosperm to a simple sugar, which produces energy and gives off carbon dioxide and water, leading to loss of Dry Matter with a shift from starch in the seed to fiber and pectin in the roots and green shoots.

HUMIDITY AND TEMPERATURE CONTROL CHALLENGE

These are highly sophisticated, fully automated fodder production system with controlled environments and are immune to natural weather variations. The required water, light, temperature, humidity and aeration are fully controlled by sensors. Expose to direct sunlight, strong wind and heavy rain. During the growing period the seed are kept moist by either drip or spray irrigation but are not saturated. The environmental factors for optimum growth of a fodder are; temperature between 19

to 25 ^{o}c humidity between 40 to 80 % (optimum being 60 %) light (2000 lux intensity between 12 to 16 h) El-Deeba *et al*. (2009). The sprouts grow, albeit slowly outside the optimal condition mention above, but at higher temperature humidify mold infestation is one of the biggest challenge that needs to addressing.

MANAGEMENT CHALLENGE ON PRODUCTION OF HYDROPONICS FODDER

The quality of hydroponics fodder is greatly influenced by the management of the hydroponics system. Some of the best practices that must be observed in the hydroponics fodder production are; use of clean planting materials, maintaining the correct moisture, pH and temperature in the green house and disinfecting the trays using chlorine solution Sneath and McIntosh, (2003).

MOLD

There are a number of challenges in producing hydroponics fodder. A common challenge that causes many problems for those with fodder sheds is mold. Given the warm moist environment within a fodder shed mold can easily take hold, ruin the fodder and cause livestock health issues if fed. Thus, active management of mold risk is essential. Moldy sprout have decreased livestock performance in trials and has been known to result in animal deaths. Mold is actively managed within sheds through pretreatment of the seed. Additives to the water are used for pre-soaking the grain to minimize the risk of mold. Shed hygiene is also important and thus considerable attention is paid to ensuring the growing trays are well cleaned following each seed and prior to the sowing of the new seed Al-Karaki and Al-Hashimi, (2012).

PATHOGEN AND DISEASE

Pathogen and disease can spread throughout your hydroponics system. They can be brought in by pest or bought on by environmental conditions keeping your hydroponics house clean, a sterile environment free of pests, and at the proper temperature, you can reduce the chance of pathogen and disease infection your greenhouse. An outbreak of pest or infections in hydroponics grown fodder can be quickly controlled by spraying the crops with appropriate pesticide or fungicide. Fresh and clean water should be used for irrigation as water borne plant disease spread quickly Bakshi *et al*. (2007).Hydroponics fodder heavily infested with *Aspergillusclavatus* should not be fed to dairy/beef cattle. Animals may develop posterior ataxia, knuckling of fetlocks, dragging of hind legs, high stepping in the hind limbs, stiff gait, tremors, progressive paresis, hypersensitivity, recumbences, clonic convulsions, decreased milk yield and possibly death McKenzie *et al*. (2004).

LIGHTING CHALLENGE

Proper lighting is one of the most important aspects of plant environment. Plants use light to create energy, so if they do have the proper light they can create energy needed growth. O'Sullivan (1982) as cited in Morgan *et al*. (1992) reported increased losses of Dry Matter, where no light was provided. The authors found that the rate of decrease of Dry Matter content slowed down after the fourth day in lighted experiments, when leaves began photosynthesizing. Lighting prior to day 3 was of little significance Morgan *et al*. (1992). Results obtained by El-Deeba *et al*. (2009), indicated that root length dose not influence lighting operating hours, however its value was about 6 cm under all treatments of lighting (8, 12, 16, and 24 hours/day).

CONCLUSION

Hydroponics fodder production systems produce large quantities of green, palatable livestock feed. However, the research reviewed in this report shows that there are challenges associated with the production and economic competitiveness of hydroponics fodder relative to alternative feed sources. The costs associated with the establishment and daily operation of a fodder shed, coupled with dry matter yield losses during the sprouting make hydroponic fodder an expensive feed source. There is

an opportunity for some research to be undertaken to examine the performance of livestock on hydroponics fodder and the attributes of the final product.

ABSTRACT

The study was carried out to estimate the chemical composition and in vitro rumen fermentation o ginger fortified diets. The diets consisted of four treatments A; Cassava peel (65%) + Moringa leaf (15%) + PKC (20%) + Ginger (0g), B: Cassava peel (65%) + Moringa leaf (15%) + PKC (20%) + ginger (200g), C: Cassava peel (65%) + Moringa leaf (15%) + PKC (20%) + ginger (300g), D: Cassava peel (65%) + Moringa leaf (15%) + PKC (20%) ginger (400g). A completely randomized design (CRD) was adopted with three replicates per each treatment and samples were incubated for 24hrs. The chemical composition showed that dry matter ranged from 40.86% (diet B) to 54.68% (diet D). There was no significant ($p>0.05$) difference in the crude protein content (13.30 – 14.88%). The crude fibre content of the samples was significantly ($p<0.05$) different and it ranged from 14.67 – 22.15%. The in vitro potential gas production and effective degradability of dry matter (%) values were highest (39.03mL/36.14%) in diet D. The highest proportion of cumulative gas production at 24hr incubation was observed also in diet D. Based on this study, it seems fortifying ruminant feed with ginger could improve nutrient degradability.

Keywords: *Zingiber officinale*, gas production, effective degradability, ruminant, silage

INTRODUCTION

Growth and productivity of ruminants are mostly limited by the quality of feed available to the animals. The nutritive value of ruminant feed is determined by its chemical composition as well as rate and extent of digestion in the rumen (Songsak *et al.,* 2007). Moringa leaves are a valuable source of protein for ruminants. Its protein and organic matter are readily digestible in the rumen and/or in the intestine (Kakengi *et al.,* 2005). Ginger (Phytogenic) is in the family *Zingiberaceae*, it is reported to stimulate the appetite of animal and improve nutrients palatability (Tilgner,1999) and has favorable effects on digestion and absorption of lipids. *In vitro* gas production is a technique used in evaluating feed quality . It involves volumetric measurement of gas production in phosphate and bicarbonate buffered *in vitro* incubations in syringes (Abegunde, *et al.,* 2009). It is a rapid method used for predicting organic matter digestibility, short chain fatty acids and metabolizable energy content of ruminant feeds (Menke and Steingass, 1988). *In vitro* methods have the advantage of being less expensive and less time-consuming and accurate to predict feed intake, digestibility, microbial nitrogen supply, animal performance, short chain fatty acids, carbon dioxide and metabolizable energy of feed for ruminants (Getachew *et al.*,1999; Babayemi and Bamikole, 2006; Akinfemi, *et al.*,2009). Gas production reflect all fermented nutrients, soluble as well as insoluble and fractions that are not fermentable which do not contribute to gas production and from the total gas production, methane, individual volatile fatty acids can be predicted (Fievez *et al.,* 2005). This study was conducted to determine the *in vitro* gas production and effective dry matter degradability of ensiled cassava peel, moringa leaves, palm kernel cake diet fortified with ginger (*Zingiber officinale*) for ruminant feeding.

MATERIALS AND METHODS

The gross composition of the feed samples is shown below;

DietA: cassava peel (65kg) + palm kernel cake (15kg) + moringa leaves (20kg) + ginger (0g)

DietB: cassava peel (65kg) + palm kernel cake (15kg) + moringa leaves (20kg) + ginger (200g)

DietC: cassava peel (65kg) + palm kernel cake (15kg) + moringa leaves (20kg) + ginger (300g)

DietD: cassava peel (65kg) + palm kernel cake (15kg) + moringa leaves (20kg) + ginger (400g)

FERMENTATION KINETICS

The rate of gas production during 24h incubation was determined according to the procedure of Menke and Steingass (1988). Rumen fluid was collected using a stomach tube into a preheated thermos flask, strained through a sieve cloth and flushed with CO_2. The buffer containinig $NaHCO_3$+Na_2HPO_4+KCl+NaCl+$MgSO_4$.7H2O was used and kept in the incubator for warming prior to being mixed with rumen fluid. The experimental samples (200mg) were incubated in 100-mL calibrated glass syringes at 39^oC with the ruminal fluid and volume of gas production was recorded at 3hourly intervals for 24 hours. All samples were incubated with three syringes containing only rumen fluid -buffer mixture as blank. Gas production from the experimental sample was calculated by subtracting the volume of gas produced from the blank. At post incubation period, 4ml of 10M NaOH was introduced to estimate methane production per sample. Cumulative gas production data was obtained using the method of Ørskov and McDonald (1979). The effective degradability (ED) of dry matter was calculated according to the method of (Umunna *et al* 1995). Metabolizable Energy (ME) and Organic matter digestibility (OMD%) were calculated as ME=2.20+0.136GV+0.057CP+0.0029CF and 14.88+0.88GV+0.45CP+0.651XA respectively(MenkeandSteingass,1998), Short chain fatty acids (SCFA) as 0.0239Gv-0.0601(Getachew *et al,* 1991) was obtained where Gv, CP, CFand XA are total gas volume, crude protein, crude fibre and ash respectively. Data obtained were subjected to one-way analysis of variance, where significant differences occurred, the means were separated using Duncan multiple range F-test of SAS (2012)

RESULTS AND DISCUSSION

Dry matter ranged from 40.86-54.68%, however there was no significant ($p>0.05$) difference in the crude protein content (13.30 – 14.88%). The CP values are above the critical 8% crude protein requirement by ruminants for optimum microbial activities in the rumen (Norton, 2003). The crude fibre content of the samples which ranged from 14.67 – 22.15% suggests that many of the soluble nutrients were not degraded and would be adequate to support rumination. The values were within the requirement of 8-33% crude fibre suggested by Castrillo, (2001). Gas production reflects the degradation of dietary organic matter and more gas production, more degradation of Organic matter (Groot *et al*., 1996). Differences in potential gas production (***a*** + ***b***) and effective degradation of dry matter (ED) among the samples could also be due to the extent of lignification of NDF (Al-Masri, 2017). Lower NDF and lignin concentrations mean greater amounts of soluble cell walls which are available for fermentation (Al-Masri, 2017). Getachew *et al*. (2004) reported a negative relationship between gas production and cell wall content of diet. Samples with ginger produced relatively higher gas production. This corroborates the reports of Kim *et al*. (2012) who reported that ginger extract increased total gas production. Cumulative gas production at 24h as presented in Figure 1 showed significance at 400g of ginger inclusion. The level of SCFA indicates that the samples have potential to make energy available to animals. Although not significantly ($p>0.05$) different, samples with ginger had better organic matter digestibility denoting that ginger could improve digestibility.

Table 1: Chemical composition of ensiled experimental diets

ABSTRACT

An experiment was conducted to evaluate the apparent nutrient digestibility and nitrogen balance of West African dwarf (WAD) goats fed diets containing Pleurotus tuber-regium degraded cassava root sievate (PTR-CRS). Four experiment diets were formulated to contain 0, 20, 40 and 60% of PTR-CRS and designated as T_1, T_2, T_3 and T_4 respectively and fed to the animals in a 4x4 Latin square design pattern. The apparent nutrient digestibility coefficient showed higher ($p < 0.05$) DM, CP and crude fibre digestibility for T_4 compared to other treatments. Nitrogen intake and N balance, differed significantly ($P < 0.05$) with goats on T_4 having the best results. It could therefore be concluded that goats on T_4 had the highest dry matter, crude protein and crude fibre digestibilities. In addition, nitrogen intake and retention was highest at T_4, hence the inclusion of 60% PTR-CRS is recommended for enhanced N utilization and apparent nutrient digestibility by WAD goats.

INTRODUCTION

Cassava root sievate (CRS) is the waste, which results from processing cassava root into fufu, a popular West African food. The sievate is the solid waste produced as a product of cassava root production and made up of 88.60, 2.57 and 13.38% dry matter, crude protein and crude fibre respectively (Jiwuba *et al*., 2018); it constitutes about 25% of the whole plant (Aderemi and Nworgu, 2007). Jiwuba *et al*. (2018) reported 3.79 MJ/kg gross energy value for cassava root sievate meal. They are usually discarded poorly as waste heaps near streams or homes where they are soaked, fermented and processed thereby producing a strong offensive smell and contaminations; hence the need to add value to this agro-waste. The low protein content (Jiwuba *et al*., 2016), high cyanide content (Ubalua and Ezeronye 2008; Morgan and Choct 2016) and high fibre contents are the limiting factor in the utilization of cassava root sievate by goats. Due to high lignin content of cassava root sievate, its utilization is impaired in goat feeding. These have affected the general performance of animals fed such diet; hence the needs to improve the nutritive value of cassava root sievate through biodegradation (use of white rot fungi). The *Pleurotus* species have been shown to be more efficient (Taniguchi *et al*., 2005). The *Pleurotus tuber-regium* have different ability to grow on agro waste and decompose its structural carbohydrate because of the variation in culture behaviour and culturing conditions. Information on cassava root sievate biodegradation in goat feeding is virtually non-existing. The study was therefore designed to determine the apparent nutrient digestibility and nitrogen balance of West African dwarf goats fed diets containing *Pleurotus tuber-regium* degraded cassava root meal.

MATERIALS AND METHODS

The experiment was carried out at the sheep and goat Unit, Federal College of Agriculture Ishiagu, The dried cassava root sievate were sourced from Akawa, Nneato, Umunneochi L.GA. Abia State. The dried cassava root sievate were coarsely milled using a blur mill to reduce its particle size and create a greater surface area for microbial activity. Treatment of cassava root sievate with *Pleurotus tuber regium* was by inoculation of composted cassava root sievate with slides of the *Pleurotus tuber regium* in white perforated bucket were kept on a concrete floor at room temperature covered with polythene sheet and allowed to ferment for 45 days. The Experimental diets designated as T_1, T_2, T_3, T_4 were formulated from non-biodegraded cassava root sievate, biodegraded cassava root sievate, brewers dried grain, palm kernel meal, soybean meal, bone meal, salt and premix. The biodegraded cassava root sievate replaced the non - biodegraded cassava root sievate at, 0, 20, 40 and 60% respectively as shown in Table 1.

Table 1: Composition of the Experimental Diets

	Dietary levels (%)			
Ingredients	T_1 (0%)	T_2 20%)	T_3 (40%)	T_4 (60%)
Non-biodegraded cassava root sievate	60.0	40.0	20.0	0.0
Biodegraded cassava root sievate	0.0	20.0	40.0	60.0
Brewers dried grain	15.0	15.0	15.0	15.0
Palm kernel meal	14.0	14.0	14.0	14.0
Soybean meal	7.0	7.0	7.0	7.0
Bone meal	3.0	3.0	3.0	3.0
Salt	0.5	0.5	0.5	0.5
Premix	0.5	0.5	0.5	0.5
Total	100	100	100	100

Four WAD bucks of about 6 – 8 months old were used for this experiment. The animals were subsequently transferred to previously disinfected individual metabolism cages provided with facilities for collecting faeces and urine. They were fed four experimental diets in a 4 x 4 Latin square design. Each animal received the experimental diets consecutively in 4 phases. During phase 1, which lasted for 28 days, each animal received 1.5kg of an assigned experiment diet for 21 days. During this period, each animal had access to free drinking water daily. Total faeces and urine voided by the experimental animals were collected during the last 7 days (22-28). During phases 2 - 4, each animal was offered each of the remaining 3 experimental diets in rotational periods of 28 days each. The last 7 days in each of the feeding periods, was used for total urine and faecal collection. Each animal constituted a replicate while each feeding phase represented an observation. The quantity of each diet offered to the goats during each period ensured about 5% left over. The left overs were collected after 24 hours, weighed and used to determine the voluntary intake. Total faeces were collected in the mornings before feeding and watering during days 22 - 28 of each period. The faeces weighed fresh, dried and bulked for each animal. A sub-sample from each animal was dried in forced draft oven at 100-105^{0}C for 48 hour and used for DM determination. Total urine for each animal was collected daily in the morning before feeding and watering. The urine trapped in a graduated transparent plastic container placed under each cage and to which 15ml of 25% H_2SO_4 was added daily to curtail volatilization of ammonia from the urine. The total volume of urine output per animal was measured and about 10% of the daily outputs was saved in plastic bottles numbered and stored in a deep freezer at 5^{0}C. At the end of each 7 – day collection period, the sample collections were bulked for each animal and sub-samples taken for analysis. The experimental design used was 4 x 4 Latin square experiment. Data obtained were analyzed using analysis of variance (ANOVA) as described by SAS (2008). Significant means were separated using the Duncan Multiple New Range Test.

RESULTS AND DISCUSSION

The apparent nutrient digestibility coefficient of WAD goats fed *Pleurotus tuber regium* degraded cassava root sievate in their diets are presented in Table 2. Dry matter digestibility (DMD), crude protein digestibility (CPD) and crude fibre digestibility CFD) were positively ($p<0.05$) influenced by the experimental diets diets. The DM digestibility of this study ranged between 64.25 and 69.97% and compared well with the range of 63.44 – 71.56% reported by Hamchara *et al*. (2018) for goats fed oil palm fronds treated with *Lentinus sajor-caju* but lower than 82.20 – 88.70 % for WAD goats fed fungal treated rice straw in their diets as reported by Wuanor and Carew (2018). The variations may be attributed to age of the goats and the diets fed to the animals. CP and CF were least digested in T_1 (63.79% and 55.90%) and best digested in T_4 (80.34% and 68.19%), respectively. The highest ($P<0.05$) digestibility coefficient of crude protein obtained in treatment T_4 showed that the dietary protein was better utilized by the animals fed diet T_4 relative to others. This could be attributed to the fact that treatment of lignocellulosic feedstuffs with white rot fungi improves the available amino acid content of the residual biomass. Akinfemi and Ogunwole (2012) noted that fungal treatment of rice straw did not only improved the CP contents but also enhanced digestibility of the diets. Furthermore, Ahemefule (2005) observed that dietary protein enhanced digestibility. The reported CP digestibility coefficient in this study compared with 71.60 -78.80% for WAD goats fed fungal treated rice straw in their diets as reported by Wuanor and Carew (2018). The results of crude fibre digestibility in this study showed that crude protein content of diets were positively correlated with the CPD and CFD. This agreed with earlier reports (Fasae *et al*., 2005) that CFD and CPD decrease with decreasing level of CP in diets. A very important consideration in the utilization of nutrients by animals may be the synchronization of nutrients especially protein and energy. This may explain why the digestibility coefficient of CP and CF increased from treatment $T_1 – T_4$, in the same pattern with DM. The reported CF digestibility coefficient in this study is in agreement with the findings of Wuanor and Carew (2018) for WAD goats fed fungal treated rice straw in their diets.

Table 2: Apparent Nutrient Digestibility Coefficient of African Dwarf Goat fed biodegraded Cassava root sievate in their diets.

	Dietary levels				
Parameter (%)	T1 (0%)	T2 (20%)	T3 (40%)	T4 (60%)	SEM
Dry Matter	64.25[b]	65.35[b]	66.19[b]	69.97[a]	0.71
Crude Protein	63.79[d]	68.00[c]	73.96[b]	80.34[a]	1.66
Crude Fibre	55.90[d]	58.31[c]	64.25[b]	68.19[a]	1.28
Ash	51.96	50.95	51.04	51.48	0.06
Ether Extract	52.87	53.08	53.03	53.54	1.23
Nitrogen fee extract	57.63	55.73	55.63	57.36	0.97

[a-d] means on the same row with different subscript are significantly ($P < 0.05$).

Table 3 shows the nitrogen utilization of WAD goats fed *Pleurotus tuber-regium* degraded cassava root sievate (PTR-CRS) in their diets. The Nitrogen intake (g/day) obtained in this study (12.39-19.62 g/d) followed a particular trend, increasing with increasing levels of PTR-CRS. There was significant ($p<0.05$) difference for Nitrogen intake with T_4 been significantly ($p<0.05$) higher than T_3, T_2 and T_1. The higher N intake observed for the WAD goats in T_4 maybe attributed to the higher CP of the diet. The nitrogen retention increased ($p<0.05$) for WAD goats fed graded levels of *Pleurotus tuber regium* degraded cassava root sievate based diets; indicating that protein supplementation increased nitrogen retention. The high nitrogen balance and nitrogen retention percentage observed in this study, may be attributed to high digestibility of nutrients and low reduction in total N excreted among the *P. tuber regium* degraded CRS diets which resulted to higher utilization of nitrogen from microbial protein, suggesting that the nitrogen was well tolerated and utilized by the WAD goats. The increased Nitrogen retention values among the treatment groups further indicated the potentials of *Pleurotus tuber regium* degraded cassava root sievate to enhance N utilization among the WAD goats.

Table 4: Nitrogen Balance of West African Dwarf Goat fed biodegraded Cassava root sievate in their diets.

Parameters	T_1	T_2	T_3	T_4	SEM
Nitrogen Intake ((g/day)	12.39^{d}	15.63^{c}	17.45^{b}	19.62^{a}	0.69
Urinary Nitrogen(g/day)	1.42	1.23	1.3	1.08	0.08
Faecal Nitrogen (g/day)	3.77	3.72	3.69	3.57	0.08
Total Nitrogen Output(g/day)	5.19	4.95	4.99	4.65	0.12
Nitrogen balance (g/day)	7.22^{d}	10.68^{c}	12.46^{b}	14.97^{a}	0.72
Nitrogen retention (g/d $Wkg^{0.75}$)	4.40^{d}	5.79^{c}	6.49^{b}	7.52^{a}	0.30
Nitrogen utilization (%)	58.16^{c}	66.41^{b}	69.41^{b}	75.09^{a}	1.72

$^{a-d}$ means on the same row with different subscript are significantly ($P < 0.05$).

CONCLUSION

The results revealed that replacement of non-biodegraded cassava root sievate with *Pleurotus tuber-regium* degraded cassava root sievate in West Africa Dwarf (WAD) enhanced crude protein and crude fibre digestibility. The results also showed enhanced nitrogen utilization by the goats fed *Pleurotus tuber-regium* degraded cassava root sievate in their diets. *Pleurotus tuber-regium* degraded cassava root sievate can, therefore be included up to 60% to improve nutrient digestibility and nitrogen utilization in West Africa Dwarf (WAD) goats.

ABSTRACT
The study was conducted to evaluate the chemical composition and dry matter degradability of four (4) Agro-industrial by-products (Cassava peel, Yam peel, Brewer's waste and Maize offal) from Jalingo, Taraba State using the nylon bag technique. Crude protein content was highest (23.77%) in Brewer's dry grain (BDG) and lowest (4.67%) in Cassava Peel. All the feedstuffs were at least 50% degradable at 48hours incubation period and as such are good feed resources for ruminant stock. Cassava peels had the highest (87.0%) dry matter degradability, followed by Yam peels (86.42%), Maize offal (75.44%) and Brewers dry grain (56.17%). The effective degradability(ED) of 74.3% at 50 hour rumen incubation of Maize offal coupled with its moderate crude protein content (CP) of 13.16% suggests that it is the most nutritive of the tested feedstuffs followed by BDG (55.7% ED ; 23.77% CP), Yam peel (82.4% ED; 7.64% CP) and Cassava peel (81.2% ED; 4.67% CP). The high (>10%) fat content of Maize offal may however place BDG at a better comparative advantage over Maize offal, more so that BDG may provide more bypass protein than the maize offal.

KEYWORDS: By-products, Rumen degradability, Effective degradability, Nylon bag technique, Ruminant

INTRODUCTION
The goal of meeting the growing need for animal protein in the diet of the ever increasing human population in the Sub-Saharan Africa is fraught with poor livestock nutrition. Achieving optimal levels of feeding is one of the most important factors determining profitability in livestock enterprises. This is most problematic during the dry season when forages decline in quantity and quality with consequent fluctuations in the growth rate of the animals (Mbahi *et al.*, 2006). Maize offal, BDG, yam and cassava peels abound in Jalingo, being products from well grown food crops. An adequate appreciation of the value of crop residues and agro-industrial by-products and their use in feeding animals can help reduce pollution, minimize waste-treatment costs, and reduce the cost of feeding in livestock production as well as generate some additional income to crop producers and agro-industrialists (Crickenberger and Carawan, 1996).

FAO (1986) recommended a degradability range of 40 – 50% for a feedstuff to be considered acceptable for feeding ruminant stock. In addition to degradability, the crude protein content of the feedstuff is important as it affects the activities of the microbes in the rumen. Norton (1994) stated that any feed with less than 1.35% nitrogen (8.4% CP) is nitrogen deficient and cannot provide the minimum ammonia levels required to support the activities of the rumen microbes. The bulkiness of most agro-industrial by-products necessitates the need to determine which of them is the most nutritive so as to justify the investment into its procurement and storage for feeding ruminant animals (Onaleye *et al.* 2012).

MATERIAL AND METHODS

PREPARATION OF EXPERIMENTAL SAMPLES

Cassava peel, Yam peel, Maize offal and Brewer's dry grain (BDG) were collected from Jalingo in Taraba State and used for the study. The dry samples were ground through a 2mm sieve and stored in sealed bottles after drying them for 48 hours in the oven at 65°C.

EXPERIMENTAL ANIMALS

Three (3) fistulated male goats of an average weight of 18kg were used for the study. The animals were housed individually on concrete-floored pens and supplied with Groundnut haulms and Maize offal morning and evening. Salt lick and water were given *ad- libitum.*

INCUBATION OF FEED SAMPLES

Three (3) grams of triplicates samples of each feed ingredient per incubation period was weighed into nylon bags of size 7cm x 12.5cm and mesh (pore) size of about 45µm. The bags were made of filter cloth, weighed and numbered for easy identification. Each bag was attached to PVC string with the aid of rubber band. The bags were incubated for 6, 12, 24, 48, and 72 hours in the rumen of the cannulated goats.

After each incubation time, the bags were withdrawn from the animal; washed under running tap with a gentle squeeze between the fingers until the rinse water became clean and clear. They were then drained and oven-dried at 65°C for 48 hours, cooled and weighed to determine the loss in weight due to degradation by rumen microbes. The loss in weight was used to calculate the percent actual dry matter disappearance (ADMD) of the samples. The washing loss (zero time dry matter disappearance) was estimated by soaking three (3) bags of each feed sample in warm (about 37 ^{0}C) water for 30 minutes and following the same procedure as described for incubated samples above.

CHEMICAL ANALYSIS OF SAMPLES

The experimental feedstuffs were chemically analyzed according to standard procedure of AOAC (2000) for DM, Ash, CP, CF and EE. Samples were also analyzed for Neutral Detergent Fiber (NDF), Acid Detergent Fiber (ADF) and Acid Detergent Lignin (ADL) using the Van Soest *et al.* (1991) method.

FIT CURVE ANALYSIS

The results of the incubation were analyzed using Fit curve macro (Chen, 1995) for Microsoft Excel (NEWAY Excel). Degradation constants were estimated from the non-linear equation: $PD = a + b (1-e^{-ct})$, proposed by Ørskov and McDonald (1979). Where PD = potential degradability of dry matter and crude protein at time t, a = soluble fraction (intercept); b = insoluble but rumen degradable fraction and; c = the rate of degradation of b at time t (6, 12, 24, 48, and 72 hours).

The effective degradability (ED = a + {bc/(c+k)}) of DM was calculated at rumen outflow rates (k) of 0.02, 0.05 and 0.08 /hr according to Ørskov and McDonald (1979): where a, b, and c are as described above and 'k' is the fractional out flow rate from the rumen. Percent actual dry matter degradability values were analyzed in a completely randomized design using the one-way analysis of variance procedures of SAS (1999) and significant means were separated Fisher's LSD

RESUL T AND DISCUSSION

Proximate composition and cell wall content

The Proximate composition and cell wall content of the agro-industrial by-products tested are presented in Table 1. The CP values ranged from 4.67% in Cassava peels to 23.77% in Brewer's dry grain. Maize offal had the highest (12.13%) ether extract (E.E) and the least Ash (5.52%) content. The high (12.13%) E.E in maize offal may result to low feed intake in ruminants as well as low calcium content as seen in the ash content of maize offal compared to other feedstuffs. This is consistent with the findings of Crickenberger and Carawan (1996) who noted that if fat exceeded 10% of the diet dry matter, feed intake and performance may be restricted though the problem can be overcome by adding more calcium to the diet, which invariably increases production cost. Brewer's dry grain had the highest (45.25%) neutral detergent fiber (NDF) followed by Maize bran (32.98%), Cassava peels (22.48%) and Yam peels (15.95%)

The CP content of the Cassava peel obtained in the experiment (4.67%) is close to the 5.33±2.52% reported by Morgan and Choct (2016). The values of the DM and CP of the Brewer's dry grain used in this experiment are also similar to those reported by Arigbede *et al.* (2002). The DM, CP and Ash content observed for Maize offal in this experiment are higher than those reported by Arigbede *et al*. (2002) but with similar NDF value. The differences may be due to harvesting time, location, variety and soil fertility (Heuzé *et al*., 2017). However, their high solubility and high NFE content qualify them as readily available carbohydrates for supplementing maize residues-based livestock feed (Lardy and Andersen, 1999).

Table 1: Proximate composition and cell wall content of the feedstuffs

Sample	DM	CP	ASH	EE	CF	NFE	NDF	ADF	ADL	HC	C
Cassava peel	95.61	4.67	7.62	1.04	6.05	75.78	22.48	10.92	5.89	11.56	5.03
Yam peel	95.31	7.64	7.63	3.50	5.91	70.63	15.95	7.73	4.04	8.22	3.69
BDG	95.20	23.77	6.29	3.28	6.10	55.76	45.25	13.04	0.91	32.21	12.13
Maize offal	95.10	13.16	5.52	12.13	8.64	55.65	32.98	7.90	1.24	25.08	6.66

DM = Dry matter, CP = crude protein, EE = ether extract, CF = crude fibre, NFE = Nitrogen free extract, NDF = Neutral detergent fibre, ADL = Acid detergent fibre, ADL = Acid detergent lignin, BDG = Brewer's dried grain. HC= Hemicelluloses, C= Cellulose, HC = NDF – ADF, C = ADF – ADL

Rumen degradability of feedstuffs

The actual dry matter disappearance (ADMD) by incubation time and the overall means by sample are shown in Table 2. The overall % ADMD ranged from 44.43% in BDG to 76.30% in Yam peels which was significantly ($P < 0.05$) higher than that of BDG. With these degradability values, all the tested feedstuffs may be considered acceptable for ruminant feeding in accordance with the 40 – 50% degradability range recommended by FAO (1986).

Table 2: Actual Dry Matter Disappearance (%ADMD) of incubated feed samples

		Incubation time								
Sample	%DM	0hr	6hr	12hr	24hr	48hr	72hr	Mean	LSD	P value
Cassava Peels	95.61	50.99	65.79	77.13	83.82	87.00	87.67	75.40	18.47	0.0058
Yam peels	95.31	47.66	70.53	79.42	85.78	86.42	88.00	76.30		
BDG	95.20	22.21	28.56	39.03	47.60	56.17	72.99	44.43		
Maize offal	95.13	51.68	57.72	64.37	69.13	75.44	85.00	67.22		

LSD = Least significant Difference

Effective Degradability of feedstuffs

Table 3 shows the Effective Degradability (ED) of feedstuffs at degradability constants a, b, c and rumen fractional outflow rate K = 0.02, K = 0.05 and K= 0.08. The ED values shown are the predicted *in vivo* degradability at mean retention time (MRT) of 50hrs, 20hrs and 12.5hrs respectively (i.e. K = 0.02, 0.05, 0.08). Yam peel and BDG had the highest (77.1%) and lowest (41.0%) ED respectively at k= 0.05 (i.e. 20 hr incubation time). By the 40-50% recommendation of FAO (1986), all the feedstuffs tested are qualified as ruminant feedstuffs on the basis of DM degradability. Yam and Cassava peels with high (> 80%) degradability (at k = 0.05) but low (<8.4%) CP could serve as readily available carbohydrates when ammoniated straw-based diet is fed to ruminants. The high (23.77%) CP content of BDG and its medium (55.7%) ED may imply that a large portion of its nutrients will escape rumen degradation as by-pass nutrients into the intestine goats for digestion and utilization for tissue development (Reddy, 2001).

Table 3: Effective Degradability (ED) (%) of feedstuff at degradability constants a, b, c and fractional outflow rates K = 0.02, 0.05 and 0.08 where ED = a + {bc/(c+k)}

SAMPLE	a	b	c	RSD	Effective Degradability at K =		
					0.02	0.05	0.08
Cassava peels	45.5	41.7	0.114	0.71	81.2	74.8	70.4
Yam peels	51.3	36.0	0.127	0.76	82.4	77.1	73.4
Brewer's waste	26.4	88.3	0.010	4.37	55.7	41.0	36.1
Maize offal	56.1	49.7	0.012	2.37	74.3	65.4	62.4

a = readily soluble fraction, b = insoluble but degradable fraction, c = degradability rate, RSD = regression standard deviation, K = fractional outflow rate

CONCLUSION AND RECOMMENDATION:

All the tested feedstuffs are good feed resources except that cassava peels and yam peels should not be fed solely as they are poor in crude protein. Based on the CP content, rumen degradability and E.E content, BDG is the best feedstuff among the tested samples, followed by Maize offal, Yam peel and Cassava peel. A mixture of BDG and yam or cassava peel meal is recommended for ruminant dry season feeding.

ABSTRACT

The study assessed the physical features, proximate composition and fibre fractions of ensiled maize stover and groundnut haulms for sustainable ruminant production. Maize stover and groundnut haulms were collected, wilted for 3 – 4 days, chopped and ensiled in different proportions to make three 3 treatments (T1: 100% maize stover; T2:100 % groundnut haulms; T3:50 % maize stover and 50 % groundnut haulms) and replicated four (4) times in glass Bamma® bottles for 30 days. Physical features and chemical composition of the silage were examined. Results showed that the colour of the silage were cream, greenish brown and light brown for T1, T2 and T3. Texture was smooth for T1, coarse for T2 and slightly coarse for T3. All the silage were moist with pleasant aroma. The pH and temperature value ranges from 3 – 4.5, 30 – 31.5^{o}C, respectively. There were significant differences (P<0.05) in the proximate compositions and fiber fractions of the silage. Treatment 3 T3 had highest (P<0.05) content for the proximate composition and fiber fractions except the hemicellulose which was similar (P>0.05) in T2 and T3. Conclusively, the silage exhibited good physical features, appropriate proximate composition and fibre fractions that justified its potential in solving the challenges of dry season feed scarcity for ruminant production. Treatment 3 (50% maize stover and 50% groundnut haulms) is recommended for farmers based on the proximate composition and fibre fractions.

Key words: Chemical composition, groundnut haulms, maize -stover, ruminant, silage,

INTRODUCTION

In Nigeria, fodder scarcity is considered a major limiting factor to ruminant production. Lamidi *et al*. (2009) reported that available forage for most part of the year is low in crude protein, this leads to marked decreases in voluntary intake and digestibility and causes marked weight loss of animals, and economic return of the venture.

Crop-livestock farming is an integrated agricultural production system in which crop products especially wastes can be used as feed resources for the animals. Also the dung and urine of the animals can be used to improve the soil fertility. Increase in crop production will consequently lead to increase in the production of crop waste which will transform to feed for animal production.

The best way to maximally utilize crop wastes is to convert them to useful materials such as feed resources for animals, especially ruminant animals. Silage production has been used as a means of adding value to different crops waste.

Maize stover is a left over when maize cob has been harvested by the farmers. It can be a waste if left on the farm to dry off, it can also be ploughed back into the soil or destroyed by rodents or insect.

Groundnut haulms is the entire groundnut plant after groundnut were removed after harvesting, it is made up of the leaves, stem and root. It is also crop wastes which were left on the farm. Some were dry when the weather was conducive as hay; where weather is not favorable, it is left on the farm and wasted. Groundnut haulms have a higher crude protein content (11-17%) compared to (2 - 8%) in cereal residues. Addass *et al*. (2011) reported 91% DM, 8.30% ash, 10.90% CP, 31.80 CF and 1.31% EE for groundnut haulms.

This study intends to examine the physical features and chemical composition of ensiled maize stover and groundnut haulms for sustainable ruminant production.

MATERIALS AND METHODS

Experimental site and collection of experimental materials: The experiment was conducted at Forage Science Laboratory, Department of Animal science, University of Port Harcourt, Port Harcourt, Rivers State. Maize stover was collected from the Faculty of Agriculture Demonstration Farm after maize cobs were harvested. Groundnut haulms were gathered after groundnut seeds were harvested and haulms, cleaned of soil from the root. Both crop wastes were allowed to wilt for 2-3 days.

Silage production: The wilted maize stover and groundnut haulms were chopped with forage chopper machine separately and later weighed on percentage bases as: T1(100 % maize stover), T2 (100% groundnut haulms), T3(50 % maize stover+ 50 % groundnut haulms), replicated 4 times in glass bottles to have 12 Bamma® bottles and ensiled for 30 days

Data collection, chemical and data analysis: Physical features were monitored as reported by Lamidi and Akhigbe (2018). Chemical analysis was according to AOAC (2000). The experimental design was a completely randomized design (CRD), in which the experimental treatments were the only source of variability.

The model of analysis is as follows: $Xij = \mu + Ti + \sum ij$

Where Xij = value of observation; μ = population mean; Ti = treatment effect; $\sum ij$ = error term

All data obtained were subjected to the analysis of variance (ANOVA). Means were separated using Least Significant Difference (LSD) SAS (1999) package.

RESULTS AND DISCUSSION

Table 1: Physical features of ensiled maize stover and groundnut haulms

Parameters	Experimental treatments		
	T1	T2	T3
Colour	Cream	Greenish brown	Light brown
Texture	Smooth	Coarse	Slightly coarse
Wetness	Moist	Moist	Moist
Aroma	Mild sweet	Mild sweet	Mild sweet
pH	3.5	3	4.5
Temperature (^{0}c)	32	30	31.5
Mouldiness	No mould	No mould	No mould

T1: 100% maize stover; T2:100 % groundnut haulms; T3:50 % maize stover and 50 % groundnut haulms.

The physical features of ensiled maize stover and groundnut haulms are indicated in Table 1. The colour of the silage were cream, greenish brown and light brown for T1, T2 and T3. Texture was smooth for T1 and coarse for T2 and slightly coarse for T3. All the silage was moist with pleasant aroma. The pH and temperature value ranges from 3 – 4.5, 30 – 31.5^{o}C, respectively.

The colour of the silage was close to the original colour of the grass, which was an indication of good quality silage that was well preserved (Oduguwa *et al*., 2007). The range of pH value (3 – 4.5) recorded in this study was within the value reported (3.81 - 4.90) by Akinbode *et al.* (2017) when sugarcane top was ensiled with broiler litter. Generally, the mild sweet aroma perceived in all the silage is an indication of normal physical characteristics of good silage (Lamidi and Akhigbe, 2018).

Table 2: Proximate composition and fiber fractions of ensiled maize stover and groundnut haulms

Parameters	Experimental treatments				
	T1	T2	T3	SEM	LOS
Dry matter	86.96^b	87.07^b	87.24^a	0.05	**
Crude protein	11.67^c	12.18^b	12.69^a	0.15	**
Ether extract	2.12^c	2.23^b	2.37^a	0.04	**
Crude fibre	13.21^c	13.35^b	13.67^a	0.07	**
Ash	6.56^c	6.78^b	6.89^a	0.05	**
Neutral detergent fibre	47.39^c	49.23^b	51.15^a	0.54	**
Acid detergent fibre	25.67^c	27.12^b	29.05^a	1.35	**
Nitrogen free extract	52.33^b	52.47^b	51.15^a	0.07	**
Acid detergent lignin	8.59^c	8.76^b	9.23^a	1.00	**
Cellulose	17.75^c	18.36^b	19.82^a	0.36	**
Hemicellulose	21.72^b	22.10^a	22.11^a	0.07	**

[a, b, c] Means on the same row with different superscripts differ significantly (P<0.05).

SEM= standard error of mean; T1= 100% Maize stover; T2=100% Groundnut haulms; T3=50% Maize stover + 50% Groundnut haulms.

There were significant differences (P<0.05) in all the proximate composition and fiber fractions of the silage across the experimental treatments. The T3 had highest (P<0.05) content for proximate composition and fiber fractions except the hemicellulose which was similar (P>0.05) in T2 and T3.

The CP contents of the silage (11.67 – 12.67%) were above the critical lower limit (7% CP) which forage intake by ruminants and rumen microbial activity could be negatively affected (Norton, 2003). It implies that the silage would provide the adequate nitrogen requirement for the rumen microorganisms to maximally digest the main components of dietary fibre leading to the production of volatile fatty acids (Lamidi and Ogunkunle, 2016) this in turn facilitate microbial protein synthesis (Lamidi and Aina, 2013) and improve the production of meat, milk, skin and hide for man uses. Higher levels of NDF and lignin have been reported to have negative effect on DM intake and digestibility (Bakshi and Wadhwa, 2004). However, the NDF (47.39 – 51.15 %) values observed for the silage were less than 60% which is considered safe for acceptable intakes of forage in ruminants (Meissner *et al*., 1991).

CONCLUSION AND RECOMMENDATION

Conclusively, ensiled maize stover and groundnut haulms had good physical features of a silage. The proximate composition and the fibre fractions further justified its potential T1: 100% maize stover; T2:100 % groundnut haulms; T3:50 % maize stover and 50 % groundnut haulms in solving the problem of dry season feeding for ruminant production. Treatment 3 (50% maize stover and 50% groundnut haulms) is recommended for farmers based on the proximate composition and fiber fractions.

ACKNOWLEDGMENT

The authors acknowledged the efforts of Group 1 members (Victorious Group, ANS 403, U2015 Sets of University of Port Harcourt, Port Harcourt, Rivers State, Nigeria).

PLANT SECONDARY COMPOUNDS: A VIABLE OPTION FOR MITIGATING ENTERIC METHANE EMISSION IN NIGERIA

Lawal M.

Agricultural Education Department, Federal College of Education Katsina Tel: +2348035927818, E-mail: lawalmohd@yahoo.com

ABSTRACT

This paper highlights the role of ruminants as important contributors to global warming through enteric methane emission with a focus on Africa and Nigeria in particular. It goes on to identify the dearth of research emanating from the country towards developing strategies for mitigating enteric methane emission despite the large ruminant population. The process of methane production by ruminants is briefly described along with the different strategies used for mitigating it. The paper proposes the use of plant secondary compounds as a good potential option of mitigating enteric methane for a country like Nigeria. The need for equipment for measuring enteric methane production in developing any effective strategy was raised. The paper was concluded by calling on scientists and researchers to conduct more research on developing strategies for mitigating enteric methane production; and on government on the need for a policy framework towards achieving this aim.

Keywords: ruminants, methane mitigation, plant secondary compounds, Nigeria.

INTRODUCTION

Ruminant production is very important in Nigeria which has the highest amount of cattle, sheep and goats in Africa with estimates totaling approximately 130 million in 2014 (FAO, 2016). Ruminant animals play numerous economic and social roles in the lives of rural farmers in Nigeria in terms of food, income, security and other festive and ceremonial activities However, ruminant production is said to contribute to the global green house gas emission which contributes to global warming (Moss *et al*., 2000). Ruminant animals produce large amount of methane which is the second most problematic green house gas. Over the years, much effort have been put into mitigating global methane emission but despite that little effort is seen in Africa towards mitigating methane emission. Developing methane mitigation strategies form one of important components of reducing methane emission. In Africa, particularly sub Saharan African very little effort is being put in terms of research towards developing strategies for mitigating enteric methane emission. This is especially true of Nigeria as evidenced by little research literature on the subject matter originating from the country. Nigeria has the highest estimated population of ruminants in Africa and this implies that she may also be the highest enteric methane producer in the continent. With the evident dangers of this on global warming, it becomes necessary for the country take responsible steps in lowering its enteric methane production especially that the country has signed the Paris climate change agreement on lowering methane production in 2017.

METHANE PRODUCTION BY RUMINANTS AND STRATEGIES FOR MITIGATING IT

Ruminant animals are able to utilize forage to obtain their energy requirement but in this natural process, methane is released as a bi-product into the atmosphere as a result of forage degradation in the rumen (Morgavi *et al*., 2011). The rumen is a large fermentation vat which habours millions of various species of bacteria, fungi, protozoa and archaea. Forage ingested by ruminants is broken down by enzymes produced by bacteria, fungi and protozoa into volatile fatty acids (VFAs), carbon dioxide (CO_2) and hydrogen (H_2) (Moss *et al*., 2000). Archaea in turn reduces the CO_2 produced into methane (CH_4) using H_2 in process known as methanogenesis (Morgavi *et al*., 2011). Apart from the negative environmental impact, enteric methane production represents a loss of energy for ruminants estimated up to about 2-12% of GE intake Johnson and Johnson (1995). Various approaches for mitigating

enteric methane production have been described by Hristov *et al*., (2013) to include dietary strategies, breeding, vaccination, and management.

Among the strategies for mitigating enteric methane emissions, dietary manipulation using plant secondary compounds (PSC) is one of the promising options that can be explored in Africa and Nigeria in particular. This is because they are contained in many forages which are widely abundant in the country making it a cheap option and one that can easily be accepted and adopted into the local ruminant production systems. Plant secondary compounds are several chemical compounds produced by plants which are not directly involved in their growth and other vital processes. Some of these compounds like tannins, saponins and essential oils have been found to reduce methane production in ruminants. Many tropical plants used as forage contain high quantities of these compounds thus providing an opportunity for developing dietary strategies for mitigating enteric methane production in the region.

Table 1 Nigerian forages containing PSC with anti methanogenic effect

Gliricidia sepium and *Brachiaria ruziziensis*	Meale *et al*., (2012)
Acacia nilotica, Guiera senegalensis and *Lannea. acida*	Lawal *et al*., (2017 unpublished)

In developing any strategy for mitigating methane emission, a very important requirement is the ability to measure methane production. Several methods have been developed for measuring and estimating methane production from ruminants. These include:

Lab based in vitro incubation

Open circuit respiration chambers

Ventilated hood

SF6 tracer

Polyethylene tunnel

Open path laser

Greenfeed emission monitoring apparatus

Portable accumulation chambers

These methods have been extensively described by Makkar and Vercoe (2007), Goopy *et al*., (2016) and Hill *et al*., (2016). Lab based in vitro incubation methods like Hohenheim Gas Test, Pressure transducer systems and RUSITEC are relatively cheap, rapid and can be used to screen large amount of plant samples for anti-methanogenic properties. These equipments are available in few very universities in Nigeria. However, the open circuit respiration chambers have the greatest accuracy and are said to be the gold standard for measuring methane production from ruminants. To the best knowledge of the author, no such equipment is available in any of Nigeria's universities or research institutes.

CONCLUSION AND RECOMMENDATIONS

Methane is the second most important green house gas which contributes to global warming. Ruminant animals contribute significantly to global methane emission. Nigeria which has the highest estimated population of ruminants is likely to be the highest emitter of enteric methane in Africa. Very little effort is being done to curb enteric methane emission in the country in terms of developing strategies. More research is needed to develop strategies for cutting enteric methane emission. Plant secondary compounds are a promising option for developing strategies for cutting enteric methane emission in Nigeria. The ability to measure enteric methane emission is very necessary in developing effective strategies for cutting methane emissions. Equipment necessary for measuring enteric methane emission should be provided in universities and research institutes in various regions in the country. This paper is call on fellow scientists and researchers to conduct more researches in this area with a view to developing strategies of cutting enteric methane emission that is appropriate to our local conditions. For this to be successful, government support is needed in terms of developing a policy framework towards curbing enteric methane emission in the country.

Corresponding author: amoh881@yahoo.com 08027091937

ABSTRACT

The influence of different supplemental protein sources on the performance of Balami Rams was conducted using twenty (20) experimental Rams. The rams were allocated to four treatments with five animals per treatment as replicates. Supplementary diets A, B, C and D were allocated as one supplement per treatment. The supplementary diet containing Cotton Seed Cake and Maize offal was fed to group A, Group B animals were fed supplementary diet containing Poultry litter and Maize offals. Diets containing Moringa olifera and Maize offals was fed to C treatment and D group was the Control treatment with only maize offal (Table I), while Signal grass (Brachiaria decumbens) as the basal diet, water, and salt blocks were provided ad libitum throughout the feeding trial of ninety (90)days. The result showed that the average daily feed intake shows significant (P<0.05) difference between the treatments with a value of 996.00g//d in treatment C to 888.00 g//d in treatment D (control).The total weight gain(TWG) indicate significant (P<0.05) difference between the treatments .The mean total weight gain of 4.52kg was obtained in treatment C followed by 4.12 and 3.56kg for treatment A and B respectively while treatment D (2.68kg) had the lowest weight gain. The highest average daily weight gain (50.22g/d) was recorded in treatment C (P<0.05), while treatment D (Control) had the least value of 29.78g/d. Feed conversion ratio (FCR) was highest (27.75) in treatment D and lowest in treatment C (19.82) However, supplementing Balami lambs with Moringa olifera mixed with Maize offals performed better than poultry litter and cotton seed

KYE WORDS: Supplement, Basal, Weight gain, Balami

INTRODUCTION

Animal protein consumption in Nigeria and other developing countries has been reported to be comparatively low (Ayorinde and Aromolaran, 1998).Livestock feeding on poor quality native pasture and cereal straws, result in perpetual low productivity (Maigandi *et al*., 2003). Magaji (2004) reported that finding an effective way of utilizing the available feed resources and storage devices of feeds remain the subject of interest to many animal nutritional scientists in order to meet up the nutrients quality and availability at a lower cost. Adegbola (2002) reported that in the dry season, ruminant livestock cannot meet their nutritional requirements on grass alone.

Signal grass (*Brachiaria decumbens*) is one of the tropical grasses with tolerance to low soil fertility, relative freedom from pest and diseases, withstand heavy grazing and remain green long into the dry season (Ndikumana and Leeuw de, 1996), but its potential as feed resource is not well recognized in the ecological zone. ***Brachiaria decumbens*** is the most high-yielding species of the genus Brachiaria. Unlike Congo grass, it has no or very few diseases and can be used as permanent pasture. It is palatable to sheep and goats and withstands heavy grazing. Signal grass can be grazed, it can be fed fresh or to be made into hay. Signal grass is also used as a cover crop and in the control of weeds (AFRIS, 2015). However, ruminant animals cannot survive and produce on this grass alone, therefore supplementation has to be provided.

Therefore, this study is designed to assess the influence of supplemental protein sources on the performance of Balami rams fed *Brachiaria decumbens* as basal diet.

MATERIAL AND METHODS

Composition of Supplementary Diets

Composition of the supplementary diets is shown in Table 1. The diets containing CSC + MO is treatment A. The one containing PL + MO is treatment B that of C treatment is made up of MRL + MO while D served as control with MO only as was the case in Table I. The maize offals (MO) mixed with the other supplemental protein sources served as a booster.

Table 1: Gross Composition of the Supplementary Diets

Ingredients	Treatments			
	A	B	C	D
MO	100	100	100	100
CSC	200	00	00	00
PL	00	200	00	00
MRL	00	00	200	00
Total	300g	300g	300g	100g

MO=Maize offal, CSC= Cottonseed cake, MRL= *Moringa olifera* leaves, PL= Poultry litter

Experimental Design and Treatments

Twenty (20) experimental Rams were balanced for weight and allocated to four treatments with five animals per treatment. Each of the experimental Rams was randomly assigned to a treatment. Complete Randomized Design (CRD) was used for the experiment.

Management of the Experimental Animals

Twenty (20) Balami rams between 7 to 10 months (average of 17.5 kg) of age were used for the experiment. They were procured from Dambam local Livestock market, Dambam, Bauchi State. They were quarantined for fourteen days in which animals were fed groundnut haulms. They were ear tagged and given a prophylactic treatment with a broad spectrum antibiotic, dewormed and vaccinated against *Pest Des Petis Ruminant.* Each of the rams was kept in individual pen of 1 by 2M size for proper record keeping.

The experimental animals were fed with *Brachiaria decumbens* as basal diet, water, and salt blocks were provided *ad libitum* throughout the feeding trial. The feeding trial was conducted for 90 days after the adaptation period. Three hundred grams (300g) of supplements was offered for each experimental animal except those in the control treatment where they were offered 100g between 08.00 and 09.30 am before the basal diet i.e. at least 30 minutes before giving the basal diet. Feed offered and refusals were weighed every day before daily morning feeding.

DATA COLLECTION

The data collected during the feeding trials were supplementary, basal and total daily feed intake and water intake on daily basis. The weight gain for each animal was taken weekly throughout the feeding trials.

Feed intake was calculated by measuring daily offered and refusal of each treatment diet throughout the experiment. Daily feed intake was determined as the difference between the feed offered and the residue for both the supplement and the basal feed for each of the experimental Ram. Feed conversion ratio was determined as a ratio between total feed consumed and the total weight gain.

$$\text{Feed conversion ratio} = \frac{\text{Average daily feed intake}}{\text{Average daily weight gain}} \quad \ldots\ldots 1$$

The animals were weighed individually using weighing scale before the commencement of the experiment and then at weekly intervals between 8: 00 and 9:00 am after overnight fasting. The changes in weight of each of the animals was monitored throughout the period of feeding trial. Average daily weight gain (ADG) was calculated using the following formular as cited by Venkateswarlu *et al.* (2013).

$$\text{ADG} = \frac{\text{Final weight (g) - Initial weight (g)}}{\text{Number of days}} \quad \ldots\ldots 2$$

RESULTS AND DISCUSSION

The supplementary feed intake showed significant ($P<0.05$) difference across the treatments. The control diet (D) recorded the least supplementary feed intake of 92 g/a/d while rams fed diet C recorded the highest mean intake of 275 g/a/d. Treatment A and B had mean daily feed intake of 251 and 242 g/a/d (gram per animal per day) respectively. There was significant ($P<0.05$) difference among the dietary treatments on daily basal feed intake. Animals on diet B had the least value of 698 g/a/ d while animals fed diet D (control) had the highest mean daily basal feed intake of 796 g/a/d followed by treatment A (736 g/a/d) and C (721 g/a/d),. The average Daily feed intake shows significant ($P<0.05$)difference among the treatments. The intake ranged from 888 g/a/d in treatment D (control) as the least value to 996 g/a/d in treatment C as the highest. Treatment A and B recorded the mean values of 987 and 940 g/a/d respectively. This is within the range of 848.50 to 982 g/a/d reported by Muhammad *et al.* (2016) when the authors fattened Uda sheep with Fore-stomach digesta as supplement.

Mean final body weight showed significant ($P<0.05$) difference among the treatments with the least value of 26.28 kg recorded for animals on the control diet (D) and highest mean body weight of 27.96 kg for animals on diet C. Rams on diets A and B had mean values of 27.54 and 27.16 kg weights respectively.

The range tally with 28.75 to 30.38 kg obtained by Muhammad *et al.* (2016) when the authors fattened Uda sheep with Fore-stomach digesta as supplement.

The total weight gain showed no significant ($P>0.05$) difference across the treatments with the rams fed the control diet (D) as the least mean value of 2.68 kg weight gain and the highest mean value of

4.52 kg weight in treatment C followed by A and B with mean total weight gain of 4.12 and 3.56 kg respectively. Mean daily weight gain showed significant (P<0.05) difference across the treatments with the least value of 29.78 g/a/d for rams fed diet D (control) and the highest daily mean weight gain of 50.22 g/a/d for rams fed diet C. Diet A recorded 45.78 g/a/d while rams fed diet B had the mean daily weight gain 39.56 g/a/d. Dry matter intake as percentage body weight had no significant (P>0.05) difference across the treatments with treatment D as the lowest (3.11%) and the highest value of 3.29% recorded for treatment A. Feed conversion ratio (FCR) ranged from 19.82 for treatment C to 27.75 for animals fed diet D (Control).

CONCLUSION

In conclusion, it was observed that Signal grass had better performance when supplemented with *Moringer oleifera* than other supplemental protein sources used in this experiment in terms of feed intake and weight gain.

ABSTRACT

A survey was conducted in Argungu Local Government Area of Kebbi State comprising of 3 villages. A structured questionnaire was administered to 60 farmers within the study area. The data collected was analyzed by using simple statistical tools such as frequency counts and percentages. Majority (48.33%) of the respondents reared cattle, sheep and goats with about 48.33% having the highest flock/herd size of about 21-30 animals. Most (90%) of the farmers offered Kalgo parts as feed to their animals in combination with other ingredients and about 58.33% offered Kalgo parts in dried form to feed their animals with sheep and goats (58.93%) preferring Kalgo parts most. The parts of the Kalgo mostly preferred by ruminants indicated that the pods are mostly (70%) preferred and 21.67% of animals prefers the leaves alone. Kalgo parts is obtained for usage in the dry season as agreed by all (100%) the respondents with about 61.67% covering a distance of 1-2km from their homes/farms before obtaining Kalgo for usage. About 75% and15% obtained the kalgo parts by self and by purchase respectively. The parts are offered as whole as observed in this study, there is no any form of processing such as grinding, pounding and milling done on the leaves/pods before serving it to the animals. All the respondents (100%) in the study area agreed to the fact that Kalgo is naturally occurring plant. The results obtained in this work revealed that Kalgo is an important browse for ruminant production among the farmers.

Key words: Kalgo, utilization, ruminant farmers, Kebbi State

INTRODUCTION

Rural dwellers people generally recognize the trees and shrubs which are well appreciated by ruminants, and their nutritive importance (Thapa *et al.*, 1997; Briggs *et al.*, 1999; Thorne *et al.*, 1999; Komwihangilo *et al.*, 2001; Muftau *et al*., 2019). The role of browse during periods of drought has been recognized and has attracted attention from scientists (Hadja, 2007). Hence, farmers' preference of browse species was related to their availability, palatability and drought resistance.

In a previous survey conducted by Hassan *et al*. (2010), the authors observed that parts of browse species utilized by livestock were leaves, pods twigs and flowers. The pods of *Piliostigma reticulatum* were important feed resources for goats, sheep and cattle during the dry season (Nounhoun *et al*., 2013). Earlier study (Muftau, 2018) indicated that Camel's foot is highly abundant in Kebbi State and as a potential feed resource in the diet of sheep.

It is against the above back ground of the importance of woody shrubs and trees in rangelands that the study was embarked upon to investigate and ascertain the claim made by farmers on the utilization of *Piliostigma reticulatum* which is commonly known as Camel's foot and locally called Kalgo in the northern region of Nigeria as a potential feed resource in Kebbi Sate.

MATERIALS AND METHOD

Study Area

The survey was conducted in Argungu Local Government Area (LGA) of Kebbi State during the dry season period of 2017. Argungu LGA is located between latitudes 12^0 44'N $4^0$31'E/ and longitudes 12.733^0N 4.517^0E. The area has a longer dry season of 8 to 9 months and short rainy season of 4 to 5

months, the vegetation of the area is Sudan type with farming as the major activities of the people residing in this area. The Argungu Local Government also hosts an annual international fishing competition (KARDA, 2014),

Data collection and analysis

A total of 60 structured questionnaires were administered to randomly selected livestock farmers within the Local Government covering 3 out of 6 villages with 20 respondents per village during the dry season of 2017. The respondents were selected by systematic sampling procedure and interviewed. The structured questionnaires captured, flock size; species kept, availability and utilization of Kalgo among others. Statistical tools such as frequency distribution and percentage were used in analyzing the collected data.

RESULTS AND DISCUSSION

All the respondents in this study (Table 1) reared ruminant animals with the majority rearing more than one ruminant species mostly dominated by cattle, sheep and goats (48.33%). This might be attributed to complementary in feeding habits of the species. This finding is in line with the work of Smith (2006) who reported that cattle and sheep grazes lower grasses while goats browse shrubs and trees. Majority of the respondents (48.33%) had a flock/herd size of about 21-30 in numbers. Kalgo plant parts for usage in the study area (Table 1) are obtained mostly (100%) during the dry season (late October to late March). This is in line with the findings of Heuze and Tran (2011) who reported that browse species are particularly available for usage during the cool and hot dry season, which correspond to their fructification period (Yelemou *et al*., 2009) when herbaceous forages are scarce. Ways of obtaining Kalgo pods in this study (Table 2) includes; by self (75%) and by purchase (15%). However some farmers (10%) obtained the pods in both by self and purchasing. This observation is in agreement with the findings of Nounhoun *et al*. (2013) who reported that children and women in the northern Sudanian zone of Burkina Faso are engaged in the collection and storage of the pods of *P. reticulatum* and *F. albida* for sales at local fodder markets. Most of the respondents (61.67%) covered a distance of about 1-2km from their homes/farms before obtaining Kalgo for usage (Table 1). The distance travelled as observed in this study is lower than those reported by Nounhoun *et al*. (2013). All (100%) the respondents in the study areas agreed to the fact that Kalgo is naturally occurring plant which is in line with the reports of (Simbaya, 2000; Akinsoji, 2003; Ugbogu and Akinyemi, 2004; Fayemi *et al*., 2011).

Table 1: Animal species kept and numbers, availability and accessibility of Kalgo plant

Items	n=60 frequency	Percentage (%)
A. Types of Animal kept

Different forms of using Kalgo parts (Table 2) for feeding animals in the study area revealed that majority (58.33%) of the farmers preferred the dry form especially the pods. The parts are offered as whole to the animals as observed in this study, there is no any form of processing such as grinding, pounding and milling done on the leaves/pods before serving it to the animals. Most of the farmers (90%) offered Kalgo parts to their animals in combination with other ingredients such as concentrates and supplements. This is in agreement with the work of Crowder and Chheda (1982) who reported that browse plants alone can keep animals in a fair condition but may be inadequate as the sole feed stuff. All the farmers reported an increased use of the parts of kalgo (leaves/pods) by ruminants. Sheep and goats (58.93%) are found to prefer Kalgo (leaves and pods) than cattle (21.43%) in this study (Table 2). This observation was in line with the report of Nouhoun *et al*. (2013); they reported that some browse plants preferred by small ruminants in the sub-sahalian zone were not used by cattle while goats and sheep had nine browse plants preferred in common. All the parts of Kalgo (leaves/pods) are preferred by ruminants but the most (70%) preferred part is the pods as shown in Table2. Nouhoun *et al*. (2013) observed that pods of some browse plants such as *Piliostigma spp* and *F. albida* are especially preferred and used by all ruminant species across the Sahelian zone of Burkina Faso.

The use of Kalgo for animal health apart from feeding as agreed by all (100%) the farmers (Table 2) is in line with the findings of Garba and Muhammad (2008); Awohouedji *et al*. (2013); Nounhoun *et al*. (2013). These authors reported the various uses of browse plants for animal health care ranging from stimulation of milk in cows and goats, and anthelmintic.

Table 2: Kalgo plant usage, preference and method of utilization

Items	n=60 frequency	Percentage (%)
A. In what form is Kalgo fed to animals?		
i. Fresh (pods/leaves)	04	6.67
ii. Dry (pods/leaved)	35	58.33
iii. Wilted (pods/leaves)	21	35
B. How is Kalgo offered to animals?

Source: field survey, 2017

CONCLUSION AND RECOMMENDATION

Browse plant is an important component in ruminant production especially during the long dry season in the semi-arid environment. The results obtained in this work revealed that Kalgo plant is a permanent browse indigenous to the semi-arid environments. Kalgo is an important browse for ruminant production among the farmers in the study area. Management is however necessary in the production of Camel's foot (Piliostiga reticulatum) in order to improve ruminant production. It is recommended that the pods should be milled and incorporated with other ingredients for effective utilization by animals.

COMPARATIVE STUDY OF AMINO ACID PROFILE OF UREA PLUS METHIONINE SUPPLEMENTED AND FERMENTED SORGHUM BEER RESIDUE WITH THAT OF OTHER PROTEIN STANDARDS

***Ndams, S.S. and Alli-Balogun, J K**
College of Agriculture and Animal Science, Ahmadu Bello University, Mando Rd. Kaduna. Nigeria
**Corresponding Author's Email and Phone: samuelndams@gmail. com, +234 808 618 3938*

ABSTRACT
Sorghum beer residue (SBR), a by-product of local brewery was purchased dried, supplemented with urea and methionine at concentrations of 1.5: 0.37 %. It was inoculated with rumen liquor of cow and subjected to four days fermentation in a 5ft deep pit. After 4days fermentation, the urea plus methionine supplemented and fermented sorghum beer residue (RSBR) was sundried for 7days on concrete floor and samples taken for the determination of amino acid composition. The amino acid profile of RSBR sample revealed the availability of all essential amino acids except tryptophan (alanine, arginine, glycine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine and valine) in the sample. The amino acid profile of RSBR were higher than those of SBR, Groundnut cake (GNC), Soya bean cake (SBC), Food and Agricultural Organization (FAO) and other Animal Feed Standards (AFS). The superiority of essential amino acids in RSBR sample is an indication that it can serve as protein sources in place of conventional plant protein sources.

Keywords: Sorghum beer residue, Urea, Methionine, Fermentation and Amino acid.

INTRODUCTION
In Nigeria today, more than 50% of the country's poultry farms have closed down and another 30% forced to reduce their production capacity because of shortage of feed (Esonu el at., 2001). This feed shortage has been blamed on high cost of the conventional sources of feed ingredients which was rated by Madubuike and Ekenyem, 2006 at 70- 80% of total cost of poultry production. Soya bean and groundnut cakes have been used as protein supplements in poultry diets but their high cost has engineered the need to look for locally available and cheap sources of feed ingredients particularly those that do not attract competition between humans and livestock and for which Pousgha et al ., 2007 suggested traditional Sorghum beer residue. The nutritional qualities of sorghum beer residue (SBR) have been evaluated in the diets of chickens with some success (Demeke,2007 and Pousga et al 2007), it's maximum utilization as a plant protein source have been limited by its high fibre content (Aduku, 1993). The fibre fraction of a feedstuff has the greatest influence on its digestibility. The need to further recycle SBR through the process of fermentation in order to reduce its fibre content, obtain a high protein biomass and interesting amino acid composition becomes eminent. Protein quality is measured by the type of amino acids present. There are twenty different types of amino acids, eleven of which are essential in poultry nutrition because they are notmanufacturedby the animal's body. These include Lysine, Leucine, Isoleucine, Methionine Phenylalanine, Threonine, Tryptophan, valine, Arginine, Histidine and Glycine (Anhwange et al., 2004). Dietary protein with all the essential amino acids in the proportion required by the animal is said to be a high quality protein. In this study, sorghum beer residue was supplemented with urea and methionine and fermented for 4-days and its amino acids composition compared with those of FAO protein standard and Animal Feedstandard.

MATERIALS ANDMETHODS
Sample collection and Inoculumpreparation.

The sorghum beer residue was obtained from the local gin ("Burukutu") producers within Kaduna metropolis, Nigeria. Rumen content of cow was collected fresh just after slaughter at the Sabon-Tasha abattoir, Kaduna. This was then

mixed with water in a 2:1 ratio on a weight by weight (w/w) basis and filtered through a mosquito net of pore size 2.78mm^2 (Ndams *et al.*, 2011). The residue was discarded and the filtrate used as inoculum.

Substrateinoculation

The inoculation of sorghum beer residue prior to fermentation was carried out as described by Ndams *et al*. (2011). SBR was moistened with water at a ratio of 1:5 (w/w). SBR was supplemented with urea and methionine concentrations at a ratio of 1.5: 0.37 % (Fazaeli et al., 2007). The quantities of urea and methionine were first dissolved in the water containing the inoculum before wetting the substrate (SBR).

Substrateinoculation

On quantitative measurement, 2.67kg of methionine and 10.80kg of urea were dissolved in 3600kg of water in which 72.00kg of rumen liquor has been introduced before wetting 720kg (twelve bags of 60 kg each) of SBR. The SBR was inoculated on concrete floor and then turned into a 5ft deep pit lined with polythene materials. It was properly compacted by feet to maintain perfect anaerobic condition. The urea and methionine supplemented SBR was allowed to ferment for 4days. After fermentation, the pit was opened, and the fermented material removed. The fermented product (RSBR) was sundried for 7days on concrete floor and samples taken for determination of amino acidscomposition.

Determination of amino acidscomposition

The determination of amino acids profile in SBR, RSBR and GNC samples were carried out at the Department of Zoology, University of Jos using methods described by Sparkman *et al*. (1958).

RESULTS

The amino acids profile of RSBR sample revealed the availability of all essential amino acids except tryptophan (alanine, arginine, glycine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine and valine) in the samples.

Table 1 and figure 1 shows the amino acids profile of SBR, RSBR, GNC and other animal feed protein standards. The amino acids profile of the protein biomass (RSBR) produced after 4days fermentation, except for arginine, glycine and valine which were lower, all other essential amino acid concentrations were higher in RSBR than those of GNC. The amino acid concentrations of RSBR was numerically higher than those of Soya bean and FAO standards (with the exception of lysine which was lower compared to both) as well as that of Animal Feed Standard. Moreover, it had a superior profile in amino acid concentrations when compared to plantproteins.

Table 1: Comparison of the amino acid profile (g/100g protein) of the protein biomass of re-fermented sorghum beer residue with that of other protein standards

Amino acid	SBR	*RSBR	GNC	FAO[a]	SBC [b]	Animal feed standard (AFS)[c]
Alanine	8.66	8.89	2.10	-	-	-
Arginine	4.66	5.18	6.35	-	8.3	-
Cysteine	2.18	2.38	2.1	2.0	1.0	0.74
Glycine	3.17	3.60	7.8	-	4.5	2.43
Histidine	2.40	2.9	2.8	-	3.0	-
Isoleucine	4.18	4.63	2.1	4.20	5.6	2.57
Leucine	13.17	14.31	9.9	4.80	8.2	3.80
Lysine	2.38	3.02	2.1	4.20	6.8	3.20
Methionine	1.93	2.19	0.49	2.20	1.4	0.72
Phenylalanine	5.15	5.48	4.3	2.80	4.9	2.20

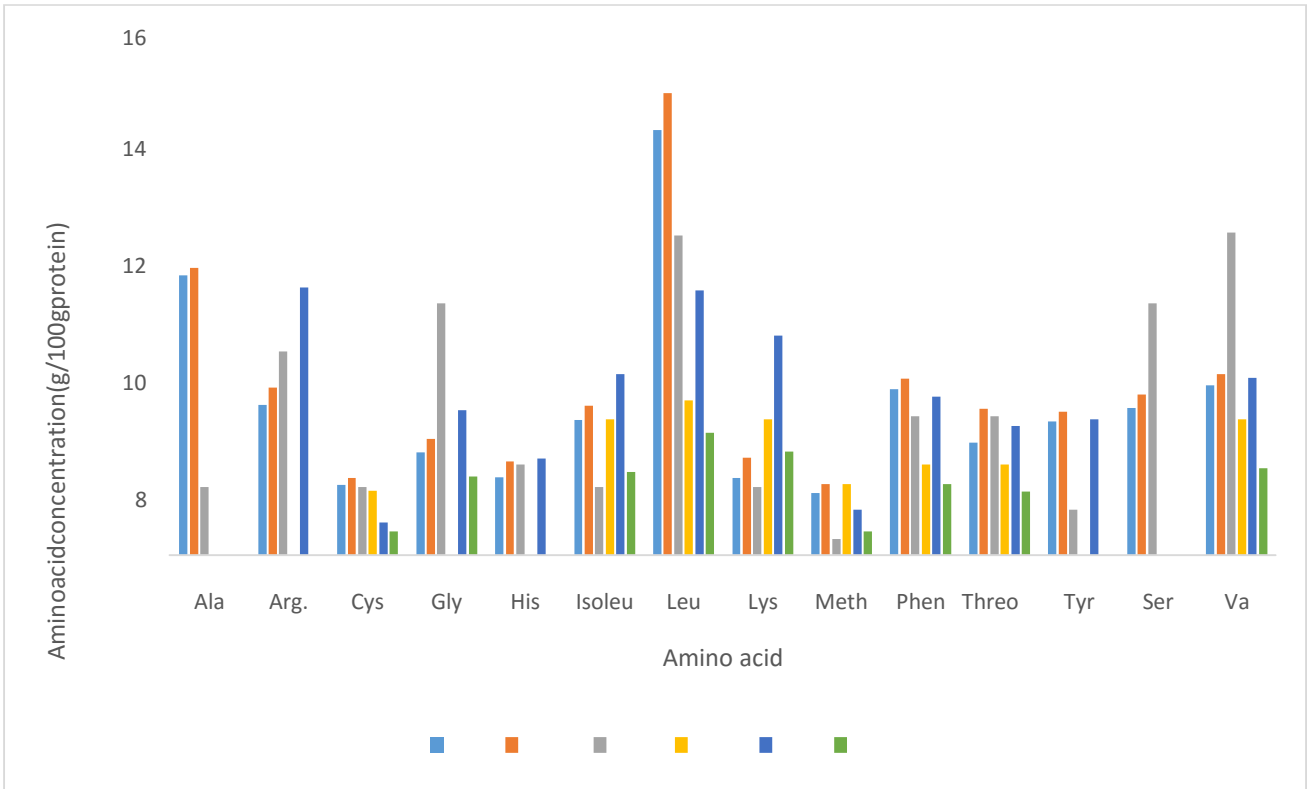

Figure 1: Comparison of the amino acid profile (g/100g protein) of the protein biomass produced (RSBR) with other protein standard

DISCUSSION

The availability of essential amino acids in SBR and RSBR is an indication that RSBR can serve as protein sources in non-ruminant nutrition (McDonald *et al*., 1998). The amino acid content of all the essential amino acids of RSBR samples were numerically higher compared to the unfermented (SBR) sample in this study. This is not inagreement with Spear *et al*., (1978) who observed numerical decrease in essential amino acids in lambs fed tall fescue supplemented with l-methionine Sulphur at 0.05 and 0.15% compared to the control (0%).The amino acid profile of the protein biomass (RSBR) produced in this study, was observed to be higher numerically than those of GNC. It was also superior to the amino acid profile of other plant proteins. The quality of the RSBR protein produced was equal or greater than that of the conventional ingredients in terms of its amino acid profile and the standard set for animal feed. This revealed that RSBR has all the essential amino acids for animal feed. This is in agreement with Ofuya and Obilor (1993) who observed that *Rhizopus* fermented cassava peel feedstuff contained all the essential amino acids that were far more digestible than the control. Also Almeida *et al*. (1995) observed that the protein obtained (34% of the biomass) contained all the essential amino acids for animal feeds when eucalyptus hydrolyzate was fermented using *paecilomycestes variottii*(fungus).

When compared to the FAO and soya bean standards, one can see that the protein standards and the protein biomass produced after 4days fermentation of SBR with urea and methionine supplementation contains all the essential amino acids for animal feeds. Moreover, it has a superior amino acid profile when compared to other plantproteins.

CONCLUSION

In conclusion, the results of this study indicates that 4-days fermentation of sorghum beer residue supplemented with urea and methionine resulted in a protein biomass (RSBR) with superior amino acid profile compared to GNC, Soyabean cake, FAO and Animal Feed Standards and can be used as an alternative to conventional feed ingredients in animalfeed.

RECOMMENDATION

Urea plus methionine treated Sorghum beer residue fermented for four days can be used in place or groundnut cake or soyabean cake as a protein source in monogastric nutrition.

ABSTRACT

This paper investigated the effects of some growth conditions i.e. forage-liquid ratio and fermentation time on the laccase activity of Pleurotus ostreatus (PO) and Ceriporiopsis rivulosus (CR) when used to upgrade selected low quality forages as possible dry season feed for ruminants. PO and CR were cultivated on Brachiaria decumbens (BD), Andropogon gayanus (AG), Triticum aestivum (TA) and Lolium perenne (LP) alongside untreated forages using two forage-liquid ratios (1:3 and 1:5) for each selected solid state fermentation times (14 and 28 days). The laccase activity of CR increased when the forages were in liquid ratio of 1: 5 at higher fermentation time with the exception of BD in ratio 1:3 at 28th day. The laccase activity of PO was increased when the forages were in liquid ratio of 1:3 at higher fermentation with the exception of TA in liquid ratio of 1:5. Generally increased fermentation time did not have much effect on the laccase production of each of the fungi on LP and TA; had minimal effect on AG; and had much effect on BD. It can therefore be concluded that for a higher laccase production to be recorded, CR should be cultivated on LP and TA in ratio 1:5 for shorter time, AG in ratio 1:5 for longer time, and BD in ratio 1:3 for a longer period. PO should be cultivated on AG and BD in ratio 1:3 for longer time, LP in ratio 1:3 for shorter time, and TA in ratio 1:5 for shorter time.

Keywords: Fungi, fermentation time, forages, laccase, ruminant feed

INTRODUCTION

The pre-treatment of low quality forages (LQF) with aerobic fungi (i.e. selective white rot fungi) have been one of the possible ways of upgrading the nutritive value of LQF found during the dry season. Among these white –rot fungi, PO and CR have increased ligninolytic ability to upgrade agro-industrial by-products and crop residues (Niu *et al*., 2018). However, the conditions of growth needed to be favourable for the release of ligninolytic enzymes especially laccase that are involved in the lignin degradation, a constituent that limits the access of other carbohydrates in feed to animals. Among these growth conditions, substrate-liquid ratio and incubation time were selected as they influences the release of enzymes. Substrate-liquid ratio affects the moisture content and optimal moisture content tends to positively influence fungal growth and laccase production by preventing substrate porosity or agglomeration (Patel *et al*., 2009). On the other hand, the incubation time has been identified to affect the rate and extent at which the fungi are capable of exhibiting their enzymatic functions, an essential or basic pre-requisite for fungal improvement of low quality feed (Arora and Sharma, 2009). This current work was carried out to identify the best substrate-liquid ratio and fermentation time that supports the release of laccase enzyme by each of the selected fungi on the selected low quality forages, as a criteria needed in the upgrade of low quality feed.

MATERIALS AND METHODS

A 2 (forage-liquid ratio) x 2 (fermentation time) factorial arrangement was used to obtain the main and interactive effects of the treatment on the laccase production of the fungi when used to inoculate the forages. Five (5g) of each of the forage samples (i.e. BD, AG, TA straw, and LP) used were weighed into 250ml Erlemneyer flasks, rehydrated with two different amounts (15ml and 25ml) of 1% Potato dextrose broth (CR) and 1% malt extract broth (PO) respectively to set the solid/liquid ratio for each of the fermentation time (14 and 28 days) respectively and then autoclaved at 121^0C for 15mins. Each of the Erlenmeyer flasks was then inoculated with three agar plugs (5mm) obtained from plates cultured on Potato dextrose agar at 20^0C (CR) and Malt extract agar at 30^0C (PO) for 10 days respectively and was replicated thrice for each treatment. This growth conditions have been identified in previous experiment. The flasks were thereafter incubated at either 20^0C (CR) or 30^0C (PO) in a dark environment at 95% humidity. Triplicated control flasks containing the substrates and the media but no fungal mycelium were also made available. After each time, 25ml of 10mM sodium acetic buffer solution (pH 5.0) was added to each selected flask for extraction of enzymes. The flasks were then kept in a shaking incubator (200rpm) for 20mins at 20^0C. The contents of each flask were filtered through a dried what-man filter paper no. 1 (150 mm diameter) and the filtrate was centrifuged at 10,000 rpm at 4^0C for 20 min. The supernatant was collected and laccase was determined by monitoring the oxidation of the diammonium salt of ABTS (2, 2' – azino – bis (3 – ethylbenz – thiazoline – 6 – sulfonic acid) as a substrate (Geng *et al*., 2004).

RESULTS AND DISCUSSION

Figure 1 and 2 shows the main effect of forage-liquid ratio at each inoculation time on laccase production by CR and PO respectively on the selected forages after 14th and 28th days of inoculation respectively. The highest laccase activity produced by *C. rivulosus* was at 1:5 ratio with the exception of BD at 28th day. The highest laccase activity produced by *P. ostreatus* for BD, AG and LP was at 1:3 ratio and that of TA was at 1: 5 ratio. The increase in laccase production with increase in inoculation time for CR was not different ($P > 0.05$) for LP; minimal for AG; and maximal for BD and TA. However, that of PO was not different ($P > 0.05$) for LP and TA but was different for AG and BD. The variations recorded in this study can be attributed to the effect of forages and fungi. Forage characteristics and the capacity of the system plays a major role on the fungal activity (Daniel, 2016). Fungi tends to require different optimal moisture content in their substrate before their ligninolytic activity can be exerted. Furthermore, fungi also vary in the incubation time at which they liberate solubles from substrates in preparation for lignocellulose degradation (Sharma and Arora, 2015)

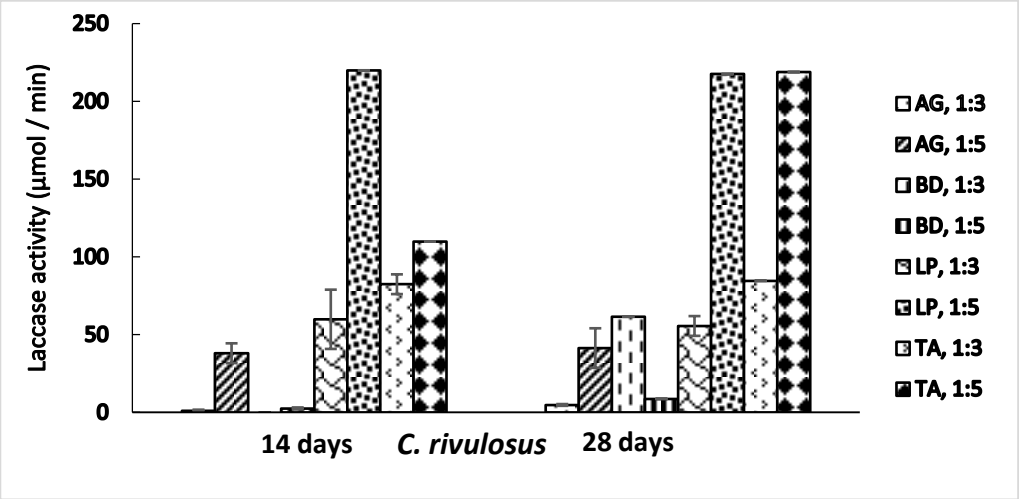

Figure 1.The main effect of substrate-liquid ratio on the laccase activity (µmol / min) of C. rivulosus *after 14th and 28th days of inoculation with the selected forages*

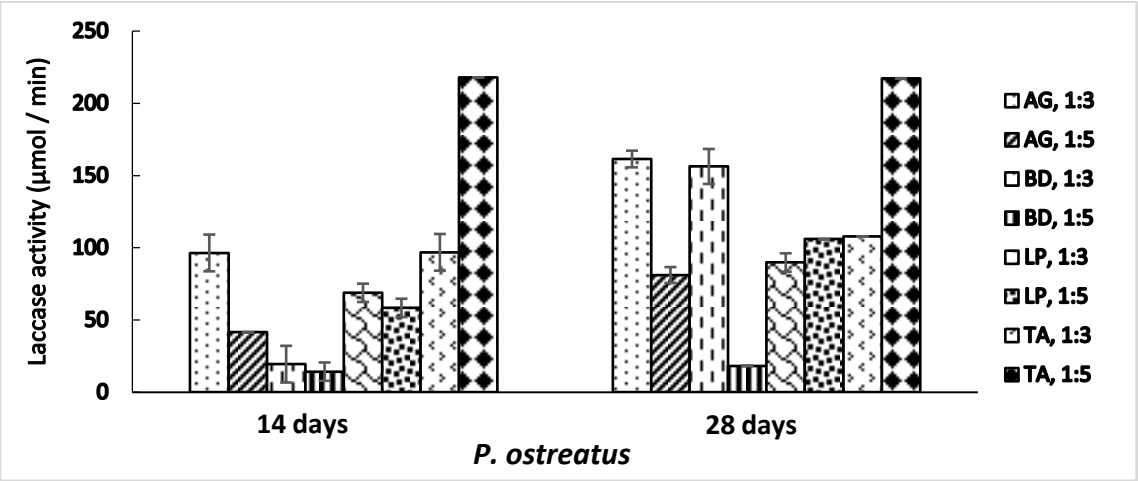

Figure 2.The main effect of forage-liquid ratio on the laccase activity (µmol / min) of P. ostreatus *after 14th and 28th days of inoculation with the selected forages*

Figure 3 shows the laccase activity produced by each of the fungi on the forages at different liquid ratios for 28 days is presented in Figure 3. In general substrate-liquid ratio 1:3 increased the laccase activity in *A. gayanus* and *B. decumbens* than ratio 1:5 and vice versa in *L. perenne* and *T. aestivum*. The forages can be grouped into two groups based on their ability to support laccase activity by the fungi: the low laccase producing group (i.e. BD and A) and the high laccase producing group (i.e. TA and LP). The forages varied in that LP and TA supported a higher production of laccase activity by the fungi by the 14th day of inoculation while for *BD* and AG it was by the 28th day of inoculation. The variations recorded in the forages is an indication that forages used for fungal treatment played a significant role in the liberation of solubles (Bhargav *et al*., 2008). Several factors such as their nutrient composition, degree of crystallinity of structural components especially cellulose, differences in the cell wall composition of C_3 and C_4, forage particle size etc. did have an influence on the ability of the fungi to get the required nutrients needed to initiate their growth and activity (Daniel, 2016).

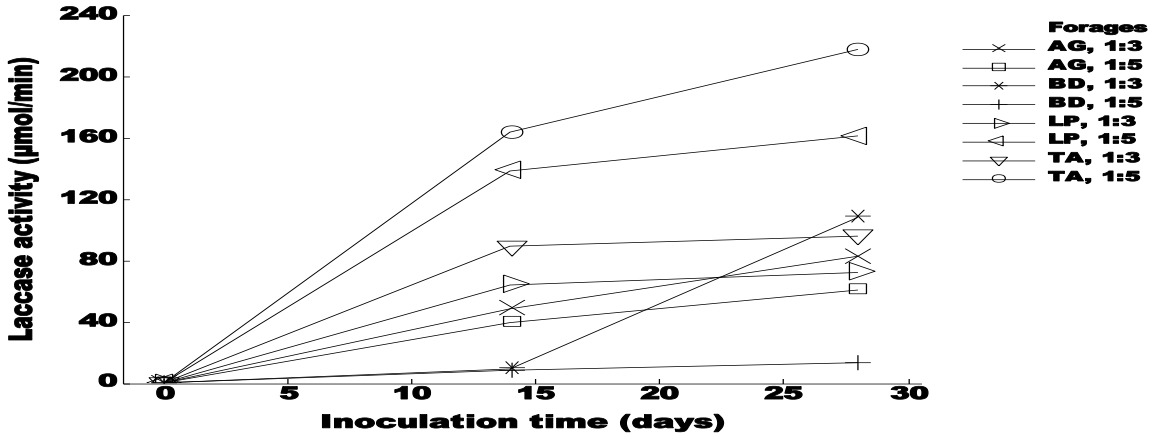

Figure 3 The laccase activity produced by the fungi as influenced by the forages at different sub – liquid ratios for 28 days.

CONCLUSION AND RECOMMENDATION

The fungi varied in their growth conditions requirement as increased laccase production was influenced by substrate-liquid ratio and fermentation time. CR should be cultivated on LP and TA in ratio 1:5 for shorter time, AG in ratio 1:5 for longer time, and BD in ratio 1:3 for a longer period. PO should be cultivated on AG and BD in ratio 1:3 for longer time, LP in ratio 1:3 for shorter time, and TA in ratio 1:5 for shorter time. The shorter fermentation helped in achieving laccase activity by the fungi earlier on LP and TA while longer fermentation time helped in achieving a higher laccase activity by the fungi on BD and AG. Further research in evaluating the effect of these fungi on the chemical composition and degradability potential of the treated forages should be investigated.

ABSTRACT

The study was conducted to evaluate interaction effect of breeds of goat and levels of turmeric powder (TP) inclusion on milk yield for 12 weeks post-kidding. Forty-five lactating Does comprising of 15 Kalahari Red (KR), 15 KalaWAD and 15 West African Dwarf (WAD) were used. The Does were randomly allotted to 3 treatments comprising of 5 Does of same breed per treatment. Three diets, that is concentrate diet (CD) as T0; CD+2g/kg TP as T2; and CD+5g/kg TP as T5 were fed at 5% bodyweight during pregnancy and for 12 weeks of lactation. Data obtained were arranged in a 3x3 factorial layout in a completely randomized design, while ANOVA was done using SAS 9.1. Results obtained revealed that KR fed T0 had the highest significant ($p<0.05$) milk yield (1100.00ml/24hrs) at 1st week of lactation compared to other dietary treatments. KR fed T2 had the overall best performance in terms of milk yield from 2nd to 12th week of lactation except at week 5 where KR fed T0 had the highest significant ($p<0.05$) value of 1160ml/24hrs. Peak value ($p<0.05$) of 1560ml/24hrs was recorded for KR fed T2 at 4th week of lactation, whereas WAD fed T0 had the lowest values for milk yield from weeks 1 to 12 with a peak value of 464.67ml/24hrs at 6th week of lactation. It could be concluded from the results of the study that feeding of concentrate diet with TP especially at the rate of 2g/kg of concentrate to KR Does generally improved the milk yield compared to other breeds of goat used and TP levels.

INTRODUCTION

Goats are important for the supply of high quality protein in milk through conversion of feed from non-competitive sources. In developing countries like Nigeria, sheep and goats are often kept in marginal environments with scarce grazing and unfavourable climatic conditions (FAO, 2019). Goats are the third ranking source of milk after cows and buffaloes (Devendra, 1980). Goats are dairy animals of the poor because of the lower capital investment and production costs required, and the animals' rapid generation turnover (and thus earlier milk production compared to other dairy animals), short pregnancies and milk supply in quantities that are suitable for immediate household consumption (FAO, 2019). The efficiency of milk production is dependent on high milk yields. Development of milk production from goats by small farmers in the tropics can complement commercial milk production especially from cows, and it is important for alleviation of undernutrition and malnutrition due to its high nutritional content (FAO, 2010) among the rural dwellers, people with lactose intolerance and other health challenges.

Turmeric (*Curcuma longa*) is believed to have spread from South-East Asia to nearby places like Indonesia, China, Japan and other South Pacific Islands and from there to tropical West and East Africa (Velayudhan *et al.*, 2012). The active ingredients found in turmeric are curcumin, demethoxycurcumin, bisdemethoxycurcumin (Wuthi-Udomler *et al*., 2000) and tetrahydrocurcuminoids (Osawa *et al*., 1995). The curcumin contained in turmeric is believed to have a wide range of biological effects such as anti-inflammatory, antioxidant, anti-tumour, antibacterial, and antiviral activities among others (Prasad *et al*., 2011). Despite the usefulness of turmeric to livestock production, there is no information on its effect on milk yield of goats, thus necessitating conduct of this study

MATERIALS AND METHODS

Preparation of turmeric powder

Fresh turmeric rhizomes were sourced from Oyo State. The rhizomes were sorted, washed, drained and spread in a dry cool to allow drying. Slicing was done afterwards using sharp knives into smaller pieces and thereafter oven dried at 60°C to a constant weight. The dried rhizomes were milled into fine powder using electric blender before its inclusion in the experimental diet and for necessary laboratory analyses.

Animal Management Procedure

A total of 45 matured non-pregnant, and non-lactating Does of at least parity one within age range of 2-2$^{1}/_{2}$ years were sourced from IFSERAR, Federal University of Agriculture Abeokuta, Nigeria. These included 15 Kalahari Red (KR), 15 KalaWAD (KW) and 15 West African Dwarf (WAD) Does. The Does were synchronized after flushing with 1st and 2nd intramuscular injection of Lutalyse® according to the procedure of Heise (2012). Thereafter, mating was done when the synchronized Does came on heat by introducing 6 healthy and proven KR bucks (i.e. 2 bucks per goat breed) into the pens where the Does were housed for at least 5 hours/day for a week. The Does were randomly allotted to 3 treatment groups comprising of 5 Does of same breed per treatment. Flock treatment was carried out prior to mating.

EXPERIMENTAL DIETS

T0: Basal concentrate diet (Control)

T2: Basal concentrate diet + 2g/kg turmeric powder

T5: Basal concentrate diet + 5g/kg turmeric powder

The basal concentrate diet is composed of maize (15kg); wheat offal (42kg); palm kernel cake (30kg); soybean meal (4kg); groundnut cake (3kg); bone meal (3kg); limestone (1.5kg); common salt (1kg); and premix (0.5kg). The dietary treatments were used for flushing of the Does for 2 weeks before the commencement and throughout the experimental period.

FEEDING TRIAL

The pregnant Does were fed individually with experimental concentrate diets for 24 weeks (162 days) until when all the Does kidded. The Does were also fed the diets during lactation phase that lasted for 12 weeks. The diets were administered at 5% body weight throughout the feeding trial. Stall feeding was done using *Brachiaria ruziziensis*. Cool and clean drinkable water was provided for the Does *ad libitum*.

Milk Collection Procedure

Milk was collected from all the Does for 12 weeks starting from a week after kidding by hand milking. Kids were allowed to suckle by themselves before the cisterns are emptied by draining the milk contained in them manually each time milk is collected. The kids are usually separated from the dams for 4hours after which milk produced during the period by individual Does housed in a separate wooden cubicle is collected. At the time of milk yield collection, a neat napkin dipped in warm water is used to clean the udder, followed by slight massaging of the udder with a full palm after which the teats (left and right) on the udder are put in between the thumb and fourth finger; and stripped up-down until the cisterns are empty. Milk collected from each Doe for the 4hrs of separation is measured using a measuring cylinder.

Milk yield (ml/24hrs) = Milk collected per Doe after 4hrs of separation (ml) x 6

Proximate and Fibre Analysis of Concentrate, Turmeric powder and Grass Fed

Samples taken from dietary concentrates, turmeric powder and *Brachiaria ruziziensis* were milled, and kept until when needed for proximate composition (AOAC, 2005) and fibre fractions (Van Soest, 1991).

STATISTICAL ANALYSIS

Data obtained were arranged in a 3x3 factorial layout in a completely randomized design, while ANOVA was done using the procedures of SAS (2004). Significant level was taken at 5% probability, while means was separated using Duncan's multiple range test of the same statistical package.

RESULTS AND DISCUSSION

The proximate and fibre fraction compositions of the basal experimental concentrate diet is presented in Table 1. The crude protein (CP) of the diet (16.49%) was sufficient to meet the need of the Does during pregnancy and lactation according to the report of NRC (2007) which recommends CP ranges of 13-14% and 12-17% for goats during pregnancy and lactation respectively.

Table 1: Proximate and fibre fraction compositions of basal experimental concentrate diet

Parameters (%)	TM-0
Dry Matter	88.19
Crude Protein	16.49
Ether Extract	2.48
Crude Fibre	27.50
Ash	10.98
Nitrogen Free Extract	41.74
Organic Matter	89.02
Neutral Detergent Fibre	62.67
Acid Detergent Fibre	38.00
Acid Detergent Lignin	10.67
Hemicellulose	24.67
Cellulose	27.33
*ME (MJ/kg DM)	12.27

ME= Metabolisable Energy

*Calculated using De Boever *et al.* (1997) equation

The interaction effect of breeds of goat and levels of turmeric powder inclusion on milk yield from 1st week of kidding to 12 weeks post-kidding in Table 2 showed that KR fed T0 had the highest significant ($p<0.05$) milk yield at 1st week of lactation compared to other dietary treatments. This might be due to the fact that it recorded the highest level of oxytocin and reasonable level of prolactin within 24hrs of kidding. KR fed T2 had the overall best performance in terms of milk yield from 2nd to 12th week of lactation except at weeks 2 (KR fed T5); 5 (KR fed T0); and 10 (KR fed T5). Peak value of 1560ml/24hrs was recorded for KR fed T2 at the 4th week of lactation which was the highest significant ($p<0.05$) milk yield obtained for the study. The lowest milk yield (240mls/24hrs) recorded for KR was for those fed T0 at weeks 11 and 12 of the study. KW compared favourably with KR in terms of milk yield, where KW fed T2 had the peak value of 1040ml/24hrs at week 4, whereas lowest value (375ml/24hrs) was recorded for KW fed T0 at the 12th week. WAD fed T0 had the lowest values for milk yield from weeks 1 to 12 with peak value of 790ml/24hrs which was recorded for WAD fed T2 at the 2nd week of lactation. Lowest milk yield of 206.67ml/24hrs was recorded for WAD fed T0 at week 12. The results obtained corroborate that of Mardalena *et al.* (2011) who reported that milk of Etawah dairy goats supplemented with diets containing antioxidant at 0.02%, 0.04% and 0.06% inclusion levels had improved milk yield compared to those without antioxidant supplementation.

ACKNOWLEDGEMENT

The authors acknowledge research support from the World Bank through Africa Centre of Excellence in Agricultural Development and Sustainable Environment (CEADESE) with Grant No. ACE 023. The research was partly funded by Tertiary Education Trust Fund (TETFund), which was facilitated by Directorate of Grants Management and Institute of Food Security, Environmental Resources and Agricultural Research (IFSERAR), Federal University of Agriculture Abeokuta, Nigeria.

CONCLUSION AND RECOMMENDATION

It could be concluded from the results of the study that feeding of concentrate diet containing turmeric powder especially at the rate of 2g/kg of concentrate to Kalahari Red Does generally improved the milk yield of the goat compared to other breeds of goat used and turmeric powder inclusion levels.

ABSTRACT

Forage scarcity in the dry season is very challenging for ruminant production in the tropics. The utilization of browse species, particularly as silage can bridge this gap. This study assessed the potentials of Moringa oleifera leaves ensiled with varying levels of cassava peels as dry season feed for West African Dwarf (WAD) goats.

Different mixtures of Moringa oleifera leaves and cassava peels were ensiled and designated as follows: T1= 100% Moringa, T2= 60% Moringa + 40% Cassava peels, T3= 40% Moringa + 60% Cassava peels, T4= 50% Moringa + 50% Cassava peels, T5= 100% Cassava peels. Chemical composition and silage characteristics were investigated. 25 WAD goats with weights ranging between 4.83-6.90 kg were used in the growth study. Chemical composition of the silage diets showed that it contained 27.79 – 36.26 % dry matter (DM), 7.45 – 22.25 % crude protein (CP), 8.92 – 16.45 % crude fibre (CF), 2.55 – 7.01 % ether extract (EE), 6.10 – 10.08 % ash content, 42.40 - 68.14 % Nitrogen Free Extract (NFE). Appearance, odour and texture of the silage had acceptable physical attributes with pH values ranging from 3.53 – 5.80. Average daily feed intake (ADFI) and Feed conversion ratio (FCR) were not significantly (P<0.05) affected by diets while Average daily weight gain (ADWG) was significantly improved in T3 (40% M. oleifera + 60% cassava peels) than in others.

It was concluded that Moringa oleifera leaves silage with 40% cassava peels as additive elicited the best performance indices in WAD goats fed diets consisting of mixtures of Moringa oleifera leaves and cassava peels ensiled together in graded levels or alone.

Keywords: Feed Intake, Growth, *Moringa oleifera*, Silage, WAD Goats.

INTRODUCTION

Livestock productivity in the tropics has suffered major setback due to inadequate quantity and quality of feeds for animals especially during dry season (Peters, 1998). Tree fodders maintain higher protein and mineral contents during growth than do grasses, which decline rapidly in quality with progress to maturity (Aganga and Tshwenyane, 2003). Due to the deciduous nature and leaves-shattering of some of these tree fodders, silage making which has great potential to solve shortage of feed for small ruminants by preserving excess forage produced during the wet season for use at the dry period could be adopted . Protein content of *Moringa oleifera* leaves is high. They also contain high mineral value and high yield potential (Aregheore, 2002) and can be exploited for feeding animals during the dry season when forage is scarce. Low levels of fermentable carbohydrates in *Moringa oleifera* limit its use as a silage material, hence there is a need to mix with highly fermentable carbohydrate to enhance its silage value. Cassava peels contains readily fermentable carbohydrates and have been used as additive (Olorunnisomo, 2011) in grass silage fed to Red Sokoto goats. Ensiling moringa together with cassava peel presents an opportunity to preserve their nutrients and enhance their feeding value for small ruminants during the dry season. This study was therefore designed to assess the silage quality and growth performance of WAD goats fed *Moringa Oleifera* leaves ensiled with different levels of cassava peels.

MATERIALS AND METHODS

EXPERIMENTAL STATION AND DURATION

The experiment was carried out at the Sheep and Goat Unit, Obafemi Awolowo University (OAU) Teaching and Research Farm, Ile – Ife located approximately between latitude 7^0 31´N and 7^0 33´N; and longitudes 4^0 33´E and 4^0 34´E (Amujoyegbe *et al*., 2008). The experiment lasted Twelve (12) weeks.

SILAGE PRODUCTION AND EXPERIMENTAL DIETS

Moringa oleifera leaves were collected from plots within the Obafemi Awolowo University Teaching and Research Farm, Ile – Ife, Osun State. Fresh cassava peels were also collected from a cassava processing Unit within the OAU Teaching and Research Farm. They were chopped into bits using a forage chopper machine and then included in the silage mixture in levels as designated:

T1= 100% *Moringa oleifera*; T2= 60% *Moringa* + 40% Cassava peels; T3= 40% *Moringa* + 60% Cassava peels; T4= 50% Moringa + 50% Cassava peels; T5= 100% Cassava peels.

Mixture was packed, compacted and sealed in thick polythene bags to create an anaerobic condition for proper fermentation. The silage was ensiled for 21 days after which they were opened.

EXPERIMENTAL ANIMALS AND THEIR MANAGEMENT

Twenty-five growing WAD goats with average weight of 6.02 ± 0.88 kg were randomly assigned to the five experimental diets in a completely randomized design. There were 5 goats per treatment with each animal serving as a replicate. The goats were housed in open sided, well-lighted and adequately ventilated building with slated floor. The house was disinfected before the animals arrived. The animals were vaccinated against *Pestes des Petite Ruminantes*, quarantined and observed for any disease symptom for seven days. The goats were also dewormed and treated against ectoparasites using ivomec ® prior to the commencement of the experiment. Animals were feed at 5% of their body weight. Water was supplied *ad libitum*.

GROWTH PERFORMANCE DETERMINATION

Growth trial lasted twelve weeks. Each animal was weighed using hanging scale and weighing sack before the commencement of the study and subsequently were weighed weekly throughout the experimental period. Parameters measured included; feed refusal, feed intake and weight gain.

Determination of silage quality: After 21 days, the fermentation was terminated by opening the silage bags and silage quality characteristics (colour, aroma and texture) were assessed using the method of Babayemi (2009). Silage pH was determined according to the methods described by Falola *et al*. (2013). Colour assessment was carried out through visual assessment with the aid of a colour chart. Aroma of the silage was assessed by 5 different people. Sub-samples from the treatments and at different depths were taken and mixed together for dry matter determination by oven drying at 65^0C until a constant weight was achieved. The samples were later milled and stored in triplicates in cellophane bags until needed for chemical analysis.

CHEMICAL ANALYSIS:

Crude protein, crude fibre, ether extract and ash of the silages were determined according to the methods of AOAC (1990). Neutral Detergent Fibre (NDF), Acid Detergent Fibre (ADF) and Acid Detergent Lignin (ADL) were determined using the procedure of Van Soest *et al*. (1991).

STATISTICAL ANALYSIS

All data were subjected to a one way analysis of variance (ANOVA) of SAS (1999) in a completely randomized design and treatment means, where significant, were separated using Duncan's Multiple Range Tests of the same package.

RESULTS AND DISCUSSION

The chemical composition of *Moringa oleifera* and cassava peels based silage diets are presented in Table 1. The Dry matter content and Nitrogen Free Extract (NFE) of silage increased as the proportion of the cassava peels in the silage increased while the crude protein, Fibre fraction and Ash reduced. The increased level of NFE and reduced crude protein in the silage mixture with increasing proportion of cassava peels indicate that the addition of cassava peels to Moringa based silage diets improved the energy at the expense of the protein. This is similar to the result obtained by Olorunnisomo and Adesina, (2013) when they assessed the preference of Zebu cows for Moringa leaves ensiled with different levels of cassava peels. The feed mixtures except T5 (sole cassava peels silage) with a CP level of 7.45% met the requirement for protein recommended for ruminants (10-12%) (ARC, 1980). This implies that animals fed high percentage of cassava peels would need protein supplementation to meet their requirement for maintenance and production.

Table 2 shows the silage characteristics of *Moringa oleifera* and cassava peels based silage diets. Appearance, odour and texture of the silage had acceptable physical attributes with pH values ranging from 3.53 – 5.80. Good silage usually preserve well of the original colour of the pasture or any forage (t'Mannetje, 1999). The greenish and dark spots colour of the silages showed that the original colours of the silage constituents were well preserved.

Table 3 shows the growth performance of WAD goats fed *Moringa oleifera* and cassava peels silage diets fed to WAD goats. Average daily feed intake ADFI (g) of diets were not significantly ($P<0.05$) affected by silage diets. Final weight of goats in T2 was significantly higher in T2 than in T5, but similar in T1, T3 and T4.

The Average Daily Gain (ADG) obtained in this study (12.30 -19.05 g/day) is similar to values of 10.60 - 24.60 g/day reported by Okolo *et al*., (2012) for WAD goats fed graded levels of cashew nut shell with some other non-conventional feed stuff. They are also similar to the range of 14.88-21.43 g/day reported by Asaolu *et al*., (2012) for WAD goats offered dried leaves of Moringa, Gliricidia and Leucaena as supplement to a basal diet of cassava peels. Animals fed silage diets consisting of a mixture of 40% Moringa and 60% cassava peels elicited the highest ($P<0.05$) weight gain (19.05) compared to others. Result appears to suggest an associative effect of the combination of Moringa and cassava at this level which gave the best ADG beyond which values were observed to decline. FCR were similar in diets.

Table 1: Proximate composition of *Moringa oleifera* and cassava peels based Silage diets fed to WAD goats

Parameters	T11	T2	T3	TT4	T5

ABSTRACT

This study was carried out to evaluate the proximate composition of plant parts of Pennisetum purpureum harvested at selected locations in South-west Nigeria. The experiment was laid out in a 6 × 2 factorial design comprising of six (6) locations (Ewekoro, Odeda, Ibarapa, Ido, Oriade and Ejigbo) and two (2) plant parts (stem and leaf) replicated three times. The dry matter (DM) value ranges from 83.83% in P. pupureum harvested at Ibarapa to 93.00% in P. purpureum harvested at Ejigbo and P. purpureum harvested at Ido had the highest (10.71%) crude protein (CP) content with the lowest value (9.68%) observed in P. purpureum harvested at Odeda. Meanwhile, P. purpureum harvested at Oriade had the highest (7.33%) ether extract (EE) content with the lowest value (5.17%) observed in P. purpureum harvested at Ewekoro. The leaf fraction of the harvested P. purpureum recorded the highest value (88.16% and 11.74%) for DM and CP content respectively with the lowest value (5.67%) for EE content and the leaf fraction also had the highest value (15.00% and 13.60%) for Ash and NFC content respectively. The leaf fraction of P. purpureum harvested at Ejigbo recorded the highest value (94.33%) DM content with the lowest value (81.00%) observed in stem fraction of P. purpureum harvested at Ibarapa and the CP content range from 7.83% in stem fraction of P. purpureum harvested at Odeda to 12.38% in leaf fraction of P. purpureum harvested at Ido. While the leaf fraction of P. purpureum harvested at Ewekoro and Ejigbo had the lowest value (4.67%) of EE content with the highest value (8.00%) observed in stem fraction of P. purpureum harvested at Ibarapa, Ido and Oriade. It is therefore concluded that there were variations in the nutrient of P. purpureum harvested at the selected locations with different plant parts.

(Keywords: natural pasture, *Pennisetum purpureum*, plant parts, location)

INTRODUCTION

The ever-increasing human population and their high demand for animal protein, especially from meat and milk will depend on better utilization of available feed resources by the ruminant livestock for improving household food security and income (Kabi and Bareeba, 2008). Among feed resources, forage crops, especially grasses have shown unique characteristics in different agricultural systems. They can be grown in harsh environments, utilized as functional components in providing environmental services in soil erosion control and greenhouse gas emission mitigation efforts (Beard and Green, 1994) and income generation as basic animal feed (Wright and Turhollow, 2010). Currently, there is increasing demand for ruminant animal products owing to the growing population and improved livelihoods (Dastagiri, 2004). Ruminants rely more essentially on pasture for their nutrient requirement than any other feed resources and inadequate feed supply is a major constraint of livestock production in sub-Saharan African countries (Arigbede *et al.,* 2011). Forage is important to livestock production since it is a major source of ruminant feed and nutrition for sustainable animal protein and ruminant is the largest source of animal protein. Forage crops make up a significant part of the total agricultural land in Africa and provide a critical food supply for the livestock industry. Grasses are the most abundant flowering plants that are useful to man. They are

one of the most important sources of nutrients for domesticated ruminants during a large part of the year (Taweel *et al*., 2005). The nutritive value of forage, as related to ruminants, may be regarded as the product of the intake of the forage and its digestibility, with intake being the more important of the two parameters (Mott, and Moore, 1969).

MATERIALS AND METHODS

The research was carried out at the Laboratory of Pasture and Range Management Department of the Federal University of Agriculture, Abeokuta. The grass was harvested from natural pastures from selected locations across south-west Nigeria. The plant were separated into two (2) parts (stem and leaf) and oven dried for laboratory analysis. The study was laid out in 6 × 2 factorial design comprising of six (6) locations (Ewekoro, Odeda, Ibarapa, Ido, Oriade and Ejigbo) and two (2) plant parts (stem and leaf) and data collected were subjected to a Two-way analysis of variance and the treatment means were separated using Duncan's Multiple Range Test using SAS (1999) package. The dry matter, crude protein, ether extract and ash contents of the milled grass sample was determined according to procedure of A.O.A.C. (2000) and NDF was determined according to Van Soest *et al*, (1991). Non-fibre carbohydrate was calculated as NFC = 100 - (CP+Ash+EE+NDF).

RESULTS AND DISCUSSION

There was significantly ($p<0.05$) difference on the proximate composition of plant parts of *Pennisetum purpureum* harvested at different location in South-west (Table 1). It is quite evident that there were variations in the proximate composition of the *Pennisetum purpureum* across locations as revealed in the study and these variations could be affected by various factors, in which seasonality and species specific feed resources were known to be the major factors in affecting the nutritive value of native grasses (Subhalakshmi *et al.*, 2011). It was also reported by Kavana *et al.* (2007) that bimodal distribution of rainfall, uneven seasonal growth and availability of pasture had been considered as the major limitations to constant supply of forage for ruminant animals. The dry matter (DM) value ranged from 83.83% in *P. pupureum* harvested at Ibarapa to 93.00% in *P. purpureum* harvested at Ejigbo and the leaf fraction of the harvested *P. purpureum* recorded the highest value of 88.16% for DM content. The increase in the DM value of the leaf proportions as the *Pennisetum purpureum* advance in age conforms to the submission of McDonald *et al*. (1995) who reported that dry matter content increases with advancing maturity which reflects decrease in cell content. *P. purpureum* harvested at Ido had the highest (10.71%) crude protein (CP) content with the lowest value (9.68%) observed in *P. purpureum* harvested at Odeda while the leaf fraction of the harvested *P. purpureum* had the highest value of 11.74% for CP content (Table 1). There was significantly ($p<0.05$) difference on interaction effect of location and plant parts on the proximate composition of harvested *P. purpureum*. The leaf fraction of *P. purpureum* harvested at Ejigbo recorded the highest value (94.33%) DM content with the lowest value (81.00%) observed in stem fraction of *P. purpureum* harvested at Ibarapa and the CP content range from 7.83% in stem fraction of *P. purpureum* harvested at Odeda to 12.38% in leaf fraction of *P. purpureum* harvested at Ido (Table 2). The crude protein content of the *P. purpureum* was considerably influenced by location. There were variations in CP contents of the *P. purpureum* with the different location and this was in comformity with the report of Da Silva *et al*. (2011) in which similar reports was also obtained from previous findings of Teka *et al*. (2012). The variation in the crude protein of *Pennisetum purpureum* might also be attributed to site potential in terms of differences in edaphic factors and temperature condition.

P. purpureum harvested at Oriade had the highest (7.33%) ether extract (EE) content with the lowest value (5.17%) observed in *P. purpureum* harvested at Ewekoro while the leaf fraction had the lowest value (5.67%) for EE content (Table 1). While the leaf fraction of *P. purpureum* harvested at Ewekoro and Ejigbo had the lowest value (4.67%) of EE content with the highest value (8.00%) observed in stem fraction of *P. purpureum* harvested

at Ibarapa, Ido and Oriade (Table 2). The ash content range from 13.00% in stem fraction of *P. purpureum* harvested at Odeda to 15.33% in leaf fraction of *P. purpureum* harvested at Ibarapa, Ido , Ejigbo and Oriade. Meanwhile, the leaf fraction of *P. purpureum* harvested at Odeda recorded the highest value (14.47%) of NFC content and stem fraction of *P. purpureum* harvested at Ewekoro had the highest value (63.67%) for NDF with the lowest value (52.33%) observed in leaf fraction of *P. purpureum* harvested at Oriade (Table 2). The higher fibre levels of the grasses in this study might be a demerit in facilitating the colonization of ingesta by rumen microorganisms, which in turn might induce higher fermentation rates, hence digestibility, intake and animal performance might be impaired.

ABSTRACT

Eighteen (18) West Africa Dwarf (WAD) growing buck of six months of age, having weight ranges from (6.5kg-7.5kg) were used in experiment to determine the effect of feeding varying dietary levels of mixed sawdust as a replacement for wheat offal on macro mineral in blood of grower buck. The bucks were randomly allocated to three dietary treatments. The treatments were replicated thrice with two growing bucks per replicate. Three dietary treatments were formulated containing 0%, 25% and 50% of mixed sawdust respectively. Feed and water were served ad-libtum throughout the period of the experiment. The experiment lasted for eight weeks. Data obtained were arranged in a completely randomized design (CRD). The result revealed significant difference (P>0.05) in the values obtained for calcium, phosphorus and magnesium across the treatments. The highest value of calcium was recorded in T2 (6.05) while the lowest value of calcium was observed in T1 (5.18), The lowest value of phosphorus was recorded in T2 (9.00) while highest value was recorded for T1 (10.22). Highest value of magnesium was recorded in T2 (2.13) while lowest value was recorded in T1 (1.98). It could be concluded that 50% replacement level of mixed saw dust could effectively substitute for wheat offal without adverse effect on the health status of growing buck.

Keywords: Macro minerals, Buck goats, Mixed sawdust, Wheat offal, *Panicum maximum*

INTRODUCTION

Since the last century, and especially after the Second World War, there has been a dramatic increase in global production of wastes, indicative of the industrial and scientific revolutions that preceded the war and the unprecedented global levels of economic activities resulting from these revolutions, especially in developed nations (Adetunji, *et al*, 2006). Large quantities of human, agricultural, forestry and industrial wastes that are not being effectively utilized are produced annually in the tropics, thereby constituting environmental and health hazards (Agboola, 1993). In developing countries, it is becoming increasingly difficult to raise ruminant livestock on conventional feed ingredients such as maize, soybean meal, groundnut cake etc. This is as a result of their increased consumption by human beings due to increasing population thereby making it very expensive to incorporate them into ruminant rations (FAO, 1997). Aletor (1986) stated that the most important factors affecting the availability of feed are high cost arising largely from fluctuations in feed supplies, rising prices of feed ingredients, poor quality feeds and inefficiency in production and distribution in the feed industry. The feeding of these animals therefore depends on finding cheaper alternatives or unconventional feedstuffs with little or no competition from human beings (Douthwaite, 2002). Since sawdust is readily available and it can be gotten from neighboring sawmill, this can serve as a source of free ingredient in livestock diet compared to any other livestock nutrition. This experiment aimed at determining the selected macro-Mineral of West African dwarf (WAD) growing buck goats fed varying levels of sawdust as partial replacement for wheat offal using *Pannicum maximum* as basal diet.

MATERIALS AND METHODS

The experiment was carried out at the Teaching and Research Farm of, Oyo State College of Agriculture and Technology, Igboora, Nigeria. The experimental area lies in savannah forest zone on latitude 7.43°N,,longitude 3.2^0E and maximum average humidity in the study area is 58°/$_0$ .The average minimum temperature is above

21.1^{0}C and maximum average temperature is 32.5^{0}C . The double maximum rainfall is about 214.3mm in June and 165.2mm in September (Sanusi, 2011). Eighteen West African dwarf grower bucks were quarantine for two weeks and used for the study. The goats were randomly allotted to treatment diets comprising of 0%, 25% and 50% saw dust. Each treatment was replicated thrice with two animals per replicate in a completely randomized design. At the end of 8weeks, selected serum macro minerals parameters were carried out by collecting 5ml of blood samples via jugular vein from one animals per replicate, and poured into plain bottles separately. The blood sample were processed and analysed for selected macro minerals parameters such as calcium, phosphorous and magnesium. Data collected were subjected to Analysis of variance using general linear model. Treatment mean were compared with Ducan Multiple Range Test.

Table 1: Gross composition of experimental diet

Ingredients	T1 (0%SD)	T2 (25% SD)	T3 (50% SD)
Corn Bran	60.00	60.00	60.00
PKC	20.00	20.00	20.00
Saw dust	0.00	4.00	8.00
Wheat Offal	16.00	12.00	8.00
Bone Meal	3.25	3.25	3.25
Salt	0.50	0.50	0.50
Grower Premix	0.25	0.25	0.25
Total	100.00	100.00	100.00
C.P (%)	13.46	13.20	12.94
M.E (Kcal/Kg)	2681.45	2734.03	2786.61

RESULTS AND DISCUSSION

Table 2 shows the selected serum macro mineral concentrations of West African Dwarf bucks fed varied proportions of saw dust in concentrate diet with *Panicum maximum*. In the current study, the Ca concentration for T_1, T_2, and T_3 were 5.18mg/dl, 6.05mg/dl and 5.83mg/dl respectively. There were significant ($P<0.05$) difference in the values of Ca concentrations across dietary treatments. The value of Ca obtained in this study were below the values reported by Underwood and Suttle, (1999), healthy sheep can contain from 9 to 12mg/dl of Ca in serum. The value of Ca obtained in this study also contradict with the report of Kaneko (1989) who reported that normal level of serum Ca in healthy lamb ranged from 11.0 to 12.4 mg/dl. The concentration of Ca in all treatment groups were slightly below moderate hyper-calcium level from 12 to 15mg/dl reported by Little dike *et al*. (1976) which causes Calcifications of soft tissues and depress feed intake. The variation in serum Ca concentrations between animals might be associated with endocrine secretions (Underwood and Suttle, 1999). The plasma Ca concentration was greater in the goats fed 25% of saw dust and followed by goats maintained on 50% of saw dust in concentrate diet. The Phosphorus (P) concentration in serum of goats were significantly ($P<0.05$) varied across the treatment groups. The obtained values (9.00 – 10.22mg/dl) in this study were above the normal range of Phosphorous (P) in serum of sheep which ranges from 4 to 8mg/dl reported by Latimer *et al*. (2003). The Mg concentration recorded in T_2 (2.13mg/dl) was higher than other treatments and significantly ($P<0.05$) different across treatment groups. Analysis of Mg minerals in the serum samples from all treatment groups indicated adequate amount of Mg in the serum of the goats. This could be due to higher Mg concentration in the diets. The values of Mg in this current finding were comparable with the critical level which ranged from 1.0 to 2.0mg/dl for sheep reported by McDowell (2003), normal range from 2.0 to 2.7mg/dl reported by Latimer *et al*. (2003) and from 1.0 to 3.0mg/dl reported by (Pulse,1994). However, concentration of Mg in current study is below toxic level (>6ppm), which causes diarrhea in sheep (NRC, 2007). Deficiencies in Mg can cause many problems for livestock, especially those with high nutritional demands such as rapidly growing weaners and

pregnant or lactating ewes (Mayberry *et al.*, 2010). The lower concentrations of Mg recorded for animals fed diet T_1 might be due to the higher potassium concentration in the diet which might affect the absorption of Mg. Magnesium is usually absorbed from the rumen and any excess is excreted via the kidneys (Underwood and Suttle, 1999).

Table 2: The effect of mixed sawdust on macro mineral

	T1	T2	T3	SEM
Calcium(mg/dl)	5.18^{c}	6.05^{a}	5.83^{ab}	0.21
Phosphorus(mg/dl)	10.22^{a}	9.00^{c}	9.64^{b}	0.28
Magnesium(mg/dl)	1.98^{c}	2.13^{a}	2.05^{b}	0.04

^{abc} Means on the same row with different superscript differ ($p<0.05$) significantly

CONCLUSION AND RECOMMENDATION

It is therefore concluded that 50% sawdust supplementation in goat diet does not have deleterious effects on macro mineral elements in blood of goat. However, more research should be carried out by subjecting sawdust to different treatment for better utilization of ruminant animals.

ABSTRACT
The study was conducted to determine the blood parameters of Yankasa rams fed urea ensiled crushed corn cobs (UECCC) with supplementation. The treatment groups were 1 crushed corn cobs (CCC), 2 urea ensiled corn cobs for seven days (UECCC7), 3 urea ensiled corn cobs for fourteen days (UECCC14) and 4 urea ensiled corn cobs for twenty one days (UECCC21). 20 animals were supplemented with 300g per head per day of concentrate made of maize bran and cotton seed cake. The experiment was conducted in a completely randomized design (CRD). Haematological parameters and Rumen pH were not affected by the dietary treatments, but all values were within the normal range for healthy animals. Rumen metabolites (total volatile fatty acids and rumen ammonia nitrogen) were significant. It was concluded that corn cobs ensiled with urea at 7, 14 and 21 days and supplemented with 300g/day of maize bran and cotton seed cake (1:1) had no adverse effect on the blood composition pH, total volatile fatty acids and rumen ammonia nitrogen of growing Yankasa sheep. Urea ensiled crushed corn cobs is therefore recommended as diet for sheep.

Keyword: Blood, Rumen pH, Rumen metabolites, Corn cobs, urea, *Yankasa* rams

INTRODUCTION
Nigeria is one of the four leading livestock producers in Sub-Sahara (FAO, 2006). The livestock sector plays a significant economic role in most developing countries, and is essential for food security of the rural population. Small ruminant production rarely exist as a sole enterprise but is often a part of an enterprise mix, involving Cattle rearing, Sheep and Goat husbandry, rural poultry, arable farming and vegetable gardening Baah, *et al*., (2012). Pastoralists engage in some farming while crop farmers engage in some livestock production (Osinowo, 1999). Among the major constraints limiting the development of livestock production in many developing countries, inadequacy of animal feed resources is most often the crucial factor. This study was therefore designed to determine the effect of feeding urea ensiled crushed corn cobs with supplementation on blood parameters, rumen ammonia nitrogen, total volatile fatty acids and pH of rumen liquor of growing Yankasa rams.

MATERIALS AND METHODS
EXPERIMENTAL SITE:
The experiment which lasted for ten weeks (70 days), was carried out at the Abubakar Tafawa Balewa University (ATBU) Teaching and Research Farm Bauchi. Bauchi metropolis has an average annual rainfall of 700mm-1300mm lying between lat. $9^0$3 and 12 ^{0} North, long. $8^0$49 and 11East and an altitude of 69^0.2 meters above sea level in the Northern Guinea Savanna ecological zone of Nigeria (Kowal and Knabe, 1972).

Experimental Animals and their Management

Twenty (20) growing Yankasa male Sheep aged 11-15 months with mean live weight of 15.7 kg were purchased from a market in Bauchi suburb and used for the trial. The experimental animals on arrival were examined and quarantined for a period of 14 days, during which they were ear-tagged using numbered plastic tags. The animals were also vaccinated against *PPR* using a tissue cultured rinderpest vaccine. Each animal was housed individually in cross-ventilated pens and allotted to its respected experimental diet. Good clean drinking water and salt lick were provided to the animals *ad libitum.* Initial weights of the animals were recorded before the commencement of the experiment. Weekly weight was taken for the period of the experiment to determine weight changes. Feeds and water were offered and remnant weighed daily to determine voluntary intake.

Experimental Diets Preparation

The experimental feed ingredients were; Crushed Corn Cobs, Cotton Seed Cake, Urea graded fertilizer and Maize Bran. The Corn Cobs of PZE-W composite 5 variety of maize was obtained from a farm in Gubi on the University land. The Corn Cobs were crushed using crushing machine. The Crushed Corn Cobs were ensiled for 7, 14, and 21 days. Four kilograms was dissolved in 100 liters of water to treat 100kg of crushed corn cobs. (Abubakar *et al.,* 2006; Ngele., 2007 and Ngele *et al.,* 2010). The treated Crushed Corn Cobs was ensiled in airtight plastic tanks (200 litres) lined with polyethene. After ensiling, the treated Crushed Corn Cobs were dried under shade for 5 days to allow for the escape of ammonia (Abubakar *et al*., 2006; Ngele., 2007).

Animal Feeding

Supplement of 50 % maize bran + 50 % cotton seed cake mixed, untreated and urea treated corn cobs were fed to the experimental animals.

The experimental animals were fed thus;

Treatment one: 300g of supplement + Untreated Corn Cobs.

Treatment two: 300g of supplement + Urea Treated Corn Cobs at 7 days.

Treatment three: 300g of supplement + Urea Treated Corn Cobs at 14 days.

Treatment four: 300g of supplement D + Urea Treated Corn Cobs at 21 days.

The experimental diet was fed to the animals every morning.

Data Collection

At the 4th week of experiment, 5mls of blood was collected from each animal. The blood samples for hematology were collected in to a well labeled, sterilized vacutainer tube containing ethylene diamine tetra-acetic acid (EDTA).

Rumen liquor/fluids was collected during the 7th week before feeding and 4hrs after feeding using stomach tube and immediately after collection, the pH of the rumen liquor was taken and recorded using AGB-75 laboratory pH meter for total volatile fatty acids determination and rumen ammonia nitrogen (RAN).

RESULTS AND DISCUSSIONS

The effect of dietary treatment on Blood counts of *Yankasa* rams fed Experimental diets.

Table 1 shows the effect (pre and post feeding) of the diets on the blood counts; white blood cells (WBC), red blood cells (RBC), haemoglobin (HGB), packed cell volume (PCV). The WBC, RBC, HGB, PCV, were not significantly different, however, there was decrease in the mean values especially on white blood cells pre and post feeding. The values for the blood counts ranged thus: white blood cells (WBC) 102.52 to 118.24 x 10^3/ul and 33.04 to 97.06 10^3/ul, red blood cells (RBC) 7.89 to 8.7710^3/ul and 7.28 to 7.9710^3/ul, haemoglobin (HGB) 9.32 to11.78 g/dl and 10.22 to 10.70 g/dl, packed cell volume (PCV) 36.32 to 43.18 % and 32.72 to 42.0 g/dl g/dl 4 %. Therefore, the values recorded in this study for blood metabolites (white blood cells, red blood cells, haemoglobin, packed cell volume) were not affected by the dietary treatment. The PCV for sheep falls within the range of 24 to 45 % (Sirois, 1995). This indicates the high nutritive value of the experimental diets. The none significant difference ($P>0.05$) obtained across the treatments in this study could mean that the untreated crushed corn cobs and urea ensiled crushed corn cobs had no negative effects on the performance of the experimental animals and can be said to be safe for feeding Yankasa sheep.

Effect of dietary treatments on ruminal pH, total volatile fatty acids (TVFA) and rumen ammonia (RNA).

Table 2 shows the effect (pre and post feeding) of the diets on rumen liquor pH (RLpH), total volatile fatty acids (TVFA) and rumen ammonia - nitrogen (RNH_3-N).

Rumen pH

Rumen pH Pre- feeding was significantly ($P<0.05$) affected by the dietary treatments. The values for pre-feeding ranged between 6.14 and 6.40. However, there was general decrease in pH post- feeding across the treatments and the values were similar across the treatment (5.36, 5.34, 5.78 and 5.30 for diet 1, 2, 3 and 4 respectively).

This suggests that there was proper digestion of the treatment diets when fed to the animals across the treatments. The pH values recorded before feeding was similar to the findings of Khan *et al.* (2006) who reported 6.5 Mmol/100ml but much lower to the study conducted by Hamad *etal*, (2011) who reported 7.43 Mmol/100ml before feeding, 7.70 Mmol/100ml; 3hours after feeding and 5.30 to 5.78 Mmol/100ml; 4 hours after feeding. Proper digestion usually triggers rumination which results in the production of saliva. The rumen pH recorded falls within range. This an indication of high fermentable diets fed to the animals. This observation agrees with the earlier findings of Adegbola, (2002) and Oddoye *et al.*, (2005).

RUMEN METABOLITES

The total volatile fatty acids (TVFA) post feeding was significant (P<0.05) across the dietary treatments whereas pre feeding was not affected by the dietary treatments; the values were 78.00, 46.00, 81.40 and 53.20, and 42.40, 49.40, 71.40 and 62.40 Mmol/100ml for post and pre feeding respectively. The TVFA in the post feeding increased in treatments 1 and 3 and reduced in treatments 2 and 4. The rumen ammonia nitrogen pre-feeding was not significant across the treatments. However, the post feeding values was statistically significant (P<0.05) across the treatments. The ruminal ammonia nitrogen values recorded after feeding was much lower than the earlier report by Hamad *et al.* (2011) and Khan *et al.* (2006) who reported 13.58 to 16.36 mg/100ml before feeding, 22.87 to 23.64 mg/100ml 3hours after feeding and 29.4 mg/100ml after feeding. The high level of RAN in this current study may be indicating rapid fermentation and degradation of the experimental diets especially for the urea ensiled crushed corn cobs. The levels of volatile fatty acids recorded before feeding and after feeding (78.00, 46.00, 81.40 and 53.20, and 42.40, 49.40, 71.40 and 62.40 Mmol/100ml) were quite high than the earlier report by Hamad *et al.*, (2011) and much lower than the study conducted by Khan *et al.* (2006). Earlier report by Oddoye *et al.*, (2005) suggested that for rumen microbes to operate at a maximum level, the release of nitrogen and fermentable carbohydrate must be synchronized. Khan *et al.* (2006) also noted that, slow release of NH3 and sufficient production of VFA leads to better utilization of the nutrients for rumen microbial growth that resulted in improved digestibility.

CONCLUSION AND RECOMMENDATION

Corn cobs ensiled with urea at 7, 14 and 21 days and supplemented with 300g/day of maize bran and cotton seed cake (1:1) had no adverse effect on the blood composition, pH, total volatile fatty acids and rumen ammonia nitrogen of growing Yankasa sheep. Base on the performance of the animals placed on diet four (4) fed corn cobs ensiled at 21 days and supplemented with 300g/head/day is recommended for growing *Yankasa* Sheep.

NUTRIENT INTAKE OF WEST AFRICAN DWARF GOATS FED DIETS CONTAINING GRADED LEVELS OF ALKALINE TREATED MALTED SORGHUM SPROUT

SAKA, A. A., ADEKUNJO, R. K., ADEDEJI, O. Y., JINADU, K. B. AND ADEKANBI, O. A

FEDERAL COLLEGE OF ANIMAL HEALTH AND PRODUCTION TECHNOLOGY, P. M. B.5029, MOOR PLANTATION, IBADAN.

ABSTRACT

A twelve week trial was conducted to determine the nutrients intake, digestibility and nitrogen utilization of West African dwarf (WAD) goats fed diets containing graded levels of Alkaline treated malted sorghum sprout (AMSP) using Panicum maximum as the basal diet. A total number of sixteen (16) WAD goats with an average live weight; 5.8 ± 0.6 kg were allotted on weight equalization into four (4) dietary treatments consisting of four goats per treatments in a completely randomized design. Four (4) diets were formulated to contain 0%, 20%, 40% and 60% AMSP. Data was collected on feed intake and nutrient intake was determined. Significant difference (P<0.05) were observed in all the nutrient intake parameters observed except the dry matter intake. Goats fed 40% AMSP recorded the highest total ash intake (27.01%), total acid detergent fibre (11.46%) and total cellulose intake (83.13%) compared with other dietary treatments. It can therefore be concluded that 40% AMSP can be used as potential sources of supplements in ruminants feed most especially during dry season as it enhanced nutrient intake.

INTRODUCTION

Malted sorghum sprout (MSP) is a by-product of sorghum malting simply referred to separated root and shoots left after the malt extractions from the young germinating sorghum seedlings (Aletor *et al*., 1998). It is rich in organic nitrogen (Ikediobi, 1989) and also contains 88.79% dry matter, 26.38% crude protein, 2.35% ether extract, 5.21% ash, 51.06% nitrogen free extract, 49.57% neutral detergent extract, 31.25% acid detergent fibre, 3.92% acid detergent lignin, 18.32% hemicellulose and 27.33% cellulose (Saka *et al*., 2016). The anti-nutritional factors in MSP are tannin and hydrogen cyanide. Van Buren and Robinson (1969) reported that tannin influences the growth of animals in three main ways simply because they have astringent taste which affects palatability; decrease feed intake; form complexes with proteins thereby reducing its digestibility and finally act as an enzyme inactivators. More so, cyanide in MSP caused feed poisoning in animal (Wheeler, 1994). In order to improve the nutritional quality and to provide effective utilization of MSP in ruminant, it is essential that anti-nutritional factors be removed or reduced. Detoxification by alkaline treatments might be a good means of reducing the level of anti-nutritional factors and possibly increase MSP nutritive values. Alkaline treatment is economical because it involves the use of wood ash being regarded as a waste. More so alkaline treatments of high fiber roughages have been investigated extensively, and there are numerous reviews of their effect in increasing feeding value for ruminants (Wanapat *et al.*, 1985). This study is to determine the nutrient intake of West African dwarf (WAD) goats fed diets containing graded levels of Alkaline treated malted sorghum sprout.

MATERIALS AND METHODS

Experimental Site and Duration: The experiment was carried out at the Teaching and Research farm of Federal College of Animal Health and Production Technology, Moor Plantation, Ibadan and the acclimatized period and feeding trial lasted for a period of four and twelve weeks respectively.

Experimental animals, diet and design: A total of sixteen WAD goats were obtained from Olorunda village in Ibadan, Oyo state. The animals were confined in well-ventilated individual pens that was cleaned, washed and disinfected with Royal Guard Lysol prior to the arrival of the animals. On arrival, the animals were acclimatized for a period of four weeks during which the goats were given prophylactic treatments; consisting of intra-muscular injection of oxytetracycline LA at 1ml/10kg live body weight and ivomectin at 1ml/25kg live weight. They were also administered vaccine against *Pestes des petit ruminant* (PPR). *Panicum maximum* was fed to the animals during the adjustment period. Fresh, cool, clean water was also made available throughout the experiment. After the adaptation, the animals were balanced on weight equalization into four dietary treatments in a completely randomized design. The dried brown malted sorghum sprout (MSP) was purchased from Life care ventures limited, Sango Otta, Ogun State and it was subjected to alkaline treatment (Fanimo and Akinola, 2006). The alkaline treatment was done by mixing 5kg of raw MSP with 300g of wood ash. The entire mixture was then mixed with 20 litres of water and left in a container for 72 hours (3 days) with frequent stirring. On the 3rd day, the mixture was brought out of the container, the water was allowed to seep out after which it was sundried on the concrete floor. The sundried alkaline treated MSP was then incorporated into the experimental diet at varying levels of 0%, 20%, 40% and 60% to formulate four dietary treatments.

Chemical and Statistical Analysis: The Proximate and fibre fraction analysis of the experimental diets and faecal samples were determined according to the procedure described by AOAC (2001) and Van soest *et al*. (1991) respectively. Data obtained were subjected to one way analysis of variance (ANOVA) using (SAS, 2005). Significant means were separated using the Duncan multiple range test of the same software.

Data Collection/ Feed intake: Feed offered daily per animal were recorded and refusal were weighed and recorded to compute feed intake on daily basis. In short, voluntary intake was estimated as the difference between the feed offered and that consumed. The feed was offered at 5% body weight of the animals. Intakes: Dry Matter Intake ($gday^{-1}$) = Feed intake on wet basis x DM of the feed/ 100

Nutrient Intake ($gday^{-1}$) = Dry Matter Intake ($gday^{-1}$) × Nutrient in feed/ 100

Nutrient in Feed was obtained from the proximate and fibre fractions analysis

Table 1: Chemical Composition of the Experimental Diet

Ingredients	Inclusion Levels of Alkaline Malted Sorghum Sprout			
	T_1 (0%)	T_2 (20%)	T_3 (40%)	T_4 (60%)
Dry matter	87.32	81.63	68.58	60.11
Crude protein	12.41	13.18	10.92	9.07
Ether extract	2.58	0.54	0.90	1.30
Ash	8.61	7.33	16.11	11.56
Nitrogen free extract	50.14	51.32	44.71	29.08
Neutral Detergent Fibre	65.00	75.00	72.00	52.00
Acid Detergent Fibre	18.00	15.00	33.00	26.00
Acid Detergent Lignin	8.00	5.00	5.00	12.00
Hemicellulose	47.00	60.00	39.00	26.00
Cellulose	10.00	10.00	28.00	14.00

RESULTS AND DISCUSSION

Presented in Table 2 is the nutrient intake of West African Dwarf goats fed diet containing graded levels of AMSP. There was significant difference ($p<0.05$) in all the parameters observed except the dry matter intake. The total dry matter intake value observed in this study decreased across the dietary treatment as the AMSP inclusion level increased. A non-significant dry matter intake values observed in this study showed that the alkaline

treatment employed was effective and efficient in reducing the bitterness that could have influenced the intake as it had been established by Morrison (1984) that MSP was somewhat bitter and unpalatable. The result obtained from this study was in agreement with the result of Choi *et al.* (2005) who reported no significant differences in feed intake when Korean black goats consumed diets containing CP ranging from 12 to 18% CP. The concentrate crude protein intake decreased across the dietary treatments as the inclusion levels of AMSP increased. Generally, it is well known that feed intake increases with an increase in dietary CP level (Cheema *et al.,* 1991) but here in this study the DMI was not affected but the concentrate crude protein intake decreased across the dietary treatments. The decrement observed in concentrate crude protein intake of the experimental goats across the dietary treatments could be attributed to the influence of alkaline treatment on MSP in reducing their crude protein content. This observation contradicted the study of Jia *et al.* (1995) who reported an increase in DMI of goats fed higher dietary CP levels. However, this was in line with the observation of Hwangbo *et al.* (2009) who reported that increasing or decreasing CP levels had no significant effect on DMI. Goats fed 40% AMSP recorded the highest concentrate and total ash intake and this could be attributed to the fact that the nutrients were better absorbed. The concentrate NDF intake values obtained was similar in goats fed 0, 20, and 40% AMSP based diet but significantly higher than goats on 60% AMSP based diet group. The concentrate ADL and ADF intake values obtained in this study decreased and increased respectively across the dietary treatment up to those that were fed 40% AMSP based diet. It was evident from the results of this study that the processing method employed to reduce the anti-nutritional factors of MSP was effective and therefore enhanced the nutrient intake.

Conclusion: It was concluded that alkaline treated malted sorghum sprout can be included up to 40% in compounded ration as it enhanced nutrient intake in WAD goats.

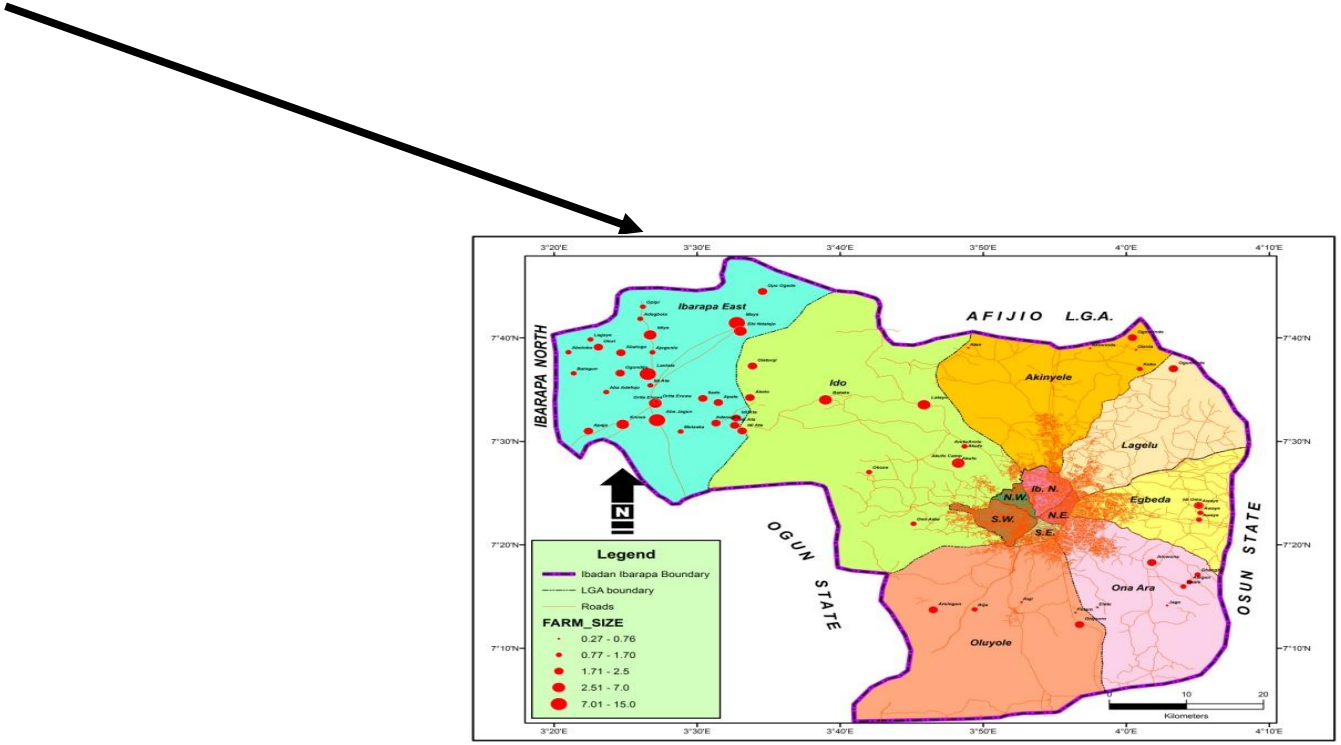
GOAT PRODUCTION AND DISTRIBUTION PATTERN IN IBADAN/IBARAPA ZONE, OYO STATE, NIGERIA

Sosina A.O.[1], Adeoso O. A.[1]
[1]Department of Animal Science, University of Ibadan, Ibadan, Nigeria
Corresponding Author: dayososina@gmail.com, 08038270701.

ABSTRACT
The availability, population, and distribution of goat at the system level are of great concern to the livestock policymakers. Hence, this study on the mapping of goat production and distribution in Ibadan/Ibarapa zone of Oyo state was undertaken. A three-stage sampling technique with 270 sampling population was used. Six Local Government Areas (LGAs) with a high prevalence of crop-livestock production system, three villages per LGA and fifteen respondents per village were purposively selected. Distribution pattern of goat population (Tropical Livestock Unit, TLU) was appraised with spatial analytical tools following standard methods. The Global Positioning System (GPS) was used to locate the population of farmers and appreciate the spatial distribution of goat production among farmers in the study area. A GIS (Geographic Information System) is a computerized database management system which was used to capture, store, retrieve, manipulate, analyze and display spatial information. Ibarapa East LGA had the highest TLU (37) for Goat when compared with Egbeda, Ido, Ona-ara, Akinyele and Oluyole LGA with TLU of 30, 20, 6, 4 and 2, respectively. The availability of abundant crop residues and feed resources in Ibarapa area coupled with a large expanse of land encouraged goat production activities in Ibarapa East, Egbeda and Ido LGA. In conclusion, using the spatial analytical tool of GIS, various activities of the goat production can be monitored, assessed and designed to meet market intervention.
Keywords: Crop residues, Global positioning system, Goat population and distribution, Ecological zones.



INTRODUCTION

Income from goat production in the derived savannah area of Nigeria is generally low mainly due to inadequate linkage to market. The availability, distribution, and population of goats at the system (village) level are of great concern to the policymakers and livestock planners. The local and uncoordinated market appears to be the only avenue for sales in an area with a high intensity of goat production. However, with the launch and subsequent operation of NigeriaSat 1, the need to exploit the merits of geo-informatics in agriculture in Nigeria is ripe (Nigeria Sat 1 report, 2003). Olatoye and Odularu (2013), Sosina (2017) reported the relevance of geo-information techniques in agricultural development, examine the situation in Nigeria and consequently made a case for the adoption of geo-information techniques, and in particular Precision Farming techniques in Nigeria. There is paucity of information on coordination of production and marketing as well as other actors in the goat production value chain. There is a need to identify the location of the livestock producers with a view to driving agricultural planning and policy implementation. This study therefore assessed goat production and distribution pattern in the Ibadan/Ibarapa zone, Oyo state, Southwest, Nigeria.

MATERIALS AND METHODS

The study was carried out in the Ibadan/ Ibarapa Area of Oyo State of Nigeria (as shown in Figure 1). The area is ethnically heterogeneous with a high concentration of smallholder crop and livestock farmers, considered as the occupational group with a high incidence of poverty. A three-stage-sampling technique was used to elicit information from 270 respondents. Ibadan/Ibarapa Zone of Oyo state was purposively selected for the study. Six cells (LGAs- Akinyele, Egbeda, Ibarapa East, Ido, Oluyole and Ona Ara) were randomly selected for the research, three villages were randomly selected in each cell and fifteen farmers were selected using the snowball selection technique. The data obtained from the Participatory Rural Appraisal were analyzed using descriptive statistics. The GPS of the farmers' location, livestock population and distribution were recorded, taking the longitude and latitude of the locations in question. The recorded GPS data of the study area were transferred into the ARC-GIS. The ARC-GIS software processed the data into location using the ARC-GIS model 10.0 from the GIS unit of the Department of Geography, University of Ibadan.

Fig.1: Map of Ibadan/Ibarapa area study area

The data collected were accompanied by the administration of a structured questionnaire (conducted through an interview session) which was designed to obtain information on socioeconomic characteristics of the farm owners and characteristics of the sampled farms. Data were analyzed using descriptive statistics.

Results

Mapping of Goat Production and Distribution in Ibadan/Ibarapa zone in Fig 1 showed; the GIS mapping of Goat Production of farmers in Ibadan/Ibarapa zone using the GPS location. The GPS was used to locate the population of farmers and appreciate the spatial distribution of goat production among farmers in the study area. The graphical representation shows the Tropical Livestock Unit (TLU) of goat kept by the farmers in the Ibadan/Ibarapa zone. GIS map showed the location of the various farmers' involved in Goat production in the study area. Fig. 2 revealed the Goat production data collected from the Local Government Areas (LGA) Ibarapa East had the highest TLU of 37 for Goat. Ido, Ona-ara, Akinyele, and Oluyole with Goat TLU of 20, 6, 4 and 2 respectively.

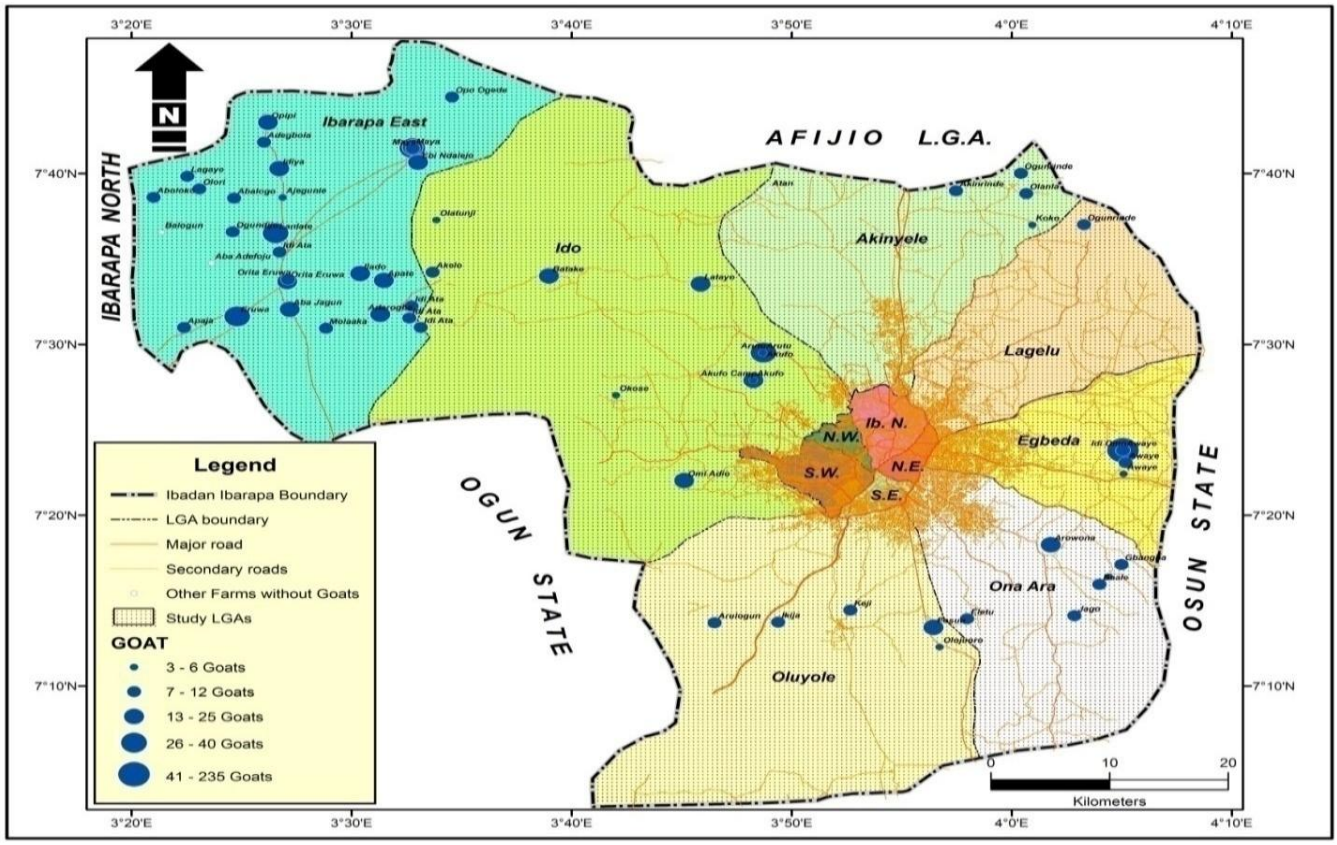


Fig.2: GIS/GPS Mapping of goat production pattern in Ibadan/Ibarapa zone, Southwest, Nigeria

DISCUSSIONS

Goat production and distribution patterns could be due to the availability of abundant crop residues and feed resources in the Ibarapa area coupled with a large expanse of land for goat production activities. These findings agreed with Olafadehan and Adewumi (2011) and Fakoya (2007) that reported similar findings on cattle and goat production among agro-pastoralist in South West, Nigeria. The high populations of goat farmers found in Egbeda and the lower populations in Akinyele, Ona-ara, and Oluyole suggested that the rain-forest ecological zone still favored small ruminant production especially the dominant West African Dwarf (WAD) Goat. The average herd sizes of goat farmers were similar in Akinyele, Oluyole, and Ona-Ara. This was probably due to the urbanization of the area that affected the goat production adversely. The result supported the work of Onwuka ***et al***. (1997) that reported low TLU of goat in the urban area compared with the agrarian communities in

Ogun State. This was against the report of Amole and Ayantunde (2016) that ruminant is produced in the rural areas in Niger state. For commercial goat production and distribution, using the spatial analytical tool of GIS, various activities of the goat production can be monitored, assessed and designed for possible intervention. Spatial analytical using GIS revealed the prevalence of Crop-Livestock farming in the study area. This agreed with the findings of Olugaza ***et al***. (2014); Omodele and Okere, (2014) that reported mapping exercise using the spatial analytical tool of GIS. About the TLU, Ibarapa East is highly favorable for the establishment of commercial goat production compared with other locations in the study area.

RECOMMENDATION

The adoption of information technology (GIS) by farmers in a modern goat production management system that will link production to market in a demand-driven economy is therefore recommended.

Conclusion

In conclusion, the distribution pattern of goat in Ibadan/Ibarapa area of Oyo State showed clearly that Ibarapa East LGA is the most favorable for goat production. This is justifiable because of the abundance of feed materials and large expanse of agricultural land in the area.

Conflict of Interest

Authors declared that there was no conflict of interest.

ABSTRACT
Availability of forages for ruminant feeding and the quality of the forage which the animal utilizes continues to be studied. This research was conducted to determine the palatability of Sorghum hay in relation to its nutritive value by evaluating the chemical composition and the nitrogen balance in red Sokoto bucks. Animals were assigned to two dietary treatment groups such that each group consisted of three red Sokoto bucks. Those in treatment 1 (T1) were given sole sorghum hay at 2.5% of their body weight while those on treatment two (T2) were given sorghum hay and concentrates in a ratio of 60:40 (2.5%) of their body weight. The result of the experiment shows that the nitrogen balance of bucks in T2 was significantly ($p < 0.05$) higher than those in T1. In conclusion feeding sole sorghum bicolor hay was not adequate to meet the nutritional requirement of red Sokoto bucks. However, supplementation of sorghum bicolor hay with concentrate at 60:40 ratios increased nitrogen retention.
Keywords: Nitrogen balance, Red Sokoto, Sorghum

INTRODUCTION
Crop residues are readily available and cheap in the tropics. The abundance of these residues could mean reduction of concentrate cost in the rations since available residues that are nutritious and palatable could be utilized. An important residue that can be found on the sorghum plant is the hay and chaff. Sorghum hay is obtained by cutting and drying Sorghum when it is between the soft-dough stages to avoid wastages (Sutti, 2000). This could encourage the cultivation of forage crops which has not been properly harnessed for the purpose of feeding small ruminants in Nigeria.

MATERIALS AND METHODS
The study was conducted to determine the palatability of Sorghum hay in relation to its nutritive quality by evaluating the chemical composition and the nitrogen balance when it is fed to red Sokoto bucks. The experiment was conducted from October to December 2016 at the experimental unit of the small ruminant research program of the national animal production research institute (NAPRI) Ahmadu Bello University Shika, Zaria. Animals were assigned to two dietary treatment groups such that each group consisted of three Red Sokoto Bucks. Those in treatment 1 (T1) were given sole sorghum hay at 2.5% of their body weight while those in treatment two (T2) were given sorghum hay and concentrates in a ratio of 60:40 at 2.5% of their body weight.

Animals were housed in individual feeding pens (metabolism cages) and fed their treatment diets. They were allowed an adjusted period of 14 days to fine-tune to the feed and metabolism cages. Animals were weighed before the commencement of the experiment and were weighed after the adjustment period prior to commencement of data collection. The bucks' mean body weight was 13.5kg and aged between 12 and 21 months of age. Four days before the experiment commenced, all the animals were de-wormed using albendazole (eagle chemical co LTD). The experiment was of completely randomize design in which the red Sokoto bucks were distributed into two groups of four animals per group. The bucks were weighed and then put into metabolism cages equipped for faecal and urine collection. Fourteen days adjustment period was allowed before faecal and urine collection was done for a period of twenty one days. For each animal, total daily urine output was collected into

plastic bottles containing10ml of 0.05N Sulphuric to prevent ammonia loss from the urine [2]. Total urine collected was measured and 10% of each day's collection was taken, bulked at the end of collection period and stored in a freezer at 0^0C until it was required for nitrogen analysis (Ajayi, 2011).

Total faecal output from each animal was collected and weighed fresh and 20% of each day's collection was taken and dried in the oven for 48 hours at 70^0c and its weight recorded before storing for proximate analysis. Water intake was also collected by using calibrated 9 liters bucket.

2.1 Experimental Diets

Sorghum hay was fed as basal diet supplemented with concentrates consisting of maize offal (MO), wheat offal (WO), cotton seed cake, bone meal and salt. The CP of the concentrate is 13.63%. The chemical composition of the dietary ingredients and concentrates are presented in table 1, while table 2 shows the proximate composition of the experimental diets.

Table 1: Composition of concentrate supplement fed red Sokoto bucks

Ingredients	Percentage %
Maize Offal	40.0
Wheat Offal	31.5
Cotton Seed Cake	25.0
Bone Meal	2.5
Salt	1.0
Total	100
Crude Protein	13.63
Metabolisable Energy (kcal/kg)	2679.0

Table 2: Proximate composition of experimental feed stuffs

Parameters	T1	T2
Dry matter	95.20	93.38
Crude protein	5.36	16.13
Crude fiber	28.66	18.40
Ether extract	2.14	3.19
Ash	2.36	6.56
NFE	61.48	55.72
ADF	29.87	20.06
NDF	52.22	18.70

NFE= Nitrogen free extract, ADF= Acid detergent fibre, NDF= Nuetral detergent fibre.

Feaces were analysed for dry matter (DM), crude fibre (CF), crude protein (CP), ether extract (EA) and ash using an established procedure [(4)]. Nitrogen free extract (NFE) was calculated by difference NFE=100-(CF+CP-EE+ASH). Acid detergent fibre (ADF) and neutral detergent fibre (NDF) were determined according to the method of Van-Soest *et al*. (1991). Urine was analysed for urinary nitrogen and crude protein using Kjeldahl procedure (AOAC, 2005). Samples of experimental diets, orts and feaces were ashed by charring in muffled furnace at 500^0C for six hours. Organic matter (OM) was obtained as the difference between the dry matter and ash content.

2.2 Statistical analysis

Data collected on nitrogen intake and coefficient of nitrogen balance was analyzed by ANOVA using General Linear Model procedure of SAS (2008). Significant treatment means were separated using Duncan's Multiple Range Test (1955).

RESULTS AND DISCUSSION

Table 3: Chemical composition and metabolisable energy of experimental diets fed to growing red Sokoto bucks

	Sorghum Hay Bicolor: Concentrate		
Parameter (%)	100:0 Sorghum hay	Concentrate (NAPRI)	60:40 Sorghum hay + concentrate
Dry matter	95.20	91.11	93.38
Organic matter	92.84	85.22	86.82
Crude protein	5.36	18.94	16.13
Crude fibre	28.66	8.01	18.40
Either extract	2.14	4.60	3.19
Ash	2.36	5.89	6.56
Nitrogen free extract	61.43	62.56	55.72
M. E (Mj/kg)	11.53	11.68	11.56
Acid detergent fibre	29.87	26.12	20.06
Neutral detergent fibre	52.22	48.37	38.67

Table 3 shows the proximate composition of the experimental diets (sorghum bicolor hay/ concentrate) mixture and concentrate supplement. The dry matter (DM) contents of the experimental diets containing sorghum bicolor hay/concentrate mixture at 100:0 and 60:40 ratio are 95.20% and 93.38% respectively. The CP content was 5.36% in 100:0 diet and 16.13% in 60:40 diet. The CF content was 28.66% in 100:0 diet and 18.40% in the 60:40 diet. Ether extract for 100:0 and 60:40 were 2.14% and 3.19% respectively. The ash content was 2.36% in 100:0 diet and 6.56% in 60:40 diet.

The concentrate supplement used for the experiment had a crude protein (CP) content of 18.94%, dry matter (DM) of 91.11%, organic matter (OM) content of 85.22%, crude fibre (CF) of 8.01%. Nitrogen fibre extract (NFE) of 62.56% and metabolisable energy (ME) of 11.68% MJ/kg DM.
The ME content was similar in all treatment with 11.53MJ/kg DM in 100:0 and 11.56MJ/kg DM in 60:40. However, the highest values of 29.87% acid detergent fibre 52.22% neutral detergent fibre and 16.70% lignin were observed in 100:0 diet while low values of 20.06% acid detergent fibre, 38.67% neutral detergent fibre and 8.44% lignin were observed in 60:40 diet.

Table 4: Nitrogen balance of red Sokoto bucks fed Sorghum Hay: Concentrate ratio

	Sorghum Hay Bicolor: Concentrate		
Parameter (g/day)	100:0	60:40	SEM
	Sorghum hay	Sorghum hay + concentrate	
Nitrogen intake	3.03[b]	10.96 [a]	0.21
Feacal nitrogen loss	1.90[b]	2.36[a]	0.20
Urinary nitrogen loss	0.45[b]	1.06[a]	0.20
Total nitrogen output	2.35[b]	3/.42[a]	0.34
Nitrogen absorbed	1.14[b]	8.60[a]	0.20
Nitrogen retained	0.69[b]	7.55[a]	0.33
Nitrogen retained as % intake	23.87[b]	68.76[a]	6.71
Nitrogen absorbed as % intake	38.15 [b]	78.46[a]	4.31

[ab]; means with different superscripts differed significantly ($p<0.05$), SEM = standard error of mean.

Table 4 reveals the nitrogen balance of red Sokoto bucks fed sorghum bicolor hay: concentrate ratio. The result showed that there were significant ($p<0.05$) differences in nitrogen balance parameters across all the treatment. There was an increase ($p<0.05$) in all parameter measured when concentrate was supplemented. There were 72%, 19%, 58%, 31%, 87%, 91%, 65% and 51% increase in nitrogen intake, feacal nitrogen loss, urinary nitrogen loss, total nitrogen output, nitrogen absorbed, nitrogen retained, nitrogen retained as % of intake in red Sokoto bucks fed 60:40 diets when compared with bucks fed 100:0 diet.
The DM content of sorghum bicolor hay concentrate mixture in Table 3 above is was above 91%. This might be due to the fibrous nature of the sorghum forage and cotton seed cake. The value of DM observed was higher than 92.5 and 91.56% reported by Ishiaku (2016) for sole sorghum almum. The CP content of sorghum bicolor hay/concentrate mixture increased with the inclusion of concentrate. The CP range from 5.36-16.13% in sole sorghum bicolor hay and sorghum bicolor hay supplemented with concentrate. The CP values observed in this study for 100:0 were lower than the requirement of 10-12% CP for sheep and goat (Wada *et al*., 2016) but above the requirement of the 60:40 diet. As argued by Munza *et al*. (2017), who stated that the low CP for sole sorghum bicolor hay may be attributed to the stage at harvest of the forage because CP content reduces as the plant advanced in age. The high CP in 60:40 diets might be due to the presence of cotton seed cake.

The CF of the diets, 28.66%, 8.01% and 18.40% were greater than the report of Ishiaku (2016) probably due to varietal difference. The neutral detergent fibre (NDF) was below 60.0% suggested by Munza *et al*. (2017) as critical limit for efficient utilization of roughages. The ME obtained ranged from 11.53-11.56MJ/kg DM. This was lower 12.17MJ/kg, reported by Ishiaku (2016).

Table 4 shows the nitrogen balance of red Sokoto bucks fed sorghum hay: concentrate ratio. The nitrogen balance parameter of Re d Sokoto Bucks fed 60:40 diets were significantly ($p<0.05$) higher than those fed 100:0. This is in line with Hassan *et al.* (2016) who reported that supplementation of protein source improve microbial nitrogen yield and retention with subsequent increase in the performance of growing red Sokoto Bucks.

The higher nitrogen absorbed and retained in Bucks fed (60:40) sorghum bicolor hay/concentrate could be (10.96%/day). Munza *et al.* (2017) stated that superior nitrogen absorbed and retained in Red Sokoto Bucks fed sorghum hay/concentrate mixture as compared to those fed sole sorghum hay might be due to the efficient utilization of nitrogen. Also, higher nitrogen retention (7.55g/day) absorbed in bucks fed 60:40 hay/concentrate mixtures indicated the favorable role of concentrate in post ruminal nitrogen metabolism and utilization compared to 100:0 (0.69g/day).

The nitrogen retention and absorbed as percentage intake were above 68.0%. This was higher than 47.98% reported by Yashim *et al.* (2014), but lower than 95.84% and 74.24% reported by Wada *et al.* (2016) and Ishiaku (2016).

The result of this study revealed that feeding sole sorghum bicolor hay was not adequate to meet the nutritional requirement of red Sokoto bucks. However, supplementation of sorghum bicolor hay with concentrates at 60:40 ratios increased nitrogen retention.

CONCLUSION AND RECOMMENDATION

The result of this study revealed that feeding sole sorghum bicolor hay was not adequate to meet the nutritional requirement of red Sokoto bucks. However, supplementation of sorghum bicolor hay with concentrates at 60:40 ratios increased nitrogen retention.

ACKNOWLEDGEMENT

The contribution by NAPRI is highly appreciated.

ABSTRACT
Thereby achieving the dual aim of feed provision and reduction of materials from refuse heaps. This study was conducted with the objective of investigating the nutrient composition of some food processing waste materials. The materials studied were walnut shells, Thaumatococcus daniellii leaves and Banana leaves. The nutrient composition of the materials showed a profile for dry matter, crude protein, ether extract, crude fibre, ash nitrogen free extracts and metabolizable energy to be 89.62%, 7.00%, 0.36%, 67.10%, 2.27%, 23.27%, 1,273.65 Kcal/kg; 89.22%, 15.51%, 5.45%, 19.57%, 20.46%, 28.43%, 2,334.04 Kcal/kg and 97.21%, 10.62%, 12.65%, 15.82%, 14.21%, 46.70% and 3,490.1 Kcal/kg for walnut shells , Thaumatococcus daniellii leaves and Banana leaves respectively. It was recommended that these materials could be converted to ruminant feedstuff
Key words: Walnut, *Thaumatococcus daniellii*, Banana, Nutrient composition

INTRODUCTION
The quest for conversion of hitherto unusable materials for livestock feeding has formed the basis for unconventional feed development. Processing of food for human consumption generates so much by products, most of which are not useful and end up on refuse heaps contributing to environmental concerns. Walnut shells become a waste material after the nuts are removed and are discarded due to absence of alternative use. Consumption of walnuts has increased due to the purported inherent advantages viz: Provision of plant-based omega-3 fats along with high amounts of copper, manganese, molybdenum, and biotin which may help reduce not only the risk of prostate cancer, but breast cancer as well and contain the amino acid l-arginine, which offers multiple vascular benefits to people with heart disease, or those who have increased risk for heart disease due to multiple cardiac risk factors, contains several unique and powerful antioxidants that are available in only a few commonly eaten foods that may improve sperm quality, weight control, and offer support for brain health and Type 2 diabetes

Leaves of *Thaumatococcus daniellii* (TDL) used in preparing moi moi or Okpa, a breakfast meal are equally discarded after the meal is eaten. Observation have shown that scavenging pigs, goats, sheep and cattle usually struggle over these leaves on refuse heaps, emphasising the need for its nutrient characterization. Banana leaves, used in wrapping food also end up on refuse heaps. The leaves have been investigated for their nutrient composition (Wuanor et al., 2018) and also used in feeding rabbits (Waikyo, 2019). The objective of the study was to conduct a nutrient characterization of these materials as a prelude to possible ruminant feeding.

METHODOLOGY
Cooked walnuts were bought from retailers in Makurdi town over a period of three months, amounting to nine times, and the nuts separated from the shells. The shells were then sun dried and sent for proximate analysis. TDL and Banana leaves (collected from same source, over same period and number of times as the walnut shells) were sourced by buying the food wrapped in them and after removal of the food, the leaves were also sun dried and sent for proximate analysis. Proximate components of the shells and leaves were analyzed using AOAC (2005) procedure while the metabolizable energy was estimated using the formula of Carpenter and Clegg (1956).

RESULTS AND DISCUSSION

Proximate and metabolizable energy compositions of the waste materials are shown in Table 1. In general, all the materials had a high dry matter profile. This is particularly advantageous because nutrients are contained in the dry matter of a material as opposed to moisture. The crude protein ranged from 7.00 to 15.51 and qualifies the materials as ruminant feedstuff since the rumen microbes need a minimum crude protein of 7.0% to carry on their role of breaking down the scabrous feed materials that form the basal diets of ruminants. Particularly, the high crude protein of the TDL is reasoned to be caused also by the proteinous nature of the beans used in preparing pudding cooked in the leaves. The ether extract profile of the materials 0.36 to 12.65 shows that useful fatty acids will be made available for metabolism after the rumen micro organisms would have hydrogenated the fats. The higher ether extract of these banana leaves than that reported by Wuanor et al. (2018) is reasoned to be caused by the palm oil used in preparing the moi moi or Okpa that was cooked in these leaves. In general, the ash, nitrogen extract and metabolizable energy profiles of these materials showed their potential to furnish animals fed with them with minerals and energy.

CONCLUSION AND RECOMMENDATION

It was thus concluded that these materials possess attractive nutrient potentials. It was therefore recommended that the materials should be utilized in feeding ruminant animals.

Table1. Proximate and metabolizable energy compositions of some food processing waste materials

Material	DM	CP	EE	CF	ASH	NFE	Metabolizable Energy Kcal/kg
Walnut shells	89.62	7.00	0.36	67.10	2.27	23.27	1,273.65
Thaumatococcus daniellii leaves	89.22	15.51	5.45	19.57	20.46	28.43	2,334.04
Banana leaves	97.21	10.62	12.65	15.82	14.21	46.7	3,490.1

ABSTRACT

An experiment was carried out at the Federal College of Education (Technical) Gombegrazing area with the objectives to identify the major forage resources in the area and their chemical composition as affected by seasons in the year 2018. Samples for both dry and wet season were collected using constructed quadrant frame which was randomly thrown on the ground for grasses and legumes species, plants inthe hoop were clipped. Botanical composition, chemical composition were analysed using the procedure described by AOAC (1990). Major grasses identified included Cenchrusciliaris, and Pennisetumpolystachyon.While leguminous and shrubs includeAlysicarpusviginalis, and Cassia singuena. Mean apparent nutrients composition for Neutral Detergent Fibre in dry season were found to increase significantly (P < 0.05) from 39.30% in the wet season to as high as 57.24% in the dry season in cenchrusciliaris. Acid detergent fiber from 24.39 in the wet season to 46.63% in the dry season in Digitariadebilis while lignin from 23.15 to 36.43 in Cenchrusciliarisrespectively. Crude protein and ether extracts were higher during the wet season 14.86% and 7.54% in Arachishypogeaecompared to the dry season. Anti nutitional factors were found to be higher during the wet season. It was concluded that forages such as Digitariadebilis, andCenchruscitiariswhich had over 70% dry matter content in both wet and dry season and lower content of anti-nutritional factorsin both seasons should be conserved during the time of abundance due to its abundance and high nutritional values

Key Words: Botanical Composition, Seasonal Variation, Nutritional Values, Savannah Forages, North Eastern Nigeria

INTRODUCTION

The term forage refers to herbaceous material including grasses, legumes, browse plants trees and fibrous crop by products. In seasonally dry environments, the main limitations to animal production are lack of green feed for at least half of the year coupled with the low nutritive quality of forages during most of the period of active pasture growth (Jones and Wilson, 2018). The low nutritive quality of the forage during the growth period is mainly due to environmental stresses such as high temperature (Goering and Van Soest, 2008).

Nigeria has two broad belts of vegetation types, namely, the forest and savannah types. As obtained in southern coastal areas where humid tropical conditions favour tree growth and some species of grasses which include *Pennisetumspp*, Southern Gamba (*Andropogontectorum)* and Buffel grass (*Cenchrusciliaris*). The savannah zone is commonly used to describe areas within the tropics under grass or grass with scattered trees. The vegetation in this zone includes Northern gamba (*Andropogongayanus)*, Elephant grass (*Pennisetumpurpureum)*, Guinea grass *(Panicummaximum*), Stylo (*Stylosathesgracilis)* and Bermuda grass (*cynodondaclylon*) among others, (Fayemi, A.A, Odu, C.T. and Fagbemi, A. (2012).

The area is excellent for rearing and breeding of ruminants (sheep, goats, cattle, camels, horses and donkeys (Onifade and Agishi, 2017). However over the years feeding constitute the major problem of livestock industry in the country, low nutritive value of pasture and forages affect the quality of milk and meat of farm animals (Provenza, 2013). Therefore, the study determined the major forages in the area and their chemical compositionduring dry and wet season periods. It is hoped that identifying these components of the feeds would improve livestock production and the living standard of pastoralist and the general public.

METHODOLOGY

Samples in wet seasons were collected using a constructed quadrant frame which was randomly thrown on the ground and all the plants inside the hoop were clipped. Similarly, dry season samples were taken from the same position, identified and labelledin separate containersin the laboratory. Proximate analysis according to Association of Official Analytical Chemists (AOAC, 1990) was used to determine the dry matter (DM) contents, the crude protein (CP) crude fibre (CF) ether extract (EE) total ash (TA) and nitrogen free extract (NFE). acid detergent fibre (ADF) neutral detergent fibre (NDF) and lignin were analysed using the procedure of Goering and Van Soest (2008). The data generated were subjected to analyses of variance, using the General Linear Model (GLM) of SPSS (2001). Means were separated using Duncan Multiple Range Test (DMRT) method described by (Humburg 1990).

RESULTS AND DISCUSSION

Major pasture plants in the grazing area during dry season

The effect of seasonal variation on ruminant livestock production is important. During the mid-wet season; forage biomass is higher in quality and quantity, with crude protein values of up to 12.00% in most of the native grasses. Natural grasses and legumes are rich and highly digestible at this period as supported by Provenza, (2013). The severity and duration of low- quality feed during the dry and wet seasonvaries with species within the ecology. However, there are factors that reduce the availability of thesefeed resources such as widespread annual burning of native grasslands, which drastically reduces the amount of forage on offer ((Nyako, 2010; Nuru, 2015). Table 1 shows the major forages or plants identified in the study area.

Table 1: Scientific and common names of some forage species available in F. C. E(Tech) Gombe grazing during the dry season

S/N	Botanical Names	Common names
Grasses		
1	*Andropogongayanus*	Gamba
2	*Cenchrusciliaris*	Karangiya
3	*Digitariadebilis*	Harkiya
4	*Pennisetumpolystachyon*	Kansuwa
Legummes

11	*Ziziphusspinachristi*	Magarya

Chemical composition of forage species during dry seasons

Table 2 indicated the chemical composition of the available forages within the study area. *Digitariadebilis*shows a higher level of DM content of 88.79%, while *Vignaunguiculata*and *Arachishypogeae*indicated a lower level of DM content of 83.54 and 83.62% respectively. Generally,

the forages dry matter content, crude fibre, acid detergent fibre, andneutral detergent fibreweresignificantly different *(P<0.05).*and were higher than the wet season values. This may be connected to the fact that the nutrient content of the forages leached out or are lignified with little or no value as indicated by (Nyako 2010). However, thecrude protein and ether extract were higher during the wet season.

CONCLUSION AND RECOMMENDATION

It is concluded and recommended that forages such as *Digitariadebilis, Cenchruscitiaris*and*Arachis hypogea* which had over 70% dry matter content in both wet and dry season and lower content of anti-nutritional factors in both seasons should be conserved during the time of abundance (wet season) as animal feeds in order to ameliorate feed shortage during dry season periods.

ABSTRACT
The study was conducted to evaluate the effects of using sorrel seed meal as a supplement to groundnut hay on nutrient digestibility in mixed breeds of goats and it lasted for 68 days. A total of four (4) bucks were used for the experiment which comprised of an animal per treatment with an average weight of 19.8kg. They were individually weighed and were randomly allocated in metabolic cages. The observed and recorded parameters were; feed intake, weight changes and digestibility. Groundnut hay was used as the basal diet supplemented with SSM at graded levels of 0%, 20%, 40% and 60% for treatment 1, 2, 3, and 4 in a Latin Square Design. The nutrient digestibility was higher in all the animals, The study indicated significant difference (P< 0.05) in total feed intake among the animals. However, there was no significant (P>0.05) difference in live weight changes, hence of animal D tends to have higher value of 650/period with corresponding feed intake of 1012g/DM/day. There was no significant difference (P>0.05) difference in nutrient digestibility among the animals, although the values were all higher which indicates that supplementing goats with SSM result to better nutrient digestibility and a good protein source.
Key words; sorrel seed meal, groundnut hay, nutrient digestibility and goats

INTRODUCTION
Goats have economic potentials due to high fertility, fecundity, prolificacy, early maturity and their adaptability to the humid environment (Fasae, 2011), but the economic benefits obtained from these animals are far below expectation due to low productivity because of poor nutrition. Olorunsomo (2008) reported that available feed resources are low on nutritive values and supplementary concentrates are very expensive. Therefore, there is need to search for non-competitive and low cost alternative feeds for livestock. Hence sorrel seeds can serve as one. Sorrel (*Habiscus sabdariffa*) is a popular plant belonging to the family *malvaceae* and the presumed origin is South East Asia in the region of India to Malaysia. It has long been cultivated in Africa, probably, it was carried by slaves to the new world (Duke, 1999), Sorrel can tolerate little shade and can be grown in green house but it normally grows best in field conditions under full sunlight. It is widely grown in north Eastern and middle belt regions of Nigeria (Akanfa *et al*., 1997). The plant has been found to thrive on a wide range of soil conditions. It can perform satisfactorily on relatively infertile soil but for economic purposes, a soil well supplied with organic materials and essential nutrients is needed (Tindal, .
Literature shows that sorrel seed is comparable to soybeans with regard to the essential amino acid profile. The fat of the seed is a good source of essential fatty acids (arachidonic, linoleic and linolenic acids) which are required to prevent fatty acid deficiency diseases such as skin lesions and low growth rate (Kinsella, 1987). This study was therefore aimed at determining the effect sorrel seed meal for groundnut hay in goat diet.

MATERIAL AND METHODS
This research was carried out at the University of Maiduguri Teaching and Research farm Department of Animal Science, Faculty of Agriculture. Maiduguri is located at latitude of 11.15° north and longitude 30.05° east and at an elevation of 364m above sea level in the North – eastern part of

Nigeria (Alaku, 1983). It is characterized by hot and dry climate and the annual rainfall ranges from 300mm-700mm and falls mostly between June to September. The ambient temperature ranges between30 - 45°C and usually cold during the harmattan period which falls to about 15°C to 19°C and relative humidity ranges from 3 – 43.5% (Alaku, 1983). A total of four (4) mixed breed male goats were used for the study, with an average weight of 19.8kg in a 4×4 Latin Square Design (LSD). Ten (10) days adjustment period were allowed by each animal followed by (7) days collection period, in all the periods. The experiment lasted for 68 days. The animals were weighed and allocated to metabolic cages. The observed and recorded parameters were; feed intake, live weight changes and nutrient digestibility. Two (2) experimental diets were used, groundnut hay as the basal diet supplemented with sorrel seed meal (SSM) at graded levels of 0%, 207%, 40%and 60%. Each of the experimental diets was subjected to proximate analysis, according to the method of AOAC (1988).
The dry matter content of the feeds was determined by taking a weighed quantity of the feed and oven dried at 105°C for 24 hours. This was repeated twice until a constant weight was obtained. The crude protein was determined using kjeldalh method. This method involves digesting the different samples using digesting tablets and concentrated sulphuric acid. The samples were further diluted with distilled water and later distilled using sodium hydroxide (NaoH) and boric acid. The distilled samples were then titrated using 0.1 normal hydrochloric acid. The crude fiber was determined using trichloroacetic acid (TCA) method. The sample were digested with trichloroacetic acid (TCA) to boil and allowed to reflux for about 40 minutes. The digested sample were later rinsed several times with hot water and then with petroleum ether. The Samples were then allowed to oven dry overnight at 105°c before being taken for ashing, during which final weight was obtained. The fat content was determined by using the soxhlet apparatus, 2g of the experimental diets were put into a timble and corked with cotton wool. It was then placed into extraction Chamber. The collection flask contains 50ml of petroleum ether. The apparatus was heated to boil and reflux for two (2) hours. Fat was collected in the flask and cooled then weighed. The ash was determined by direct burning of the samples to ash. Here the samples were subjected to muffle furnance at a temperature of 500-600°C for 3 hours until ash was obtained. The weight of the ash was obtained.
The data generated were subjected to analysis of variance using statistical package (Statistix8.0). Significant differences between the means were compared Least Significant Difference (LSD

RESULTS AND DISCUSSION

The proximate composition of the experimental diets is presented in table 1. The crude protein (CP) and ether extract (EE) content of the raw sorrel seed was 16.19% and 4.0% respectively which is lower than the range value of 25.85-27.10% and 5.0% reported by Duwa *et al*., (2012). It's also lower than the range value of 37.4-38.59% and 16% reported by kwari *et al*., (2011) and FAO (1968). The ash value of sorrel was within the range reported by Dashak and Nwanegbo, (2002), John *et al*., (2010) and Duwa *et al*., (2012), But it was above the values reported by FAO (1968). The dry matter (DM) content of groundnut hay was 97.1% which is higher than 91.08% and 94% reported by Siulapwa and Mikoko (2001) and Yahaya *et al.,* (1999) respectively. It has crude protein (CP) of 6.260% which is lower than the value of 10.9% reported by Addass *et al*., (2011). Crude fiber (CF), nitrogen free extract (NFE) and ash values were less compared to the values reported by Smith (1988) and ether extract value of 2.0 was within the range of 1.5 -2.5reported by Smith (1988). The differences could also be due to variety, type of soil and storage conditions.

For feed intake and live weight changes, there were no significant differences ($P>0.05$) among the animals in supplement intake, the values are the same because they all ate the same amount at different periods. There was significant difference ($P<0.05$) among the animals in basal diet intake with animal D having the highest value of 983.13g, it shows that it consumed more of the basal diet

than the other treatments. The total feed intake ranges from762.6-1012.3g which shows that there was a significant difference in T4 having 1012.3g as the highest value. There was no significant (P>0.05) differences among the animals, however, D tends to have higher live weight gain then other animals. The results obtained compares favorably with the report of Reddy (2001).

Table 3 shows the nutrient digestibility of goats supplemented with SSM. It was observed that nutrient digestibility was higher in all the animals. The value for dry matter digestibility ranges from 56.085-64.977 and no significant (P>0.05) differences were observed among the treatments. This result agrees with that reported by Siebert and Hunter (1982). The values of crude protein (CP), crude fiber (CF) and ash ranges from 75.915-79.435, 73.228-79.073 and 62.788-66.268 respectively which shows that there was no significant(P>0.05) differences. The ether extract digestibility values ranged from 91.245-93.883 with animal D having the highest value. This agreed with the report of Olaleru (1995) who stated that proteinous feed increase ether extract digestibility in ruminant because it supplies the rumen microbes with enough nitrogen that will nourish them and multiply their population thereby increasing the host animal digestibility.

ABSTRACT
The work was carried out to study the intake, nutrient digestibility and nitrogen study of Red Sokoto bucks fed grade levels of Albizia labbeck flower meals in a complete diet. 16 Red Sokoto bucks average weight 13.40kg ±2 were randomly assigned into four groups with four bucks per group in a completely randomized design. Involving four dieting treatments T1, T2, T3 and T4 containing 0, 10, 20 and 30% levels of inclusions of Albizia labbeck flower meals. The result of the trial showed that animals fed 30% Albizia labbeck flower meals had highest ($p<0.05$) intake of all the nutrients. The result indicated that the apparent digestibility of Dry Matter (70.96%) and crude Protein (76.58%) was high ($p<0.05$) in animals fed 30% Albizia labbeck flower meals level of inclusion and had the best digestibility of almost all the nutrients. the Nitrogen balance and the Nitrogen retained percent were significantly higher in Bucks fed T_4. It can be concluded that Albizia labbeck flower can be included in the diets of Red Sokoto buck up to 30% without adverse effect on intake and digestibility of nutrients.

Key words: Bucks, A*lbizia labbeck*, Digestibility, Sorghum panicle and Maize offal

INTRODUCTION

The nutrition of goat is the most important factor affecting performance. Poor nutrition results in low rates of production. It is however an accepted fact during dry season of the year, that grassland in the tropics does not supply sufficient nutrients to stock for greater productivity. Moreover, Range is declining due to increase in land use for crop production, overgrazing, urbanization and population increase (Lamidi, 2005).

Tree fodder maintain higher protein and animal contents during growth than do grasse ,which decline rapidly in quality with progress to maturity . Gupta (1980) found inter *alia* that siris leaves had a dry matter digestibility of 68.5%. A subsequent paper concerning with the effect of molasses supplementation on nitrogen retention for small ruminants on a diet of siris leaves appears to be regard to the plant as a standard feed Flowers contain no adverse constituents but pods contain saponins which may limit intake but appear to have no other adverse effect. Protein and neutral detergent fibre contents are as follows: green leaf, 16-23 and 41-35%; fallen leaf, 10 and 49%; fallen flower, 23 and 51%; pods, 19 and 55 %.(Varshney *et al.*, 1971)

. Therefore, the objectives of this study were to evaluate the intake, digestibility and nitrogen balance in Red Sokoto bucks fed with *albizia labbeck* flower meal

MATERIALS AND METHODS

The experiment was conducted at the Department of Animal Science Farm; Ahmadu Bello University Experimental animals were sourced from Tudun Sebu market in Soba Local Government Area. The *Albezia Labbeck* flowers were harvested In GRA Zaria and Main campus, A.B.U., Zaria,

The animals were dewormed and dipped in ascaride solution. The diets consisted of *Albezia Labbeck* flowers, Cotton seed cake, Sorghum panicle, Salt and Bone meal. Included at the levels of 0, 10, 20 and 30% levels of inclusion.

Digestibility and Nitrogen balance studies were carried out using 16 Red Sokoto bucks average weight 13.40kg ±2 were randomly assigned into four groups in a completely randomized design. Last for 21 days in which 14 days were for adaptation, 7 days for Data collection. The diets were offered to the animals daily at 0800hr. 3% of their body weight. Chemical compositions of the feed and faeces samples were analyzed according to AOAC (2001). Data collected during the trials were subjected to one-way ANOVA SAS (1998) .Duncan multiple range tests (DMRT) was used to compare treatment means (Duncan, 1955).

RESULTS AND DISCUSSION

Chemical composition and Feed Intake

Table 1 shows the proximate composition of the *Albizia labbeck* flowers used in the study. The *Albizia labbeck* had crude protein (CP) 21.00% The crude protein (CP) 21.00% obtained in this study was higher than the values For a feed stuff to be regarded as a potential protein source and this finding confirms with various reports that legumes are. It was observed that the flowers had low lipid contents, a necessary factor in preventing rancidity in the flower for a long period of time. The variation in the crude protein level could be attributed to the season and the soil upon which is growing.

Table 2 presents the results of effect of varied levels of nutrient intake in Red Sokoto bucks. T4 had the highest nutrients intake and statistically ($P<0.05$) differed across the treatments. This was likely due to increase in protein and palatability of the diet.. This was similar to the finding reported by Nguyem *et al*. (2008). The dry matter intake increased with concentrate supplementation due to increase in supply of protein and readily available energy to the rumen microbes which speed up digestion and create more space for intake (Njwe and Olubajo,1992). The increase in TDMI in the supplemental group may be due to palatability of concentrate supplemental diets which agrees with finding of Jamie *et al*.(2009).

DIGESTIBILITY AND NITROGEN STUDY

The results of nutrient digestibility of Red Sokoto goats fed diets containing different levels of *Albizia Labbeck* flower meals are presented in Table 3. The result showed that the nutrient digestibility across the treatments differed significantly ($P<0.05$) and were improved ($P<0.05$) in the supplementary group (T3 and T4) and agreed with the report of Adamu (2013). The current result could be attributed to the additional protein source in the supplemental diet that may have increased protein availability to the rumen micro organisms to speed up the digestion process (Jamie et al, 2009). The dry matter digestibility values obtained T3 and T4 (66% to 71%) were indicated as high digestible level though T2 and T1 (50% to 60%) digestibility were still within the range regarded as moderately accepted for average animal production performance (Devendra and McLeory, 1982).

The results of nitrogen utilization of Red Sokoto goats fed diets containing different levels of *Albizia Labbeck* are presented in Table 4. The results showed that nitrogen utilization across the treatments differed significantly ($P< 0.05$). The nitrogen intake increased as the inclusion level of *Albizia Labbeck* increased across the dietary treatments. The nitrogen loss in urine was higher in T4 (30%) this report agreed with the report of Ibeawuchi *et al*. (1993) which says that "Urine nitrogen is a function of nitrogen ingested, the more nitrogen intake, the more nitrogen excreted in the urine. Nitrogen absorbed (g day^{-1}) was higher in T4 (30%)

CONCLUSION

Based on the results of this study, it can be concluded that *Albizia labbeck* flower meals can be included in the diets of Red Sokoto buck up to 30% without adverse effect on intake and digestibility of nutrients.

ABSTRACT
Sixteen growing Uda rams weighing between 20 and 25kg were used to determine the utilization of cattle fore-stomach digesta ensiled with African locust bean pulp (ALBP) and non-protein nitrogen (NPN) sources. The study was conducted in Katagum, Zaki Local Government Area, Bauchi State. The animals were randomly allocated to four dietary treatment groups in a completely randomized design (CRD). The research lasted for eighty four (84) days of feeding and seven (7) days digestibility trials. Data were taken on feed intake and body weight changes. Blood samples were also collected and analyzed for haematological indices. The results showed that feed intake and dry matter intake (%body weight) were significantly (p<0.001) different. The weight gain, ADWG, total feed intake, feed conversion ratio, haemoglobin, park cell volume, red blood cell, white blood cell, mean corpuscular volume, mean corpuscular haemoglobin, mean corpuscular haemoglobin concentration were not significantly different. There was no significant difference in terms of digestibility of DM, CP, CF, EE, and Ash across the treatments. The cost of production showed no significant differences across the treatments means, but treatment A with 40% fore-stomach digesta and 60% African locust bean pulp was recorded the least cost of ₦332.51 and is recommended to farmers for feeding ruminant animals.

Keyword: Rumen Content, African Locust Bean Pulp, Poultry Litter, Non Protein Nitrogen Sources, Growing, Uda Rams

INTRODUCTION
Ruminant animals play active role in converting feedstuffs of no human dietary value to meat and milk. Efforts have been on using such feeds to reduce cost of feeds and subsequently cost of animal production. In recent years, several authors (Garba and Maigandi, 2008; Fawol and Fajemisin, 2011) investigated the use of cheap agro-industrial by-products and waste materials; such as slaughter/abattoir waste and poultry droppings and cassava peels at various levels of inclusions in small ruminant diets to determine their efficiency of utilization in term of growth and production. Also with a view to identifying the most suitable one in terms of nutrition, cost effectiveness and year round availability.

The findings will further buttress the need for the populace in the developing world's to turn to these cheaper sources of protein to combat the problem of malnutrition.

MATERIALS AND METHODS
EXPERIMENTAL SITE
The study was conducted at Katagum, Zaki Local Government Area, Bauchi State.Zaki is a Local Government Area in Bauchi State, Nigeria, and its coordinates are 12º08'N and 10º17'EIt has an area of 1,436km^2 and a population of 191,457 as at 2006 census. The postal code of the area is 752. The predominant ethnic groups in the area are the Hausa with some

Kanuri and Kare-Kare in the east of the area. Zaki Local Government Area has two main seasons, the dry season, which last from October to May/June and the rainy season that last from June/July to September. Zaki Local Government Area as part of the sahel region of Nigeria is blessed with abundant livestock resources because of its climate which is more suitable for livestock production, due to absence of Tse-tse fly on the open grassland. The experiment was conducted between the months of July-October 2019.

EXPERIMENTAL MATERIALS

Rumen contents (RC), Africa locust bean powder, poultry litter, Urea, water mixing bowl, masking tape, marker and weighing scale.

Experimental Animals and their Management

Sixteen (16) growing Uda rams weighing between 20 and 25kg and 6-7 months of age were purchased from Gamawa town of Bauchi State for the experiment. The rams were transported to Zaki Local Government Area. On arrival, the rams were quarantined, dewormed and sprayed against ecto parasites (using permethrin). The experimental rams were allocated to four different dietary treatment groups and water was provided *ad-libitum.* The feeding trial lasted for eighty-four (84) days.

EXPERIMENTAL DESIGN AND FEEDING PROCEDURE

The experimental design used was complete randomized design (CRD). A total of 16 growing Uda rams were used, such that each treatment contained four replicates. Each group of four animals was assigned to one of the experimental diets for 84 days feeding trial. Each ram was fed individually at the rateof 2kg/ram body weight. Apart from the experimental diets (Table 1), each animal was fed the concentrate diet with the formulation shown in Table 2 at the rate of 1kg.

RESULTS AND DISCUSSIONS

CHEMICAL COMPOSITION OF THE EXPERIMENTAL DIETS

Chemical compositions of the experimental diets are present in table 5. Crude protein content was higher in treatment A (16.43%) which was higher than the 6-8% CP recommended by Norton (2003) for growing sheep and goat. Gatenby (2002) indicated 10-12% CP as moderate level for ruminant production.

The higher CP content in this study could be due to the ensiling effect like rapid increase in soluble component of crude protein due to proteolysis and deamination. The DM value (89.61%) obtained in this study was similar with the values of (87.61-87.71%) observed by ochepo *et al*. (2012) in diets containing sugarcane peels. The higher DM value might be attributed to the types of materials used which were all dried. Higher DM suggest a good source of energy and roughage that could enhance rumination and prevent digestive upset in the rumen.

The crude fibre value (10.11-9.63%) in the present study were lower than the value (31.30-33.60%) obtained by Ahmed *et al*. (2007) when sugarcane baggase was ensiled with chicken manure. This may be as a result of the experimental materials present in the ensiled mass. Ether extract values (8.14 – 6.93%) obtained from this trial was higher than those reported by Tukur and Maigandi (2010). These are authors obtained EE values ranged of (4.3-5.5%) when fattening rams was fed varying levels of fore-stomach digesta (FSD). The higher ether extract (EE) in diets indicate fats content which give rise to high concentration of volatile fatty acid (VFA).

The Ash values 6.52-7,69% in the present study was lower than (12.91-19.54%) reported by Garba *et al*. (2010) when *Guirera Senegalensis* was fed to yankasa rams as complete diets.

GROWTH PERFORMANCE

Growth performance of the experimental animals higher in feed intake is a good indication of proper utilization of the experimental diets (ensiled FSD with ALBP NPN) by the animals, which could also be attributed to the aroma and palatability of the ensiled diets. Initial, final body weight (BW), daily feed intake (DF1) weight gain, average daily weight gain (ADWG), total feed intake, feed conversion ratio and dry matter intake percentage body weight (DMI%BW) of growing uda rams fed graded levels of the experimental diets were shown in table 2.. Statistical analysis revealed that, there was no significant different ($p>0.05$) effects among the experimental diets across the various treatments on the life weight gain and average daily weight gain. The results of voluntary feed intake were varied statistically ($p<0.001$) among the treatments. Treatment D and C had the higher feed intake. Variation in feed intake between treatments could be as a result of better quality of the materials (urea and poultry litter) used to treat fore-stomach digesta (FSD) and African locust bean pulp (ALBP) which might have aided better intake and improved palatability of the diets.

These results are in line reported by Mondal *et al*. (2013) who found that inclusion of Dry rumen contents (DRC) in diets at O, 5 and 10% DRC did not affect final live weight and average daily gain (ADG) in kids and lambs.

Dry matter intake as percentage body weight was significantly different ($p<0.001$) between the treatments. DMI% BW indicates the nutritional quality of the feed with minimal wastage. The DMI% BW generally indicates that the animals on the various diets showed positively DM status by consuming more than (2) percent of their body weight. The values obtained in this study fail within the range of 2.18-3.78% reported by Olorunnisomo (2010) for sheep fed maize and amaranth fodder.

Nutrient Digestibility

The result of nutrient digestibility is present in table 3. The result showed that nutrient in the experimental diets was well utilized. The digestibility of the nutrients obtained in this present study was comparably high. Muhammad *et al*. (2016b) observed similar trend when uda rams were fed graded levels of *Parkia biglobosa* yellow fruit pulp. Wada *et al*. (2014) observed medium digestibility (40-60%).

Generally, the entire nutrients digestibility in this study was higher and the high digestibility could the attributed to the inclusion level of urea and poultry litter in the experimental diets as sourec of protein. This agreed with the report of Garba and Maigandi (2008) that adequate nitrogen in diets enhanced the activities of rumen microbes which eventually improved the overall nutrient digestibility.

The dry matter (DM), Crude fibre (CF), Crude protein (CP) Ether extract (EE), and ASH digestibility in present trial were comparable to the finding of Muhammed *et al*. (2016b) and higher than the report of Wada *et al*. (2014a). DM values in this study ranges from 75.63-83.44% and that of Muhammad *et al*. 2016b) ranged from 77.22-78.02%.

CP values obtained in the present research ranges from 78.74-84.58% which is higher than the values 24.48-32.27% reported by Wada *et al*. (2014a).

CONCLUSIONS AND RECOMMENDATION

The result showed that daily feed intake was significantly higher in treatments C (1.21kg) and D (1.22kg) than in treatment A (1.08kg) and B (1.09kg). Dry matter intake as % BW was significantly higher in treatments C and D than in treatment A (1.08kg) and B (1.09kg). Therefore treatment D was recommended due to the high DFI, weight gain and low in FCR.

PERFORMANCE OF YANKASA RAMS FED TREATED AND UNTREATED SORGHUM STOVER WITH DIFFERENT SUPPLEMENTS

Mijinyawa A, Abubakar M, Kalla D.J.U. & Yerima .J.
Department of Animal Production, Faculty of Agriculture, Abubakar Tafawa Balewa University (ATBU) Bauchi, Bauchi State, Nigeria.
Correspondent Author: mijinyawaaminu@gmail.com +2348057443388

ABSTRACT
An experiment was conducted to evaluate nutrient intake, digestibility and performance of growing Yankasa rams fed urea treated and untreated sorghum stover with supplementation. Twenty rams were randomly allotted to four dietary treatmentsin complete randomized design. Animals on treatment 1 and 2 were fed untreated sorghum stover while those on 3 and 4 were given treated sorghum stover. Treatment 1 and 3 were supplemented with cotton seed cake (CSC alone) while those on treatment 2 and 4 were supplemented with cotton seed cake and maize bran (CSC+MB 50:50) the experiment lasted for 63 days. The result indicated that urea treatment increased crude protein (CP) content of sorghum stover by 219% and decreased acid detergent fibre 21.57%. Significant (P<0.05) difference were observed in nutrient intake and growth performance. The result of dry matter intake (DMI) was higher in treatment 1 and lowest in 4 with (576.10 g/day and 513.64 g/day respectively). Live weight gain were significantly (P<0.05) affected by the treatments with treatment 3 having the highest value of 78.89g/day and treatment 2 the least 57.46g/day. Animal fed diet 3 utilized their diet much better compared to others. It may therefore be concluded that urea treatment and supplementation of sorghum stover can improve performance. However diet 3 which gave a better average daily gain is recommended for growing Yankasa rams.

Keywords: Sorghum Stover, Cotton Seed Cake, Maize Bran

INTRODUCTION
The utilization of the cheapest and most available feedstuff is a major challenge facing livestock farmers in Nigeria amidst feed crisis (Bogoro, 1997). These cheap feed resources include crop residues, agro-industrial by-products, animal processing wastes, brewery waste and by products, farm animal waste (poultry litters, animal faces) and other forms of fibre, protein and energy by products suitable for ruminant feeding. Crop residues contribute substantially to the supply of nutrients for animals in the tropical and sub- tropical developing countries. According to Fall *et al.* (1987) about 25% of cereal crops are retained in crop residues, making them valuable nutrient sources. The feeding value of crop residues especially cereals such as sorghum and millet has been largely ignored and this has resulted in development of crop varieties and hybrids that produce fewer residues than unimproved varieties and hybrids that produce fewer residues than unimproved varieties (Williams *et al.*, 1997), yet most important feeds for ruminants in small-holder crop-livestock production system of Asia and Africa. Thus, its importance in ruminant nutrition in the long dry season of semi arid areas needs not to be over emphasized despite its limitations. Cereals straws and other crop residues are characterized by low digestibility (< 50 percent), hence low metabolizable energy content (<7.5mj/kgdm), low crude protein content (<60g/kg Dm), low intake (10-20g/kg live weight daily) and low content of available minerals and vitamins (Nicholson, 1984, Doyle *et al.*, 1986). As sole feeds they are therefore, considered too poor,

even to maintain adult ruminant. In the continuous search for ways of enhancing the nutritional status of the crop residues, two methods are commonly employed, viz; supplementation with protein, mineral and energy sources as well as chemical treatment with urea, ammonia, sodium hydroxide, potassium hydroxide and ash (Adebowale, 1987). In Nigeria, protein consumption is below 67g recommended by the World Health Organization (WHO) (Akintola *et al.,* 1999). There is therefore, the need to increase the protein intake to a level which compares to that of the developed nations (Okereke *et al.,* 2005), sheep population in Nigeria which is estimated to be 33.9million (FAO, 2008) and which are primarily kept for meat production can bridge the supply-demand of animal protein gap in Nigeria. However, effective and efficient sheep production cannot be enhanced with the use of conventional feedstuffs such as maize, soybean cake and fish meal as supplements to low quality feeds due to their exorbitant cost, erratic supply (Akinmutimi, 2004) and the competition with humans and monogastric animals (Ajayi *et al.,* 2008; Ukpabi and Abdu, 2009). It is in this light that non conventional energy and protein materials of farm and agro-industrial wastes were being exploited for livestock production in Nigeria (Ndubueze *et al.,* 2006; Okonwo *et al.,* 2008). Such feed resources should be cheap, have high nutritive value, non-toxic, readily available, have low or no demand by both humans and other livestock species and without industrial usage (Egbo *et al.,* 2001; Amaefelu , 2002; Ndubueze *et al.,* 2006).

MATERIALS AND METHODS

LOCATION OF THE EXPERIMENTAL SITE

The experiment was carried out at the Ruminant Animal Research Farm of Animal Production Department, Faculty of Agriculture and Agricultural Technology, Abubakar Tafawa Balewa University, Bauchi.

Experimental animals and their management

Twenty Yankasa rams with average weights 15 kg of ranged 14-16 kg and aged 8 – 10 months were used for the experiment. The rams were sourced from Durun and Mararaban Liman Katagum Markets in Bauchi Local Government area of Bauchi state. The animals were housed in individual pens. The houses are with corrugated iron roof and a concrete floor with large windows to enhance ventilation. The Saw dusts/wood shavings were used as bedding materials to protect the animals from dampness and cold. Before the beginning of the experiment, the animals were treated against ector and endo parasites using ivormectin injection and albendazole bolus and also injected intra-muscularly with *oxytetracycline* long acting broad spectrum antibiotic as a precautionary measure against bacterial infections. The animals were allotted to four dietary treatments of five animals each. Each individual animal was kept separately in its on pen. The animals were kept for a period of two weeks to enable them adapt to confinement. During the adaptation period, the experimental diets were offered to the animals at adlibitum. Feed offered and feed refused were recorded for each animals in each group daily while animal weights were taken on a weekly basis, using a hanging scale/spring balance. Average daily feed intake and average daily weight gains were recorded over the 9 weeks experimental period. The diets use as follows: Treatment one (T1) untreated milled sorghum Stover (UMSS) supplemented with 300g cotton seed cake alone, treatment 2 untreated milled sorghum stover (UMSS) with 300g cotton seed cake and maize bran (50:50). Treatment 3 urea treated milled sorghum stover supplemented with cotton seed cake alone,

while those on treatment 4 were fed urea treated milled sorghum stover supplemented with cotton seed cake and maize bran 50:50. All supplements were fed at 300g per head per day. The supplements were fed twice a day, half of each time; in the morning (09:00 hrs.) and evening (16:00 hrs.)

UREA TREATMENT OF SORGHUM STOVER

One thousand kilogram of milled sorghum Stover was treated with 5% urea solution in batches. Five (5) kilograms of urea was dissolved in 100 litres of water was sprinkled to 100 kg of milled sorghum Stover. The milled sorghum stover was mixed thoroughly and compressed before inserted into an air tight polyethene bag. The sample was done in a polyethene bags of dimension 112 cm by 76 cm and ensiled for three weeks. After this period, the ensiled material was opened and air dried under shade for 3 days. Continuous raking was carried out for uniform drying and to minimize the risk of mould.

EXPERIMENTAL DESIGN

The experimental design was completely randomized design with four treatments of five animals per treatment.

CHEMICAL ANALYSIS

All the diets and faeces were analyzed for chemical composition. Each sample was milled to pass through a 1.0mm screen using a telator cyclotee 1093. The milled samples were used for proximate analysis to determine Nitrogen (N) for use in crude protein determination (N x 6.25), crude fibre (CF), ether extract (EE) and ash according to AOAC (1999). Neutral Detergent fibre (NDF) and acid detergent fibre (ADF) were determined according to procedures outlined by Van Soest *et al.* (1991).

DATA ANALYSIS

Data were analyzed using statistical package for social sciences (SPSS) where there is significant difference in analysis of variance (ANOVA) means were separated using least significant difference (LSD) (version: 21, 2006).

RESULTS AND DISCUSSION

Presented in Table 1 is the chemical composition of the experimental diet, the increase in the Crude Protein (CP) content of sorghum stover is in agreement with findings of Yulistiani *et al.*(2003) which found an increase in CP content of urea treated rice straw to be 2.7 times CP and also slightly higher compared to previous experiment reported by Prasad *et al.* (1998) were 2.34 was recorded for urea treated straw kept in bale and 2.433 kept in stack. However, the increase in nitrogen content in the experiment currently reported was higher compared to the result reported by Ahmed *et al.* (2002). This difference could be due to method of ensiling, the variety of the straws, urea treatment level as well as the nitrogen content of the straw. Yulistiani*et al.* (2000) reported that rice straw with low nitrogen content could benefit more from urea treatment to improve nutritive value especially nitrogen content. Urea treatment decreased slightly cell wall component previous study reported by Yulistiani *et al.* (2000) show that effect of urea treatment on cell wall component was not consistent. Daily feed intake of the urea treated sorghum stover was similar across the treatment which is not in agreement with some findings; Ngele *et al.* (2009) and Getahun (2014). This may be attributed to treatment rendered to the basal diet which reduced the particle size of the straw thereby given a better chance for the animals to consume relatively the same amount across the treatments. The average daily weight gain was significantly ($P < 0.05$) affected by the

treatment. The ADG recorded in this study was higher in treatment 3 (78.93 g/day) while treatment 2 with the lowest (57.46 g/day) were lower to those reported (61.70-82.54 g/day) by Aime *et al.* (1999) when determined the effect of urea treatment on digestibility and utilization of sorghum stover.

Conclusion

Based on the results obtained in this study, urea treatment increased the crude protein content of sorghum stover and decreased the acid detergent fibre. It can be concluded that treated sorghum stover with cotton seed cake supplement fed to Yankasa rams gave a better result comparable to those fed untreated sorghum stover with supplements in terms of digestibility and ADG.

ABSTRACT

This study was conducted to evaluate the effect of replacing Palm kernel cake (PKC) with Kenaf grain meal (KGM) in cassava peel-based diet on performance of WestAfrican Dwarf sheep. Sixteen female West African Dwarf sheep with the average live weight of 9.71± 0.05 kg were randomly allotted to four dietary treatments in a complete randomised design with four animals per treatment. The results showed that dry matter (88.80-88.95%) and ether extract (2.84-3.14%) contents were relatively similar.The crude protein contents were highest (16.22%) in diet 3 and lowest (14.73%) in diet 1 while the crude fibrecontent was highest in diet 1 (23.38%) and lowest in diet 2 (17.85%). The performance of the sheep differed ($p<0.05$) across the treatments. Total feed intake (662.82 g/day), weight gain (30.95 g/day) and feed conversion ratio (21.42) were best in sheep fed diet 4 (25% KGM inclusion) compared to other treatments. However, total feed intake(g/kg$W^{0.75}$) was highest ($p<0.05$) in sheep fed diet 1 (25% PKC inclusion) but lowest in sheep fed diet 2 (10% PKC and 15% KGM inclusions). In conclusion, the significant ($p<0.05$) performance of sheep fed with diet 4 (25% KGM inclusion) revealed the possibility of total replacement of PKC with KGM in cassava peel ration without negative impact on the growth of West African Dwarf sheep.

INTRODUCTION

The perennial challenge of feed scarcity and limiting Nitrogen (N) content of tropical grasses in the tropics especially in the dry season triggered several kinds of research on the exploration of crop residues and agro-industrial by-products in ruminants feeding systems. Cassava peel has been successfully used as a suitable source of energy supplement to foliage or poor quality feed but its low crude protein content requires that it should be supplemented with a dietary protein source, preferably of plant origin to make a complete feed suitable for ruminants. Similarly, palm kernel cake is a medium quality energy source, high in fibre and crude protein contents moderately (Carvalho *et al*., 2005) enough to meet the requirements of most ruminants. Though Chanjula *et al*. (2011) had reported that palm kernel cake has no effect on voluntary feed intake for ruminants at high levels, but Wan Mohammed *et al*. (1987) reported that long-term feeding of PKC could lead to copper toxicity in sheep. Often, forage legumes have been the cheapest source of protein widely accepted in ruminant feeding systems in the course of solving the limiting N content of tropical grass species. However, a promising and non-conventional protein, energy and fibre sources for ruminants that have not received adequate attention is the kenaf plant (*Hibiscus cannabinus*). Kenaf is a well-known industrial and commercial fibre crop around the world (Welber *et al.*, 2002). Even though Kenaf seed is reported as a suitable supplementary source of protein in livestock feed (Nyam *et al.*, 2009), very scanty information is available about the utilization of the grain as feed for ruminants. The high content of fibre and edible oil (LeMahieu *et al*., 2003) of kenaf seed also suggests its usefulness as a source of energy for livestock. Though kenaf plant is increasingly gaining wider acceptance by the small and large scale crop farmers for propagation as raw materials for jute and fibre industries in Nigeria, but tons of the seeds produced for subsequent propagation rapidly loss viability and get wasted because of poor storage conditions, inadequate or high cost of storage facilities which is beyond the reach of the rural poor producers. Hence, the seeds are discarded by setting it on a flame. To prevent the wastage of the non-viable Kenaf seeds and intensify efforts at promoting kenaf grain

production for wider use in the livestock industry, this study was designed to explore the potential of kenaf grain in small ruminant feeding strategy.Considering the similar dietary nutritional (protein and energy) potentials of palm kernel cake and kenaf seeds, it was hypothesized that Kenaf grain meal could replace palm kernel cake and also supplement cassava peel-based diet to promote voluntary feed intake for improved growth performance by West African Dwarf(WAD) sheep.

MATERIALS AND METHODS

The experiment was carried out at the sheep and goat unit of the Institute of Agricultural Research and Training, Moor Plantation, Ibadan. Animals selected from the herd for the experiment were given prophylactic treatments against ecto and endo-parasites and adjusted to their treatments diets over a 2-week preliminary period, followed by 84-day feeding trial. Sixteen WAD female sheep with the average live weight of 9.71± 0.05 kg were randomly allotted to individual pens and to one of four treatment diets in a complete randomized design with four animals per treatment.

FEED PROCESSING, FEEDING AND GROWTH TRIALS

Feed ingredients were sourced from animal feedstuff vendors, while dried kenaf grain was collected from the Kenaf and Jute Fibre Programme of the Institute of Agriculture Research and Training, Ibadan. Fresh Guinea grass (*Panicum maximum*) was harvested from an established pasture of the Research Institute and allowed to wilt under room temperature before feeding. Kenaf grain and dried cassava peel were crushed with attrition and hammer mills, respectively into small particle size (1.5-2.5 mm) to allow for proper mixing with other ingredients. Thereafter, the crushed feedstuffs were separately weighed and mixed according to the proportion of each dietary treatment as enumerated in Table 1. Experimental diets (Table 1) were offered separately to individual animals at 3% body weight at 08:00 h. Wilted Guinea grass was offered to all the sheep at 2% body weights at 16:00 h. Provision was made for a daily feed allowance of 10% above the previous week's consumption. Clean water was served *ad libitum*.The initial body weighs of the animals were taken and recorded before the commencement of the experiment. Daily feed intake was determined by subtracting feed refused from feed offered over a 24-h period, while live weight changes were measured once each week before feeding in the morning throughout the 105 days experimental trial excluding 2 weeks of the adaptation period.

CHEMICAL AND STATISTICAL ANALYSIS

Dried samples of the experimental diets and guinea grass were analyzed for Crude protein (N×6.25), Dry matter, ether extract, ash, and crude fibre contents as described (AOAC, 2000). Data obtained were subjected to analysis of variance and Duncan's Multiple Range Tests was used to detect significant differences among means at $p< 0.05$.

Table 5: Ingredient composition (g/100g DM) of the experimental diets

Ingredients (kg)	Diet 1	Diet 2	Diet 3	Diet 4
Dried cassava peel	55.0	55.0	55.0	55.0
Palm kernel cake	25.0	10.0	5.0	-----
Kenaf Grain	-----	15.0	20.0	25.0
Corn bran	15.0	15.0	15.0	15.0
Soya bean meal	2.5	2.5	2.5	2.5
Di-calcium phosphate	1.0	1.0	1.0	1.0
Limestone	0.75	0.75	0.75	0.75
Premix	0.25	0.25	0.25	0.25
Salt	0.5	0.5	0.5	0.5
Total	100	100	100	100

RESULTS AND DISCUSSION

Table 2 shows the proximate composition of the experimental diets, guinea grass and major test ingredients. The value of dry matter (88.80-88.95%) for the experimental diets was relatively similar. The crude protein (14.73-16.22%) content for all the diets was above the minimum requirement recommended for sheep (Gatemby, 2002). The highest CP value of diet 3 (16.22%) could be due to the combined effect of the test ingredients (palm kernel cake and kenaf grain meal) CP contents. The ash content ranged from 7.15-7.48%. The ether extract values of diets 3 and 4, 1 and 2 were respectively similar, which is an indication that ether extract values (2.84-3.14%) of the experimental diets were not above the dietary fat (5-6%) that could inhibit microbial activity and reduce nutrient digestibility (Kucuk *et al*., 2003) in ruminants. The range of crude fibre was above the minimum level of 17% recommended for ruminants (NRC, 2001). The highest value of crude fibre in diet 1 (23.38%) compared to diets 2 to 4 respectively, with varying proportion of PKC and KGM could have resulted from the inclusion of palm kernel cake, which has been reported to contain a high amount of lignin due to contamination of nutshells (Mok, 2013). The high CP, crude fibre and low ether extract values of the experimental diets reveal the nutritive value of palm kernel cake and kenaf grain meal to supplement cassava peel and ability to promote ruminal microbial activity to improve the digestibility of feed.

Table 2: Proximate composition (g/100g DM) of experimental diets, Kenaf grain meal and Guinea grass

Parameter	Diet 1	Diet 2	Diet 3	Diet 4	KGM	PKC	Guinea grass
Dry matter	88.81	88.80	88.87	88.95	93.23	93.80	88.76
Crude protein	14.73	14.93	16.22	15.73	21.44	18.44	8.60
Ether extract	2.84	2.95	3.08	3.14	3.48	6.82	2.85
Ash	7.48	7.33	7.15	7.27	5.40	5.21	9.04
Crude fibre	23.38	17.85	19.19	18.77	11.27	15.36	32.33
NFE	51.59	56.95	54.37	55.09	58.41	54.17	47.18

NFE= Nitrogen Free extract; KGM= Kenaf grain meal; PKC= Palm kernel cake

The feed intake and growth performance of WAD sheep fed cassava peel concentrate with varying inclusions of palm kernel cake and kenaf grain meal differed significantly ($p<0.05$) across the treatments (Table 3). Total feed intake ranged from 538.96-662.82 g/day, being highest in sheep fed diet 4 (25% KGM inclusion) but lowest in sheep fed diet 1 (25% PKC inclusion). However, total feed intake in metabolic body (g/kg$W^{0.75}$) weight was highest (93.41 .g/kg$W^{0.75}$) in sheep fed diet 1 and lowest (79.74 g/kg$W^{0.75}$) in sheep fed diet 2. The significantly higher total feed intake observed for all the sheep fed diets containing KGM is an indication that the experimental feed was well accepted, which corroborates the findings of Sgwane *et al*. (2008) that kenaf seed increased dry matter intake of sheep fed low-quality hay. This also suggests that the nitrogen content of kenaf seed was sufficient to improve ruminal microbial activities for feed degradability and consequently increased intake. The highest weight gain (30.95 g/day) and efficiency of feed conversion were observed for sheep fed diet 4 (25% KGM inclusion) compared to other treatments (16.07-21.43 g/day) groups. Even though the

high crude protein in KGM and moderate protein in PKC are highly degradable and soluble in the rumen (Carvalho *et al*., 2005), cassava peel which is a source of highly fermentable carbohydrate in ruminant ration could have protected the nitrogen of KGM-PKC from total degradation in the rumen for subsequent absorption in the abomasum and small intestine as documented (Kardaya *et al*., 2009). Therefore, the significantly higher weight gain of sheep fed diet 3 and 4, respectively compared with sheep fed diet 2 (15% KGM +10% PKC) affirms that between 20-25% of KGM could successfully replace PKC in cassava peel ration for sheep. Hence, the variations in performance observed across the treatments further elucidate the potential of KGM to replace PKC as supplementary protein and energy sources for small ruminant feeding.

Table 3: Performance of West African dwarf (WAD) sheep fed cassava peel with varying inclusions of palm kernel cake and kenaf grain meal

Parameters	T1	T2	T3	T4	SEM
Feed intake (g/day)					
Cassava peel-kenaf grain concentrate	280.71^{d}	295.15^{c}	313.63^{b}	344.27^{a}	7.16
Guinea grass	258.25^{d}	315.06^{c}	320.37^{a}	318.55^{b}	7.82
Total feed intake (g/day)	538.96^{d}	610.21^{c}	634.00^{b}	662.82^{a}	13.82
Total feed intake (g/kg$W^{0.75}$)	93.41^{a}	79.74^{d}	80.46^{c}	82.34^{b}	1.67
Weight gain (g/day)					
Initial body weight (kg)	9.48	9.62	9.86	9.88	0.05
Final body weight (kg)	11.20^{c}	10.97^{d}	11.66^{b}	12.48^{a}	0.18
Weight gain (g/day)	20.48^{c}	16.07^{d}	21.43^{b}	30.95^{a}	1.64
Feed conversion ratio	26.32^{c}	38.01^{a}	29.59^{b}	21.42^{d}	1.81

^{abcd}= Means with the same superscripts in the same row are significantly different ($p<0.05$)

CONCLUSION

The highest total feed intake (662.82 g/day), daily live weight gain (30.95 g/day) and better feed conversion ratio (21.42) observed for sheep fed with diet 4 (25% KGM inclusion) revealed the possibility of total replacement of PKC with KGM in cassava peel ration without negative impact on growth performance of West African Dwarf sheep. It is therefore concluded that kenaf grain meal could replace PKC and supplement cassava peel which is a low nitrogen crop residue diet often utilised in small ruminant feeding systems.

Abstract

The profitability of feeding dried poultry droppings based diet as a supplement in goat production enterprise was analyzed in the present study. The data generated in the study was analyzed using gross margin analysis and profitability ratio. The result of the budgetary analysis showed that the highest total cost of **Rs** 855.9/goat was incurred, the highest total revenue of **Rs** 1254.3/goat, highest gross margin of **Rs** 773.24/goat and highest net farm income of **Rs** 713.24/goat were observed for the supplemented treatment groups (T2- T5). The profitability ratio gave the best benefit-cost ratio of 4.62, a rate of return of 3.62, a gross ratio of 0.22 and an expense structure ratio of 0.12. This suggests that feeding of dried poultry droppings based diet to goats is a profitable enterprise. This present study, therefore, recommends the supplementation of sun-dried poultry dropping based diet at 80 % inclusion level for maximum profitability

Keywords: Economics; goats; sun-dried poultry dropping based diet

1. Introduction

Least cost feeding of livestock is immensely essential for the best productivity. Under productivity of livestock is attributed to the insufficient and exorbitant high costs of feeds (Beigh *et. al*, 2017). Therefore, to reduce feed costs and to increase production the need for proper use of comparatively low cost agricultural and industrial by-products is principally essential for profitable livestock production enterprise (Sontakke *et. al.*2014)

Thus non-conventional feeds can in part fulfill the feed needs, reduce rivalry for food between humans and animals, minimize feed cost, and add to self-sufficiency in nutrients from domestically and readily accessible feed sources (Bello, 2016; Bello and Tsado, 2014; Sontakke *et. al.*2014; Mubi *et al.*, 2008; Aro and Tewe, 2007; Onimisi and Omage, 2006; Ndubueze *et al.*, 2006; Saleh *et al.*, 2002; Belewu and Adeneye, 1996; Zinn *et al.*, 1996; Ibeawuchi *et al.*, 1993). Sun-dried poultry droppings readily come to mind as one of such non-conventional feed resources. This study was therefore designed to find out how profitable is it to feed sun-dried poultry dropping based diet as supplement to Konkan Kanyal goats consuming finger millet straw.

2. Result and discussions

Cost and Return of Feeding Sun-dried Poultry Dropping based diet as Supplement for Goats:

Table 1 reveals the estimate of cost and returns analysis obtained from feeding sun-dried poultry dropping based diet as supplement for goats using average cost (Fixed and variable cost) and average body weight gain by each of the treatment groups. The average chevon price/kg was lowest (Rs.857.5) in control treatment group (T1) and was highest (Rs.1130.5) in supplemented treatment group (T5) followed closely by (T4) (Rs.1067.5); total revenue was highest in T5 (Rs.1254.30), keenly followed by T4 (Rs.1185.95) and was lowest in T1 (Rs.958.38). The Net farm income in T1 was (-Rs.102.48) but was highest in T5 (Rs.713.24) followed closely by T4 (Rs.652.45) respectively. Gross margin result followed a similar trend as was observed for total revenue and Net farm income in which highest values were recorded for supplemented treatment group T5 (Rs.773.24), followed closely by T4 (Rs.712.45) and least in T1 (Rs.162.48). This present study revealed that feeding dried poultry droppings based diet as a supplement to goats was profitable and it is in agreement with the earlier findings of (Bello, 2016; Jokthan *et al.,* 2013, Anigbogu and Nwagbara, 2013 Fawola and Fajemisin 2011.). The authors reported that the inclusion of poultry litter in the diet of ruminants reduces feed costs and by extension increases farmer's income, therefore, it is a profitable business.

Profitability and Viability Estimate of Feeding Sun-dried Poultry Dropping based diet as Supplement for Goats:

Table 2 reveals the profitability and viability estimate of feeding sun-dried poultry dropping based diet as supplement for goats in the present study. The Benefit-cost ratio ranged from (0.94) in T1 to (4.62) in T5. From the result of this present study supplemented treatment group (T2-T5) has the best benefit-cost ratio (1.60; 1.91; 4.26 and 4.62) and this implies that supplementation of sun-dried poultry dropping based diet in the diet of goat is profitable according to rule of thumb of project evaluation which states that any business with benefit-cost ratio higher than one means is profitable, equals to one means break-even, while less than one indicates loss (Olagunju *et al.,* 2007). The gross ratio ranged from 1.06, in T1 to 0.22 in T5. This implies that in T1, for every Rs.1.00 returns to goat feeding, Rs.1.06 are being spent while for T5 for every Rs.1.00 returns to goat feeding 22 Paisa is being spent. The rate of returns ranged from -0.06% in T1 to 3.62% in T5. This shows that for every Rs. 1.00 invested into goat feeding in T1 -0.06 Paisa was lost by the farmer and in T5 for every Rs.1.00 invested into goat feeding Rs. 3.62 was gained by the farmer. The expense structure ratio ranged from 0.08 in T1 to 0.12 in T5. The best value was observed in supplemented treatment groups (0.12) which implies that about 12 % of the total cost of production is made up of fixed cost component and this makes goat farming a valuable venture because an increase in production with variable cost also leads to increase in total revenue while the fixed cost remained constant.

Table: 1 Cost and Return of Feeding Sun-dried Poultry Dropping based diet as Supplement to Goats:

S.N.	Treatment	T_1	T_2	T_3	T_4	T_5
1	Initial average body weight of goats (kg)	12.45	13.85	13.93	13.38	14.00
2	Average body weight gain (kg/ goats)	2.45	2.58	2.67	3.05	3.23
3	Average total feed consumed (kg/ goats)	55.43	55.58	59.57	58.72	60.01
4	Initial live weight cost (Rs)	4357.5	4847.5	4875.5	4683	4900

T1: had 0% sun-dried poultry dropping based diet (SDPDBD) inclusion; T2: 20% SDPDBD; T3: 40% SDPDBD; T4: 60% SDPDB and T5: 80% SDPDBD.

Table: 2. Profitability ratios

Treatment	Benefit cost ratio	Expense structure ratio	Gross ratio	Rate of return
	Value	Value	Value	Value
T_1	0.94	0.08	1.06	-0.06
T_2	1.60	0.13	0.62	0.60
T_3	1.91	0.13	0.52	0.91
T_4	4.26	0.13	0.23	3.26
T_5	4.62	0.12	0.22	3.62

T1: had 0% sun-dried poultry dropping based diet (SDPDBD) inclusion; T2: 20% SDPDBD; T3: 40% SDPDBD; T4: 60% SDPDBD and T5: 80% SDPDBD.

3. Conclusion

This present study showed that goats fed diets with sun-dried poultry droppings incorporated had better weight gain, total revenue, and net farm income, thus it is a profitable venture. Therefore based on the result of this present study, it is recommended that goats supplemented with sun-dried poultry dropping based diet up 80 % inclusion level has the best net profit.
