NIGERIAN SOCIETY FOR ANIMAL PRODUCTION

in collaboration with

ABUBAKAR TAFAWA BALEWA UNIVERSITY BAUCHI

and

FEDERAL POLYTECHNIC BAUCHI

45th ANNUAL CONFERENCE (BAUCHI 2020)

BOOK OF PROCEEDINGS

THEME:

ANIMAL AGRICULTURE:

EXPLORING THE GOLDMINE OF NIGERIA'S AGRO-REVOLUTION

DATE: 15TH - 19TH MARCH, 2020

EDITORS

Y. P. Mancha, D. J. U. Kalla, K. M. Bello, S. T. Mbap, M. Abdulkarim, T. Igila and S. Danbirni

ISBN: 978-978-981-320-9

THE 45TH ANNUAL CONFERENCE OF THE NIGERIAN SOCIETY FOR ANIMAL PRODUCTION

March 16 – 19, 2020

The Proceedings of the 45th Annual Conference of the Nigerian Society for Animal Production

Editors: Y. P. Mancha, D. J. U. Kalla, K. M. Bello, S. T. Mbap, T. Abdulkarim, T. Igila, and S. Danbirni

Hosted by Abubakar Tafawa Balewa University, Bauchi and Organized under the Auspices of Nigerian Society for Animal Production

ISBN: 978-978-981-320-9

LIST OF REVIEWERS

Folasade Jemiseye
Danbirni, S
Uchele Okpanachi
James Luka
Olayinka Victoria Adelowo
Abdulkarim, M
Muhammad, A. S
Adeyemo, G. O
Jamaa'a, N.A
Sani Ibrahim
Egbo, M. L
Ibrahin Abdu
Mancha, Y. P
Mbap, S.T
Bello, K. M
Dafur, D. S
Idi Saidu
Mai, H. M
Adamu Nuratu
Sanusi, M
Abdullahi, U. S
Akpensuen, T.T
George, O. S
Oderinwale Olatunde, A
Abubakar, M
Doma, U. D
Jibril, S. A
Oshibanjo, D. O
Adebayo, K. O
Okoli, I. C
Shaahu, D. T
Kalla, D. J. U
Odedire, J. A
Abdullahi Muhammad
Idi Rose
Akinbola Oludayo Michael
Onasanya, G. O
Babangida Saleh
Kolo, Abdulwahab
Aminu Moh'd Garba

LIST OF NSAP BAUCHI 2020 LOCAL ORGANISING COMMITTEE (LOC) MEMBERS AS INDIVIDUALS

SN	NAME	DESIGNATIONS
1.	Prof. S. T. Mbap	Chairman LOC and of the Central working committee
2.	Dr. (Mrs) Khadija M. Bello	LOC Secretary
3.	Prof. D. J. U. Kalla	Chairman Finance Committee, Member STC
4.	Prof. U. D. Doma	Chairman Accommodation and Venue Committee
5.	Mal. Lawal Abbas	Chairman Transport and Logistics Committee
6.	Prof. Y. P. Mancha	Chairman Scientific and Technical Committee
7.	Mal. Mohammed Garba Toro	Chairman Publicity and Protocol Committee
8.	Engr. A. Fachway	Chairman Security Committee
9.	Dr. (Mrs) Rose Danladi Idi	Chairperson Welfare Committee
10.	Mr. Zikrullah A. Yusuf	LOC Assistant Secretary, Member PPC
11.	Mr. Timothy TerlumunIgila	Editorial Secretary
12.	Mr. AdamuSaidu	Member, Secretariat
13.	Mal. HarunaGirma	Member, CWC. FC
14.	Prof. M. M. Abubakar	Member, CWC,, AVC
15.	Dean, Faculty of Agriculture and Agricultural Technology, ATBU	Member, CWC
16.	Deputy Dean, Faculty of Agriculture and Agricultural Technology, ATBU	Member, CWC
17.	HOD, Department of Crop Production, ATBU	Member, CWC
18.	HOD, Department of Agricultural Economics and Extension, ATBU	Member, CWC
19.	HOD, Department of Soil Science, ATBU	Member, CWC
20.	Mr. Ibrahim Abdu	Secretary, FC, Member PPC
21.	Prof. L. M. Shehu	Member, FC
22.	Prof. N. Murtala	Member, FC
23.	Prof. T. Ibrahim	Member, FC
24.	Mal. Sagir Mohammed Idris	Member, FC
25.	Mal. Idi Sai'du	Member, FC
26.	Prof. Saleh Sir	Member, FC
27.	HajiyaRuqayyaLidani	Member, FC
28.	Permanent Secretary, Bauchi State Ministry of Agriculture	Member, FC
29.	Programme Manager (PM), Bauchi State Agric. Dev. Project (BSADP)	Member, FC
30.	Bauchi State Coordinator, Fadama III Additional Financing	Member, FC

31.	Mr. Paul Y. Sulim	Secretary, AVC
32.	Mal. Musa Adamu One	Member, AVC, TLC, WC
33.	Mal. Ibrahim Muhammad Almajiri	Member, AVC
34.	Dr. J. S. Luka	Member, AVC
35.	Mal. Murtala A. S. Takko	Member, AVC
36.	Dr. I. Istifanus	Member, AVC
37.	Dr. Abdullahi Mohammed	Member, AVC
38.	Mrs. Hajara D. Kushi	Member, AVC, STC, WC
39.	MsAltiChiroma	Member, AVC, WC
40.	Prof. M. B. Yahaya	Secretary, TLC
41.	Prof. Sunusi Muhammad	Member, TLC, STC
42.	Mal. Idi Sai'du	Member, TLC
43.	Mal. Sani S. Gaya	Member, TLC
44.	Mr. Felix Gandu	Member, TLC, STC, PPC
45.	Mrs. Mantuda M. Lumana	Member, TLC
46.	Dr. M. Abdulkarim	Secretary, STC
47.	Prof. Tahir Ibrahim	Member, STC
48.	Prof. M. M. Abubakar	Member, STC
49.	Prof. M. L. Egbo	Member, STC
50.	Dr. James S. Luka	Member, STC
51.	Prof. Hassan Mai	Member, STC
52.	Dr. T. T. Akpenseun	Member, STC
53.	Dr. Shehu Zailani	Member, STC
54.	Prof. M. Abubakar	Member, STC
55.	Mal. Idi Saidu	Member, STC
56.	Dr. Ahmad I. A.	Member, STC
57.	Prof. A. J. Salawu	Member, STC
58.	Prof. A. A. Amba	Member, STC
59.	Prof. A. M. Set'le	Member, STC
60.	Dr. Okpanachi Uchele	Member, STC
61.	Bello Mummuni Munza	Member, STC
62.	Ebule Kenneth	Member, STC
63.	Monday Gidi Anene	Member, STC
64.	Zagi Simon Peter	Member, STC
65.	John Hakuri Bom	Member, STC
66.	Idi Yusuf	Member, STC
67.	Jatutu Samson Shalom	Member, STC
68.	Ismail Bala	Member, STC
69.	Mal. Abbas Muhammad Bose	Secretary, PPC, WC
70.	Mal. Ayuba Musa	Member, PPC
71.	Mrs. AminaGamboKushi	Member, PPC, WC
72.	Mal. Sagir M. Idris	Secretary, SC
73.	Prof. U. S. Abdullah	Member, SC
74.	Mal. Abdullahi H. Adamu	Member, SC
75.	Mr. James Miyim	Member, SC
76.	Hajiya Fatima S. Abdullahi	Member, SC, WC
77.	Mr. Ahmad Suleiman Sharif	Secretary, WC
78.	Mall. Halima Nuhu Yusuf	Member, WC
79.	Mal. RuqayyaLidani	Member, WC
80.	Mal. Aminu A. Aliyu	Member, WC

81.	HajiyaNuratuAdamu	Member, WC
82.	Mal. YakubuAliyu	Member, WC
83.	Mr. M. A. Mujitaba	Member, WC

TABLE OF CONTENTS

ANIMAL BREEDING, GENETICS, PHYSIOLOGY AND BIOTECHNOLOGY

S/N	TITTLE	AUTHORS	PAGE
1.	EFFECTS OF SOLAR DRIER SUPPLEMENTED WITH LANTERN OR ELECTRIC BULB HEAT ON JAPANESE QUAIL EGGS HATCHABILITY	*[1]Idahor K.O., [1]Musa A.A., [2]Kaye J., [2]Igoche L.E., [3]Egbuji A.N., [3]Sati N.M., [3]Emennaa P.E. and [3]Mwadkon P.B.	1
2.	HISTOPATHOLOGICAL STUDIES ON DROMEDARY CAMEL (*Camelus dromedarius*) MASTITIC MAMMARY GLAND	[1]Idi, Y; [1]Sanusi, M; [1]Kalla, D J U	6
3.	BETAINE HYDROCHLORIDE AMELIORATES THERMOREGULATORY RESPONSES OF BROILER CHICKENS UNDER DEXAMETHASONE INDUCED HEAT STRESS	[1]L.A. Ademu*, [2]O.M. Daudu, [3]G.T. Iyeghe-Erakpotobor, [3]P.P. Barje, [1]J.A. Olusiyi	11
4.	SEXUAL DIMORPHISM IN TWO STRAINS OF LOCAL TURKEY AT EARLY REPRODUCTIVE STAGE UNDER INTENSIVE SYSTEM OF MANAGEMENT IN ZARIA	[1]Olutunmogun, A.K. and [2]Yahaya, H.K.	15
5.	BODY-WEIGHT AND MORPHOMETRIC ATTRIBUTES OF SOME CATTLE BREEDS IN NIGERIA	A. D. Oladepo[1], A. A. Adeoye[2], O. A. Jimoh[3] and O. A. Adeniyi[4]	19
6.	BREED VARIATION IN THERMOREGULATORY PARAMTERS AND THEIR CORRELATED RESPONSES IN SOME SELECTED INDIGENOUS CATTLE	[1]Abbaya, H.Y., [2]Adedibu, I.I., [2]Kabir, M. and [3]Iyiola-Tunji, A. O	23
7.	EFFECT OF BREED ON MORPHOMETRIC CHARACTERISTICS OF TWO RABBIT GENOTYPES	M. I. Abdullahi, O. I. Suleiman, S. K. Inusa and S. S. Hussaina	27
8.	THE VALUE OF MINERAL ZINC IN ANIMAL PHYSIOLOGICAL FUNCTIONS	C.C. Achonwa[1], A.U.C. Ohanaka[1], N.J. Chukwuka[2] and I.C. Okoli[1]	31
9.	GROWTH CHARACTERISTICS OF NOILER CHICKENS AS DETERMINED BY NONLINEAR ALGORITHMS	J. Adamu*, A. Y. Shuaibu and A. O. Raji	35
10.	EGG FERTILTIY AND EMBRYO VIABILITY OF TURKEY HENS INSEMINATED WITH VARIED SEMEN DILUTION RATIO AT DIFFERENT INTERVALS	Adebisi, K. A. and Ewuola, E. O.	39
11.	CRYOSURVIVAL OF GOAT SPERMATOZOA IN TWO TRIS BASED EXTENDERS SUPPLEMENTED WITH VITAMIN E	Adekunle, E.O., Majekodunmi, B.C., Logunleko, M.O. and Daramola, J.O.	44
12.	SEMEN CHARACTERISTICS AND GROWTH INDICES OF MALE RABBITS FED DIETARY LEVELS OF *VERNONIA AMYGDALINA*	Adeyemi A. A., Oloyede C. O., Idowu G.A. & Akinlade M. O.	48
13.	CHICKEN GROWTH HORMONE GENE POLYMORPHISM OF SELECTED CHICKEN BREEDS IN NIGERIA	Adigun, U.O., Ojimah, C.O. and Egena, S.S.A.	53
14.	BREEDING, BIOTECHNOLOGY AND PHYSIOLOGY (ORAL) SURVIVABILITY OF COCK SEMEN STORED UNDER ROOM TEMPERATURE	Amaefule, B.C., Uzochukwu, I. E., Ikeh, N.E., Nnajiofor, N.W.,	58

	IN EXTENDERS CONTAINING SOME ANTIOXIDANTS	and Eze, E.C.	
15.	HAEMATOLOGICAL PROFILE AND BIOCHEMICAL RESPONSE OF WEANER RABBITS FED GRADED LEVELS OF AFRICAN STAR APPLE *CHRYSOPHYLLUM ALBIDUM* SEED MEAL	Amao, E. A., Adeoti, T. M., Olaogun, Y. A. and Oladokun, A. A.	62
16.	TESTICULAR MORPHOMETRY AND EJACULATE CHARACTERISTICS OF ISA WHITE COCKS FED VARIED LEVELS OF SALT (NaCl) AND SUPPLEMENTAL ACETYLSALICYLIC ACID(ASA)	Aro S. O.	67
17.	THE INFLUENCE OF VARIED ACETYLSALICYLIC ACID AND SODIUM CHLORIDE LEVELS ON PERFORMANCE, CLOACAL AND AXILLARY TEMPERATURES OF ISA WHITE COCKS	Aro, S. O. and Onuoha, A. N.	72
18.	EFFECT OF BODY WEIGHT AT FIRST MATING ON REPRODUCTIVE PERFORMANCE OF RABBIT DOES	*Ayo-Ajasa, O. Y., Egbeyale, L.T., Adewole, F. A., Ekunseitan, D. A. and Babalola, O. A.	76
19.	EFFECT OF NEEM LEAF MEAL ON PERFORMANCE OF PREGNANT WEST AFRICAN DWARF (WAD) DOES	Babatunde, M. O.[1], Adewumi, O. O.[2], Adelusi, O. O[3], and Aderinboye, R. Y.[3]	80
20.	STANDARDIZATION OF TWO INTRACELLULAR CRYOPROTECTANTS FOR FREEZING OF PUNJAB-2 ROOSTERS SEMEN DILUTED WITH TRIS COCONUT WATER EXTENDER	Balogun A. S[12]., Narang. R[2].,Cheema Ranjna S[3],Dube P.P[2].,Shantikant D[2]., Keashap N[2].	84
21.	COMPARATIVE EFFECTS OF TRIS EGG-YOLK ORANGE JUICE EXTENDER ON HEAVY AND LIGHT STRAIN COCKS SEMEN DILUTED AT DIFFERENT RATE	Balogun, A.S, Shobanke, I.A, Akinosun, A.A, Oluwemimo, B.Aand Bello I.I	89
22.	FERTILITY AND DURATION OF FERTILE PERIOD IN BROILER BREEDER HENS INSEMINATED WITH VARIED SEMEN DOSES	Bolarinwa, A. O., Adebisi, K. A and Ewuola E. O.	93
23.	EFFECTS OF SUPPLEMENTAL BIOTIN ON YOLK, ALBUMEN AND EXTERNAL QUALITY PARAMETERS OF NOILER HEN EGGS	*S.B Atsen., Y.P Mancha., D.J.U Kalla	98
24.	EFFECTS OF NOILER HEN STRAINS ON YOLK, ALBUMEN AND EXTERNAL EGG QUALITY PARAMETERS	*S.B Atsen., Y.P Mancha., D.J.U Kalla	102
25.	UNILATERAL TESTICULAR DEGENERATION IN DOGS ADVERSELY AFFECTS SPERMATOZOA CHARACTERISTICS IN THE TESTIS AND EPIDIDYMIS	[1*]Chike F. Oguejiofor, [1]Kenneth O. Anya, [2]Clifford N. Abiaezute, [1]Nnaemeka K. Ogbanya	105
26.	BREED AND SEX INFLUENCE ON BODY CONDITION SCORE (BCS) OF SHEEP	Dafur, B. S[*].,Mbap, S. T., Ibrahim, T[+]. and Mancha, Y. P[+]	109
27.	HAEMOGLOBIN GENOTYPE OF SOME NIGERIAN SHEEP	Dafur, B. S[*].,Mbap, S. T., Ibrahim, T[+]. , Mancha, Y. P[+]andOkoh, J. J[#].	113
28.	INFLUENCE OF PERIOD EGG PRODUCTION PERFORMANCE OF NOILER CHICKENS	[1]Dogara, M. U., [1]Kalla, D. J. U., [1]Mancha, Y. P.	117
29.	AGE BASED CLASSIFICATION OF MORPHOMETRIC TRAITS OF DIFFERENT NIGERIA GOAT BREEDS	P.F. Abolusoro[*1].,A.J. Shoyombo[2],O.O. Alabi[2], J. Izebere[2], R.A	121

		Animashahun[2], S.O Olawoye[2] H. Yakubu[3], A. A Musa[4] and M.Wheto[5]	
30.	INFLUENCE OF ROAD TRANSPORT STRESS ON CATTLE HEART RATE AND BEEF QUALITY: A REVIEW	*Ebule K., D.J.U Kalla., Mai H.M., Y.P Mancha., Igila T.T	124
31.	EFFECTS OF TOMATO LYCOPENE ON SEMEN CHARACTERISTICS AND LIBIDO OF RABBIT BUCKS	*Ebule K., D.J.U Kalla., Y.P Mancha	128
32.	EXTRACTION OF TOMATO LYCOPENE AND ITS EFFECTS ON ELECTROLYTE BALANCE, KIDNEY AND LIVER FUNCTION OF RABBIT BUCKS	*Ebule K., D.J.U Kalla., Y.P Mancha	132
33.	EFFECT OF STORAGE AND SPECIES ON THE PERCENTAGE YOLK INDEX AND HAUGH UNIT OF VARIOUS POULTRY SPECIES	* Ezeoke F. C., & ** N. J Okeudo	136
34.	GROWTH PERFORMANCE AND GHRELIN GENOTYPES OF THREE YORUBA ECOTYPE CHICKEN STRAINS	Bolarinwa M.O.[1] , Adeyemo, G.O., Awodele O.A.[1] and Popoola M.A.[1]	140
35.	A STUDY ON SOME MORPHOMETRIC TRAITS OF RED SOKOTO AND SAHEL GOATS IN MAIGATARI LOCAL GOVERNMENT AREA OF JIGAWA STATE	Adamu, H., Ma'aruf, B. S., Shuaibu, A. and Umar, H. A.	144
36.	EFFECTS OF SEX ON HAEMATOLOGICAL VALUES, BLOOD CHEMISTRY AND CARCASS CHARACTERISTICS OF NOILER CHICKEN	*Ibrahim M., Y.P Mancha., D.J.U Kalla	151
37.	INFLUENCE OF TEASER HENS ON SASSO SEMEN COLLECTION, QUALITY AND SPERMATOZOA CHARACTERISTICS	Idahor K.O.	156
38.	INFLUENCE OF MILKING HYGIENE ON PREVALENCE OF MASTITIS IN DROMEDARY CAMEL (*Camelus dromedarius*) IN AZARE, BAUCHI STATE, NIGERIA	Idi, Y1; Kalla, D J U1; Sanusi, M1	160
39.	REVIEW OF CANDIDATE GENES TOWARDS SELECTIVE BREEDING AGAINST SOME MAJOR DISEASES AFFECTING CATTLE, SHEEP AND GOATS IN NIGERIA	[1]Iyiola-Tunji, A.O., [2]John, P.A. and [3]Galadima, M.A.	165
40.	HAEMOGLOBIN POLYMORPHISM OF GOATS IN SOUTHERN KADUNA	*[1]Yayi, J., **Barje, P.P., *Makama, R.S.	170
41.	CLASSIFICATION OF DONKEY STRAINS IN NORTHWESTERN NIGERIA THROUGH EUCLIDEAN DISTANCE MEASUREMENTS	[1]John, P.A, [2]Iyiola-Tunji, A.O., [3]Millam, J.J., [3]Abbaya, H.Y., [4]Iriso, B.V. and [1]Bello, S.S.	174
42.	EFFECTS OF SODIUM BICARBONATE SALT AND TURMERIC POWDER ON PERFORMANCE AND HAEMATOLOGICAL PARAMETERS OF ISA BROWN HENS	* Hirdima L.D., Y.P Mancha., D.J.U Kalla	178
43.	EFFECTS OF SODIUM BICARBONATE SALT AND TURMERIC POWDER ON INTERNAL EGG QUALITY AND BODY PARAMETER MEASUREMENTS OF ISA BROWN HENS	* Hirdima L.D., Y.P Mancha., D.J.U Kalla	182
44.	EFFECTS OF SODIUM BICARBONATE SALT AND TURMERIC POWDER ON EXTERNAL EGG QUALITY OF ISA BROWN HENS	* Hirdima L.D., Y.P Mancha., D.J.U Kalla	186

45.	HERITABILITY ESTIMATE OF BIRTH WEIGHT IN GUINEA PIG (*Cavia porcellus*)	Maigado, A. I., Ma'aruf, B. S., Shuaibu, A. & Ahmadi, B.	189
46.	EGG QUALITY CHARACTERISTICS OF NOILER STRAIN COMPARED TO TWO OTHER COMMERCIAL STRAINS OF LAYERS	Mosobalaje, M. A., Tiamiyu, J. O. and Amuda, S. K.	193
47.	AGES AND BODY WEIGHTS AT PUBERTY OF FOUR STRAINS OF TURKEYS REARED IN NIGERIA	C. C. Nwoga, N. S. Machebe, H. M. N. Foleng and S. O. C. Ugwu	197
48.	EGG QUALITY OF LOCAL FEMALE TURKEYS ADMINISTERED AQUEOUS *MORINGA OLERIFERA* LEAF AND SEED EXTRACTS	Ogbu, O.C.	201
49.	GENETIC DIVERSITY OF SELECTED CHICKEN BREEDS IN NIGERIA, SEGREGATING AT THE CHICKEN GROWTH HORMONE GENE LOCUS	Ojimah, C.O., Adigun, U. O., Egena, S.S.A., Usman, A. and Otu, B.O.	207
50.	BENEFITS OF BIOTECHNOLOGY FOR IMPROVED LIVESTOCK PRODUCTION IN NIGERIA	Ojo, O.A and Buba, W.	212
51.	PREVALENT BACTERIA ISOLATED FROM BOAR SEMEN EXTENDED WITH THE INCLUSION OF MORINGA LEAF EXTRACT (MLE) IN BELTSVILLE THAWING SOLUTION	*Omodewu, I. A., Olorungbohunmi, T., and Boladuro B. A.	216
52.	ESTIMATION OF HETEROSIS AND HERITABILITY OF BODY WEIGHT IN PROGENIES OF CROSSES BETWEEN TWO BREEDS OF RABBITS	Onodugo, M.O., Ndofo-foleng, H.M., Udeh, F.U. and Nwoga, C.C.	221
53.	SOME PHENOTYPIC CHARACTERISTICS AND BREEDING METHODS OF EXOTIC BREEDS OF PIGEON IN BAUCHI METROPOLIS, BAUCHI STATE, NIGERIA	Onwuneme, P. C1., Abdu, I1., Ibrahim, T1 & Shuaibu, A2	225
54.	ANTIOXIDATIVE EFFECT OF WATERMELON (*Citrullus lanatttus)* JUICE ON MORPHOLOGY OF EXTENDED BOAR SEMEN	Oyeniran J.O[*], Mohammed A[*], Nuhu S.H[*],Yaro S.S[*], Sani A[*], SokunbiO.A[x]Arire E.O[+]	230
55.	SEMEN CHARACTERISTICS AND FERTILITY OF THREE STRAINS OF NOILER COCKS	*S Amur., D.J.U Kalla Y.P Mancha.	234
56.	EFFECTS OF STRAIN ON GROSS TESTES MORPHOLOGY OF THREE STRAINS OF NOILER COCKS	*S Amur., D.J.U Kalla., Y.P Mancha	238
57.	EFFECT OF SEASON ON REPRODUCTIVE AND GROWTH PERFORMANCE OF WEANING NON DISCRIPT RABBIT	Sabuwa, M. A., Gambo, D., Baba, M. K., [+]Mundi, I. and Shuaibu, S.	241
58.	LIVE WEIGHT, SERUM BIOCHEMICAL INDICES AND HORMONAL PROFILES OF YEARLING MUSCOVY DRAKES (*CAIRINA MOSCHATA*) IN MAIDUGURI, BORNO STATE, NIGERIA	*Saleh, B., Iliyasu, S.H. & Zoaka, E. M.	246
59.	EFFECT OF CRYSTALLINE PROGESTERONE LEVELS ON OVARIAN CHANGES OF LOHMANN BROWN HENS	Salisu N[1], Nasir M[2], Hassan A.M[2], Khaleel A.G[2], Ashiru. RM[2], Zango M.H[1], Sabo A.A[3], Haladu S[4], MadakiS[2], Abdullahi A.Y[2], Mu'az J[5], Aliyu A.M[6]	250

60.	BODY WEIGHT AND REPRODUCTIVE PERFORMANCE OF FOUR GENOTYPES OF RABBITS RAISED IN HUMID TROPICS	*Sam, I. M., Essien, C. A, and Edet, B. M.	255
61.	EFFECT OF FLOCK AGE ON FERTILITY AND HATCHABILITY TRAITS OF SHIKABROWN® CHICKENS	Suleiman S., W.A. Hassan and A.A. Kwaido	261
62.	GENETIC DIVERSITY AT TLR7 GENE IN NIGERIAN INDIGENOUS CHICKENS AND ISA BROWN COMMERCIAL LAYER CHICKEN	[1]Ukwu, H. O., *Ibe, S. N., *Nwachukwu, E. N. and +Imumorin, I. G., [1]Audu, M. O.	266
63.	HYBRIDIZATION BETWEEN *CLARIAS GARIEPINUS* (BURCHELL 1822) AND *HETEROBRANCHUS BIDORSALIS* (GEOFFROY SAINT HILAIRE, 1809)	Wasiu Adekunle Olaniyi a* & Ofelia Galman Omitogun b	270
64.	GENETIC VARIABILITY OF GRASSCUTTER (*Thyronymus swinderianus L) IN IMO STATE* USING RANDOM AMPLIFIED POLYMORPHIC DNA (RAPD) MARKERS	Ahamba S. I., U. E. Ogundu & C. U. Ekugba	274
65.	EFFECT OF HEAT STRESS ON MILK YIELD AND MILK COMPOSITION TRAITS OF HOLSTEIN-FRIESIAN COWS IN KANO STATE	[1]Garba, M.S., [1]Adedibu, I.I., [1]Kabir, M. and [1]Agboola, L.O.,	278
66.	EFFECT OF ALOE VERA GEL ON SEMEN PRODUCTION AND QUALITY CHARACTERISTICS OF NOILER COCKS	[1]Nuhu, S. H., [1]Oyeniran J. O., [2]Kalla, D. J. U., [3]Saleh, B. [1]Mohammed, A., [1]Yaro, S. S. and [1]Sani, A.	283
67.	EFFECT OF AQUEOUS ADMINISTRATION OF *MORINGA OLERIFERA* LEAF AND SEED EXTRACTS ON THE GROWTH PHYSIOLOGY OF LOCAL MALE TURKEYS	Ogbu, O.C.	287
68.	COMPARATIVE ANALYSIS OF EGG QUALITY PARAMETERS OF GUINEA FOWL AND LOCAL CHICKENS IN BENUE AND TARABA STATES	[1*]Olusiyi, J. A., [2]Igila, T. T, [3]Yusuf, H. B., [2]Jatutu, S. S and [2]Ebule, K	293
69.	FERTILIZING ABILITY OF BOAR SEMEN EXTENDED WITH GARLIC (*Allium sativum* L.) EXTRACTS	Sokunbi, O.A, *Alaba, O., Ogunwumiju, B. and Eboh, S.	298
70.	THE EFFECT OF AGE AND EGG SIZE OF JAPANESE QUAILS ON FERTILITY AND HATCHABILITY	S.O. AJIDE[1*], G.S. BAWA[2], T.S. OLUGBEMI[2], D.J.U. KALLA[3], J.O. MAKINDE[4] AND E.S. INAPE[1]	302
71.	BIOCHEMISTRY, DIFFERENTIAL COUNT AND LIVER FUNCTION PROFILE OF BROILER CHICKENS SERVED DIETARY INCLUSION OF PROBIOTICS (*Saccharomyces cerevisiae*) AND ENZYME (BIO-ENZYME)	F.U. Udeh, C.O. Osita, M.O. Onodugo, V.C.Udeh and P. Chukwudi	306
72.	EFFECT OF DURATION OF STORAGE ON EGG QUALITY	*Adeoye, A.A., **Udoh, J.E., ***Oladepo, A.D.,and ****Ojajuni, J.B	311
73.	WEIGHT GAINS OF FRIESIAN X BUNAJI CALVES AS AFFECTED BY FEED GRADE SELENIUM AND	*[1]Achi, N.P., [1]Barje, P.P. and [2]Achi, J.N	315

	VITAMIN E SUPPLEMENTATION		
74.	PREDICTION OF BODY WEIGHT OF TWO STRAINS OF LAYERPULLETS USING MORPHOMETRIC TRAITS	M.N. Sabo, J. Sani & R. A. Hamzat	318
75.	EFFECTS OF SEASON, SEX AND AGE ON BODY WEIGHT, PACKED CELL VOLUME, HAEMOGOLOBIN AND FEACAL EGG COUNT IN INDEGENOUS BREEDS OF SHEEP IN GOMBE STATE	[1]Boyi, B., [2]Mbap, S. T., [2]Mancha, Y. P., [1]Amaza, I. and [1]Maidala, A.	322
76.	CONTRACTION RATE AND RE-EPITHELIALIZATION TIME OF FULL THICKNESS EXCISION WOUNDS OF RATS TREATED WITH DIFFERENT CONCENTRATIONS OF HYDROGEN PEROXIDE	Udegbunam S.O.[1], Ogbobe S[1], Okereke H. N[1*], Udegbunam R.I[1], Enejere A.S.[1], Ezeobialu T.H.[1]	327
77.	EFFECT OF VITAMIN E FORTIFIED DIET ON SEMEN QUALITY AND BODY WEIGHT OF GUINEA COCKS	Elile, C.F* Ugwu, S.O.C**and Ogbonna, O.C**	331
78.	INFLUENCE OF STRAIN ON HAEMATOLOGICAL VALUES, BLOOD CHEMISTRY AND CARCASS CHARACTERISTICS OF THREE STRAINS OF NOILER CHICKEN	*Ibrahim M., Y.P Mancha and D.J.U Kalla	336
79.	EFFECTS OF VARYING DIETARY ENERGY AND PROTEIN ON EGG QUALITY PARAMETERS OF QUAILS	*Njam, R.L., **Kalla,D.J.U., **Sanusi,M.	341
80.	ESTIMATION OF GENETIC PARAMETERS IN UNN CATTLE POPULATION	Ohagenyi, I.J., and Udeh, V. C.	345
81.	EFFECTS OF AGE ON EGG NUMBER AND WEIGHT IN CHICKENS	*Olanihun A.O[1].,D.J.U Kalla[2]., Igila T.T[2]., Ebule K[2]	349
82.	SCRUTINIZING COURTSHIP ETHOGRAM OF RED SOKOTO BUCK EXPOSED TO TWO OESTRUS NULLIPAROUS DOES	[*]Gaddafi S., [*]Usman H.U., [*]Aliyu, A.M and [**]Abdulrashid, M.	352
83.	HAEMOGLOBIN AND MORPHOMETRIC POLYMORPHISM OF FOUR STRAINS OF DONKEY (*Equus asinus L.*) IN GAMAWA LOCAL GOVERNMENT AREA, BAUCHI STATE, NIGERIA	Anene, M.G.; Mancha, Y.P.; Ibrahim, T. & Samaila, L. M.	357
84.	PIGEON (COLUMBIA LIVIA VAR DOMESTICA) BIODIVERSITY WITHIN BAUCHI METROPOLIS	Kalla, D. J. U. Lohfa, M. M. Sale ,B., Gure, M.M. Idi,Y.	364

ANIMAL HEALTH AND WELFARE

S/N	TITLE	AUTHORS	PAGE
85.	MICROBIOLOGICAL EVALUATION OF FIVE COMMERCIAL BROILER SUPER STARTER FEEDS IN JOS NORTH LGA OF PLATEAU STATE	[1]Idachaba, C.U., [1]Agada, A. I., [2]Wetkum, F. and [3]Abdullahi, I.	368
86.	DOSE RESPONSE AND AMELIORATIVE EFFECTS OF RESVERATROL ON TRYPANOSOMOSIS-INDUCED REPRODUCTIVE TOXICITY IN DIMINAZENE ACETURATE TREATED *TRYPANOSOMA BRUCEI* INFECTED MALE DOGS	[1]Rita I. Odo, [1]Isaac U. Asuzu, [2]Chuka Ezema	372
87.	AN ASSESMENT OF HIGH SLAUGHTER OF SMALL RUMINANT AT EARLY SET OF RAINING SEASON IN KIBIYA LOCAL GOVERNMENT AREA, KANO STATE	[*]Abdullahi, A.Y. [±], [*]Zango, M.H., [*]Madaki S., [*]Nasir M., [#]Dambatta, M.A., [∞]Bala, A.G., [€]Ghude, M.I., [+]Abubakar A., *Abubakar S.M., [*]Murtala S.K.	378

260.	EFFECT OF TUMERIC (CURCUMA LONGA) AS FEED ADDITIVES ON HAEMATOLOGICAL PARAMETERS OF BROILER CHICKENS	Daramola, O.T[*], Oloruntola, O.D [+], Jimoh, O.A[*] and Ayodele, S.O*	1169

261.	HAEMATOLOGICAL AND SERUM BIOCHEMICAL INDICES OF BROILER STARTER BIRDS FED DIET SUPPLEMENTED WITH NIACIN AND YEAST	*. Edeh, H. O, Ogwuegbu, M.C, Ani, A.O and Okonwor, C.S	1173
262.	EFFECT OF DIFFERENT INCLUSION LEVELS OF GINGER (Zingiber officinale Roscoe) MEAL ON THE PERFORMANCE OF STARTER BROILER CHICKENS	*Egenuka, F. C., Obi, H. N., Achi, J. C., Okere, P.C., Kadurumba, O. E. and Iwuji, T. C.	1177
263.	GROWTH PERFORMANCE AND FEED COST BENEFITS OF BROILER CHICKENS FED GRADED LEVELS OF BRIMSTONE (Morindalucida Benth.) LEAF POWDER AS DIETARY PHYTOGENIC ADDITIVE	*Fasasi, M.O, *Bamgbose, A. M., *Oso, A.O., *Adelusi, O.O, **Oke, O.E, ***Olayemi, W.A, and *Ogunsola, I. A.	1181
264.	UTILIZATION OF GRADED LEVELS OF PEARL MILLET AS DIETARY ENERGY SOURCE BY JAPANESE QUAILS	S.I. Garba[1], O.V. Adelowo[1], M. Abubakar[2], A.S. Muhammad[2] and A.T. Bello[3]	1185
265.	PERFORMANCE OF BROILER STARTER BIRDS FED SORGHUM WITH DIFFERENT ENERGY LEVELS AS REPLACEMENT FOR MAIZE	H. B. Usman, M. Anande and M. N. Sabo	1189
266.	PERFORMANCE OF WEANER RABBITS FED SELECTED FORAGES AS SUPPLEMENT	Ibrahim, H. and Mohammed, U.	1193
267.	EFFECTS OF REPLACING WHEAT OFFAL WITH COWPEA TESTA ON THE PERFORMANCE AND ECONOMIC ANALYSIS OF BROILER CHICKENS	Igwebuike, J. U[1*]., Garnvwa, I[2]. Medugu, C. I[1]. and Augustine, C[2].	1198
268.	PERFORMANCE AND NUTRIENT DIGESTIBILITY OF BROILER CHICKENS FED FERMENTED SHEA BUTTER CAKE BASED DIETS WITH SUPPLEMENTAL NUTRIZYME®(COCKTAIL OF ENYZMES+PROBIOTICS)	*Aguihe P.C, +Ilaboya I.I and #Ukom, S. K.	1202
269.	GROWTH PERFORMANCE AND CARCASS CHARACTERISTICS OF WEANER RABBITS FED DIETARY LEVELS OF PARKIA (Parkia biglobosa) PULP MEAL	Imam, D. N., *Bello, K. M., Adamu, N and Egbo, M. L.	1206
270.	GROWTH PERFORMANCE AND COST BENEFITS OF BROILER CHICKENS FED DIETS CONTAINING GARLIC AND GINGER POWDER AS ADDITIVES	Irekhore O. T.*, Alli O. O.+, Bello K. O.#, Oluwalana E. O. A.*	1210
271.	EFFECT OF DIFFERENTLY PROCESSED MANGO SEED KERNEL MEAL ON PERFORMANCE OF BROILER CHICKENS	Jatutu, S. S., Bello, K. M., Kalla, D. J. U	1214
272.	PERFORMANCE AND HAEMATOLOGICAL PARAMETERS OF LAYING HENS FED DIETS SUPPLEMENTED WITH SELENIUM AND VITAMIN E	Jemiseye, F. O., Ogunwole, O. A., Adedeji, B. S. and Mosuro, A. O.	1221
273.	HAEMATOLOGICAL RESPONSE OF BROILER CHICKENS FED GRADED LEVELS OF SWEET POTATO (Ipomoea batatas) MEAL	A. I. Jibril, *N. B. Rano	1225
274.	BIOCHEMICAL INDICES OF BROILER CHICKENS FED DIETS CONTAINING GINGER, GARLIC AND GARLIC-GINGER MIXTURE	John, U. E*. Onunkwo, D. N. and Udofia, S. M.	1229
275.	EFFECT OF DIFFERENT HEAT TREA TMENT OF BAOBAB (Adansonia digitata) SEED AS AN ALTERNATIVE PLANT PROTEIN SOURCE ON HAEMATOLOGICAL AND BLOOD CHEMISTRY OF LOCAL TURKEY	L. A. Saulawa, M. G. Garba, M. N. Sabo and A. Umar	1233
276.	EFFECTS OF CAGE LOCATION AND TIER LEVEL ON PERFORMANCE AND EGG QUALITY CHARACTERISTICS OF ISA BROWN HENS	[1]Lamidi, A.W., [1]Obi, C.C., [1]Ojelade, A.Y.P. and [2]Ayoola, A.A.A.	1236
277.	PERFORMANCE AND SERUM BIOCHEMISTRY OF BROILER CHICKEN FED GRADED LEVELS OF GARLIC (Alliumsativum) POWDERAT STARTERPHASE IN SOKOTO, NIGERIA	M. M. Mikailu*., Z. S. Jega*., A. M. Dalhatu*., K. M. Aljameel* and A. Z. Sanusi**	1243
278.	COMPARATIVE PERFORMANCE OF TWO STRAINS OF LAYER CHICKS FED HONEY AS REPLACEMENT	M. N. Sabo, M. Umar and L. A. Saulawa	1250

	OF ANTIBIOTICS		
279.	EFFECT OF SPLIT MEALING ON GROWTH PERFORMANCE OF PIGS	M.H. Ogunsipe, I. Ibidapo and O.A. Dada	1254
280.	HEMATOLOGICAL AND SERUM BIOCHEMICAL PARAMETERS OF JAPANESE QUAILS FED DIFFERENT ENERGY SOURCES IN SEMI ARID ENVIROMENT OF GASHUA, YOBE STATE	Maidala, A., lawan, A., Amaza, B.I., Sudik, S.D., Dunya, M.A., Adejumo, I.O., Makinde, O.J., Hanafi, S. and Bomoi, A.	1257
281.	EFFECT OF RED HOT PEPPER (Capsicum annum) ON PEROXIDE VALUE, FREE FATTY ACID AND THIOBARBITURIC ACID OF MEAT OF HUBBARD BROILER CHICKENS	Makinde, A.A.* Egena, S.S.A. and Otu, B.O	1261
282.	HAEMATO-BIOCHEMICAL RESPONSE OF GROWING RABBITS FED BOILED AFRICAN STAR APPLE (CHRYSOPHYLLUM ALBIDUM) KERNEL MEAL AS REPLACEMENT FOR MAIZE IN THE DIET	Makinde O.J[1,2]*., Aremu, A[2]., Alabi O.J.[2,4], Jiya E.Z[2]., Omotugba, S.K[3], Sikiru, A.B[2], Opoola E[4] and Ibikunle K.Y[5]	1265
283.	REPLACEMENT VALUE OF AFRICAN LOCUST BEAN (Parkia biglobosa) FRUIT PULP FOR MAIZE IN WEANER RABBITS DIET	Mohammed S[1*], Ijaiya A.T[2], Ayanwale B.A[2], and Kudu Y.S[2]	1270
284.	GROWTH PERFORMANCE, NUTRIENT DIGESTIBILITY AND CARCASS CHARACTERISTICS OF RABBITS FED VARYING LEVELS OF GROUNDNUT HAULM WITH CONCENTRATE	Mohammed, J.D., Adama, T.Z. and Tsado, D. N.	1274
285.	PERFORMANCE OF BROILER CHICKEN FED DIETS CONTAINING COWPEA MILLING WASTE AND PLANTAIN PEEL MEAL MIXTURE	*A. J. Mohammed, A. A. Malik and Y. S. Kudu	1279
286.	SOCIO-CULTURAL CHARACTERISTICS OF SMALLHOLDER PIG FARMERS AND THEIR FEED INGREDIENTS USE APPROACHES AT PERI-URBAN AND RURAL FARMING LOCATIONS IN IMO STATE, NIGERIA	P.C. Moses[1], I.C. Okoli[1], C.C. Achonwa[1], A.U.C. Ohanaka[1] and A.A. Omede[2]	1283
287.	PERFORMANCE AND COST BENEFIT OF FNISHER BROILERS FED PROCESSED SICKLE POD (Cassia tora) SEED MEAL AS REPLACEMENT FOR DIETARY FULL FAT SOYA BEAN	[1]Muhammad, B. A., [2]Kawu, Y. U., [3]Yusuf, S. Z.[4]Doma, U.D., [4]Abubakar, M. and [4]Bello, K.M.	1287
288.	EFFECT OF BOILING ON THE MICRO AND MACRO MINERAL COMPOSITION OF MORINGA (Moringa Oleifera) SEEDS	Musa J., Zakka G. C. and Kachong Y. K.	1293
289.	REPLACEMENT VALUE OF GROUNDNUT HUSK FOR MAIZE IN RABBITS DIETS	*N. Adamu, A. S. Aliyu, I. Sani, S. Adamu and N. A. Jama'a	1297
290.	GASTROINTESTINAL TRACT MORPHOMETRY AND VISCERAL ORGAN WEIGHTS OF GROWER RABBIT FED DRIED GINGER (Zingiberofficinale) ROOT MEAL	Ochefu, J., Emmanuel, B. and Onho, S. C.	1302
291.	GROWTH RESPONSE AND CARCASS CHARACTERISTICS OF BROILER CHICKEN SERVED WITH ETHANOLOIC Petiveria alliacae LEAF EXTRACT	Odetola, O.M., Adekanbi, A.O., Adetola, O.O., Akingbade, O.A and Ijadunola, T.I	1306
292.	DIETRY EFFECT OF SUBSTITUTING MIXED SAW DUST FOR WHEAT OFFAL ON GROWTH PERFORMANCE OF BROILER STARTER	Ogungbenro, S. D., Amusa, H. O., Adam, T. O and Bako, B. A	1310
293.	EFFECT OF FEEDING GRADED LEVELS OF ENZYME TREATED AND UNTREATED BAMBARA GROUNDNUT OFFAL ON DIGESTIBILITY COEFFICIENT OF BROILER CHICKENS FED MAIZE-SOYBEAN BASAL DIET	Ogwiji, O.,Tarhemba, F., Famave, M.T., Agishi, S.T. and Wayo, N. S.	1314
294.	ON FARM QUALITY EVALUATION OF FOUR COMMERCIAL PROTEINS CONCENTRATES USING BROWN EGG – TYPE LAYERS	*Ojebiyi O. O., Idowu A. O., Bakare, A. M. , Ogundokun, A. S., Hammed, M. B. and Adeyemo	1318
295.	COMPARATIVE EVALUATION OF THE GROWTH PERFORMANCE AND CARCASS CHARACTERISTICS OF WEANED RABBITS FED SELECTED FORAGE	Okon, E.E.,* Ayanwale, B.A., and Jiya, E.Z	1322

	LEAVES		
296.	PERFORMANCE AND HEMATOLOGICAL VALUES OF RABBITS FED GRADED LEVELS OF BOILED DELONIX REGIA SEED MEAL	Olaiya, O.D., Aliyu, I.P., Adelowo, O.V., Aka-Tanimo, H.A., Tiffi, A.B., Peter, A.L. and Showul, R.	1326
297.	EFFECT OF DIETARY MULTI-ENZYME COMPLEX AND FIBRE SOURCES ON PERFORMANCE AND NUTRIENT DIGESTIBILITY OF GROWING PIGS	*Omidiwura, B. R. O, Agboola, A. F, Oshai, B, I, Olomola, O. O and Iyayi, E. A.	1329
298.	GROWTH RESPONSE OF BROILER CHICKS FED FRIED COOKIES (CHINCHIN) WASTE MEAL AS REPLACEMENT FOR MAIZE	Onigemo M. A., Agbalaya K. K., Oso Y. A. A., Anjola A.O. J., Tijani L. A., Agunbiade M. A., Agbaye P. F., Osupe D. U., Lawal A. A., Adebayo G. B., Adetilewa O. D. and AbdulAzeez M. S.	1333
299.	DIETARY EFFECT OF MIXED SAW DUST AS A SUBSTITUTE FOR WHEAT OFFAL ON INTERNAL ORGANS OF GROWER RABBIT FED EXPERIMENTAL DIET	Oseni, T. A., Amusa, H. O., Ogungbenro, S. D and Amoo, T. A.	1337
300.	GROWTH PERFORMANCE AND HAEMATOLOGICAL INDICES OF WEANER RABBITS FED DIETS SUPPLEMENTED WITH SACCHAROMYCES CEREVISIAE	Osita, C. O., Ani, A.O., Udeh, F. U., Udeh, V. C., and Ezewuzie, V.	1340
301.	GROWTH PERFORMANCE OF CROSSBRED LOCAL (INDIGENOUS) CHICKENS FROM HATCH TO MATURITY	Rabiu A. K/bai	1344
302.	RESPONSE OF BROILER CHICKENS TO DIETARY LEVELS OF MAIZE OFFAL	Rabo, S. T., Doma U. D and Bello K. M	1348
303.	GROWTH PERFORMANCE, ORGANS, CARCASS CHARACTERISTICS AND MEAT QUALITY OF BROILER FED BITTER LEAF (Vernonia amygdalina) AND CATMINT (Nepeta racemosa) LEAF MEAL SUPPLEMENTS	*Rafiu T. A., Sagoniyi O., Adewale A. A. and Raheem N. O.	1353
304.	EVALUATION OF VARYING LEVELS OF SUNDRIED CASSAVA STARCH EXTRACT PULP ON SERUM ENZYMES OF BROILER STARTER	Raji, M.O., Akinosun, A.A., and Mosobalaje, M.A	1357
305.	HAEMATOLOGICAL AND BIOCHEMICAL PARAMETERS OF BROILER FINISHER FED GRADED LEVELS OF MAGGOT MEAL	S. U. Ilo[1], Ogbu, O. C.[2]	1360
306.	PERFORMANCE OF BROILER CHICKENS FED VARYING LEVELS OF LOCAL FISH MEAL AS REPLACEMENT FOR IMPORTED FISH MEAL	Sa'idu, I.* Yakubu, N. and Sharhudden, Y.	1364
307.	INFLUENCE OF CASTRATION AND DIFFERENT DIETS ON GROWTH PERFORMANCE AND NUTRIENT DIGESTIBILITY OF WEANER RABBITS	Saheed, S., Tsado,D. N., Tiamiyu, S. A., Habu, T., and Habu, T.	1370
308.	PROXIMATE COMPOSITION OF BRACHIARIA RUZIZIENSIS-MUCUNA PRURIENS MIXTURES AND RELATIVE FEED INTAKE OF GROWER RABBITS FED MIXTURE HAY WITH CONCENTRATE	Sani I.[1], Anyebe O. W.[1], Adamu, N.[1], Amodu, J. T.[2], Hassan, M. R. [3]and Tanko, R. J.[2]	1374
309.	PERFORMANCE OF BROILER CHICKEN FED SUN-DRIED PINEAPPLE (Ananas comosus) AND ORANGE (Citrus sinensis) PEELS WASTE BASED DIETS UNDER SINGLE PHASE FEEDING	* M. J Shaibu, A. Aremu and O.J Alabi	1377
310.	EFFECTS OF REPLACING MAIZE WITH PROCESSED MANGO SEED KERNEL MEAL ON PERFORMANCE, NUTRIENTS DIGESTIBILITY AND ECONOMIC OF PRODUCTION OF WEANER RABBITS	[1]Shuaibu, U. S., [1]Bello, K. M. [1]Mancha, Y. P. [1]Jatutu, S. S. [1]Shuaibu, B. and [2]Muazu, M. S.	1382
311.	PIG POPULATION AND DISTRIBUTION PATTERN IN IBADAN/IBARAPA AREA OF OYO STATE	Sosina, Adedayo Olalekan	1388
312.	GROWTH PERFORMANCE OF MALE GROWER RABBITS FED DIETS WITH IBURU OFFAL	Sudik, S. D., Bagudu, I. A., Maidala, A. andLawan, A.	1392

	REPLACING MAIZE AS ENERGY SOURCE		
313.	PERFORMANCE CHARACTERISTICS OF BOILER CHICKENS FED DIET CONTAINING DIFFERENT OIL TYPES	Tauhid, G.., Y.S. Kudu.., and B.A. Ayawale	1396
314.	EFFECT OF REPLACING WHEAT OFFAL WITH RICE BRAN ON CARCASS CHARACTERISTIC AND COST BENEFIT OF BROILER CHICKENS	1Usman, Y., 2Egbo, L.M., 2Abdulkarim, M.,2Doma, U.D.	1400
315.	CARCASS CHARACTERISTICS AND ECONOMIC BENEFITS OF USING SUPER SOSAT MILLET (Pennisetum glaucum) IN BROILER CHICKENS DIETS	Yakubu[1],N. ; U. D. Doma[2]; D. J. U. Kalla[2]; Saidu[1], I. and Ahmed[1], I. A.	1405
316.	UTILIZATION OF DIETARY LEVELS OF SUPER SOSAT MILLET (Pennisetum glaucum) BY BROILER CHICKENS	Yakubu[1],N., Doma[2],U. D., Kalla[2], D. J. U., Saidu[1], I. and Ahmed[1], I. A.	1412
317.	HAEMATOLOGICAL PROFILE OF WEANER RABBITS FED DIETS CONTAINING DRIED SCENT LEAF (*Ocimumgratissimum*) MEAL	[18]Yashim, S.M., [1]Ahmad, A., [2]Makama, R.S. and [3]Ephraim, F.Y.	1419
318.	GROWTH PERFORMANCE OF BROILER CHICKENS FED DIETS CONTAINING GRADED LEVELS OF BREWER'S DRIED GRAIN	* Yisa, A. G. and Piental, S. A.	1423
319.	EFFECTS OF REPLACING MILLET OFFAL WITH MAIZE MILLING RESIDUE ON THE PERFORMANCE OF BROILER STARTER CHICKS	*Yusuf S.Z.[1],Kawu Y.U.[2] Bah, U.J.[3] K. M. Bello[4] and Doma, U. D.[4]	1427
320.	GROWTH PERFORMANCE OF JAPANESE QUAILS (Coturnix coturnixjaponica) FED DIETS CONTAINING VARYING DIETARY LEVELS OF PROTEIN AND ENERGY	Zakari, A.[*] Alabi, O.J. and Aremu, A.	1432
321.	RESPONSE OF GROWER PIGS FED DIETS CONTAINING HIGH FIBRE SUPPLEMENTED WITH COCKTAIL OF ENZYMES	Adesehinwa* A. O. K., Etop S. C.[1], Ajayi E.[1], Ogunyemi D. J.[2],Boladuro B. A., Sorunke A. O. and Abiola J. O.[3]	1437
322.	PROXIMATE, MINERAL AND PHYTOCHEMICAL COMPOSITION OF SOME SELECTED FEED INGREDIENTS IN SEMI-ARID REGION OF NORTH EASTERN NIGERIA	Amaza, I. B., Boyi, B., Maidala, A., Adejumo I. O., Garba, A. M.	1441
323.	EVALUATION OF THE EFFICACY OF CHOLINE CHLORIDE AS A FEED ADDITIVE IN BROILERS	C.J. ARONU, C.N. UJU, P.C. UGWU, A. MORGAN, G. SUNDAY, C. AHAMEFULA, O.W. IDIGOH & C. EZEMA.	1446
324.	CARCASS CHARACTERISTICS OF BROILER CHICKENS FED ACHA HUSK AS REPLACEMENT FOR WHEAT OFFAL	Chomo, F.K., Kalla, D. J. U., Igila, T. T. and Jatutu, S. S	1450
325.	PERFORMANCE OF GROWING COTURNIX QUAILS (COTURNIX COTURNIX JAPONICA) FED DIFFERENT WATER SOURCES	J.A. EDACHE[1], C.D. TULEUN[2], A.G. YISA[1], U.R. MUDUUDTAI[3], D.O. EDACHE[2], BONGTUR, G.E.[1.1]	1453
326.	EFFECT OF PROCESSING OF LABLAB BEANS AT VARRYING DURATION OF TIMES ON THEIR PROXIMATE COMPOSITION AND ANTI-NUTRITIONAL FACTORS CONTENT	[1]Igila, T. T[*]., [4]Yaakugh, I.D.I [2]Olusiyi, J. A., [3]Yusuf, H. B., [1]Ebule K	1457
327.	COMPARATIVE EVALUATION OF SELF-FORMULATED AND THREE COMMERCIAL DIETS ON THE GROWTH PERFORMANCE OF BROILER STARTER	[1]Adamu, M. O., [1]Bello, K. M., and [2]Muazu, M. S.	1462
328.	RESPONSE OF STARTER BROILER BIRDS FED DIFFERENT COMMERCIAL FEED	Ohagenyi, I.J., Onah, C.S. and Udeh, V. C.	1466
329.	NUTRIENTS AND PHYTOCHEMICAL COMPOSITION OF SOME NON-CONVENTIONAL FEED SUPPLEMENTS	Haladu S[1]., Akande T.O. [2], Nasir M[3]. and Oguntade M.O.[1]	1470

330.	GROWTH PERFORMANCE, DIETARY SELECTIVITY AND NUTRIENTS PROFILE OF BROILER CHICKENS ON A CAFETERIA FEEDING REGIME	*AJETUNMOBI, A.W.; + OLOGHOBO, A.D. AND ++EGUAOJE, S.A.	1474
331.	EFFECTS OF VARYING LEVELS OF SUN DRIED YAM PEEL MEAL ON THE GROWTH PERFORMANCE, CARCASS CHARACTERISTICS AND ECONOMIC EFFICIENCY OF WEANER RABBITS	Nuhu, T[1]., Bello, K. M[1]., I. M. Hassan[2], Husa, H[3].	1479
332.	NUTRIENT DIGESTIBILITY AND CARCASS CHARACTERISTICS OF WEANER RABBITS FED DRIED CABBAGE LEAF MEAL	Igila, T. T., Bello, K.M., and Kalla, D. J. U	1484
333.	UTILIZATION OF GRADED LEVELS OF DRIED CABBAGE LEAVES BY WEANER RABBITS	Igila, T. T., Bello, K.M., Kalla, D. J. U.	1488
334.	EFFECTS OF VARYING LEVELS OF MORINGA (Moringa oleifera) LEAF MEAL ON THE GROWTH PERFORMANCE AND CARCASS CHARACTERISTICS OF WEANER RABBITS	D.U. Mmadu*, M.M. Abubakar**, D,J,U Kalla** U.D. Doma** and Agishi S.T***	1493
335.	PROXIMATE COMPOSITION OF RED FINGER MILLET VARIETY	Bot, M.H., **Bawa, G.S., **Omage, J.J. and **Onimisi, P.A.	1497
336.	REPLACEMENT VALUE OF AFRICAN LOCUST BEAN (Parkia biglobosa) FRUIT PULP FOR MAIZE IN WEANER RABBITS DIET	Mohammed S[1*], Ijaiya A.T[2], Ayanwale B.A[2], and Kudu Y.S[2]	1501
337.	HAEMATOLOGICAL PROFILE AND BIOCHEMICAL RESPONSE OF WEANER RABBITS FED GRADED LEVELS OF AFRICAN STAR APPLE CHRYSOPHYLLUM ALBIDUM SEED MEAL	AMAO, E. A., ADEOTI, T. M., OLAOGUN, Y. A. and OLADOKUN, A. A.	1505
338.	EFFECT OF SUPPLEMENTAL LEVELS OF LEMON GRASS LEAF MEAL ON THE GROWTH PERFORMANCE AND HAEMATOLOGICAL CHARACTERISTICS OF STARTER BROILER BIRDS (A CASE STUDY IN ISHIAGU, IVO, L.G.A OF EBONYI STATE)	[1]Olabode, A.D. and [2]Okelola, O.E.	1511
339.	PERFORMANCE AND HAEMATOLOGICAL PARAMETERS OF LAYING HENS FED DIETS SUPPLEMENTED WITH SELENIUM AND VITAMIN E	Jemiseye, F. O., Ogunwole, O. A., Adedeji, B. S. and Mosuro, A. O.	1515
340.	MONOGASTRIC NUTRITION SECTION GROWTH PERFORMANCE AND NUTRIENT DIGESTIBILITY OF WEANER PIGS FED CEREAL OFFALS IN DIETS	*Wafar, R.J., Tarimbuka, L.I and Sini, T.	1519
341.	NUTRIENT DIGESTIBILITY OF CROSSBRED WEANED PIGS FED SUNDRIED CASSAVA STARCH EXTRACT PULP	Ogunbode, A.A., Adams, T.O and Oyeboade, A.A	1523
342.	EVALUATION OF SUBSTITUTION LEVELS OF UNRIPE PLANTAIN PEEL (*Musa paradisca*) MEAL ON THE PERFORMANCE OF GROWING JAPANESE QUAILS (COTURNIX).	*E.O. Ahaotu[1], and C.N. Nze	1527
343.	EFFECT OF FEEDING GRADED LEVELS OF ENZYME (NATUZYME®) TREATED AND UNTREATED BAMBARA GROUNDNUT OFFALS ON GROWTH PERFORMANCE AND CARCASS CHARACTERISTICS OF FINISHER BROILER CHICKENS	Tarhemba,F., Ogwiji,O., Famave,M.T., Agishi,S.T.&, Wayo,N.S.	1531
344.	ASSESSING THE CHANGES IN LIPID PROFILE OF BROILER FINISHER CHICKEN FED DIETS CONTAINING PROCESSED BALANITE AEGYPTIACA FRUIT MEAL	*Abdulahi I., +Omage J. J., *Abeke F. O., +Onimisi, P. A. +Idachaba, C.U., ++Anoh K. U., *Ahmad, S.A.,	1535
345.	HAEMATOLOGICAL AND CARCASS CHARACTERISTICS OF BROILER CHICKENS FED DIFFERENTLY PROCESSED MANGO SEED KERNEL MEAL	Jatutu, S. S., Bello, K. M., Kalla, D. J. U	1539

346.	PERFORMANCE OF BROILER STARTER BIRDS FED SORGHUM WITH DIFFERENT ENERGY LEVELS AS REPLACEMENT FOR MAIZE	H. B. USMAN, M. ANANDE AND M. N. SABO	1546
347.	GROWTH PERFORMANCE, NUTRIENT DIGESTIBILITY AND CARCASS CHARACTERISTICS OF RABBITS FED VARYING LEVELS OF GROUNDNUT HAULM WITH CONCENTRATE	MOHAMMED, J.D., ADAMA, T.Z. AND TSADO, D. N.	1550
348.	EFFECTS OF FEEDING GRADED LEVELS OF BAOBAB (Adansonia digitata) PULP SEED MEAL ON APPARENT NUTRIENTS DIGESTIBILITY AND CARCASS CHARACTERISTIC OF BROILER CHICKENS	*Lawan, A[1]., Olugbemi, T. S.[2]., Duru, S.[2]., Onimisi, P.A.[2] and Maidala, A[1]., Abdullahi U[1]., Abdullahi A.M[1].	1555
349.	PRODUCTIVE PERFORMANCE OF LAYERS FED KAURA SORGHUM REPLACING MAIZE WITH FULL-FAT SOYA BEAN DIETS	H. Jamilu*[1], U. D. Doma [2], M. L. Egbo[2], M. Abubakar[2], D. Zahraddeen[3], N. A. Jama'a[2] and H. S. Buhari[4],	1564
350.	CARCASS TRAITS AND RELATIVE ORGAN WEIGHTS OF BROILER FINISHER CHICKEN FED COMMERCIAL FEED SUPPLEMENTED WITH VARYING LEVELS OF BLACK SEED (Nigella sativa L.) CAKE	Olayeni, T.B., Adedoja, M.A. and Salaudeen, M.	1568
351.	PERFORMANCE AND CARCASS CHARACTERISTICS OF GROWER RABBITS FED GRADED LEVELS OF CASSAVA LEAF (Manihot esculenta) MEAL	Lalabe, B. C., Wafar, R. J., Mary, S. I., Agyo, A, and Odunze, I. N.	1574
352.	EFFECTS OF RUMEN EPITHELIAL SCRAPINGS INCLUSION IN DIETS FOR GROWER RABBITS	Adedoyin A. A.	1578
353.	EFFECT OF DIFFERENT HEAT TREA TMENT OF BAOBAB (Adansonia digitata) SEED AS AN ALTERNATIVE PLANT PROTEIN SOURCE ON HAEMATOLOGICAL AND BLOOD CHEMISTRY OF LOCAL TURKEY	L. A. SAULAWA, M. G. GARBA, M. N. SABO AND A. UMAR	1582
354.	GROWTH PERFORMANCE OF JAPANESE QUAILS (Coturnix coturnix japonica) FED DIETS CONTAINING VARYING DIETARY LEVELS OF PROTEIN AND ENERGY	Zakari, A.* Alabi, O.J. and Aremu, A.	1586
355.	MONETARY COST ANALYSIS OF REPLACEMENT VALUE OF ACHA (Digitaria exilis Staph) FOR MAIZE IN BROILER CHICKENS DIETS	Wumnokol, D.P, Latu, M. Y and Magaji, S.T	1591
356.	PERFORMANCE OF BROILER CHICKENS FED RED SORGHUM VARIETY REPLACING MAIZE AT THE STARTER PHASE	H. S. Buhari*[1], A. S. Muhammad[2], A. S. Naibi[2], N. A. Jama'a[2]and H. Jamilu[3],	1596
357.	BIOCHEMICAL AND HAEMATOLOGICAL INDICES OF WEANER RABBITS FED SORGHUM BREWERS DRIED GRAIN (SBDG)	*Ayandiran, S.K[1]., Adedokun, M.A[1]., Odeyinka, S.M[2]., Adekunle, I[1].,Kazeem, A.A[1]. and Okunlola, N.A[1].	1600
358.	CARCASS AND GUT CHARACTERISTICS OF BROILER BIRDS FED SORGHUM AS A REPLACEMENT FOR MAIZE	ZAGI, S. P., BELLO A. MUSA and AJIGHJIGH, D. T	1604

PASTURE AND RANGE MANAGEMENT

S/N	TITLE	AUTHORS	PAGE
359.	EFFECT OF NITROGEN LEVELS ON YIELD AND QUALITY OF *PENNISETUM PEDIACELLATUM* FORAGE IN YOBE STATE, NIGERIA	1Abdullahi, U., 2Amodu, J. T., 3Hassan, M. R., 1Maidala, A., 1Lawan, A., 1Abdullahi, A. M., 2Ishiaku, Y. M., 2Ahmed, S. A., 4Munza, B. M. & 1Raymond, B. J.	1605
360.	CHEMICAL COMPOSITION, *IN VITRO* TOTAL GAS AND METHANE PRODUCTION OF CONCENTRATE DIETS CONTAINING *Gliricidiasepium*	*O. O. Adelusi, M. T. Balogun, E. E. Igonor, D. E. Olaniyan, K. M. Stephen and A. O. Oni	1609
361.	EFFECT OF CINNAMON (*Cinamonum cassia*) POWDER ON *IN VITRO* METHANE PRODUCTION AND FERMENTATION OF MAIZE STOVER-BASED SUBSTRATE	R. Y. Aderinboye, T. A. Salami, O. O. Adelusi, K. O. Adebayo, R. M. Akinbode and C. F. I. Onwuka	1613
362.	PROXIMATE AND MINERAL COMPOSITION SCREENINGS OF *Clitoria ternatea* LEAVES AND SEEDS	*Alalade, J.A.,[1]Fabule, S.A[2]., Okunlola, O.O[1]and Adebisi, I. A[1]	1617
363.	PERFORMANCE OF LABLAB (*Lablab purpureus*L.) AS INFLUENCED BY PHOSPHORUS FERTILIZER RATES AND INTER-ROW SPACING IN THE NORTHERN GUINEA SAVANNA, NIGERIA	[1]Bature, M. S., *[1]Bala, A.G., [1]Hassan, A. H and [1]Tinau, A.T	1621
364.	PROXIMATE COMPOSITION OF RED FINGER MILLET VARIETY	*Bot, M.H., **Bawa, G.S., **Omage, J.J. and **Onimisi, P.A.	1624
365.	EFFECT OF HOT WATER AND SULPHURIC ACID PRE-TREATMENT ON TOTAL GERMINATION OF HORSE TAMARIND (*Leucaenaleucocephala)* SEEDS AT DIFFERENT IMMERSION TIME	[1]Hassan, A. H., *[1]Bala, A. G., [1]Bature, M. S.,Sulaiman, A and [1]Tinau, A.T	1627
366.	CHEMICAL COMPOSITION OF MILLET PANICLE WASTE ENSILED WITH POULTRY MANURE AT GRADED LEVELS	N. Kadi[2], Muftau,M. A[1]	1630
367.	INTERCROPPING MULTIPURPOSE TREES (*Moringa, Albizia and Leucaena*) WITH MAIZE AND ITS UTILIZATION AS DRY SEASON FEEDS FOR RUMINANTS IN SOUTHERN GUINEA SAVANNAH, NIGERIA	D.O Ogunbosoye[1,*] and Afe A.I[2]	1633
368.	EVALUATION OF PHYTOCHEMICAL AND NUTRIENT COMPOSITIONS OF HOG PLUM (*Spondiasmombin*)	Bishir, B. B.,[1] Adamu, H.Y.,[2] Abdu S.B. [2] and Aliyu, A.M.[1]	1639
369.	EFFECT OF WATERING VOLUME AND PLANTING DENSITY ON FODDER YIELD OF SELECTED TROPICAL CEREALS IN HYDROPONIC PRODUCTION	*Odedire, J.A., Akinropo, T.F. and Akinleye, J.A	1642
370.	EFFECT OF ORGANIC AND INORGANIC MANURE ON CHEMICAL COMPOSITION AND *IN SACCO* DEGRADABILITY OF GAMBA GRASS (*Andropogangayanus*) HARVESTED AT FOUR WEEKS	[1]ONWIH, E.E and[2] MILLAM, J.J	1646
371.	EVALUATION OF SELECTED CEREAL STOVER HAYS FOR NUTRIENT COMPOSITION AND *IN VITRO* GAS PRODUCTION IN WUKARI, NIGERIA	*A.J., Amuda[1], R.T., Binuomote[2] and R.D., Isaac[1]	1650
372.	COMPARATIVE NUTRITIONAL AND ANTI–NUTRITIONAL COMPOSITION IN CUCUMBER (*Cucumissativus*) AND SPONGE GOURD (*LUFFA AEGYPTICA*) SEED MEALS	Obun, C. O., OLUSIYI, A.J. and Audu, A	1655
373.	PROXIMATE COMPOSITION OF PLANT PARTS OF *Pennisetumpurpureum* HARVESTED AT SELECTED LOCATIONS IN SOUTHWEST NIGERIA	*Okukenu, O. A., Dele, P. A., Akinyemi, B. T., Jolaosho, A. O., Olajide, A. A. and Oriola, R. A.	1659

RUMINANT NUTRITION

S/N	TITLE	AUTHORS	PAGE
374.	EFFECT OF SUBSTITUTING MAIZE GRAIN WITH COBS TREATED WITH A COMBINATION OF UREA AND WOOD ASH ON SHEEP PERFORMANCE AND RUMEN PARAMETERS	[1]Abdulazeez, A., [2]Tsopito, C.M. and [2]Madibela, O.R.	1663
375.	PHYSICOCHEMICAL CHARACTERISTICS OF GRAIN SORGHUM (*Sorghum bicolor* L.) SILAGE AS INFLUENCED BY VARIETY AND PLANTING DATE	*[1]Munza, B. M., [2]Hassan, M. R., [3]Tanko, R. J., [2]Yashim, S. M., [2]Zakka, T., and [2]Adewumi, A.E.	1671
376.	CARCASS CHARACTERISTIC OF SOME NIGERIAN BREEDS OF SHEEP	*[1]Salihu, D. Y., [2]Duru, S., [2]Abdu, S. B., [3]Munza, B. M., [1]Abdu, M. B. and [4]Gaddafi, S.	
377.	YIELD AND PROXIMATE COMPOSITION OF *BRACHIARIA RUZIZIENSIS* FERTILIZED WITH GOAT MANURE AS POTENTIAL DRY SEASON FORAGE FOR RUMINANTS	A. Y. Shuaibu* O. A. Fasae[t], O. O. Adeleye,[t] B. O. Oluwatosin[t] and A. Olugbokiki[+]	1679
378.	EVALUATION OF SELECTED CEREAL STOVER HAYS FOR NUTRIENT COMPOSITION AND ***IN VITRO*** GAS PRODUCTION IN WUKARI, NIGERIA	*A.J., Amuda[1], R.T., Binuomote[2] and R.D., Isaac[1]	1684
379.	NUTRIENT INTAKE AND DIGESTIBILITY IN WEST AFRICAN DWARF GOATS FED DIETS CONTAINING *Vernonia amygdalina* (BITTER LEAF) AS PHYTOGENIC ADDITIVE	Adebayo, K.O., Olatomiwa, O.A. Olaleye T.O., Akinbode, R.M. and Onwuka, C. F.I.	1689
380.	EFFECTS OF REPLACING CORN BRAN WITH *Cajanus Cajan* LEAF MEAL IN THE SUPPLEMENT DIET ON THE GROWTH PERFORMANCE OF WEST AFRICAN DWARF RAMS	Adebisi, I.A., Ajibike, A.B., Oladepo, O., Okunlola, O.O., Alalade, J.A., Amusa, H.O. Mustapha, T.B. and Emiola, C.B.	1694
381.	EFFECT OF *Cajanus Cajan* LEAF MEAL IN TOTAL MIXED RATIONS ON THE GROWTH PERFORMANCE OF WEST AFRICAN DWARF RAMS	Adebisi, I.A., Ajibike, A.B., Oladepo, O., Okunlola, O.O., Alalade, J.A., Amusa, H.O. Mustapha, T.B. and Emiola, C.B.	1698
382.	RUMEN FERMENTATION PARAMETERS AND MICROBIAL PROFILES OF WEST AFRICA DWARF SHEEP FED SUGARCANE TOP TREATED WITH DIFFERENT NITROGEN SOURCES	Akinbode, R. M.[*], Isah, O. A., Oni, A. O., Adebayo, K. O. and Omoniyi, L. A.	1702
383.	PHYSICO-CHEMICAL, PHYTOCHEMICAL AND ANTI-OXIDANT PROPERTIES OF BOTANICAL GALACTOGOGUES USED IN RUMINANT FEEDING	*B.N. Umar and **Y. Garba	1707
384.	EFFECTS OF FEEDING *Panicum maximum* SUPPLEMENTED WITH LEGUME PELLETS ON THE RUMEN FERMENTATION CHARACTERISTICS OF WEST AFRICAN DWARF SHEEP	D. K. Oyaniran[+]*, V. O. A. Ojo[+], O. O. Adelusi[-], S. A. Adeoye[+] and A. O. Ogunsakin[+]	1714
385.	EFFECT OF PELLET MILL AND BINDER ON QUALITY AND ACCEPTABILITY OF CASSAVA-GLIRICIDIA PELLETS FED TO ZEBU COWS	[*]Dada O.A. , [+]Olorunnisomo O.A and *Ogunsipe M.H.	1719

386.	EFFECT OF BREWERS' DRIED GRAIN ON GROWTH AND LACTATION PERFORMANCE OF YANKASA SHEEP IN GUINEA SAVANNAH	Dikko, A. H*, T. Z. Adama*, P. P. Barje** and D.N. Tsado*	1724
387.	AVAILABILITY OF GRASS FORAGES IN AKINYELE INTERNATIONAL CATTLE MARKET, IBADAN	Fagbenro, R. B., Komolafe, P. L., Analoh, J. C., Babayemi, O. J.	1730
388.	NUTRIENT INTAKE, NITROGEN METABOLISM AND FEED GAIN RATIO OF WEST AFRICAN DWARF GOATS FED CASSAVA PEEL BASED DIETS SUPPLEMENTED WITH GRADED LEVEL OF *SACCHAROMYCES CEREVISIAE*	*Fajemisin, A. N., Omotoso, O. B., Ajayi, H. J. and Alokan J. A.	1734
389.	EFFECT OF FEEDING COMPLETE DIETS CONTAINING RICE STRAW ON CARCASS BY-PRODUCTS AND VISCERAL ORGANS OF FATTENED *YANKASA* RAMS	*Garba S., Isaac S. & Halliru S.	1738
390.	CHALLENGES AND USE OF HYDROPONICS FODDER AS LIVESTOCK FEED--A REVIEW	H.D Nyako[1], M.S Tanimu[1], M.M Yahaya[1], S Abdullahi[2]	1743
391.	*IN VITRO* FERMENTATION CHARACTERISTICS OF PHYTOGENIC FORTIFIED DIETS FOR RUMINANT ANIMALS	*[1]Ibhaze, G. A,[1] Fajemisin, A.N., [1]Obasuyi, O., [1] Ogunjemite, G.E., [1]Usifo, B., [2]Odufuoye, A.,[2]Aromoye, R.A	1746
392.	NUTRIENT DIGESTIBILITY AND NITROGEN BALANCE OF WEST AFRICAN DWARF GOATS FED *PLEUROTUS TUBER-REGIUM* DEGRADED CASSAVA ROOT SIEVATE	*Jiwuba, P.C., **Ahamefule, F.O., *Onwujiariri, E.B., **Jiwuba, L.C., *Azodo, N.L. **Ikwunze, K. and Nwefuru, M.O.	1751
393.	NUTRITIVE EVALUATION OF SELECTED AGRO-INDUSTRIAL BY-PRODUCTS FOR SMALL RUMINANT PRODUCTION	K. J. Onaleye, A. J. Amuda, R. Elkanah and E. L. Buba	1756
394.	PHYSICAL FEATURES AND CHEMICAL COMPOSITION OF ENSILED MAIZE STOVER AND GROUNDNUT HAULMS FOR SUSTAINABLE RUMINANT PRODUCTION	*Lamidi, A. A., Etela, I., Ukanwoko, A. I., Ingweye, J. N., Ologbose, F. and Oruene, I. A.	1761
395.	PLANT SECONDARY COMPOUNDS: A VIABLE OPTION FOR MITIGATING ENTERIC METHANE EMISSION IN NIGERIA	Lawal M.	1766

ABSTRACT
Artificial incubation in Japanese quails commercial production is unavoidable because the hens do not incubate their eggs. But artificial incubators require electricity, expertise and are not readily accessible hence alternative strategies that seem affordable and easy become indispensible. Two separate studies: electric incubator and solar drier supplemented with lantern heat; electric incubator and solar drier supplemented with electric bulb heat were carried out using two hundred Japanese quail eggs. Incubation period, number of hatchlings, chick weight, fertility rate, hatchability and chick yield were determined. Thermometer was used in monitoring the incubation temperature and relative humidity. Hatchability failure was recorded in both solar drier supplemented with lantern and electric bulb heat but 74.3%; 85.7% was recorded in control. All the incubated eggs in both solar drier supplemented with lantern and electric bulb appeared unfertile. These observations could be due largely to irregular incubation temperature of 30.3 to 58.8^{o}C; 23.9 to 42.6^{o}C during the day and 21.3 to 36.5^{o}C; 27.1 to 38.7^{o}C during the night in solar drier supplemented with either lantern or electric bulb heat. Therefore, solar drier supplemented with lantern or electric bulb heat, may not provide the required microclimatic conditions required to sustain Japanese quail embryos development.
Keywords: Embryo growth, incubator, Japanese quails, physiological status

INTRODUCTION
Initially, Japanese quails were known for singing, with time it was observed that the eggs and meat were nutritionally rich with medicinal attributes (Fah, 2009; Howes, 1964). More importantly, it is preferred in avian research to other poultry species (Reese and Reese, 1962). Unfortunately, the hens hardly incubate their eggs, so use of artificial incubators is inevitable for commercial production. Regrettably, artificial incubators are not manufactured locally, available, affordable and it is powered by electricity which may not be available always. Hence, the quest for alternative heat source to provide the required microclimatic conditions, required to sustain Japanese quail embryos development with improved hatchability. Consequently, this study was aimed at investigating the use of solar heat in poultry eggs incubation, in order to make good some elements of climate change.

MATERIALS AND METHODS
Study I
One hundred Japanese quail eggs obtained from National Veterinary Research Institute, Vom, were weighed and 50 each were randomly allotted to electric incubator: control (38°C) and solar drier. At night, hurricane lantern was placed inside the solar drier to supplement heat only at night (See plates 1 and 2).
Study II
Anotherclutch of 100 Japanese quail eggs from the same source as in study I, were weighed and randomly allocated (50 each) to control (38°C): electric incubator and solar drier. A 100W electric bulb was fixed inside the solar drier and switched on only at night to supplement heat (See plates 1 and 2).
DATA COLLECTION AND ANALYSIS
The studies were conducted separately and incubation temperature as well as relative humidity was recorded daily during the day: (midday and evening) and during the night: (midnight and morning) using a thermometer with a sensitive probe. At hatch, incubation period, number of hatchlings, chick weight, fertility rate, hatchability and chick yield were determined as described by Copper Akpinar *et al*. (2017). After the emergence of chicks, 5 days allowance was given for late hatching and on incubation day 22, the unhatched eggs were carefully windowed and the physiological status of the eggs vis-à-vis the developing embryos was recorded as proposed by Idahor *et al*. (2018), but was

modified to include further categorisation as either "Unfertile: no evidence of embryo growth" or "Fertile: evidence of embryo growth".

Plate 1: Electric incubator: Control

Plate 2: Solar drier where lantern or electric bulb was used to supplement heat only at night

Those that were "infertile", "caked" and "not clear whether fertile or not" were categorised as **Unfertile**: **no evidence of embryo growth**. Whereas, those with "early dead embryos", "fully developed but dead embryos", "pipped and dead embryos", "pipped and alive but not able to emerge embryos" as well as "pipped and hatched alive" were considered as **Fertile**: **evidence of embryo growth**. Data were subjected to descriptive statistics and ANOVA at $\alpha_{0.05}$ using SPSS (2010).

RESULTS AND DISCUSSION

Temperature and relative humidity in electric incubator and solar drier supplemented with lantern heat is presented in Table 1. There were statistical differences (P<0.05) in all the parameters measured, except temperature during the day and night in electric incubator (control) and relative humidity during the day in solar drier supplemented with lantern heat.

^{a,b,c,d}: Mean values on the same column with different superscripts differ significantly at p<0.05; ID: Incubation day; Temp: Temperature; RH: Relative humidity; STD: Standard deviation.

While the temperature was constantly 38°C in control, it fluctuated from 30.3 to 58.8°C during the day and 21.3 to 36.5°C during the night in solar drier supplemented with lantern heat. This was evidently out of a range of 36 – 38°C recommended for poultry eggs incubation (Archer and Cartwright, 2018; Sartell, 2018). The relative humidity varied between 29 and 45% in solar drier supplemented with lantern heat and 31 – 52% in electric incubator (control). These were within a range of 32 – 75% reported by Archer and Cartwright (2018).

Table 2 shows the temperature and relative humidity in electric incubator and solar drier supplemented with electric bulb heat. There were statistical variations ($P<0.05$) in all the parameters monitored, except temperature in control that was seemingly constant at 38°C both day and night but, varied from 23.9 – 42.6°C during the day and 27.1 to 38.7°C during the night in solar drier supplemented with electric bulb heat.

^{a,b,c,d}: Mean values on the same column with different superscripts differ significantly at $p<0.05$; ID: Incubation day; Temp: Temperature; RH: Relative humidity; STD: Standard deviation.

.

Though these values seemed to be close to 38°C given as normal incubation temperature in poultry eggs, the fluctuation margin was wider than a range of 0.2 – 3.0°C reported to be a margin of safety (Poultry Hub (2018; French, 2000). Relative humidity was close to the values given as normal during poultry eggs incubation (Archer and Cartwright, 2018).

Table 3 provides the physiological status and hatchability of Japanese quail eggs incubated in electric incubator and solar drier supplemented with lantern or electric bulb heat. There was hatchability failure in both solar drier supplemented with either lantern or electric bulb heat whereas, as high as 74.3%; 85.7% was recorded in control during the studies. This observation lent more credence to the report of Idahor *et al.* (2016) that improvising solar drier as poultry eggs incubator may not be possible. But was at variance with the findings of Osanyinpeju *et al*. (2016) who recorded 44% hatchability in fowl eggs incubated in solar powered poultry egg incubator. All the incubated eggs in both solar drier supplemented with lantern and electric bulb heat appeared unfertile. This probably signified unsuitable microclimatic conditions for the blastoderm to develop into embryos resulting in hatchability failure.

Table 3: Physiological status and hatchability of Japanese quail eggs incubated in electric incubator and solar drier supplemented with either lantern or electric bulb heat

	Treatments			
Parameters	**Control**	**Solar drier supplemented with lantern heat**	**Control**	**Solar drier supplemented with electric bulb heat**
Total eggs set	50	50	50	50
Egg weight (g)	10.43	10.06	10.28	10.17
IP (days)	17	-	18	-
Unfertile eggs: No evidence of embryo growth				
Infertile	5	0	7	0
NCWFN	1	38	1	35
Caked	2	12	3	15
Fertile eggs: Evidence of embryo growth				
EDE	3	0	2	0
FDDE	1	0	3	0

PAE	0	0	0	0
Hatched chicks	36	0	29	0
Fertile eggs	42	0	39	0
Fertility rate (%)	84	0.00	78	0.00
Hatchability and chick quality				
Hatchability (%)	85.7	0.00	74.3	0.00
Chick weight (g)	6.47	0.00	6.35	0.00
Chick yield (%)	62.0	0.00	61.77	0.00

IP: Incubation period; NCWFN: Not clear whether fertile eggs or not; EDE: Early dead embryos; FDDE: Fully developed but dead embryos; PDE: Pipped and dead embryos; PAE: Pipped and alive but not able to emerge embryos.

CONCLUSION AND RECOMMENDATION

Since hatchability was recorded only in the control (electric incubator), solar drier supplemented with either lantern or electric bulb heat, may not be feasible in Japanese quail eggs incubation. Therefore, further investigations on how to harvest solar heat during the day, conserve and stabilize it during the night become imperative, in order to make good some elements of climate change.

ABSTRACT

The study aimed at investigating the effect of mastitis on dromedary camel **(*Camelus dromedarius*)** mammary tissue using histopathological examination. The study was carried out on seven (7) dromedary camel mammary gland; three (3) apparently healthy and four (4) mastitic mammary gland. The samples were collected from Maiduguri main abattoir, preserved and taken to histology laboratory, Faculty of Veterinary Medicine, University of Maiduguri. At slaughter, the udder was incised immediately, and mammary tissues were fixed in 10% formalin solution at room temperature. The tissue were subjected to routine histological staining using Haematoxylin and Eosin (HandE) staining method and safranin and fast green (SandFG) for examination under the light microscope. Histological studies indicated significant pathological changes in the tissue; dense interlobular connective tissue, atrophied gland, fibrous tissue proliferation, lower alveolar population and lower alveolar diameter.

Key words: Udder, Health, Disease

INTRODUCTION

Mastitis is a complex disease occurring worldwide among dairy animals, with heavy economic losses largely due to sub-clinical mastitis. Mastitis is an inflammation of the parenchyma of the mammary gland, which can result from cow exposure to a variety of infectious agents. It is characterized by an array of physical and chemical changes in milk (discolouration, presence of milk clots and presence of large number of leucocytes) (Al-Otaibi and El-Demerdesh, 2013), pathologic changes to the glandular mammary tissue, and at times systemic changes within the affected animal.

Mastitis may be due to pathogens, toxins or trauma (Schlafer and Miller, 2007). It is characterized by a decline in milk yield, physical and chemical changes in the milk and pathological changes of the udder. The pathogenesis of mastitis is well studied in cows and dependent on some factors including the species and virulence of the organism, ecology and host (Schlafer and Miller, 2007; Tibary and Anouassi, 2000). However, cases of mastitis in camel have been reported from different countries, particularly in pastoral production system of East Africa and Middle East (Abdelgadir, 2013).

Microorganisms that causes mastitis are generally classified as either contagious or environmental based upon their primary reservoir and mode of transmission. *Staphylococcus aureus* and *Streptococcus agalactiae* are contagious pathogens. Primary environmental pathogens include different types of bacteria: species of streptococci other than *Streptococcus agalactiae* (*Streptococcus* species), coliform species *(Escherichia coli, Klebsiella* species, *Enterobacter* species) and pseudomonas species. The study aimed at investigating the effect of mastitis on dromedary camel mammary tissue using histopathological examination.

MATERIALS AND METHOD

Experimental design

The study was carried out on seven (7) dromedary camel mammary gland; three (3) apparently healthy and four (4) mastitic mammary gland. The samples were collected from Maiduguri main abattoir, preserved and taken to histology laboratory, Faculty of Veterinary Medicine, University of Maiduguri for further processing.

Histopathological examination

At slaughter, the udder was incised immediately and the tissues fixed in 10% formalin solution at room temperature. The specimens were then removed from the buffered-formalin and dehydrated through a graded series of ethanol and xylene prior to paraffin embedment. After that, the specimens were embedded in paraffin, sectioned at the thickness of 5-6µ using rotary microtome, mounted on

slide, and stained with Haematoxylin and Eosin (H and E) Stain method and safranin and fast green (S and FG) for examination under the light microscope.

RESULTS

The udder section from apparently healthy dromedary camel showed no pathological lesions and the glands showed alveoli containing milk and thin interlobular connective tissue were observed (Plate IA and B). Milk was apparently observed in the lumen and it accumulated in the lactiferous duct of the mammary gland (Plate IIA and B). Protein cast were also observed in the convoluted duct system (Plate IIIA and B). However, the tissue section from mastitic udder revealed dense interlobular connective tissue and severe atrophied gland (Plate IVA and B). Infected mammary parenchyma tissue showed destruction of alveoli and fibrous tissue proliferation (Plate VA and B). Mastitic udder showed significantly lower alveolar epithelial cell population and alveolar luminal diameter. The lobular structure was completely replaced by scattered aggregates of granulation. The interlobular ducts were dilated and their lining epithelium was necrotic and disrupted (Plate VIA and B).

DISCUSSION

The most common histopathological findings in this study were dense interlobular connective tissue, severe atrophied gland, broken alveoli, fibrous tissue proliferation, lower alveolar epithelial cells population and lower alveolar luminal diameter. This result indicated pathological changes occurring in udder tissue, and could be due to severe tissue damage due to different mastitis pathogens or the toxins secreted by various species of mastitis pathogens. Similar changes in udder tissue was reported by Abeer *et al*, (2016) which observed profuse proliferation of fibrous tissue, necrotic, fragmented and atrophic mammary gland secretary acini. He went further and stated that, in advanced changes, the lobular structure were completely replaced by scaring and scattered aggregate of mononuclear cells or granulation. The histopathological changes included the number of alveoli, alveoli diameter and secretary alveolar cell population significantly decreased in mastitic cattle (Hussain *et al.*, 2012). Also, Quinn *et al* (1994) mentioned that, the chronic mastitis changes induced intensive proliferation of fibrous tissue in the inter and intra-lobular forming areas of scarring, infiltration of mononuclear cells, histocytes or macrophages, plasma cells and lymphocytes.

CONCLUSION

Histological studies on udder indicated significant pathological changes in the tissue; dense interlobular connective tissue, atrophied gland, fibrous tissue proliferation, lower alveolar population and lower alveolar diameter.

ABSTRACT
A study was conducted to investigate the ameliorative effect of betaine hydrochloride under dexamethasone induced heat stress. A total of 300 day-old *Arbor acre* broiler chickens randomly assigned to five treatments in a completely randomized design were used in the study. The five treatments with three replicates (n= 20 birds/rep) made up of a treatment containing no dexamethasone and no betaine served as the control. Another treatment was fed 0.30% betaine only supplemented diets, with the other three treatments given daily dexamethasone concentrations at 1, 2 and 3 mg/L in water, respectively. All dexamethasone treated birds were fed 0.30% betaine HCl in their diets. Results indicated a decrease (P>0.05) in rectal temperature and respiratory rate with increasing dose of dexamethasone, especially with the betaine only group. Betaine HCl had a positive effect on thermoregulatory parameters of broiler chickens by ameliorating the negative effect of heat stress.
Keywords: Stress, Dexamethasone, Broilers, Betaine, Osomolyte

INTRODUCTION
Broiler chicken production under high ambient temperature and high relative humidity has been shown to induce heat stress (Ali *et al*., 2010). Heat stress results in the excess production of reactive oxygen species (ROS) which cause oxidative damage (Zhang *et al*., 2014). Given its similarity to endogenous corticosteroids, dexamethasone's ability to reproduce the effects of high levels of corticosterone, thus mimicking stress associated signalling pathways has been demonstrated (Eid *et al*., 2006; Aengwanich, 2007; Ademu *et al.*, 2018) A. With stress a costly problem for the broiler industry, nutritional strategies to lessen its effects are being developed. Betaine supplementation to diets for livestock has increased during the last decade (Fernandez-Figares *et al.*, 2008). Betaine, the trimethyl derivative of the amino acid glycine, is a naturally occurring compound, which is widely distributed in many plants and animal tissues. Betaine exerts an osmo-regulatory role in cells, regulating water balance, which is beneficial for alleviating physical reactions to heat stress (Ratriyanto and Mosenthin, 2018). The aim of the study was to investigate the ameliorative effect of betaine hydrochloride on the thermoregulatory responses of broiler chickens under induced heat stress conditions.

MATERIALS AND METHODS
The experiment was conducted at the Teaching and Research farm of the Department of Animal Science, Ahmadu Bello University Samaru, Zaria. Three hundred day old *Arbor acre* broiler chicks were used in the experiment. They were randomly allotted to five experimental treatments in a completely randomized design. Each treatment was replicated three times with twenty birds per replicate. A maize/soybean based broiler starter and finisher diet was formulated according to NRC (1994) nutrient requirement for broiler chickens. Birds receiving 0 mg dexamethasone and without betaine supplementation served as the control. Birds administered 1, 2 and 3 mg dexamethasone in drinking water along with a betaine only group were given diets supplemented with Betaine HCl at 0.30%. Daily doses of dexamethasone (1, 2 and 3 mg) was administered by dissolving in a litre of water and supplied for twenty-eight days beginning from when the birds attained 14 days of age.

THERMOREGULATORY MEASUREMENTS

Indoor temperature and relative humidity readings were recorded daily using an electronic digital thermo-hygrometer. Both readings were taken in the morning (8.00 am) and afternoon (3.00 pm) throughout the experimental period. Rectal temperatures and respiratory rates were measured by placing a digital thermometer in the rectum and counting of respiration (breath/minute) with the aid of a stopwatch respectively. Temperature-humidity index (THI) was calculated using the formular of Tao and Xin (2003).

$$THI = 0.85\,T_{db} + 0.15\,T_{wb}$$

Where,
THI = temperature-humidity index in °C,
T_{db} = dry-bulb or ambient temperature in °C and
T_{wb} = wet-bulb temperature in °C.
Wet bulb temperature was determined from ambient temperature and relative humidity using the empirical expression functions by Stull (2011). Heat stress was classified as absence of heat stress (<27.8), moderate heat stress (27.8-28.8), severe heat stress (28.9-29.9) and very severe heat stress (>30.0).

DATA ANALYSIS

All data collected from the experiment was subjected to analysis of Variance (ANOVA) using the general linear model procedure of JMP (2012).Where the result of ANOVA was statistically significant, test for multiple comparisons was performed to compare means of all groups using Tukey (1949).

RESULTS AND DISCUSSION

The average temperature humidity index (THI) inside the poultry house during the experimental period for mornings and afternoons is shown in Figure 1. THI in the afternoons were 25.4% higher than in the mornings indicating the absence of heat stress in the morning and the presence of very severe heat stress in the afternoon. Tao and Zin (2003) also observed that the body temperature of broilers tends to rise at THI 30.0.

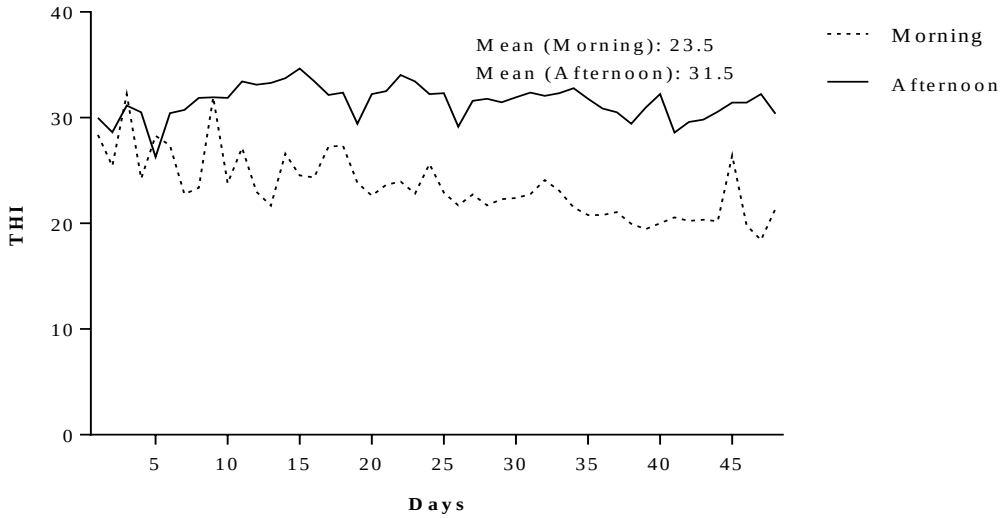

Figure 1: Daily Temperature-humidity index inside the poultry house during the experimental period

The effect of betaine HCl on rectal temperature of broiler chickens **under** dexamethasone **induced stress** is shown in Figure 2. A decrease in rectal temperature with increasing doses of dexamethasone was observed. Birds in the betaine only group had the lowest rectal temperature compared to other treatment groups. This result is supported by Hassan *et al*. (2011) and Nofal *et al*. (2015) who concluded that betaine supplementation in diets reduced rectal temperature. As an osmolyte, betaine may have a stabilizing function on cells subjected to osmotic stressors (Klasing *et al.*, (2002) by

regulating the water balance, resulting in the stability of tissue metabolism especially in the gastrointestinal tract (Lipinski *et al.*, 2012), protecting them from heat shock.

The respiratory rate (Figure 3) across the treatment groups was not significant (P>0.05). However, a decrease in respiratory rate with increasing dose of dexamethasone was observed. Birds in the betaine only group had the lowest respiratory rate. One of the visible symptoms of a bird under heat stress is panting or increased respiratory rate (Etches *et al.*,2008)When the environmental temperature exceeds the comfort limit, chickens suffer heat related stress resulting in physiological and metabolic changes (Borges *et al.*, (2007).

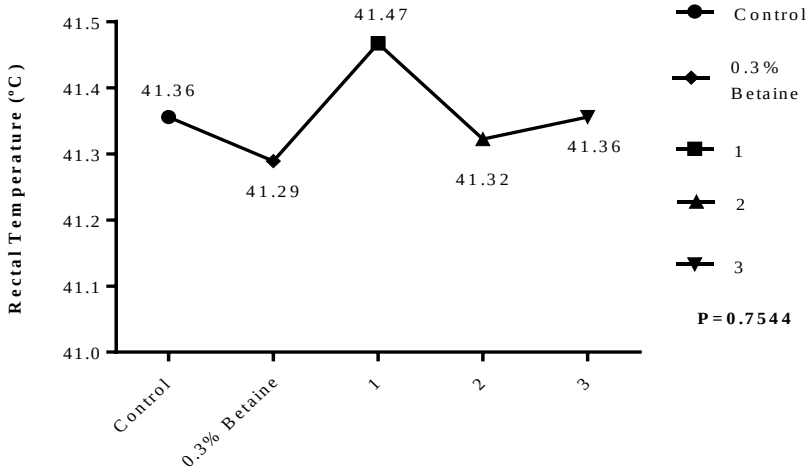

Figure 2: Effect of 0.30% Betaine HCl on Rectal Temperature of Dexamethasone Stress-induced Broiler Chickens

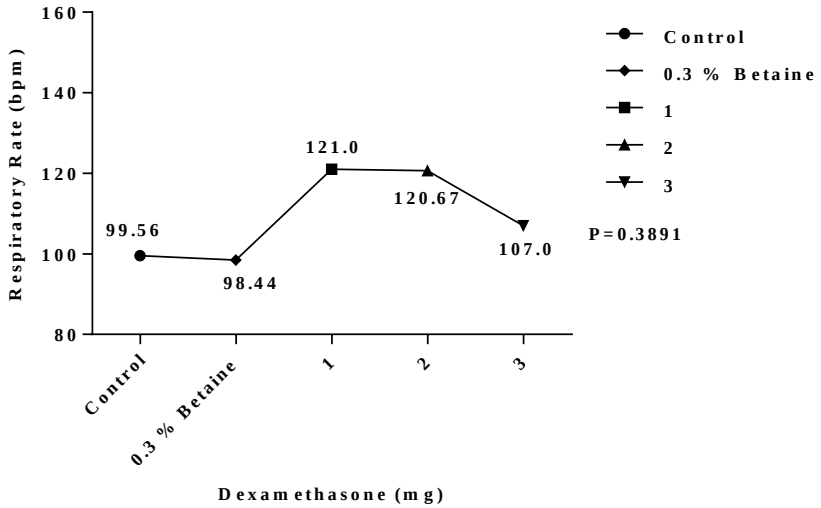

Figure 3: Effect of 0.30% Betaine HCl on Respiratory Rate of Dexamethasone Stress-induced Broiler Chickens

This study also agrees with Aengwanich (2007) who administered dexamethasone at 1-5 mg/kg to broiler chickens. Respiratory rate was found to be reduced even below that of the control group for the betaine only group indicating the ameliorative effect of betaine.

CONCLUSION

The supplementation of betaine HCl in broiler chicken diets had an ameliorative effect on thermoregulatory parameters of broiler chickens.

SEXUAL DIMORPHISM IN TWO STRAINS OF LOCAL TURKEY AT EARLY REPRODUCTIVE STAGE UNDER INTENSIVE SYSTEM OF MANAGEMENT IN ZARIA

[1]Olutunmogun, A.K. & [2]Yahaya, H.K.

[1]National Animal Production Research Institute, Ahmadu Bello University, Shika-Zaria, Kaduna State, Nigeria

[2]Department of Animal Science, Ahmadu Bello University, Zaria, Kaduna State, Nigeria

Corresponding author: olutunmogunkayode@yahoo.com; +234 7039338987

ABSTRACT

The study was designed to access the variations existing in traits of local turkey's strains at their early reproductive ages with the purpose of recommending useful economic traits for selection at early reproductive age. Body weights, body length, neck length, breast girt, thigh length, shank length and keel length of 36 early reproductive turkeys reared in the intensive system of management were taken and analyzed in a one-way ANOVA. The results showed that variability was prominent between the two sex of turkey which favoured the male as an expression of sexual dimorphism for all traits while the white strain was superior over the black in traits of body weight and breast girth. It can be concluded that breeders can select this unimproved local turkey strains considering the high level of coefficient of variation exhibited between sexes and strains for improved productivity.

Key words: Sexual dimorphism, Strain, Local Turkey, Intensive system

INTRODUCTION

Turkey (*Meleagris gallopavo*) is a large gallinaceous bird that belongs to the of family *Meleagridae* and occupies an important global position next to chicken and duck in world poultry population (Besbes, 2009). In Nigeria, Turkey is not common among poultry growers: a number of farms are beginning to multiply the bird at commercial level owing to increasing interest as a provider of lean meat among all domestic avian species and complementing chicken meat (Das *et al*., 2018). They are mostly located in urban areas and are gradually spreading even to village farms (Ogah, 2011). They have a unique and remarkable phenomenon in adaptability to wide range of climatic conditions and can be raised successfully almost everywhere in the world if they are well fed and protected against diseases, predators and adverse weather conditions (Bhanja and Majumdar, 2001). Apart from the role in protein supply where some consumers refer to its meat as luxury meat (Das *et al*., 2018), the birds have an aesthetic value due to their beauty (Ogundipe and Dafwang, 1980). Many varieties of turkeys exist around the globe however principal varieties that have attained commercial importance in many parts of the world are, broad breasted large white and broad breasted bronze. Other varieties are White Holland, Beltsville small white, Black Turkey, Bourbon Red and Narrangansett Turkey (Ogundipe and Dafwang, 1980). Sexual dimorphism is a phenomenon where variations exits between the male and female either in size, plumage colour or ornamentals. In size or bodyweights, male animals are adjudged to be consistently bigger than their female counterparts, an attributed linked to sex differential hormonal effect on growth (Musa *et al*., 2015). Therefore, this current study is focused on investigating the body and linear measurements of two local Turkey strains at their early reproductive stage under intensive system of management in Zaria.

MATERIALS AND METHODS

Experimental location

The study was conducted at the Teaching and Research Farm of the Department of Animal Science, Faculty of Agriculture, Ahmadu Bello University, Zaria, Nigeria. The farm is located at latitude 11° 09' 06' N and longitude 7° 38' 55' E, at an altitude of 706 m above sea level (Ovimaps, 2019). The climate is relatively dry with a mean annual rainfall of 700-1400mm occurring from late April to mid-October. The temperature varies from 26°C to 35°C depending on the season while the relative humidity during the hamattan period, hot and wet seasons are 21, 37 and 77% respectively (IAR, 2019).

EXPERIMENTAL DESIGN AND DATA COLLECTION

A total of thirty-six (36) poult turkey toms and hens of two different strains (black and white plumage strains) were purchased from an open market in Gurbi, Zurmi Local government area of Zamfara State, Nigeria. The birds were initially quarantine for a period of about two (2) weeks and given anti-biotic medications against any possible infection. After which the birds were managed on the deep litter system with each of the turkey in separate pens for proper identification and collection of data. The birds were fed with compounded feed meant for adult turkey birds containing 3,350Kcal/kg metabilizable energy and 17% crude protein. Feed and clean drinking water were given *ad libitum*.

EXPERIMENTAL DESIGN AND DATA COLLECTION

Thirty-six (36) adult turkeys of two different strains (black and white plumages) were used for the study. They were randomly assign into individual pens in a completely randomized design (CRD) for easy data collection. Body measurements taken were as described by Gueye *et al*. (1998) with the weight taken with the aid of a weighing scale while body measurements were taken using a flexible measuring tape.

Body weight: This is the weight of the birds taken by use of a 20kg weighing scale in kilogram.
Neck length: This was considered as the distance between the occipital condyle and the cephalic borders of the caracoids.
Shank length: This was measured from the hock joint to the tarso-metarsus digit-3 joint.
Thigh Length: This was taken as the distance between the hock joint and the pelvic joint.
Body length: This was measured as length of the body from the base of the neck to the base of the tail.
Keel Length: This was taken as the length of the cartilaginous keel bone or metasternum.
Breast girth: This was taken under the wing at the edge of the sternum.

Statistical Analysis

Data collected from the study were subjected to one-way Analysis of Variance (SAS, 2002) and the differences between means were separated using the Duncan Multiple Range Test (Duncan, 1955). The appropriate statistical model used was:

$Y_{ijk} = \mu + T_i + A\sigma_j + e_{ijk}$

Where Y_{ijk} = observation of the kth random error on the jth covariate of age effect on the ith strain of turkey. μ = the overall common mean, T_i = the effect of ith strain of turkey (i = 1, 2), $A\sigma_j$ = the covariate of age, e_{ijk}= random error.

RESULTS AND DISCUSSION

The descriptive statistics showing means standard error (±SE) and coefficient of variation estimate (CV) of body weight and linear body measurements of the two strains of local turkey at early reproductive age has affected by sex is presented in Table 1 while Table 2 showed the pooled descriptive statistics. The result on sex effects showed that all the traits had significant ($p<0.05$) differences thereby been ascribed to sexual dimorphism. The pooled effect by strain showed that body weight, breast girth and keel length were significantly ($p<0.05$) different with the white strain been superior. This result shows a variance with that of Ogah (2011) who reported lesser values for body weight, neck length, thigh length and breast girth in indigenous turkeys. However, it was similar for shank length, body length and keel length with that of Ogah (2011). Similarly, the results in this present study differs from those of Fayeye *et al*. (2019) who reported black and mixed strain being superior over the white strain in body weights. In the report of Janjecic and Muzic (2007) in Zagorje turkey, body weights of 6.01kg for male and 3.97kg for female were similar with those of this current study. Oblakova (2007) reported different values on turkey broiler parents which is not in agreement with this study. The differences between this study and similar once could be associated to age, strain or management differences although these studies were able to identifier the phenomenon of sexual dimorphism. Also, the difference with those from tropical region may have been due to the unfavourable environmental conditions such as temperature, feed supply and non-selection characteristics of tropical animal genetic resources as discussed by Ogah (2011) and as observed from the high coefficient of variations in some traits. Furthermore, the differences could be attributed to sex

differential hormonal effect which affect growth and muscle development more in males as discussed by Musa *et al*. (2015).

CONCLUSION

The variations observed from the various traits between the sexes supports the phenomenon of sexual dimorphism as noted from the descriptive analysis while the white strain demonstrate superiority in traits of bodyweight and breast girth. Therefore, breeders can select this unimproved turkey strains considering the variability and high level of coefficient of variation between sex and strain for improved productivity.

ABSTRACT

In Nigeria, population characteristics of selected indigenous cattle breeds have not been fully documented. Therefore, morphometric attributes of selected indigenous cattle breeds in Nigeria were assessed. Three hundred and one White Fulani (WF), Two hundred and forty two Red Bororo (RB), Two hundred and forty seven Sokoto Gudali (SG), Two hundred and thirty three Bornu Kuri (BK) and One hundred and eighty four Muturu cattle in the age group of 3 to $3^1/_2$ years were purposively sampled. Eighteen morphometric parameters were measured using standard procedures. Data were analysed using descriptive statistics, ANOVA at $\alpha_{0.05,}$cluster analysis and Euclidean genetic distance. The longest geneticdistance at the morphometric level was 146 between Muturu and BK and shortest (44) between BK and RB. Differences existed in face length, rear leg length; wither height and rump height among the breeds.

Keywords: Attributes, bodyweight, breeds, cattle, morphometric

INTRODUCTION

One of the ways of characterizing livestock breeds is to evaluate their morphostructural characteristics and determine genetic distance among contemporary populations (Metta *et al.* 2002).The initial step in characterization is identification of distinct populations using information on their geographic and ecological isolation, traditional nomenclature (traditionally, recognized populations), phenotypic distinctness and level of genetic differentiation among the population (Gizaw *et al.* 2011). Indigenous cattle breeds are important to preserve as they are well adapted to local climates, food supply and other local environmental factors, which often shows in their robustness and hardiness. Indigenous livestock resources are also strategic in the socio-economics of rural agricultural systems to ensure food security in developing countries. The selected cattle breeds are found throughout Nigeria, but are most common in the northern part the country.

The wither height and rump height among these breeds differentiated them. This study is designed to unveil the phenotypic and genetic diversity among selected Nigeria indigenous cattle breeds using primary data obtained from field morphological survey to assess diversity of the selected indigenous populations in order to update published variations as well as document genetic distances between the populations.

MATERIALS AND METHODS

Animals were sampled from four different isolated areas where they were abundant in Nigeria (Ipokia – Ogun State; Biliri – Gombe State; Bida and Kontagora – Niger State). Each location was divided into clusters of ten units for easy measurements and adult animals that were within the age bracket of 3 to $3^1/_2$ years were sampled. A total of one 1207 indigenous cattle comprising 301 White Fulani 247 Sokoto Gudali, 242 Red Bororo, 233 Bornu Kuri and 184 Muturu were sampled.

Eighteen linear body measurements (cm) were taken on each sampled animal with the use of a measuring tape (Table 1). Quantitative variables measured in this study were adapted from the standard cattle descriptor list (FAO 2002) and a final list of variables were developed and used. Documented morphological features described by (Hall 1991) were used as base line markers to ascribe sampled animals to a breed. Individuals that did not strictly conform to primary breed characters; visibly pregnant, sick and castrated animals were excluded. Data collected were subjected to Generalized Linear Model Analysis of Variance (ANOVA) procedure of the Statistical Analysis System (SAS 2002) and cluster analysis of Palenotological Statistics (PAST). Least Square Means (x) and Standard Error (SE) associated with each linear body measurements were estimated. Genetic distances among the five breeds based on their actual morphometric variables measured were

calculated using Euclidean genetic distance measure. The statistical model used for analyzing quantitative phenotypic variations among the breed populations was as follows:

$$Y_i = \mu + B_i + e_i$$

where Y_i are the observed body measurements, μ is the overall mean, B_i is the fixed effect of breed (i = 1,2,..5) and e_i is the standard error.

RESULTS AND DISCUSSION

Mean values of morphological variables and their SE are depicted in Table 1 for aggregated gender. Pairwise mean comparison showed significant differences for most of the morphological variables among the breeds. Wither height, rump height, body length, and tail length were significantly higher ($p<0.05$) for White Fulani and Sokoto Gudali as compared to other breeds considered in this study. Muturu breeds had significantly ($p<0.05$) larger face length and head width than other four breeds. The genetics distance among the cattle population ranged from 43.77 to 145.52 (Table 2). The longest genetic distance was observed between Bornu kuri and Muturu while the shortest distance was observed between Red Bororo and Bornu Kuri. The cluster analysis generated showed two main clusters having Muturu in a cluster and White Fulani, Sokoto Gudali, Bornu Kuri and Red Bororo in the other.

The significantly higher values for most of the morphometric measurements of White Fulani, Sokoto Gudali, Red Bororo and Bornu Kuri that were predominantly in the northern part of the country than Muturu that is predominantly in southern part of the country seem to be an adaptation where tallness (wither height) and large body size (heart girth and body length) are suitable for trekking long distances to water and grazing points and this is in agreement with what Mwacharo et al., 2006 and Hall 1991 reported. These observations could be as a result of genetic and species differences. The differences in body measurements of the five cattle breeds with respect to some morphological variables indicates that the five cattle breeds were sub-divided into distinct populations perhaps due to differences in availability of feed resources, breeding practices used and inherent genetic differences (Mwambene *et al.*, 2012).

A shorter genetic distance obtained between White Fulani and Sokoto Gudali suggests a close genetic relationship between the breeds while the longer genetic distance was observed between White Fulani and Muturu is an indication that an appreciable heterosis especially with regard to most body measurements which are of economic importance can be obtained by crossing any of the two breeds.The phylogenetic tree separated the five cattle breeds into two main clusters. In addition, the close genetic relationship between the breeds may also be attributed to similarity in ecological zones and production systems as well as the incidents of cross border livestock rustling contributing to the migration and movement of livestock and subsequent interbreeding between such livestock, this in agreement with had been reported by (Nwacharo *et al.* 2006). There were clear disparities in the wither height and body length of the five breeds. White Fulani was found superior to any of the other four breeds studied. Genetic distance based on morphological indices among the breeds as revealed by the cluster analysis showed that the breeds were genetically distinct.

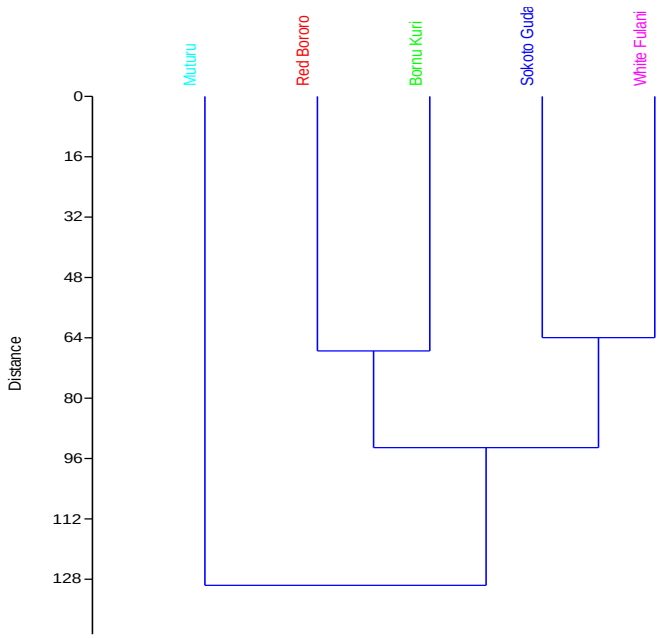

Figure 1. Dendogram showing genetic relationship among five indigenous cattle from Nigeria

CONCLUSIONS

Morphometric attributes are very good tools in differentiating cattle on the basis breeds. The closer genetic relationship among White Fulani, Sokoto Gudali, Red Bororo and Bornu Kuri five cattle breeds may be attributed to possible interbreeding among these populations that were predominantly abundant in the northern part of the country forming homogeneous population separated by no physical geographic boundaries.

ABSTRACTS
The study, breed variation in thermoregulatory parameters and their correlated responses in some selected indigenous cattle was conducted to evaluate breed differences in thermoregulatory parameters of four Nigerian indigenous breeds of cattle (Bunaji, Rahaji, Bokoloji and Adamawa Gudali). A total of eighty (80) cattle were used for the experiment (20 from each breed). Data were taken three times within the period of three months (August- October) and were subjected to ANOVA using SAS software. Parameters measured were rectal temperature, respiratory rate, pulse rate and Heat Tolerance Coefficient . There were significant ($p<0.05$) effect of breed all the parameters measured except ($p>0.05$) rectal temperature. Bokoloji recorded the highest in respiratory rate (21.80 beats/minutes) and Heat Tolerance Coefficient (1.91) while the highest recorded value for pulse rate (22.10) was in in Bunaji. The correlation coefficient between parameters shows that significant ($p<0.05$; $r = 0.40- 0.49$) positive relationship exist between HTC and RR in all the breeds studied. Also, significant ($p<0.05$; $r = - 0.29- 0.31$) negative relationship exist between PR and RT except for the positive relationship ($p< 0.05$; $r = 0.73$) in Rahaji breed. It was concluded that Bokoloji and Bunaji breeds of indigenous cattle are more reactive to heat stress than Rahaji and Adamawa Gudali. Also, correlated responses within breed for thermoregulatory parameters can be maximized for selecting animals for improved heat tolerance.
Key words: breed, thermoregulation, indigenous, cattle

INTRODUCTION
Tropical cattle are known for their ability to tolerate heat while maintaining standards of milk yield, reproduction, and disease resistance (Atrian and Aghdam, 2012). Thermo-tolerance in cattle is one of the desired adaptive ability of tropical cattle. Cow demonstrate certain physiological responses when under heat stress. It was reported that any change in the environmental conditions, as is the case during heat stress, threatens the normal metabolic balance and usually produces a positive feedback once the temperature is above the upper critical temperature (UCT) (Hayes *et al*., 2009; Atrian and Aghdam, 2012). Some physiological traits are related to the ability of the animal to cope with heat stress (Garner *et al*., 2016). For example, sweating rate, rectal temperature and respiration rate increase when animals are exposed to warm environment (Garner *et al*., 2016; Rashamol *et al*., 2018). Inclusion of these heat tolerance indicator traits in large-scale phenotype recording systems for selecting thermo-tolerant animals appears rather problematic in terms of logistics and costs (Nguyen *et al*., 2016).

High producing cattle have been reported to suffer more from heat stress than low producing cattle (West, 2002; Nayak *et al*., 2018). Heat-tolerant cows, ranked according to a genomic breeding value of heat tolerance based on milk yield, showed lower values of physiological indicators (core body temperature, rectal and intra-vaginal temperature) than heat-sensitive cows (Macciotta *et al*., 2016). Heat stress causes changes in phenotypic and genotypic traits in livestock and is quantified by the measurement of physiological responses such as respiration rate (RR), rectal temperature(RT), skin temperature(ST), pulse rate (PR) and sweating rate (SR) (Rashamol *et al*., 2018). Among the physiological parameters RR, RT and ST are identified as the biomarkers for quantifying the heat stress impact on livestock (Shaji *et al*., 2016).

Some physiological parameters were reported to be associated with thermo-tolerance in Indian Thartarker cattle, Angus cattle, Holstein- Friesian cross bred and Deoni cattle raised in India and Sahiwal cows in India. But there are dearths of information on the thermos-tolerant ability of the Nigerian indigenous cattle. Therefore, this paper seeks to present the thermo-tolerance of four selected indigenous cattle using physiological biomarkers.

MATERIALS AND METHODS

Study location: The study will be conducted in some selected dairy herds in Adamawa State. Adamawa State is located at an altitude of 200 to 300 metres, between latitude 9°20' and 9°33'N and longitude 12^0 30' and 12º50' E. It is bordered by Borno State to the North West, Gombe to the West and Taraba to the South West and has an Eastern border with Cameroun Republic. It has average daily minimum and maximum temperatures of 23.2 and 35.2ºC respectively. The average annual rainfall is 718.1 millimetres and relative humidity, 44.2 %. It occupies an area of 39,742.12 square kilometres. (National Bureau of Statistics, 2010; Ovimaps, 2018).

SOURCES OF EXPERIMENTAL ANIMALS AND MANAGEMENT

Eighty (80) clinically healthy dairy cows made up of twenty (20) each of Adamawa Gudali, Red Bororo, Sokoto Gudali and Bunaji of similar ages in selected Farms in Adamawa State were used for the experiment. The experiment spanned the period of three months (August- October). These The animals that will be used were in their first parity and early lactation stage (1-60) days.

THERMOREGULATORY DATA COLLECTION

Rectal temperature (RT):This was taken using a digital thermometer. The sensory tip was disinfected and inserted into the rectum at the display of L^0C by a thermometer (which is an indication that the thermometer was set for temperature reading) and was removed by the sound of alarm signal. It was recorded in ^0C.

Respiratory rate (RR): This was determined by counting the number of flank movements per minute. It was measured by placing the fingertips on the femoral arteries of the hind limb for 1 minute. It was recorded in beats/minute

Pulse rate: this was taken by using placing a stethoscope at the

Heat tolerance coefficient (HTC): HTC was calculated based on heat tolerance index developed by Benezra, (1954). The formula is based on both respiration rate and rectal temperature.

HTC: RR/23 + RT/38.33

Data Analyses

Statistical model

The statistical model for the experiment is as given below;

$Y_{ij} = \mu + B_i + e_{ij}$

Where; μ = general mean, $B_i = i^{th}$ fixed effect of breed; e_{ij} = experimental error

.

STATISTICAL ANALYSIS

The data collected on thermoregulatory parameters was subjected to analysis of variance (ANOVA) using General Linear Model of (SAS) (2002) while significant difference was separated using Duncan Multiple Range test (Duncan, 1955). The degrees of relationship between all pairs of thermoregulatory parameters was computed for all the animals within each breed groups using CORR procedure of the SAS (2002) statistical package.

RESULTS AND DISCUSSION

Table 1shows the breed variation in thermoregulatory parameters of four selected indigenous breeds of cattle. There were significant ($p< 0.05$) effect of breeds on the parameters measured except for rectal temperature ($p<0.05$). Bokoloji recorded the highest in respiratory rate (21.80 beats/minutes) and Heat Tolerance Coefficient (1.91) while the highest recorded value for pulse rate (22.10 beats/minutes) was in in Bunaji. Respiration rate which is the intake of oxygen and elimination of carbon dioxide under thermo-neutral condition that leads to evaporation and dissipation of moisture from the respiratory tract to maintain thermal balance (Rashamol *et al*., 2018) has been considered as one of the critical biomarkers for determining heat stress in farm animals. Breed variation in RR was also reported by Sailo *et al.* (2017), the RR were reported to be 15.738 in Sahiwal and 15.779 in Karan Fries cattle during winter. In another study, Valente *et al* (2015) reported a higher RR in Angus cattle (104 breaths/ minute at 37^0C) during a heat stressed condition. Heat tolerance coefficient measures the adaptability of an animal during heat stress. Hence lower HTC may indicate an improved thermo-tolerance which had been useful in genetic improvement in cattle (Kumar et al., 2017). From this study therefore, Rahaji is the most adaptable breed in the studied area.

Table 1: Breed variation in thermoregulatory parameters of some selected indigenous breeds of cattle in Nigeria

Parameters	Bunaji	Rahaji	Bokoloji	Adamawa Gudali
RT (^{o}C)	37.84	36.98	36.96	36.80
RR (beat/min.)	18.30^{b}	18.00^{b}	21.80^{a}	19.70^{ab}
P. R	22.10^{a}	16.90^{b}	16.10^{b}	16.80^{b}
HTC	1.78^{ab}	1.75^{b}	1.91^{a}	1.82^{ab}

Table 2: Correlation among thermoregulatory breeds of cattle

Breed		RT	RR	PR	HTC
Bunaji					
	RT		0.23	-0.29*	0.40*
	RR			-0.71**	0.98**
	PR				-0.72**
	HTC				
Rahaji					
	RT		-0.61**	0.73**	-0.43*
	RR			-0.43*	0.98**
	PR				-0.29*
	HTC				
Bokoloji					
	RT		0.31*	-0.31*	0.49*
	RR			-0.09	0.98**
	PR				-0.15
	HTC				
A. Gudali					
	RT		0.23	-0.29*	0.40*
	RR			-0.71**	0.98**
	PR				-0.72**
	HTC				

Table 2 shows the correlation among the various measured thermoregulatory parameters of the selected breeds. Significant ($p<0.05$; $r = 0.40- 0.49$) positive relationship exist between HTC and RR in all the breeds studied. Also, significant ($p<0.05$; $r = - 0.29- 0.31$) negative relationship exist between PR and RT except for the positive relationship ($p< 0.05$; $r = 0.73$) in Rahaji breed. Parameters that are positively correlated suggest that a significant increase in one parameter will result in significant increase on the other correlated parameter (vice- versa).The high positive correlation observed among thermoregulatory parameters (RR and RT) suggest that these traits are influenced by the same gene (pleiotropy) (Fayeye, 2014; Abbaya*et al*., 2018).

CONCLUSION

It was concluded that Bokoloji and Bunaji breeds of indigenous cattle are more reactive to heat stress than Rahaji and Adamawa Gudali. Also, correlated responses within breed for thermoregulatory parameters can be maximized for selecting animals for improved heat tolerance.

ABSTRACT
The study was conducted to examine the influence of breed on morphometric characteristics of two rabbit genotypes. In achieving the objectives, linear body measurements were taken on the rabbits using a flexible tape. The measurements were body weight (BW), body depth (BD), body length (BL), fore-limb length (FLL), hind-limb length (HLL), tail length (TL) and ear length (EL). The coefficient of variability of the traits showed low to moderate values which ranged from 5.78% for ear length to 14.59% for body depth and BW had highest variability (17.22%). Breed had significant influence on morphometric characteristics with New Zealand White generally showing the best performance. The average body weights were 1.84 and 1.63 for the NZW and GRY respectively. Pearson correlation coefficients among the morphometric traits showed strong, positive and significant relationships with 'r' value ranging from 0.48 (BL×EL) to 0.86 (BW×BD). It can be concluded that morphology in the rabbits were influenced by breed. In addition, using linear body measurements to describe and evaluate body size would overcome the problems associated with visual evaluation and can be used to predict body weight.
Keywords: Morphological characteristics, breed, sex and genotypes.

INTRODUCTION
The rabbit (*Oryctolagus cuniculus)* is one of the most productive meat species among domesticated animals. The feeding habits offer no appreciable competition with man. It can subsist on greens as basal diets. Rabbits have high economic efficiency on account of inexpensive housing, low nutrient requirement, high reproductive rate, short generation interval and gestation period. Their daily weight gain is high hence rapid growth rate and sexual maturity (Aduku and Olukosi, 1990). The provision of suitable breeding stocks that are well adapted to backyard systems is a key requirement for the sustainability of low-input and smallholder rabbit production prevalent in many parts of sub-Saharan Africa (Oseni, 2012). On the basis of body weight, the rabbits can be selected for growth (Hassan *et al.,* 2012).Linear body measurements can also be used (Orheruata and Olutogun, 1994). Linear measurements provide information on animal morphology and have helped in making decisions on commercialization (Osario *et al.,* 2002). Morphometric traits are sometimes preferred because weighing machines can give biased measurements due to gut fullness (Obike *et al.,* 2010). Rabbits ranked third in protein content behind poultry and turkey and is overtaken them because of low cholesterol content (Tsado *et al.,* 2013). With reference to this and other indices, the productive potentials of rabbit stock and factors that affect them need to be identified. In Nigeria, low animal protein intake has remained a major nutritional problem, especially for low income earners and the unemployed (Amaefule and Obioha, 2005; Akinola, 2009). There is therefore urgent need to develop rabbit production as a cheap source of animal protein to bridge the wide gap between animal protein supply and consumption. The study examined the effect of breed on morphological characteristics of two rabbit genotypes.

MATERIALS AND METHODS
The study was conducted at the Rabbitry Unit of the Teaching and Research Farm, Department of Animal Science, Faculty of Agriculture, Bayero University Kano, Kano state Nigeria. Kano State is located in the semi-arid area of North-western and lies between latitude $10^{o}33^{'}$ and $12^{o}27^{'}$ north of the equator and longitude $7^{o}34^{'}$ and $9^{o}29^{'}$ east of the Greenwich meridian (KNARDA, 2006). The rabbits were kept under intensive management in hutches with feeding and drinking troughs provided. The hutches were made of wire measuring 52×44×32 cm and chicken wire mesh and raised on metal pole stands at 49 cm from the concrete floor.
Data on body weight (in kg) using a weighing scale and six other linear body measurements (in cm) were taken following the description of Akanno and Ibe, 2006. The measurements included the

following: (a) Body depth – the circumference of the thoracic cavity just behind the forelimb divided by two. (b) Body length – the distance from the point of the shoulder to the pin bone. (c) Tail length – the distance from the pin bone to the tip of the tail. (d) Fore-limb length – the distance from the hock to the proximal end of the humerus (e) Hind-limb length – the distance from the proximal end of the femur to the distal end of the fibula including the distal end of the femur. (f) Ear length – the distance from the base of the ear to the tip. Data were analysed using the General Linear Model (Proc GLM) procedure of SAS®(SAS, 2014). The GLM procedure included fixed effects of breed of rabbit, and body weight and morphometric measurement as response variables. Pearson correlation procedure of SAS was used to assess the relationship among variables.

RESULTS ANS DISCUSSION

Table 1 shows the summary statistics of the morphometric measurements. The mean body weight range is 1kg - 2.5kg. This range is in agreement with previous report (Lukefahr and Goldman, 1985) they reported a mean of 2.5kg for adult rabbits while a range of 1.70 - 2.1kg was reported by Omole, 1982. The present result is not in agreement with (Suleiman, Muhammad and Muhammad, 2017) who reported a range of 0.82 to 1.35kg body weight. Table 1 equally shows the means for other morphometric measurements. The coefficient of variabilities were low for ear length (5.78%), hind limb length (8.05%), tail length (8.35%) and body length (9.73%) indicating that selection base on them would tend towards homozygosity. The remaining measurements had moderate variabilities of 14.59% for body depth and 17.22% for body weight indicating that much more selection pressure can be applied on them.

Table 1. Summary statistics of morphometric characteristics measured

S/N	Variables	Mean	CV (%)	Min	Max
1	BW	1.78438	17.22	1.00	2.50
2	BD	14.23750	14.59	10.00	19.50
3	BL	25.37639	9.73	17.50	30.10
4	FLL	15.64097	10.84	11.00	18.50
5	HLL	22.61111	8.05	17.00	26.00
6	TL	11.25208	8.35	8.00	13.20
7	EL	11.56667	5.78	10.00	13.00

The mean value and variables were clearly showed. BW = Body weight, BD = Body depth, BL = Body length, FLL = Fore limb length, HLL = Hind limb length, TL = Tail length, EL = Ear length.

Table 2 shows the effect of breed on morphometric characteristics of the two rabbit genotypes. The breed generally had significant effects on morphometric characteristics ($P<0.01$) with NZW showing the better performance. This is an indication that rabbit breed has influence on morphological characteristics in terms of body form and structure.

Table 2. Effect of breed on morphometric characteristics of two rabbit genotypes

factors	BW	BD	BL	FLL	HLL	TL	EL
breeds	**	NS	*	NS	**	**	**
NZW	1.85[a]	14.39	25.65[a]	15.73	22.92[a]	11.39[a]	11.67[a]
GRY	1.63[b]	13.83	24.67[b]	15.42	21.79[b]	10.88[b]	11.28[b]
SEM	0.026	0.173	0.206	0.141	0.080	0.083	0.058

*(P<0.05),** (P<0.01), ***(P<0.001), SEM = Standard Error of Mean

Pearson correlation coefficients (Table 3) among the morphometric characteristics showed strong, positive and significant relationships with `r` ranging from 0.48 (BL×EL) to 0.86 (BW×BD). These results are similar to Suleiman, Muhammad and Muhammad, (2017) who recorded 0.38 (BD×EL) and 0.82 (BW×BL). This measurement on one character could be used to indicate another.

Table 3. Pearson correlation matrix for the morphometric traits of rabbit genotype

factors	**BW**	**BD**	**BL**	**FLL**	**HLL**	**TL**	**EL**
BW							
BD	0.86**						
BL	0.83**	0.79**					
FLL	0.77**	0.83**	0.74**				
HLL	0.79**	0.82**	0.75**	0.78**			
TL	0.78**	0.78**	0.72**	0.72**	0.76**		
EL	0.66**	0.56**	0.48**	0.62**	0.62**	0.60*	

** (P<0.01)

CONCLUSION AND RECOMMENDATIONS

From the results, it could be concluded that morphometric characters vary with breed of rabbits. Selection based on any of the morphometric measurements will positively influence the others. Furthermore, using linear body measurements to describe and evaluate body size would overcome the problems associated with visual evaluation and can be used for body weight prediction.

THE VALUE OF MINERAL ZINC IN ANIMAL PHYSIOLOGICAL FUNCTIONS

ABSTRACT
Zinc is one of the most important trace elements in the body, and it is indispensable to the growth and development of microorganisms, plants, and animals. This review work looks at the value of zinc in animal physiological functions. In domesticated species, experimental zinc deprivation was produced first in chicks and pigs. Zinc - responsive disorders were induced by excess dietary calcium in poultry attributed to a potent and complex interaction with the major source of phosphorus in feed grains (phytate). Fetal growth is especially affected by lack of zinc.Zinc deprivation increases the expression of the gene for the appetite-regulating hormone cholecystokinin and also increases the susceptibility of endothelial cells to oxidant stress. The role of zinc is probably multi-factorial. Zinc regulates genes involved in signal transduction, responses to stress, reduction–oxidation reactions, growth and energy utilization.Itis also a potent inducer of metallothionein (MT), a zinc and thiol - rich metalloprotein that scavenges free radicals and could act as a reduction– oxidation sensor or active signaling switch in cells. Zinc aids in proper assimilation of vitamins, normal growth and development.Zinc supplementation also cured and prevented parakeratosis, a thickening and hardening of the skin found in pigs given grain-based diets, rich in calcium. It is therefore important that the value of zinc in animal physiological functions be assessed and deficiency corrected in some chronic animal diseases.
Keywords: animal physiological functions, mineral supplementation, pigs, poultry, zinc

INTRODUCTION
Zinc (Zn) is a ubiquitous trace element. It is one of the most important trace elements in the body, and it is indispensable to the growth and development of microorganisms, plants, and animals. It is involved in DNA replication and RNA transcription. The first unequivocal evidence that zinc is necessary for growth and health was obtained in laboratory animals (Todd *et al*., 1934) at a time when associations were being noted between zinc and carbonic anhydrase, an enzyme eventually shown to contain zinc (Keilin and Mann, 1940). In domesticated species, experimental zinc deprivation was produced first in chicks (O'Dell and Savage, 1957) and pigs (Stevenson and Earle, 1956). In all species, the disorder was characterized by loss of appetite, growth depression, abnormalities of the skin or its appendages and reproductive failure. In the field, zinc supplementation cured and prevented parakeratosis, a thickening and hardening of the skin found in pigs given grain-based diets, rich in calcium (Tucker and Salmon, 1955). Zinc - responsive disorders were also induced by excess dietary calcium in poultry and were eventually attributed to a potent and complex interaction with the major source of phosphorus in feed grains, phytate (Py) (Ziegler *et al*., 1961).
The quest to understand the pathogenesis of zinc deprivation continues and has led to the measurement of free intracellular zinc at femtomolar concentrations (Outten and O'Halloran, 2001), while therapeutic properties have been found for zinc at near-molar concentrations (Hill *et al*., 2001). Fear of zinc deprivation is being exploited commercially by feed industry which offers wide variety of mineral additives, including organically bounded trace elements as compounds for the enhanced bioavailability of a variety of 'organic' zinc supplements (Suttle, 2010).

GENE EXPRESSION
Fetal growth is especially affected by lack of zinc (Hurley, 1981) and this may reflect the roles that it plays in DNA synthesis and, nucleic acid and protein metabolism. Zinc regulates genes involved in signal transduction, responses to stress, reduction–oxidation reactions, growth and energy utilization, including a T-cell cytokine receptor and uroguanylin (Cousins *et al*., 2003). Teratogenic defects may mostly derived from the primary effects of zinc deprivation on gene expression – effects that are most marked when cells are rapidly dividing, growing or synthesizing (Chesters, 1992).

APPETITE CONTROL

Since O'Dell and Reeves (1989) reviewed the role of zinc in the regulation of appetite, advances have continued to come from studies with rats. The pattern and rate of food intake is affected and acute zinc deprivation causes rats to nibble at food rather than 'meal eat'. Little addition of zinc (3–6 mg Zn kg−1 dry matter (DM) removes the complication, but description of such diets as 'marginal' in zinc (e.g. Kwun *et al*., 2007) is inappropriate because the diets unequivocally provide insufficient zinc for normal growth and development.

Zinc deprivation increases the expression of the gene for the appetite-regulating hormone cholecystokinin (Cousins *et al*., 2003), but the role of zinc is probably multi-factorial. There is also increased expression of leptin, a cytokine hormone whose secretion from adipocytes acts as a satiety signal (Kwun *et al*., 2007), and reduced expression of pyruvate kinase (Beattie *et al.*, 2008), which is regulated by insulin. Changes in the concentrations of neurotransmitters in the brain have been reported in zinc deprivation, but may be secondary consequences of appetite reduction (Kwun *et al.*, 2007). In what might more accurately be called acute zinc deprivation, the reduction in appetite is selective, with carbohydrate being avoided and protein and fat preferred (Kennedy *et al*., 1998).

FAT ABSORPTION

When low plasma and liver concentrations of vitamin E and fat-soluble vitamin A were reported in zinc - deprived animals, attention became focused on the possible role of zinc in fat absorption. The pancreas secretes zinc - dependent phospholipase A2 (Kim *et al.*, 1998). This hydrolyses phosphatidyl choline, facilitating its absorption and the formation of chylomicrons, which are crucial for the absorption of fat micelles (Noh and Koo, 2001). Duodenal infusion of hydrolysed phosphatidyl choline greatly increases the absorption of fats and the fat-soluble vitamins A and E in well grown rats that are 'marginally deprived' of zinc. Partial alleviation of the effects of heat stress in quail by supra-nutritional levels of zinc (Sahin and Kucuk, 2003) may be mediated, in part, by secondary improvements in vitamin status.

ANTIOXIDANT DEFENSE

In addition to the contribution of a superoxide dismutase, CuZnSOD, in protecting cells from the superoxide radical, *in vitro* studies suggest that zinc may afford protection from iron - induced lipid peroxidation by blocking iron-binding sites at cell surfaces, acting synergistically with vitamin E (Zago and Oteiza, 2001). Zinc deprivation increases the susceptibility of endothelial cells to oxidant stress (Beattie and Kwun, 2004). In humans, zinc supplementation decreases the expression of anti-inflammatory cytokines (Prasad, 2007), but it is unclear whether this is beneficial to health. Zinc is also a potent inducer of metallothionein (MT), a zinc and thiol - rich metalloprotein that scavenges free radicals and could act as a reduction– oxidation sensor or active signalling switch in cells (Beattie and Trayhurn, 2002).

Zinc aids in proper assimilation of vitamins, normal growth and development. It is found in all the fluids in the body. It assists in the maintenance of body tissue, sexual function, immune system, chemical detoxification, synthesis of DNA and helps in reducing healing time. It is stored in the thyroid, pancreas, liver, kidney, bone, voluntary muscle, prostate, sperm cells, skin, hair, nails and white blood corpuscles and parts of the eyes (Sanchez, 2010). Zinc plays an important role in poultry, particularly layers, as a component of a number of metalloenzymes such as carbonic anhydrase which is essential for eggshell formation in the hens shell gland (Scheideler, 2008). Other important zinc metalloenzymes in the hen include carboxypeptidase and DNA polymerases. These enzymes play important roles in the hen's immune response, in skin and wound healing, and for hormone production (testosterone and corticosteroids). Classic deficiency symptoms of a zinc deficiency in poultry could include a suppressed immune system, poor feathering and dermatitis, infertility and poor shell quality (Scheideler, 2008).

Lack of zinc during embryonic growth grossly disturbs skeletal development and severe abnormalities of the head, limbs and vertebrae have been found in chick embryos from the eggs of severely deprived hens (Kienholz *et al*., 1961). Zinc deficiency in breeder diets reduces egg production and hatchability. Proper zinc supplementation has proven to be important in reducing early mortality of turkey poults (Larson, 2005).

CONCLUSION

Zinc is one of the most important trace elements in the organism, with three major biological roles, the catalytic, the structural, and the regulatory one. It is a multifunctional metal compatible with satisfactory growth, health, and well-being. It is essential for the structure and function of various proteins and cellular components and plays an important role in animal physiology from its involvement in the proper function of the immune system to its role in cellular growth, cell proliferation, cell apoptosis, as well as in the activity of numerous zinc-binding proteins. It is therefore important that the value of zinc in animal physiological functions be assessed and zinc deficiency be corrected in some chronic animal diseases.

ABSTRACTS
This study sought to determine the adequacy of two mathematical functions in modelling growth characteristics of male and female Noiler chickens. The study was conducted at the Livestock Teaching and Research Farm, University of Maiduguri. Body weights were obtained weekly for 20 weeks from two hundred (200) Noiler chickens and fitted to the Gompertz and Logistic models. The results of the study showed significant difference ($P<0.05$) between males and females only at 20 weeks of age, with values of 3002.7 and 2718.7, respectively. The asymptomatic weight of the models revealed that Gompertz model had higher values for both male and female Noilers than the logistic. The coefficient of determination (R^2) of Gompertz model (0.8122) was higher than that of logistic (0.8103) for male Noilers. Similar trend occurred in female Noilers with Gompertz having a higher R^2. The Akaike information criteria (AIC) value of 6927.5 for Gompertz model was lower compared that of logistics (6933.0) in the male Noilers. Gompertz also had lower value of AIC for female Noilers compared to the Logistic. The study reveal that the Gompertz model was the better growth model for explaining the growth patterns of both male and female Noilers.
KEY WORDS: Mathematical models, Noilers, Body weight, Sex

INTRODUCTION
Poultry production is one of the best available sources for production of high biological value animal protein in terms of eggs and meat (Yakubu *et al*., 2007). The poultry sector contributed about 25% of the agricultural domestic products of the Nigerian economy (FAO, 2010). Nigeria presently produces above 550,000 mt of poultry meat per annum and 770,000 mt of eggs (FAO, 2010). Poultry meat and eggs account for about 30% of total livestock output in Nigeria, of which eggs account for over 80 percent (Fayeye *et al*., 2005).

Mathematical functions called growth models (each with a non-linear structure and sigmoid shape) have been used to explain the growth patterns of poultry species (Narine *et al*., 2017). The main advantage of non linear models is parsimony, interpretability and prediction (Bates and Watts, 2007). Growth curve parameters are highly heritable and have been widely exploited in poultry selection studies (Maginon-Grasteav, 2001). Studies had been carried out for the prediction of future growth at any age in poultry (Raji *et al.,* 2014).

The Noiler chicken is a dual purpose breed of chicken developed by Amo farm sieberer hatchery limited for small holders to address the challenges of food insecurity and financial dependency among rural populace especially women. It has been emphasized that the introduction of tropically adapted genotypes with high performance is beneficial to the resource poor poultry farmers (Yakubu and Ari, 2018). Knowledge of growth of Noiler birds is important to evaluate their development at any age. The objective of this study was to determine the most appropriate model for describing growth of Noiler chickens.

MATERIALS AND METHODS
The study was carried out at the Poultry unit of the Livestock Teaching and Research Farm of the University of Maiduguri, Borno State, Nigeria. Maiduguri is located between Latitude 11°50 N and 13 ^{o} 40 S and longitude 10°14E at an altitude of 354 m above sea level in the Northern Sudan Savanna belt of Nigeria (Kellou, 2005). The area falls within the Semi-arid zone of West Africa and characterized by short rainy season of about 3-4 months (June to September) and the mean annual rainfall ranges from 450-600 mm.

EXPERIMENTAL ANIMAL AND MANAGEMENT

A total of two hundred (200) day old Noiler chicks were obtained from a reputable hatchery. The birds were brooded for three (3) weeks on wood shavings using coal pots to supply heat, after which they were placed under deep litter management system for 140 days (20 weeks). All the birds were tagged individually for proper identification. They were fed with a commercial chick mash (1-8 weeks) containing 3000 Kcal/Kg of energy and 20% Crude protein (CP) and grower mash (8 – 20 weeks) containing 2650Kcal/kg of energy and16% crude protein (CP). Fresh clean water was given *ad libitum* and routine vaccination and other management practices were strictly adhered to.

DATA COLLECTION AND MODELS

The body weight was measured for each bird once a week for the duration of the experiment. Body weight was taken using a weighing balance calibrated in grames (g) and the data fitted into the following growth models

1. Logistic model's: the following equation describes the logistics (Roberison,1923) growth model Wt=Wa/[1+exp –K(t-Ti)] where
   Wt =the body weight at time t,
   Wa = asymptptic body weight,
   K= the exponential growth rate, and Ti the age at the inflection point.
2. Gompertz –Laird model: the laird form of the Gompertz equation (Laird *et al.*,1965) was fitted to the data. The following equation describes the Gompertz-Laird growth curve;
   Wt =Woexp [(L/K) (1 – exp Kt)] where
   Wt =weight of bird at time t,
   Wo = initial body (hatch)weight,
   L=instantaneous growth rate (per week).
   K =rate of exponential decay of the initialspecific growth rate,
   L= it measure the rate of decline in growth rate

DATA ANALYSIS

The data generated from body weight were subjected to analysis using statistix 9.0. The data was subjected to one-way Analysis of variances with sex as the fixed factor. Significant means were compared by least significant difference.

DETERMINATION OF GOODNESS OF FIT

The asymptotic body weight (A), Akaike's information Criterion (AIC) and coefficient of determination (R^2) were used for model comparisons. Goodness of fit for each model was determined by using the coefficient of determination (R^2), and Akaike's Information Criterion (AIC).

RESULTS AND DISCUSSION

The effect of sex on body weight of Noiler birds at different ages are presented in Table 1. The results showed that sex had significant influence ($p<0.05$) only on body weight at 20 weeks of age. At this age the males had superior body weight (3002.7±111.8g) than their female counterparts (2718.7±84.99g). This agrees with the findings of Rondelli *et al.* (2003) and Keshri *et al.* (1985) who reported that at growing stages, males were heavier than females. The result of the present study also agreed with Dogan *et al*.(2010) which investigated the values of 3657g for female and 4362g for male though the values were higher than the present studies.

Table 1. Effect of sex on Body weight (kg) of Noiler chickens at different Ages.

	Age (week)							
Sex	2	4	6	12	14	16	18	20
Male	102.05 ±5.55	252.73 ±13.72	414.51±2 6.08	1686.5±9 0.41	1975.7±2 20.5	2316.2±1 02.3	2624.3±1 04.3	3002.7±1 11.8[a]
Female	107.22 ±4.22	251.31 ±10.43	409.97±1 9.83	1600.0±6 8.74	2076.6±1 67.7	2121.9±7 7.81	2378.1±7 9.7	2718.7±8 4.99[b]

ab means within column with different superscripts are significantly different (P<0.05)

Table 2 presents the model parameters and goodness of fit criteria for body weight of male and female Noiler chickens. Brown *et al.* (1996) stated that asymptomatic weight (A parameter) values offered the best opportunity for direct comparison of model. The asymptomatic weight of the models showed that Gompartz model had a higher value for both the male and female Noilers than logistic. The results of this study was in line with the report of Raji *et al*. (2014) in Japanese quails. The models with higher coefficient of determination (R^2) and lower Akaike information criterion (AIC) are the best models for describing the parameter in question (Brown *et al*., 1996). The coefficient of determination for both male and female Noilers were higher in Gompertz model than Logistic model. While the AIC for body weight of male Noilers was lower (6927.5) in Gompertz than (6933.0) for Logistic model. The AIC in female Noilers followed similar trend with Logistic model having higher values than Gompertz.Gompertz model that were determined the best in the present study were found to be in agreements with the literature reports performed using different genotypes (Aggrey,2002 and Ahmadi and Golian 2008).

T**able 2. Model Parameters and goodness of fit for Body Weight of Male and Female Noilers**

Trait	Parameter	sex	A	B	C	AIC	R^2
BW (g)	Gompertz	Male	3891.9	1.5858	0.1396	6927.5	0.8122
		Female	3365.9	1.5832	0.1518	1231.9	0.7250
	Logistic	Male	3133.6	3.5544	0.2900	6933.0	0.8103
		Female	2817.2	3.5081	0.3021	1232.5	0.7233

Where: BW = body weight, A = asymptomatic weight, B = scale parameter (constant),
C = relative growth rate, AIC = Akaike Information Criteria, R^2= Coefficient of determination

CONCLUSION

The results of this study showed that the body weight parameter of male and female Noiler chickens differed (p<0.05) and such differences were more obvious during the later growing phase with the male having greater values. The comparison of the two growth models in terms of asymptomatic body weight and goodness of fit criteria revealed that the Gompertz model was better for describing the growth pattern of both male and female Noiler chickens.

EGG FERTILTIY AND EMBRYO VIABILITY OF TURKEY HENS INSEMINATED WITH VARIED SEMEN DILUTION RATIO AT DIFFERENT INTERVALS

Adebisi, K. A. & Ewuola, E. O.

Animal Physiology and Bioclimatology Unit, Department of Animal Science, University of Ibadan, Ibadan, Nigeria.

ABSTRACT

When semen is diluted, the number of sperm cells inseminated is reduced and this reduction can affect fertility especially with the frequency at which insemination is done. The objective of this study was therefore to determine the effect of the interaction of semen dilution ratio and insemination intervals on turkey fertility and embryo viability. Local turkeys were used for the study, ten toms and sixty-four hens. The hens were randomly divided into eight groups of four replicates. In a 4x2 factorial arrangement of a randomized complete block design (old and young hens), two insemination intervals (one and two weeks) and four dilution ratios of semen to normal saline (1:0, 1:1, 1:2 and 1:3) were used in insemination. Eggs collected were incubated weekly for 10 weeks. Fertility and embryo mortality (early and mid) were assessed by breakout of candling clears, while unhatched eggs were considered late embryo mortality. Analysis of variance was done on square root transformed data at $\alpha_{0.05}$.

Results of the main effects indicated no significant difference in fertility between weekly or fortnight inseminations, however, dilution of 1:0 and 1:2 were significantly higher than 1:3. When the interaction of factors was observed, 1:0 (89.3±2.8%) and 1:2 (86.8±3.0) were significantly ($p<0.05$) higher than 1:3 (72.8±4.4%) at fortnight inseminations only, though values were not significantly different from all other groups. Embryo mortality was not affected by the interaction. Therefore, to maximize fertility in local turkeys, semen should not be diluted beyond 1:2 (minimum of $30x10^6$ motile spermatozoa) at fortnight insemination intervals.

Keywords: Embryo mortality, Hatchability, Insemination interval, Semen dilution, Turkey fertility

INTRODUCTION

The additional cost incurred on insemination needs to be justified with the frequency of insemination and optimum use of semen from the toms. This is expected to reduce the labour cost associated with insemination, minimize handling of birds and also, reduce the number of males kept for breeding purpose. Thus, increasing the dilution ratio of semen at a less frequent insemination, without compromise on fertility and hatchability is expected to achieve this goal. Adebisi and Ewuola (2019a) observed optimal fertility in local turkeys at two weeks insemination interval using undiluted semen. Normal saline was also reported as a suitable diluent, if insemination is done immediately after semen collection (Adebisi and Ewuola, 2019b). Turkey semen is relatively high in sperm concentration and viscosity when compared to other poultry species (Bramwell, 2012). Its dilution prior to Artificial Insemination (AI) is therefore very essential, to increase the volume of semen and serve a wider coverage of hens to be inseminated. In diluting semen for insemination, several factors need to be considered regarding the dilution effect on the quality of the sperm cells and the effect of reduced number of cells inseminated on fertility. A typical dilution effect was observed by Sexton (1976) when turkey semen was diluted at a ratio of 1:8 and 1:12. This dilution led to an increased respiration of cells and corresponding decline in fertilizing capacity. However, at dilution rates of up to 1:4 with Lake's diluents at weekly insemination intervals, no significant difference was observed in fertility with undiluted control when held at 25℃ or 5℃ for 30 minutes prior to insemination Sexton (1976). The objective of the study was therefore to assess the effect of the interaction of insemination intervals (one and two weeks) and semen dilution ratio (1:0, 1:1, 1:2, and 1:3, semen to diluent) on fertility, embryo mortality and hatch parameters in local turkey hens.

MATERIALS AND METHODS

The research was carried out at the poultry unit of the Teaching and Research Farm, University of Ibadan, Nigeria. Locally-adapted turkeys were used for the study, ten toms and sixty-four hens. The hens were randomly divided into eight treatment groups of four replicates with two hens each. The experimental design was a randomised complete block design in a 4 x 2 factorial arrangement.Factor A was the semen dilution ratio, while factor B

was the insemination intervals.The block effect was the hen age groups (old hens of 16 months old and young hens of 9 months old). Semen was harvested from the toms, pooled and 0.02mL inseminated into hens. A portion of pooled semen inseminated was evaluated for semen quality characteristics Hens in groups 1 to 4 were inseminated with semen diluted with normal saline at a ratio of 1:0, 1:1, 1:2 and 1:3 at weekly interval while those in groups 5 to 8 were inseminated at interval of 2 weeks with the same varied dilution ratios as with groups 1 to 4. Insemination and weekly egg collection for incubation was done for 12 weeks. Candling was done on day 25 of incubation. Fertility, embryo mortality, hatch of fertile eggs and hatch of set eggs were determined as described by Adebisi and Ewuola (2019b).Data collected were analysed using two-way analysis of variance (of square root transformed data) using general linear model of SAS (2003). Means were separated using Duncan's multiple range test of same software.

RESULTS

The characteristics of pooled semen prior to dilution and insemination over twelve weeks are presented in Table 1. Spermatozoa concentration ranged from $4.29x10^6$ – $6.12x10^6$ cells/mL, progressive spermatozoa motility, 80% - 95%, while liveability was 91.3% – 97.4%.

Table 1: Characteristics of Weekly Pooled Semen Prior to Dilution and Insemination over Twelve Weeks

Semen quality parameter	Mean value	Range
Spermatozoa concentration($x10^9$ cells/mL)	5.37±0.56	4.29 – 6.12
Progressive spermatozoa motility(%)	86.39±4.86	80.00 – 95.00
Spermatozoa liveability (%)	94.83±1.87	91.30 – 97.40

The effects of semen dilution ratio, insemination intervals and their interactions on fertility and hatch parameters are presented in Table 2. Results of the main effects indicated no significant difference in the parameters between weekly or fortnight insemination. However, fertility and hatch of set eggs in groups inseminated with a dilution ratio of 1:0 and 1:2 were significantly ($p<0.05$) higher than 1:3. Interaction of the factors also indicated a significantly ($p<0.05$) higher fertility in groups of hen inseminated with diluted semen ratio of 1:0 (89.3±2.8%) and 1:2 (86.8±3.0) than 1:3 (72.8±4.4%), but at 2 weeks insemination intervals only. These values were however, not significantly different from all other groups. There were no significant differences ($p>0.05$) in the hatch of fertile or set eggs. The block effect of hen age was also not significant for any of the parameters. The effect of the interaction of semen dilution ratio and insemination intervals on early (EEM), mid (MEM), late (LEM) and total (TEM) embryo mortality in turkeys is presented in Table 3. There were no significant ($p>0.05$) differences among the groups for each of the parameters.

Table 2: Effects of Semen Dilution Ratio, Insemination Intervals and their Interactions on Fertility and Hatch Parameters of Eggs from Turkey Hens (Mean±SE)

Factors	Levels		Parameters measured (%)		
			Fertility	**Hatch of fertile eggs**	**Hatch of set eggs**
Insemination intervals	1 week		80.8±1.6	84.6±1.8	68.2±2.0

DISCUSSION

The similarity observed for the weekly and fortnight insemination intervals is in line with observations from Adebisi and Ewuola (2019a) using undiluted semen for insemination in local turkeys. The significance of the interaction of the factors implied that at weekly intervals, fertility was similar across the dilution ratios, while at 2 weeks interval, 1:3 was significantly lower than 1:2 and undiluted semen. The mean characteristics of semen inseminated during the period of the study (Table 1) implied that 1:0, 1:1, 1:2 and 1:3 contained approximately $90x10^6$, $45x10^6$, $30x10^6$ and $22.5x10^6$ motile sperm cells, respectively per 0.02mL insemination dose. The results on weekly inseminations are in line with recommendations from Sexton (1976) who reported that as few as 25 million sperm cells per weekly insemination were needed for optimum fertility in Turkeys, which is similar to 1:3 dilution at weekly intervals in this study. The significantly low fertility observed for the dilution ratio of 1:3 at 2 weeks interval may be as a result of an overall relatively lower number of sperm cells inseminated and length of insemination interval of two weeks. Ogasawara (1981) reported that at least 100 million sperm cells should be inseminated in turkeys to produce optimal fertility. Haque and Hossain (2011) suggested 80-100 million sperm cells, while Bramwell (2012) recommended 150 - 300 million viable sperm cells for insemination. There seemed to be an increasing requirement for sperm cells for insemination over the decades and this could be related to the genetic improvement of the birds over time. Requirements by Sexton (1976) may have similarities with the results from this study because the birds used at that time may not have had much genetic advancement, as with those used in this study, which were random-bred and unimproved strains.

Christensen *et al.* (2005) observed that the selection of turkeys for nearly 40 generations for increased 16-week body weight has decreased fertility and embryo survival compared with its random bred control line. They reported that in lines selected for rapid body growth, the dams affected fertility over time. The implication of this may mean more sperm cell requirement for insemination by the improved hens to attain optimal fertility. Breed differences may also cause differences in fertility. There are reports that bronze turkeys fertilised at a faster rate than that from large white turkeys when

inseminated with equal numbers of viable sperm cells (Christensen *et al.*, 2005). They therefore concluded that genetic selection for economically important traits may affect sperm hydrolysis of the perivitelline layer and subsequent fertility and embryo liveability. Despite the differences observed in fertility, the hatch parameters of the interaction of factors did not show significant differences. There were also no significant differences observed with the embryo mortality at various stages. Hemming and Birkhead (2015) suggested that under natural conditions, a minimum number of sperm cells must enter the ovum to ensure zygote formation and development. When too few cells penetrate, embryo survival is significantly reduced. The penetration of too few sperms into the perivitelline layer can be a consequence of very low number of inseminated sperm cells. The absence of significant differences in the embryo mortality and hatch parameters among the treatments is also an indication that the embryo mortality was not affected by the reduced number of sperm cells inseminated as implied from the higher dilution ratios of 1:2 and 1:3. They also added that when inseminated sperm cells are too low, female birds compensate by allowing a greater proportion of sperm reach the site of fertilisation to ensure sufficient supernumerary sperm cells penetrate the germinal disc.

CONCLUSION AND RECOMMENDATION

The result from this study therefore implied that as few as 22.5 million motile sperm cells (1:3 dilutions) inseminated at weekly intervals over a period of 12 weeks, was sufficient to ensure fertilisation and embryo survival. However, if fortnight insemination is to be adopted, semen for insemination should not be diluted beyond 1:2 (a minimum of $30x10^6$ motile spermatozoa).

CRYOSURVIVAL OF GOAT SPERMATOZOA IN TWO TRIS BASED EXTENDERS SUPPLEMENTED WITH VITAMIN E

Adekunle, E.O., Majekodunmi, B.C., Logunleko, M.O. & Daramola, J.O.
Department of Animal Physiology, Federal University of Agriculture Abeokuta, Nigeria

ABSTRACT
Tris Coconut Water (TCW) and Tris Skim Milk (TSM) extenders supplemented with different levels of vitamin E were studied for their ability to support *in vitro* cryosurvival of spermatozoa obtained from West African Dwarf (WAD) goat bucks. Semen samples collected with the aid of artificial vagina were diluted with two tris extenders supplemented with 2, 4, 6 and 8mM of vitamin E for 30 days in liquid nitrogen. Spermatozoa cryopreserved with 6mM and 8mM inclusion levels of vitamin E for TCW extenders and 8mM inclusion levels of vitamin E for TSM based extenders had highest ($P < 0.05$) percentage motility. However, the results showed highest ($P < 0.05$) percentage acrosome integrity and membrane integrity at 4mM, 6mM, and 8mM inclusion levels of vitamin E in TCW extender. Highest ($P < 0.05$) percentage live spermatozoa were observed at TSM extenders supplemented with 4mM, 6mM and 8mM inclusion levels. Spermatozoa cryopreserved with 6mM and 8mM TCW extenders had the lowest ($P < 0.05$) percentage abnormality. Moreover, TCW and TSM extenders supplemented with 6mM and 8mM of vitamin E had highest ($P < 0.05$) spermatozoa that underwent acrosome reaction and capacitation. The findings indicated that spermatozoa obtained from WAD goat bucks were better preserved in TCW extender.

INTRODUCTION
Goat is the most numerous domestic livestock species in Nigeria and presents a great potential to alleviate the problem of protein malnutrition (FAO, 2006). As the demand for these animals is constantly increasing, key steps in rapid multiplication of these animals will be important tools to reduce malnutrition. Frozen semen is normally used for artificial insemination (AI) in goat, sheep and cattle and semen extenders are the main constituents to accomplish freezing; semen extenders provide energy, maintain osmolarity, reduce bacterial contamination and protect sperms at low temperature. Quality of frozen-thawed semen is the main factor for successful application of AI. However, it is proven that the fertility of frozen semen is lower than fresh semen in all mammals including caprine (Lessard *et al.*, 2000; Watson, 2000).
The mechanism by which cryopreservation causes sperm damage is still to be explored, however, it is proven that reduction in viability and fertility occurs due to the damage on sperm plasma membrane (Abavisani *et al.*,2013). Sperm membrane is a highly dynamic structure that controls extra and intra cellular processes and plays an important role during fertilization. Formation of ice crystals reorders lipid, reduces membrane fluidity and permeability during freezing. Choice of semen extender is an important aspect of semen processing for AI and many extenders have been proposed for goat semen (Iaffaldano *et al.*, 2005). The adoption of AI technique in animal production in Nigeria has been generally low and this has accounted for the little or no documented information on storage and AI technique for goat reproduction in Nigeria. Vitamin E (α-tocopherol) functions as a peroxyl radical scavenger which helps to maintain the integrity of long chain polyunsaturated fatty acids in the membranes of cells and thus maintain their bioactivity (Traber and Atkinson, 2007).

MATERIALS AND METHODS
Experimental Location and animal
The study was carried out at the Teaching and Research Farm of Federal University of Agriculture, Abeokuta. Eight intact WAD bucks aged 2.5-3 years were used for this study.

SEMEN COLLECTION
Semen samples were collected from eight WAD bucks with the aid of artificial vagina.
Semen dilution and storage
The effect of adding different levels of vitamin E in two tris extenders on viability of spermatozoa obtained from WAD goat bucks was carried out in a study repeated twice. Only ejaculates showing >80% motility were pooled to minimize individual differences (Bucak and Tekin, 2007). The pooled semen samples were diluted at 32°C in a two-step process with a Tris-based extender composed of 2

fractions. The Fraction 1 solution contained Tris-hydroxymethyl-aminomethane (2.42g), citric acid (1.36g), glucose (1g), penicillin (0.028g), Sodium citrate (2.9g) and distils water made up 100 mL as control followed by addition of Tris-egg yolk, skimmed milk and coconut water based extender each at (20mL), consisted of Tris-hydroxymethyl-aminomethane (2.42g), citric acid (1.36g), glucose (1g), penicillin (0.028g), and distils water make up 100mL. Fraction 2 solution had the same composition as the Fraction 1 solution with the addition of 14.0% glycerol (v/v). The pooled semen samples were splited into 9 equal aliquots, diluted with the Fraction 1 solution and supplemented each with 0mM, 2mM, 4mM, 6mM and 8mM of vitamin E respectively with pH of 7.05 at a final concentration of 789 $\times 10^6$ spermatozoa per millilitre. Fraction 2 solution was subsequently added to fraction 1. Diluted semen samples were then loaded into 2 mL plastic straws, sealed with polyvinyl, cooled to 4°C at a rate of 0.25^{o}C/min and equilibrated at 4°C for 10 min in TYFSF Refrigerated Incubator. Subsequently, the straws were then placed in a canister at 4cm above liquid nitrogen in the vaporous phase for 10min before plunging them directly and quickly into liquid nitrogen for 30 days and thereafter evaluated for sperm quality characteristics.

SEMEN EVALUATION

Subjective microscopic evaluation of sperm motility, acrosome Integrity, sperm membrane integrity, sperm abnormality, live sperm, *In vitro* acrosome reaction and *In vitro* capacitation were carried out.

RESULTS

The results in Table 1 showed that spermatozoa cryopreserved with 6mM and 8mM inclusion levels of vitamin E for TCW based extenders had highest ($P < 0.05$) percentage motility. Similarly, spermatozoa cryopreserved with 8mM inclusion levels of vitamin E for TSM extenders had highest ($P < 0.05$) percentage motility. Highest ($P < 0.05$) percentage acrosome integrity and membrane integrity in 4mM, 6mM, and 8mM inclusion levels of vitamin E were observed among TCW extender and highest ($P < 0.05$) membrane integrity was also realized when 6mM and 8mM inclusion levels of vitamin E in TSM extender was used. Highest ($P < 0.05$) percentage live spermatozoa was observed among both extenders supplemented with 4mM, 6mM and 8mM inclusion levels of vitamin E and TSM supplemented with 6mM and 8mM inclusion levels of vitamin E. However, Spermatozoa cryopreserved with TCW extender supplemented with 6mM and 8mM inclusion levels of vitamin E had the lowest ($P < 0.05$) percentage abnormality.

The results in Table 2 showed that more spermatozoa ($P < 0.05$) cryopreserved with vitamin E underwent acrosome reaction and capacitation compared to the control. However, TCW and TSM based extenders supplemented with 6mM and 8mM of vitamin E had highest ($P < 0.05$) spermatozoa that underwent induced acrosome reaction.

DISCUSSION

The addition of different levels of vitamin E in this present study to TCW and TSM based extenders improved the percentage of sperm motility and viability, The improvement in motility in this tris based extenders supplemented with vitamin E suggests the beneficial effect of vitamin E on sperm motility and viability which could be due to its potential antioxidant capacity. The highest sperm motility and percentage live sperm observed from TCW following supplementation of vitamin E could be linked to the fact that vitamin E suppressed deleterious effect of ROS on WAD buck and the protective effect of coconut water which result to high content of lipids which is a major component of sperm membrane that is involved in a series of biochemical and functional change ultimately required for fertilization (Brque *et al*., 2003). The combination of vitamin E and TCW is a more complete nutrient composition that provide important source of energy for sperm to maintain their lifespan during storage and also coconut water is poor in phospholipids and rich in complex organic molecules, such as proline, glycine, glutamic acid and indole-acetic acid (IAA) which protect and extend the spermatozoa life span.

The higher acrosome and membrane integrity during cryopreservation with the tris based extenders supplemented with vitamin E indicated that vitamin E as antioxidant has capacity to increase the onset of the physiological acrosome reaction and the Indole Acetic Acid present in coconut water had a beneficial effect on goat sperm acrosomal and membrane integrity.

Evaluation of sperm abnormality is one of the commonest methods of investigating survival of frozen thawed semen and the relationship between sperm abnormality and fertility has been evaluated (Raina, 2002). Vitamin E functions as antioxidants which in turn may provide direct protection of sperm cells from morphological damage by preventing free radical oxygen from damaging sperms (Luvoni, 2006).

The physiological acrosome reaction involves activation of several signal transduction pathways, the induced acrosome reaction mainly involves a chemical effect on calcium influx that partially reflects the physiological acrosome reaction process (Breitbart and Spungin, 1997) and only capacitated spermatozoa have ability to undergo acrosome reaction (Arnoult *et al.*,1996).The present *in vitro* study indicated that vitamin E was able to maintain fertilizing capacity of spermatozoa in, TCW and TSM extenders as evidenced by better percentage of capacitation and acrosome reaction of cryopreserved spermatozoa. In ram spermatozoa, vitamin E administration increases plasminogen activator activity, known to be involved in sperm capacitation and acrosome reaction (Tsantarliotou *et al.,* 2008). This result was in agreement with Arabi and Seidaie (2008) who demonstrated that vitamin E determined capacitation of buffalo spermatozoa *in vitro*.

CONCLUSION

The findings of the present study indicated that the use of coconut extenders supplemented with vitamin E for goat semen cryopreservation could, in the future, improve the effectiveness of goat AI programs and it is concluded that there were no apparent disadvantages to switching from egg yolk extenders to coconut extenders for goat semen cryopreservation.

RECOMMENDATION

Coconut extender supplemented with 6mM and 8mM vitamin E could be used to preserve goat semen.

SEMEN CHARACTERISTICS AND GROWTH INDICES OF MALE RABBITS FED DIETARY LEVELS OF *VERNONIA AMYGDALINA*

Adeyemi A. A., Oloyede C. O., Idowu G.A. & Akinlade M. O.
Department of Animal Sciences, Obafemi Awolowo University, PMB 13, Ile-Ife, Nigeria.
Correspondence: nikeadeyemi@oauife.edu.ng

ABSTRACT
The effect of dietary levels of *Vernonia amygdalina* Leaf Meal (VLM) on semen and growth indices in male rabbits was assessed in this study. Dried *Vernonia amygdalina* leaves was milled and included into the experimental diets at 0, 5, 10 and 15 %. The diets were fed to forty male rabbit with ten bucks per group for twelve weeks. Semen was collected from the bucks weekly and assessed for semen volume (ml), spermatozoa motility (%), sperm concentration ($x10^7$/ml) and live sperm cells (%). Body weight gain was monitored weekly using a sensitive weighing scale and morphometric traits were measured once every two weeks using a measuring tape. Five rabbits per group were stunted, slaughtered; the testes were harvested and weighed. Data obtained were analyzed using Analysis of Variance. The result obtained showed that dietary inclusion of VLM had a significant ($P<0.05$) effect on semen volume and live sperm cells (%). The average weekly weight gain of the rabbit bucks was significantly ($P<0.05$) influenced by VLM among the groups. Among the morphometric traits measured, only body length was significantly ($P<0.05$) influenced by the inclusion of VLM in the diets of the animals. The highest testes weight (4.57g) was recorded in bucks fed 10% VLM diets. Inclusion of VLM in the diet of male rabbits had no adverse effect on all the parameters assessed. Improved weight gain was recorded at 10kg/100kg diet. It can be inferred that *Vernonia amygdalina* can be adopted as a component of male rabbits' diet but not for boasting their semen quality.

INTRODUCTION
Rapid growth, efficient reproduction and increased productivity are essential for profitable livestock production. The use of plant for boasting reproductive efficiency in animal production has been on the increase. However, male rabbits with poor body conformation may not be efficient breeders. Changes in the different parts of the body determine the shape, conformation and body proportion of the animal at a given time (Olutogun *et al*., 2003). Morphometric traits can be used as aid to selection in rabbit genetic improvement and live weight prediction (Hassan *et al*., 2012). However, the relationship between nutrition, growth and reproductive efficiency of an animal cannot be over-emphasized. Leaf meals have been identified as suitable replacements for some conventional feedstuff (Oloruntola *et al.,* 2016), many of which may have beneficial or adverse properties. *Vernonia amygdalina* (Bitter leaf) is one of the non-conventional feed resources which are predominantly found in Africa. It is probably the most used medicinal plant in the genus vernonia (Ijeh and Ejike, 2011). It is rich in both nutritional and phytochemical components. *Vernonia amygdalina* contains90.68% dry matter, 22.81% crude protein, 18.17% crude fiber, 16.65% ash, 4.34% crude fat and 38.03% carbohydrate (Usunobun and Okolie, 2016). Bioactive compounds identified in the leaves include oxalate, phylate, tannins, saponins, flavonoid, cyanogenic glycosides, alkaloids, anthraquinone, steroid and phenol (Udochukwu *et al.,* 2015). The modulatory role of *Vernonia amygdalina* extract on spermatogenesis and steriodogenesis have been reported (Saalu *et al.,* 2013); this is attributed to the presence of bioactive substances present in the leaf. The saponin extract of *V. amygdalina* administered to male rats has potential to increase their fertility (Oyeyemi *et al.,* 2015). Olosunde (2016) reported a significantly lower average daily weight gain in West African Dwarf goats fed diets with 30 and 45% bitter leaf inclusion. Despite the various attributes of *Vernonia amygdalina* that has been reported in literature, little is known about its effect on reproductive indices of male rabbits used for breeding purpose. This study therefore aims at assessing the effect of *Vernonia amygdalina* leaf meal on semen indices, weight gain, morphometric traits and weight of testes in rabbit bucks.

MATERIALS AND METHODS
The study was conducted at the Rabbitry unit of the Teaching and Research Farm, Obafemi Awolowo University, Ile-Ife, Nigeria. Fresh *Vernonia amygdalina* leaves were harvested and air dried until brittle; it was milled to obtain *Vernonia amygdalina* leaf meal (VLM) which was incorporated into the

experimental diets thereafter pelletized. The experimental diets (Table 1) are designated as VLM_0 - diet without VLM (control diet), VLM_5- diet with 5% VLM, VLM_{10}- diet with 10% VLM and VLM_{15}- diet with 15% VLM. Forty rabbit bucks of heterogeneous population with an average weight of 1818.3g were used for this experiment. The rabbits were randomly allocated into four groups with 10 bucks per group in a Completely Randomized Design. The experimental diets were offered to the rabbits daily and feed intake was recorded. The experiment lasted for a period of 12 weeks. Fresh semen samples were assessed for semen volume, spermatozoa motility, sperm concentration and percentage live sperm cells as described in Adeyemi *et al*. (2014). The bucks were weighed weekly using the weighing scale and the body weight gain obtained were recorded in grams. Some morphometric traits of the animals were taken in the morning before feeding the rabbits once every two weeks using a tape rule and the values were recorded in centimeters (Ogbuewu *et al.*, 2011). Traits measured included ear length, head length, body length, abdominal circumference and tail length. Five rabbits per group were stunted, slaughtered; the testes were harvested and weighed using a sensitive scale. All data obtained were subjected to statistical Analysis of Variance procedure using Statistical Analytical System (SAS, 2009). Treatment means were compared using Duncan Multiple Range Test of the same software.

Table 1: Composition of Experimental diets

INGREDIENTS	VA_0	VA_5	VA_{10}	VA_{15}
Maize	9.00	9.00	9.00	9.00
Corn bran	22.50	22.50	22.50	22.50
Rice bran	20.80	20.80	20.80	20.80
Soybean meal	9.90	9.90	9.90	9.90

VLM- *Vernonia amygdalina* leaf meal; VLM_0- diet without VLM (control diet), VLM_5- diet with 5% VLM, VLM_{10}- diet with 10% VLM and VLM_{15}- diet with 15% VLM Others: Bone meal =1.10, Salt = 0.32 and Premix = 0.33

RESULTS AND DISCUSSION

The semen indices of the bucks fed dietary levels of *Vernonia amygdalina* Leaf meal (VLM) is presented in Table 2. Dietary inclusion of VLM had a significant ($P<0.05$) effect on semen volume and live sperm cells (%). The highest semen volume (0.47ml) was recorded in bucks fed 15% VLM diets which was not significantly different from that of bucks fed diet with no VLM (0.43ml). Bucks fed diets VLM_5 and VLM_{10} had lower semen volume (0.34, 0.36 ml) and sperm concentration compare to that of bucks fed VLM_{15}. Sperm motility and concentration were not significantly influenced by the inclusion of VLM in the diets of the bucks. The result from this study corroborate that of Ajala and Owoyemi (2016) who reported no significant effect of VLM levels on milt motility and liveability in African catfish. The effects observed may be attributed to the presence of bioactive substances (Tannin, Saponin) present in VLM that may not enhance spermatogenesis. This may also be influenced by the level of VLM fed and the feeding duration. The weight gained by an animal within a unit of time is an important indicator of its growth. Table 3 shows the body weight gain, testes weight and morphometric traits of male rabbits fed dietary levels of *Vernonia amygdalina* Leaf

Meal (VLM). The average weekly weight gain of the rabbit bucks was significantly different (P<0.05) among treatments. The highest average weekly weight gain (44.04g) was recorded in bucks fed the 10% VLM while the lowest (22.46g) was recorded in those fed 15% inclusion of VLM. The results obtained from this study with rabbit bucks fed diet with 10% VLM having the higher weight gain is in corroborate the findings of Olosunde (2016) who reported reduced weight gain in West African Dwarf goat fed dietary levels of VLM above 15%. However, the value obtained in this study is at variance with the finding from the use of VLM extract which resulted in increased weight gain in broiler chicks (Oleforuh-Okoleh *et. al.* 2015). Among the morphometric traits measured, only body length was significantly (P<0.05) influenced by the inclusion of VLM in the diets of the animals. Bucks on 0%VLM diet recorded the highest value for body and head length (39.88, 11.91 cm respectively). The bucks fed diets with 10% VLM had the highest average weekly weight gain and abdominal circumference. This is at variance with the findings of Ogbuewu *et al*, (2011) who reported no significant difference in body length of pre-pubertal buck rabbits fed different levels of neem leaf meal.

Testes weight was not significantly influenced by the dietary inclusion of VLM in the diets of the bucks. The highest testes weight (4.57g) was recorded in bucks fed 10% VLM diets with the highest weight gain. This corroborates the findings of Raji *et al*., (2008) who reported a linear relationship between age, body weight and the entire testicular dimension within breeds in goats. The result from this study therefore implies that dietary levels of VLM did not have similar effects across the parameters assessed in the bucks; hence its effect on semen quality may not be optimal.

Table 2 : Semen Indices of Rabbit Bucks Fed Dietary Levels of *Vernonia amygdalina*

PARAMETERS	**VLM_0**	**VLM_5**	**VLM_{10}**	**VLM_{15}**	**SEM**	**p value**
Semen Volume (ml)	0.43^a	0.34^b	0.36^b	0.47^a	0.0097	<0.0001

Table 3 : Body Weight Gain, Morphometric Traits and Testes Weight of Rabbit Bucks Fed Dietary Levels of *Vernonia amygdalina*

Parameters	VLM_0	VLM_5	VLM_{10}	VLM_{15}	SEM	p value
Avg. Weekly Weight Gain (g)	38.82^{b}	27.29^{bc}	44.04^{a}	22.46^{c}	2.91	0.016
Morphometric Traits:						
Abdominal Circumference (cm)	28.76	28.79	29.01	27.93	0.33	0.451
Body Length (cm)	39.88^{a}	37.10^{b}	38.21^{b}	37.76^{b}	0.32	0.011
Ear Length (cm)	11.16	11.68	11.59	11.11	0.09	0.056
Head Length (cm)	11.91	11.43	11.42	11.47	0.10	0.226
Tail Length (cm)	9.85	8.49	9.72	9.97	0.24	0.106
Testes weight (g)	4.20	4.45	4.57	3.88	0.15	0.419

VLM - *Vernonia amygdalina* Leaf Meal; a, b, c -Means in the same row with different superscript are significantly ($P< 0.05$) different SEM – standard error of means

CONCLUSION

Inclusion of *Vernonia amygdalina* leaf meal (VLM) in the diet of male rabbits had no adverse effect on semen quality, weight gain, morphometric traits and testes weight. Morphometric traits cannot be used to predict weight gain in heterogeneous population of adult bucks fed VLM since the diet had no significant effect on most of the traits assessed. However, improved weight gain was recorded at 10kg VLM/100kg diet. It can be inferred that VLM can be adopted as a component of male rabbits' diet but not for boasting their reproductive efficiency in terms of semen indices.

CHICKEN GROWTH HORMONE GENE POLYMORPHISM OF SELECTED CHICKEN BREEDS IN NIGERIA

Adigun, U.O., Ojimah, C.O. and Egena, S.S.A.
Department of Animal Production, Federal University of Technology, P.M.B. 65, Minna, Niger State, Nigeria.
Corresponding Author:adigunolagoke@gmail.com

ABSTRACT
The study was carried out to investigate polymorphism at the chicken growth hormone gene of selected chicken breeds (Fulani ecotype, Noiler, FUNAAB Alpha, Frizzled feathered and Cobb 500) in Nigeria. Genomic DNA was extracted from blood samples collected from 49 birds. Amplification of specific DNA fragments at intron 3 of the *cGH* gene yielded a product size of 715bp and this was used to analyze for polymorphism using Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) technique. Banding patterns of the gene investigated, revealed the occurrence of three RFLP variants: TT, CT and CC with genotype frequencies of 0.449, 0.245 and 0.306, respectively. The allele frequencies of the T and C alleles were 0.469 and 0.531, respectively indicating that the C allele was predominant. Chi-square test revealed that the chicken population investigated was in Hardy-Weinberg equilibrium. It was concluded that, the presence of observed genetic variations in the chicken growth hormone gene, could be exploited because of its association with economically important traits.

Keywords: Polymorphism, chicken, growth hormone, gene and RFLP.

INTRODUCTION
Growth hormone affects traits in broiler chickens production such as growth rate, body weight maturation, metabolic rate, egg production, reproduction, appetite control and aging (Harvey, 2013), it also promotes muscle and bone growth and development, as well as regulation of fat content and its metabolism (Zhang *et al.,* 2007). The Chicken Growth Hormone (*cGH*) is a 22-kDa protein, containing 191 amino acid residues and consisting of 4,101bp, having five exons and four introns (Kansaku *et al.,* 2008; Hrabia *et al.,* 2008). A polypeptide, the hormone is produced and secreted by the pituitary gland. Apart from affecting a variety of physiological functions, *cGH* is reported to be one of the most important genes affecting chicken performance traits (Vasilatos-Younken *et al.,* 2000). Its linkage to growth and metabolism, leads to potential correlations between its polymorphisms and economic traits. It is also involved in the processes of sexual differentiation, pubertal maturation and participates actively in gonadal steroidogenesis, gametogenesis and ovulation (Hull and Harvey, 2001). Apart from the above mentioned; it also plays significant roles in a variety of secondary functions such as egg production, aging and reproduction (Kansaku *et al.,* 2008). Accordingly, this study was carried out with the aim of investigating the polymorphism at intron 3 of the *cGH* gene in selected chicken breeds in Nigeria.

MATERIALS AND METHODS
The study was carried out using five chicken breeds commonly reared in Nigerian (Fulani ecotype, Fizzle feathered, Noiler, FUNNAB Alpha broilers, Cobb 500). Blood samples (5mls) were collected from the brachial vein of forty nine chickens using 5ml syringes (separate needles and syringes were used for individual birds to avoid cross contamination). The blood samples were collected into Ethylene Di-amine Tetra-acetic Acid (EDTA) bottles.Samples were stored on ice packs for onward transfer to the laboratory where genomic DNA was extracted. This was done at African Biosciences Ltd., Ibadan, Oyo State, Nigeria. DNA was extracted using gSYNC^{TM} DNA extraction kit (Geneaid) according to the manufacturer's protocol. The quantity and quality of the extracted DNA was checked by spectrophotometer and agarose gel electrophoresis, respectively. The PCR products (2 samples per breed) were sequenced and then aligned against the chicken genome with the BLAST programme to verify their identity. Prior to sequencing, the DNA were cleaned to ensure that the gene is not contaminated with impurities. This was done using DNA clean and concentrator kit according to the manufacturers protocol (ZYMO Research). The primers used for the study was specific to *cGH* gene and was designed using the National Centre for Biotechnology Information (NCBI) website. The *cGH* forward primer 5'TCAGTACGCAGACCTACCCTC3'and 5'TGCACATCATGTCCCACGTTT3' (reverse) were used for the study.The extracted DNA was diluted with autoclaved distilled water to 30ng per µl. A total of 21µl of reaction mixture for the primer was mixed in eppendorf tube. The reaction volume (21µl) containing the *cGH* primers was amplified using PCR-RFLP method; each of

1.5µl, PCR Master Mix (10µl) contained water 2.7µl and 5.3µl (90ng) diluted DNA. The reaction mixture were subjected to an initial denaturation at 95°C for 4 minutes, followed by 50 cycles at 94°C for 25 seconds. Annealing then followed at 56°C for 45 seconds, an extension at 72°C for 40 seconds and a final extension was done for 10 minutes at 72°C. The PCR products were digested with the endonuclease *Taq*1. Restriction enzyme was analyzed on 2.5% agarose gel. For genomic DNA, 1.0% agarose gel was used while for the PCR product, 2.0% agarose gel was used. Electrophoresis was conducted at a constant voltage of 75 volt for 45 minutes at 37°C using 1.0xTAE buffer. The DNA ladder (100 bp) was used for sizing of the DNA bands. The stained (ethidium bromide) DNA fragments were photographed using a Blue Light (BL) transilluminator (Biologix®) to visualize the bands. Genotypic frequencies of the different PCR-RFLP patterns were estimated from the combination of various RFLP alleles generated based on the presence or absence of one or more restriction sites. Different genotypes were identified on the basis of the different patterns observed. The allele frequencies were calculated using standard methods. Chi-square (χ^2) test for goodness of fit was used to test for Hardy-Weinberg equilibrium.

RESULTS AND DISCUSSION

The agarose gel electrophoresis result of isolated genomic DNA of *cGH* of selection chicken breeds in Nigerian is presented in (Figure 1). The isolated genomic DNA of the selected chicken breeds indicated high quality and appeared as single bands without sheared fragments. DNA extraction and quality determination with electrophoresis and spectrophotometer was done for all Chickens and the obtained result was acceptable.

Figure 1: DNA extracted from chicken breeds

The agarose gel electrophoresis results of the PCR amplified *cGH* is presented in Figure 2. Amplification of specific DNA fragments at intron 3 of the *cGH* gene was successfully performed for the total samples using the designed primer pair. The amplified products appeared as clear single bands, and occupied the appropriate position with approximately 715bp of amplicon size, with no variation in sizes between the chicken breeds. The amplified products were consistent with the target fragments and had a good specificity, which could be directly analyzed through PCR-RFLP technique. This finding at intron 3 of the *cGH* gene is in tandem with the results of Muin and Lumatauw (2013) in Indonesia native chickens. However, Shahnaz *et al*. (2008), Thakur *et al.* (2009), Khoa *et al.* (2013), Makhsous *et al*. (2013), Rahmadani *et al.* (2014) and Saikhom *et al.* (2017) reported product sizes of 1200bp, 1216bp, 563bp, 1164bp, 367bp and 713bp, respectively. The differences observed in the bp of the PCR fragments suggest the possibility of insertion/duplication of the sequence. The agarose gel electrophoresis result of the PCR-RFLP analysis amplified *cGH* is presented in Figure 3. The banding pattern revealed three RFLP variants which were arbitrarily assigned as CC, CT and TT genotypes. The CC, CT and TT genotypes were detected by the presence of two bands, three bands and one band, respectively. The frequencies of the different RFLP fragments at intron 3 of the *cGH* gene are presented in Table 1. Out of the 49 chickens studied, 15 had CC (30.6%), 22 had CT (44.9%) and 12 had TT (24.5%) genotype, respectively. This occurrence of three genotypes is in agreement Bingxue *et al*. (2003) who reported three genotypes (AA, AB and BB) in a population of hybrid chickens (broilers x Silky) in China. Also, Tanmankaur *et al.* (2008) analyzed 776bp amplicon of *cGH* gene digested with *Msp*1 with the results revealing three different genotype patterns (AA, AC and CC) created by a combination of polymorphic *Msp*1 cut sites present in exon-1 and intron-1, respectively. The result however, disagrees with the findings of Thakur *et al.* (2009) and Kulibaba (2015) who reported two genotypes AA and AB in Kadaknath chickens and, AB and BB in local chicken breeds of Vietnam.

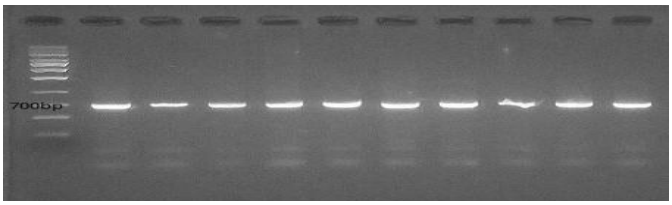

Figure 2: PCR amplified products at intron 3 of *cGH*

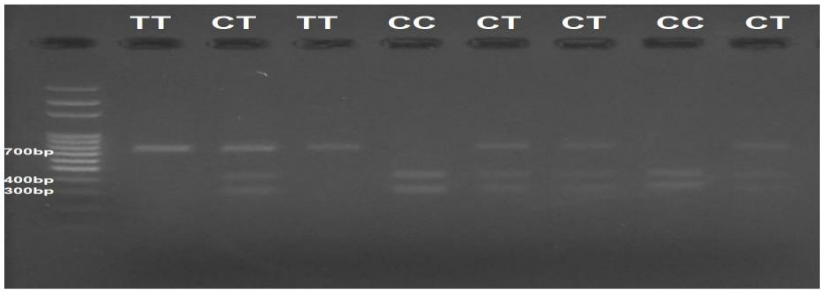

Figure 3: Genotypes amplified products at intron 3 region of *cGH*

Table 1: Frequency of RFLP patterns at intron 3 region of *cGH* gene

Pattern	Genotype	Frequency	Percentage
Two bands	CC	15	30.6
Three bands	CT	22	44.9
One band	TT	12	24.5

The genotype and gene frequencies with respect to intron 3 of the *cGH* gene is depicted in Table 2. The genotype frequencies were 0.306 for CC, 0.449 for CT and 0.245 for TT genotypes, respectively. Bingxue *et al*. (2003) reported three distinct genotypes with genotypic frequencies of 0.759, 0.213 and 0.027, respectively in a population of Chinese hybrid chickens. Thakur *et al.* (2009) and Kulibaba (2015) however, reported two genotypes in Kadaknath and local chicken breeds of Vietnam; the frequencies were 0.4151 and 0.5849, and 0.070 and 0.930, respectively. The results of Makhsous *et al.* (2013) revealed six genotypes (AA, AB, AC, BB, BC, CC) in the native chickens of Iran.

Table 2: Genotype and gene frequencies at intron 3 region of *cGH*

Genotype	Numbers	Frequency
CC	15	0.306
CT	22	0.449
TT	12	0.245
Allele		
C	52	0.531
T	46	0.469

The frequencies of C and T alleles (0.531 and 0.469) indicate that the C allele was predominant. Higher frequency of A allele (0.9028) compared to B allele (0.0972) was reported by Muin and Lumatauw (2013) in Indonesian native chickens. Other authors who also observed preponderance of A allele over B allele include: Bingxue *et al*. (2003) where A allele was 0.8655 and B allele was 0.1335; Thakur *et al.* (2009) where allele A was 0.7075 and B was 0.2925., Makhsous *et al.* (2013) reported allele frequencies as follows: 0.599 (A), 0.102 (B) and 0.299 (C), respectively. However, Kulibaba (2015) observed higher frequency of the B allele (0.964) than the A allele (0.036) in local Vietnamese chicken breeds. The calculated Chi-square value (0.312) showed that the studied population was in Hardy-Weinberg equilibrium with respect to intron 3 of the *cGH* gene (Table 3).

This indicated that evolutionary forces like migration, mutation and selection might have acted on the studied chicken breeds at the locus studied. This is in agreement with earlier observations (Khoa *et al.,* 2013: Makhsous *et al*., 2013; Rahmadani *et al.,* 2014).

Table 3. Hardy-Weinberg equilibrium at intron 3 of *cGH* gene

Genotype	Observed Individuals	Expected individuals	$\frac{(O-E)^2}{E}$	X^2
CC	12	11.028	0.087	0.312
CT	22	23.944	0.158	
CT	15	14.028	0.067	

In conclusion, the presence of observed genetic variants in the *cGH* gene could be exploited as a candidate gene in marker assisted selection to improve the performance of the studied chicken breeds.

BREEDING, BIOTECHNOLOGY AND PHYSIOLOGY (ORAL)
SURVIVABILITY OF COCK SEMEN STORED UNDER ROOM TEMPERATURE IN EXTENDERS CONTAINING SOME ANTIOXIDANTS

Amaefule, B.C., Uzochukwu, I. E., Ikeh, N.E., Nnajiofor, N.W., & Eze, E.C.

ABSTRACT
The study was conducted to determine the survivability of cock sperm stored under room temperature in extenders containing some antioxidants. A volume of 2ml of pooled semen collected from four mature Heavy Ecotype cocks was stored in Honey-Ringers solution and three other extenders containing Honey-Ringers solution supplemented with the antioxidant vitamins C and E. The semen samples were observed under a microscope at 0, 6 and 12 hours to determine sperm motility by scoring. Survivability of the sperm cells was taken as the average percentage number of motile spermatozoa in each extender recorded during 0, 6 and 12 hours storage duration. The experimental layout was a completely randomized design. The generated were analysed using one way analysis of variance (ANOVA) in SPSS. The result showed that Average sperm survivability was significantly (P<0.05) higher for semen stored in supplemented with the antioxidant vitamins C and E compared to semen stored in Ringers solution. The proportion of spermatozoa that survived within the 6 hour storage time was highest in the Vit E supplemented extender followed by the Vit C group and lowest in the control group. From the results, it was concluded that extenders supplemented with the antioxidant preserved semen motility and viability.
Key words: survivability,semen extender, antioxidants, Vitamin C, Vitamin E.

INTRODUCTION
The modern day farm animal reproduction is hinged on better reproductive techniques, one of which is artificial insemination (AI) (Akandi *et al.,* 2015). It is an effective and globally accepted method of breeding animals including poultry. Success in AI requires quality spermatozoa which have the capacity to reach the site of fertilization, fertilize the egg and activate embryonic development (Wilson, 2016). Its application is widely based on stored semen for future use. However, the length of storage of undiluted or extended semen is restricted and presents a significant decrease in spermatozoa viability and fertilizing capacity after 24 hours of storage (Donoghue and Wishart, 2000). Lipid peroxidation of sperm membrane lipids is a major cause of decreased motility and fertilizing ability of mammalian spermatozoa (Aurich *et al*., 1997). Avian semen is characterized by high level of unsaturated fatty acid within its phospholipids (Surai *et al.,* 1998c). This makes their semen susceptible to lipid peroxidation and spermatozoa deterioration during storage (Surai *et al.*, 1997; 1998c). Bozhedomov *et al.,* (2009) reported that Oxidative stress occurs when production of potentially destructive reactive oxygen species (ROS) exceeds natural antioxidant defenses thereby resulting in cellular damage. Toxic lipid peroxides are reported to cause impairments of sperm cells and may play a major role in the etiology of infertility in males (Firozeh *et al.*, 2010).
Avian semen contains natural antioxidants including ascorbic acid, tocopherol, catalase, glutathione peroxidase and superoxide dismutase that help to balance lipid peroxidation and prevent excessive peroxide formation (Beconi *et al.*, 1993). However, the endogenous antioxidant activity of seminal plasma and spermatozoa may not be enough to prevent peroxide damage after extension and *in-vitro* storage thus supplementation with antioxidants could improve the semen shelf life (Donoghue and Donoghue, 1997).

MATERIALS AND METHODS
Location of the experiment
The experiment was carried out at the poultry Unit of the Teaching and Research Farm, Department of Animal Science, University of Nigeria, Nsukka in Enugu State, Nigeria.
Experimental diets, animals and management
Thirty (30) mature heavy ecotype cocks with an average weight of 2.4±0-5kg were used for the experiment. The birds were kept in battery cage, one cock per cell to avoid physical contact between

the cocks and to avoid fight. Routine management practices including vaccination and drug administration where necessary were observed with water and feed provided *ad libitum.*

Experimental Design

The experiment was carried out in a completely randomized design (CRD). Ringer's solution + Honey extender was prepared at room temperature, and divided into 3 parts which were supplemented with the antioxidant vitamins C and E, and control corresponding to groups DII, DIII and DI, respectively. No antioxidant was added to the extender in the control group (DI).
The compositions of the different extenders per L are shown in Table 1.

Table 1 Composition of Extenders

Ingredients	DI (Ringer)	DII (Ringer + Vit. C)	DIII (Ringer + Vit. E)
Sodium Chloride (g)	9.5	9.5	9.5
Potassium Chloride (g)	0.2	0.2	0.2
Calcium Chloride (g)	0.26	0.26	0.26
Sodium bicarbonate (g)	0.2	0.2	0.2
Honey (g)	1	1	1
Vitamin C (g)	0	0.4	0
Vitamin E (g)	0	0	0.08
CMC (ml)	0	0	5
Distilled water (L)	1	1	1

Fresh honey used in this research was purchased from local suppliers in Nsukka Main Market, Enugu State. The honey was used as purchased without further processing.

Semen Collection and Evaluation

Semen was collected from the toms using the abdominal manual massage method as described by Al-Daraji, (2007). On the day of semen collection, 2 mL of pooled semen was diluted (1:4) in each of the constituted extenders. Semen samples from the four cocks were pooled to reduce any likely variation in semen quality that may be caused by individual differences in genetic blueprint of the cocks. The determination of the different physical characteristics of the semen was made as described by Peters et al., (2008). The percentage motility of spermatozoa was evaluated immediately after semen collection. For this, a drop of semen was placed on a warm glass slide and covered with a cover slip to evenly spread the semen in the slide. The slide was afterwards viewed in the microscope (400 x magnification). Observations were widely made across different areas on the slide for the various samples. Motility was expressed as percentage of sperm showing normal forward progressive movements.Motility assessment was made by the same person to minimize differences during interpretation. Motility scores taken immediately after dilution were regarded as score for 0 hour storage, while experimental motility scores were recorded for 0, 6 and 12 hours of storage. Sperm concentration was determined by the method of direct cell count using an improved Neubauer hemocytometer. The percentages of live and dead spermatozoa were determined using an eosin–nigrosin stained smear with oil emulsion and observed under a light microscope at 400x magnification. Unstained spermatozoa were regarded as live whereas stained or partially stained spermatozoa were counted as dead. This determination was made over observations of about 200 spermatozoa per slide.

Statistical Analysis

The data generated were analysed using one way analysis of variance (ANOVA) in SPSS software (IBM® version 20.0). Differences found among the treatment means were compared using Duncan's New Multiple Range Test (Duncan, 1955) and accepted at 5% or 1% level of probability.

RESULTS AND DISCUSSION

Table 2: Mean (±SE) effect of diluents and storage duration on sperm survivability of Nigerian ecotype cock

Duration of storage (hrs)	Traits (%)	Ringer solution	Ringer solution + vit C	Ringer solution + vit E	P-value
0	Motility	85.56±3.91	87.22±4.41	87. 22±2.64	0.655
	Live	83.00±6.22	81.78±7.10	81.33±6.54	0.844
	Dead	17.00±6.22	18.22±7.10	18.67±6.54	0.844
6	Motility	70.00±3.54^{c}	75.00±3.54^{b}	80.00±5.00^{a}	0.000
	Live	64.56±5.43^{c}	70.44±7.43^{b}	78.11±6.47^{a}	0.000
	Dead	35.44±5.43^{a}	29.56±7.43^{b}	21.89±6.47^{c}	0.000
12	Motility	62.78±4.41^{c}	70.00±7.07^{b}	75.56±3.91^{a}	0.000
	Live	61.78±4.02	62.56±4.98	65.56±7.40	0.407
	Dead	38.22±4.02	37.44±4.98	34.44±7.40	0.407

^{a,b,c} – Means in the same row with different superscripts are significant at 5 or 1 % (* P < 0.05; ** P<0.01), NS- Not significant, Vit- Vitamin.

The result of the study on the effect of diluents and storage duration on sperm survivability of Nigerian ecotype cock are presented in Table 2.

The result showed that within 0 hour of storage, no significant difference (P > 0.05) was observed in semen progressive motility, percentage live and dead sperm cells among the various treatment groups. All extenders maintained high motility. At 0 hour post semen dilution, spermatozoa motility were 85.56±3.91%, 87.22±4.41%, and 87.22±2.64% for DI, DII, and DIII respectively. The percentage live spermatozoa at 0 hour post dilution were 83.00±6.22%, 81.78±7.10%, and 81.33±6.54% for DI, DII, and DIII respectively while percentage dead sperm cells were 17.00±6.22%, 18.22±7.10%, and 18.67±6.54% for DI, DII, and DIII respectively.

At 6 hours post dilution, significant difference (P < 0.05) was observed in progressive semen motility. Spermatozoa motility reduced to 70.00±3.54%, 75.00±3.54 %, and 80.00±5.00% for DI, DII, and DIII respectively. The same trend was followed for percentage live sperm cells. The percentage live sperm cells for DI, DII, and DIII were 64.56±5.43%, 70.44±7.43 %, and 78.11±6.47% respectively while percentage dead sperm cells recorded 35.44±5.43%, 29.56±7.43%, and 21.89±6.47% for DI, DII, and DIII respectively. The percentage of sperm cells that were motile within the 12th hour of storage was 62.78±4.4 %, 70.00±7.07 %, and 75.56±3.91% for DI, DII, and DIII respectively. There was distinct variation (P<0.05) in the motility of spermatozoa in the extenders. The proportion of spermatozoa that were motile within the 12 hours of storage time was highest in the DIII and lowest in DI. The percentage live sperm cells for DI, DII, and DIII were 61.78±4.02%, 62.56±4.98%, and 65.56±7.40 % respectively while percentage dead sperm cells recorded 38.22±4.02%, 37.44±4.98%, and 34.44±7.40% for DI, DII, and DIII respectively. Although these figures differed numerically, they were statistically similar (P>0.05).

DISCUSSION

Motility, expressed as the percentage of spermatozoa moving through the power of their tail is used as an indicator of fertility. The mean motility value (86.33 ± 3.65) from this study was within the established normal range proposed by Sexton (1981) who reported a mean motility of 80% and above as excellent.

The motility results decreased across the groups with increase in storage time. This drop in motility was witnessed more in the control group compared with the Vit. C and Vit. E treated groups. This is because of the antioxidative properties of Vit. C and Vit. E.

The results from this study showed that antioxidant supplementation of cock semen extenders improved the viability of stored cock semen over the control. The vitamin E supplemented group (DIII) had a better viability followed by vitamin C (DII) while the least values were observed in the control (DI) over the storage period. This finding is supported by the earlier report of Donoghue and Donoghue (1997). Similar results were also reported by Tabatabaei *et al.* (2011) who observed that supplementing semen extender with vitamin E improved spermatozoa quality parameters including motility and viability of cock semen. Al-Daraji (2002) also reported an improvement in semen

quality of roosters supplemented with vitamin C and E. The better viability observed in vitamin E and C group compared to the control could be attributed to the larger distribution of Vit E within the plasma membrane of spermatozoa and its lipid solubility allows it to suppress peroxidative damage across the plasma membrane and the efficiency of ascorbic acid (Vit C) as an antioxidant which scavenges ROS thus protecting sperm membrane against lipid peroxidation.

CONCLUSION

The findings of this study have shown that antioxidant supplementation of cock semen extenders helped to preserve semen motility and viability. Cock semen supplemented with vitamin E performed better, followed by vitamin C supplemented group. These antioxidants hold great prospect in our quest to develop local extenders that are of low cost and environmentally friendly and this is of immense benefit in rural communities in many developing countries, where commercially known extenders are not readily available to farmers for AI.

ABSTRACT
This study was carried out to determine the haematological profile and serum biochemical indices of rabbits fed graded level of African star apple (*Chrysophyllum albidum) seed meal*. The study involved forty eight (48) mixed breed weaned rabbits of seven - eight weeks old, with average weight of 186.87±0.03g.The rabbits were allotted into four dietary treatments comprising twelve (12) rabbits per treatment. The dietary treatments were 0%, 5%, 10% and 15% ASASM inclusion levels. The experimental diet contained 15% crude protein and 2488.68 Kcal/Kg metabolizable energy. The feeding trial lasted eight weeks, during which period feed and water were provided *ad – libitum*. Data generated were subjected to analysis of variance. Results obtained from this study revealed that the haematological profile and serum biochemical indices of rabbits recorded no significant ($P > 0.05$) differences among dietary treatments except cholesterol, AST and ALT ($P < 0.05$) . The study concludes that inclusion of graded levels of *C albidum seed meal* up to 15% will not pose any adverse effects on the blood characteristics of rabbits.
KEYWORDS: Weaner rabbits, *C albidum*, haematology, serum biochemistry

INTRODUCTION
Feed scarcity has remained a major limitation to livestock production and productivity (Agbede and Aletor, 2003). The high cost of animal feeds precipitated by the ever increasing cost of feed ingredients has resulted in poor nutrition leading to declining productivity of animals in developing nations like Nigeria (Nodu *etal*., 2014). According to Fetuga (1997) there is a disappointing rate and low level of performance in the Nigerian livestock industry, due to high cost of feeds, poor quality feeds and inefficiency in production and distribution in the feed industry. The low level of livestock production has affected adequate protein intake. However, intensive rabbit production and domestication can help bridge the meat supply gap in Nigeria and ensure animal protein adequacy. Increase in meat production can be achieved through proper nutrition, inclusion of feed ingredients at normal or required levels (Etim and Oguike, 2010).

The domestic rabbit (*Oryctolagus cunniculus*) is an important non-ruminant herbivore for meat production. Rabbit meat is a source of healthful food as it is low in cholesterol, but high in protein, 22g/100g (Aduku, and Olukosi 1990). Rabbits can also utilize the available proteins in cellulose rich plants, whereas it is not economical to feed these to chicken and turkeys. Since there is high demand for additional source of food worldwide the exploitation of plants of low economic importance would be a step towards better resource utilization (Telek, and Martin 1983) which is in line with the strategy to achieve sustainable animal production systems by matching them with locally available feed resources (Preston and Sansoucy 1987).

African star apple (*Chrysophyllum albidum)* is a dominant canopy tree of lowland and mixed rainforests, sometimes, riverine (Madubuike and Ogbonnaya, 2003). The plant is propagated by seedlings, wildings and direct sowing. It is a seasonal fruits-bearing tree. The fruit is fleshy and juicy, producing whitish gummy exudates (Adewusi, 1997). It is widely eaten in South Western Nigeria, popular among women and children (Amusa *et al.*, 2003).

The seeds of *C. albidum* are about 1-1.5 x 2 cm, beanlike, shiny when ripe, compressed, with one sharp edge and a star-shaped arrangement in the fruits (Orwa *et al.*, 2009). The seed coat is hard, bony, shiny, and dark brown, and when broken reveal white-colored cotyledons (Amusa *et al.*, 2003).

The physiology of farm animals is affected by several factors, one of which is nutrition (Ajao *et al.*, 2013). Nutritional status of an individual is dependent on dietary intake and effectiveness of metabolic processes. These can be determined by either or combinations of chemical, anthropometric, biochemical or dietary methods (Bamishaiye *et al.*, 2009). Haematology refers to the study of the numbers and morphology of the cellular elements of the blood – erythrocytes, leucocytes, and thrombocytes and the use of these results in the diagnosis and monitoring of disease (Merck Manual,

2012). Haemtological studies are useful in the diagnosis of many diseases as well as investigation of the extent of damage to blood (Onyeyili, *et al.*, 1992; Togun *et al.*, 2007). Haematological parameters are good indicators of the physiological status of animals (Khan and Zafar, 2005). Haematological parameters are those parameters that are related to the blood and blood forming organs (Waugh *et al*., 2001; Bamishaiye *et al*., 2009). Blood act as a pathological reflector of the status of exposed animals to toxicant and other conditions (Olafedehan *et al.*, 2010). As reported by Isaac *et al.* (2013) animals with good blood composition are likely to show good performance.

However, there is no information on the effect of seeds of *C. albidum* on haematology and serum biochemical parameters of rabbits. Therefore, this study was carried out to investigate the effect of feeding graded levels of seeds of *C. albidum* on the haematological and serum biochemical parameters of rabbits.

MATERIALS AND METHODS

The study was carried out at the rabbitary unit of the Oke-Ogun Polytechnic, Saki. Oyo State, Nigeria. African Star Apple seeds were collected from primary and secondary schools in Saki, Oyo State, Nigeria. The seeds were sun dried and further broken to obtain the cotyledons. The cotyledons were sun dried and milled for inclusion in diet mixture of growing rabbits.

Experimental Animals and Management

A total of Forty-eight (48) growing rabbits (7 – 8 weeks of age with average weight 186.87 ±0.03g) of mixed sexes were obtained from a reputable farm in Oyo State, Nigeria for the purpose this study. The animals were housed in wooden cages raised from the ground level. Before the animals were brought into the rabbitary, the cages were thoroughly washed and disinfected and allowed to dry. The floor of each cage was covered with wire mesh to allow for the passage of waste materials. Feed and water troughs were provided in each cage, while feed and water were provided *ad – libitum.* The rabbits were caged individually in clearly marked cells. The feeding trial lasted eight weeks.

Experimental Diet

Four experimental diets were formulated with the inclusion of 0%, 5%, 10% and 15% African Star Apple seed meal (ASASM) as substitute for maize in rabbit diet.

Parameters	0% (ASASM)	5% (ASASM)	10% (ASASM)	15% (ASASM)
Maize	40.00	38.00	36.00	34.00
ASAS	0.00	2.00	4.00	6.00
Maize offal	25.00	25.00	25.00	25.00
Rice offal	18.00	18.00	18.00	18.00
Soybean meal	2.00	2.00	2.00	2.00
Fish meal	1.20	1.20	1.20	1.20
Groundnut cake	10.00	10.00	10.00	10.00
Limestone	1.00	1.00	1.00	1.00
Bone meal	2.00	2.00	2.00	2.00
Salt	0.20	0.20	0.20	0.20
Premix	0.30	0.30	0.30	0.30
Methionine	0.20	0.20	0.20	0.20
Lysine	0.10	0.10	0.10	0.10
Total	100kg	100kg	100kg	100kg

Blood collection:

Blood collection was done at end of the 8th week of feeding trial from six rabbits per treatment. Blood samples were obtained from the prominent ear vein with the aid of a hypodermic needle and syringe. Two blood samples each were collected per rabbit; one set of the blood samples was collected into plastic bottles containing Ethylene Diamine Tetra acetic acid (EDTA) for haematological studies while the other sample was collected into plain sterile bottles for the serum biochemical indices determination. All haematological parameters were determined by conventional laboratory methods of Baker and Silverton (1982); Bitto and Gemade (2001), while serum biochemical indices were determined by methods described by Ochei and Kolhathar (2007).

Statistical Analysis

All data collected were subjected to analysis of variance (ANOVA) technique using statistical analysis software.

RESULTS AND DISCUSSION

RESULTS AND DISCUSSION

It is well established that changes in haematological and biochemical parameters reflect the physiological status of animal. Packed cell volume (PCV) values obtained in this study were not significantly ($p>0.05$) influenced by dietary treatments. The values (39 – 40.66%) were within the reference range of 33 to 50% reported by MediRabbit (2007). The red blood cell (RBC) range of 6.33 – 6.64x106/mm3 and haemoglobin (Hb) range of 12.76 to 13.60 were within standard range of 4 – 8.6 to 7.9 x 106/mm3 for RBC and 10 - 15g/dl for Hb respectively (RAR, 2009). This result indicates that *C. albidum* seed support red blood cell synthesis. The platelet counts recorded in this study ranged from115 to 146 $x10^9$/L for rabbits fed graded levels of *C. albidum* seed. The values were however lower than the normal range (250.00 – 600.00 $x10^9$/L) for rabbits reported by Medirabbit (2011). The white blood cell (WBC) values obtained in this study which were not significant among treatments were within the normal range of $4.5x\ 10^9$ /l to $11\ x\ 10^9$ /l reported (RAR, 2009). The white blood cell differentials namely lymphocytes, neutrophils, monocytes and esonophils were not significantly influenced by dietary treatments.

Biochemical response of rabbits fed *C. albidum* seed was presented in table 3. No significant difference ($p>0.05$) was observed in the values of glucose, total protein and albumin. Values for glucose range from 64.18 to 78.39mg/dl, only animals on control diet falls within the standard range of 75 – 140mg/dl (Medirabbit, 2011) animals placed 5%, 10% and 15% had values below the standard range and this implies hypoglycemia in the rabbits. Values of total protein (5.28 – 7.14g/l) and values of albumin (3.14 – 3.89g/l) were within the standard reference of 5.0 – 7.5g/l and 2.7 – 5.0 g/l respectively (Medirabbit, 2011). This suggests that normal protein metabolism occurred in rabbits, since protein synthesis is related to the amount of protein available in the diet (Iyayi and Tewe, 1998). Cholesterol and Aspartate aminotransferase (AST) followed the same trend with animals placed on

5% having highest values, cholesterol ranged from 70.83 – 113.33 while AST value ranged from 43.40 – 97.90 values for the two parameters falls within the standard range of 10 to 80mg/dl and 10 to 98mg/dl respectively (Medirabbit, 2011). This implies no deleterious influence of ASASM on rabbit biochemical response.

CONCLUSION AND RECOMMENDATION

Results obtained in this study have shown that *C. albidum* seed can be included in weaner rabbits' feed without adverse effects on their haematological profile and serum biochemical indices.

TESTICULAR MORPHOMETRY AND EJACULATE CHARACTERISTICS OF ISA WHITE COCKS FED VARIED LEVELS OF SALT (NaCl) AND SUPPLEMENTAL ACETYLSALICYLIC ACID(ASA)

Aro S. O.
Department of Animal Production and Health, Federal University of Technology, Akure, Nigeria
E-mail: soaro@futa.edu.ng

ABSTRACT
Testicular morphometry and qualitative parameters of the semen of Isa White cocks fed varied supplemental levels of acetyl salicylic acid (ASA) and different inclusion levels of dietary salt (NaCl) were investigated in a-sixteen-week study.. A total of sixteen Isa White cocks were used for the study. The cocks were randomly distributed into four treatment diets and replicated four times where each cock served as a replicate of its treatment diet. The four experimental diets were formulated and designated as: the control (D1) with 0.00% of ASA and 0.25% NaCl while the remaining three (3) diets were labelled as D2, D3 and D4 with 0.05% ASA and 0.50% NaCl, 0.10% ASA and 0.75% NaCl and 0.15% ASA and 1.00% NaCl respectively. The cocks were subjected to semen collection once a week for 9 weeks and qualitative parameters of the ejaculates like semen volume, sperm concentration, spermatocrit, seminal plasma and viability were determined. The birds were sacrificed at the end of the experiment to determine testicular morphometry parameters. The results showed differences ($p<0.05$) in testicular weight, volume and density among the four treatment diets. Cocks fed D3 had the heaviest testicles (13.67±1.67g) and largest testicular volume (11.37±1.75ml) while cocks on D4 had the densest testicles (1.26±0.06gml^{-1}) in comparison with control. The total and average weekly ejaculate volume were best ($p<0.05$)) in D2 (3.35±0.85 and 0.37±0.09ml respectively). Most of the ejaculate parameters like the spermatocrit, sperm concentration, total sperm/ejaculate (TSE) and motility were adversely affected in birds fed D4 when compared with the three other diets. The best combination of dietary salt and ASA was achieved with 0.50 and 0.05% respectively. In conclusion, the use of acetylsalicylic acid (ASA) at 0.05% ASA and 0.50 % Salt (Nacl) could significantly improve semen production potential and viability thus enhancing the reproductive performance of the male domestic chicken.
Keywords: Acetylsalicylic acid, dietary salt, sperm motility, testicular morphometry.

INTRODUCTION
The phenomenon of climate change has put the world on its toes since the famous Rio Earth summit of 1996. Many intervention strategies have been deployed since then to mitigate the problems of climate change on humans, livestock and plants. Livestock agriculture, because of its rate of expansion in recent times, has been fingered as a major culprit in the generation of green house gases (GHG) that are the albatrosses in the depletion of the ozone layer – a protective stratospheric screen that reduces the direct impact of the dangerous ultraviolet rays of the sun on the Earth. Animal agriculture has been predicted to double its production by 2050 as a result of greater demands engendered by increase in global population and standard of living. This increase in reality foretells more generation of these GHG at the detriments of the biosphere. For instance, the contribution of livestock to the generation of the GHG is estimated to be 9% of global CO_2, 35-40% of global CH_4 and 64% of global N_2O emissions (Wikipedia: https://en.m.wikipedia.org/). To tackle this peculiar challenge, livestock practitioners have engaged in series of research channelled towards finding a lasting solution to the climate change problems. Some of such mitigation strategies are dietary manipulation and the use of feed additives, reduction of exposure of manure to water in order to reduce CH_4 emission and use of supplemental feed.

Dietary salt (NaCl) and acetylsalicylic acid (aspirin) have been used as feed additives to mitigate one of the ubiquitous ill effects of climate change in the tropics – heat stress. The ability of these two feed additives to reduce the core body temperature has been documented in the literature (Dai *et al*., 2009; Aro *et al*., 2017). The potentials of NaCl to perfectly play this role is hampered by its predisposition to wet litter in the poultry house thus providing a conducive environment for the proliferation of maggots that produce manure-related GHG like CO_2, N_2O and CH_4. However, a recent study by Aro *et al.* (2018) reported that the use of supplemental levels of acetylsalicylic acid decreased faecal moisture and volume and improved faecal consistency in layers fed high NaCl diets. This experiment was therefore conducted to determine the optimal levels at which these two feed additives could be combined in the diet to achieve the twin effects of decreasing heat stress on livestock and controlling

wet litter in poultry houses. Also, this experiment is intended to unravel any effect such dietary combination of NaCl and ASA could have on the reproductive capacity of the birds.

MATERIALS AND METHODS

Experimental site: The experiment was carried out at the livestock section of Teaching and Research Farms of the Federal University of Technology, Akure, Nigeria. Akure is located at an elevation of about 353m above mean sea level, on Latitude $7^{\circ}18^{\prime\prime}$ north of Equator and Longitude $5^{\circ}10^{\prime\prime}$ east of Greenwich meridian. The climate is of hot, wet equatorial type with a bimodal distribution pattern. The mean annual rainfall is about 1,500mm and the mean annual temperature ranges between 26-28ºC while the relative humidity averages about 77% per annum.

Experimental animals and their management: Twenty Isa White cockerels with an average live weight of 1.94kg at 16 weeks of age were purchased from a reliable source. Sixteen of these birds were randomly allotted to four dietary treatments comprising four birds replicated four times at one bird per replicate. Four treatment diets were formulated with four different inclusion levels of dietary salt (NaCl) and four supplemental levels of acetylsalicylic acid (ASA). Diet 1 (D1) which is the control diet had 0.25% NaCl and 0.00% ASA while D2, D3 and D4 had 0.50 and 0.05%, 0.75 and 0.10% and 1.00 and 0.15% of NaCl and ASA respectively. Table 1 below shows the gross composition of the experimental diets.

Table 1: Gross composition (g/100g) of the cocks' diet

Ingredients	D1	D2	D3	D4
Maize	55.10	55.10	55.10	55.10
Fish meal	1.00	1.00	1.00	1.00
Groundnut cake	9.00	9.00	9.00	9.00
Soybean meal	9.00	9.00	9.00	9.00
Wheat offal	21.00	20.75	20.50	20.25
Bone meal	2.75	2.75	2.75	2.75
Limestone	1.50	1.50	1.50	1.50
Salt (NaCl)	0.25	0.50	0.75	1.00
Premix	0.25	0.25	0.25	0.25
Lysine	0.10	0.10	0.10	0.10
Methionine	0.10	0.10	0.10	0.10
Total	100.00	100.00	100.00	100.00
ASA	0.00	0.05	0.10	0.15

These diets were fed to the birds throughout the 16-week duration of the experiment at 150g/ day/cock while water was given to the birds *ad libitum*. Routine medication and vaccination were administered as and when due. The birds were trained to respond to the abdominal massage method of semen collection for five weeks before the commencement of semen collection at the 24th week of age. Semen collection continued once weekly at 0700hours for the next 9 weeks or till the 16th week of the experiment. Data were collected on weekly weight change, daily feed intake and weekly seminal volume. The seminal qualitative parameters like the spermatocrit, seminal plasma, sperm concentration, total sperm cells/ejaculate, percentage abnormal sperm cells, sperm motility and viability were determined. All the birds were sacrificed at the end of the trial, dissected and the testes were extracted from which the testicular morphometrics like the testicular weight, volume and density were determined.

Statistical analysis: All data were subjected to a completely randomized design of one way analysis of variance (ANOVA) using SAS (2012 version 9.2 statistical package. Duncan's multiple range test (DMRT) of the same statistical package was used to separate differences among the means where applicable.

RESULTS AND DISCUSSION

The testicular morphometry showing the right and left testis weight, left testicular volume and left testicular density is presented in Table 2 below. Significant ($p<0.05$) treatment effects were observed

in the weight of both the right and left testes between D1 and the other three treatment diets. The high NaCl and ASA supplemented diets had heavier testicular size in comparison with the control ranging from 8.33±1.20g in D1 to 12.33±1.34g in D3 for the right testis and from 10.33±1.20g in D1 to 13.67±1.67g in D3 for the left testis. The same trend observed with the testicular weight was also observed with the left testicular volume where the values ranged ($p<0.05$) from 8.92±1.44ml in D1 to 11.37±1.75ml in D3.

Table 2: Testicular weight, volume and density of Isa White cock fed varied supplementation of acetylsalicylic acid (ASA) and dietary inclusion of Sodium chloride (NaCl).

Diets	Right testis weight (g)	Left testis weight (g)	Left testicular volume (ml)	Left testicular density (gml^{-1})
D1	$8.33±1.20^{c}$	$10.33±1.20^{b}$	$8.92±1.44^{b}$	$1.20±0.67^{ab}$
D2	$10.33±1.67^{b}$	$11.33±2.19^{b}$	$9.69±1.34^{a}$	$1.15±0.08^{b}$
D3	$12.33±1.34^{a}$	$13.67±1.67^{a}$	$11.37±1.75^{a}$	$1.23±0.14^{ab}$
D4	$12.00±1.75^{a}$	$13.33±1.20^{a}$	$10.69±1.35^{a}$	$1.26±0.06^{a}$

$^{a,ab,\ b,\ c}$ *= Means in the same column but with different superscripts are statistically ($p<0.05$) significant; D1= Diet with 0.00% ASA and 0.25% NaCl; D2= Diet with 0.05% ASA and 0.50 % NaCl; D3 = Diet with 0.10% ASA ;and 0.75% NaCl; D4= Diet with 0.15% ASA ;and 1.00% NaCl; ASA = Acetylsalicylic acid; NaCl = Sodium chloride.*

The lightest testicles ($1.15±0.08 gml^{-1}$) were observed in cocks fed D2 while the densest testicles ($1.26±0.06\ gml^{-1}$) were from cocks fed D4. The reproductive capacity of the male animals is closely associated with their testicular size. Males with bigger testes have bigger testicular parenchyma and hence more sperm producing architecture than individuals with smaller testes. The testicular weight in the current study compared with 10-12g obtained by Obidi *et al*. (2008) for Shika Brown breeder cocks. There is also a direct relationship between testicular function and volume. The higher the testicular volume, the more the capacity of the testes to produce sperm cells through increased production of interstitial cell stimulating hormone and testosterone. Feeding ASA in combination with NaCl at 0.10 to 0.75% respectively as used in the current study could improve the reproductive performance of Isa White cocks.

Table 3 shows the ejaculate volumes collected weekly from Isa White cocksfed supplemental levels of acetylsalicylic acid (ASA) and dietary inclusion of sodium chloride (NaCl). The weekly ejaculate volume in D1 ranged from 0.10ml in week 1 to 0.43ml in week 4, 7 and 8. In D2, it ranged from 0.15ml in week 2 to 0.58ml in week 9; it was between 0.18ml in week 2, 4 and 6 and 0.28ml in week 7, 8 and 9 in D3 while it ranged from 0.13ml in week2 to 0.40ml (week 4) in D4. The total ejaculate volume for the entire period of collection ranged ($p<0.05$) from 2.02ml in D4 3.35ml in D2 while the weekly average of the ejaculate were 0.28ml, 0.37ml, 0.25ml and 0.22ml for D1, D2, D3 and D4 respectively.

Table 3: Weekly ejaculate volume (ml) of Isa White cocks fed supplemental levels of acetylsalicylic acid (ASA) and dietary inclusion of Sodium chloride (NaCl).

Weeks	D1	D2	D3	D4
1	$0.10±0.00^{c}$	$0.18±0.03^{b}$	$0.20±0.00^{a}$	$0.15±0.05^{bc}$

Total ejaculate volume/diet (ml)	$2.56±0.65^{ab}$	$3.35±0.85^{a}$	$2.21±0.59^{b}$	$2.02±0.50^{b}$
Weekly average volume/diet (ml)	$0.28±0.07^{ab}$	$0.37±0.09^{a}$	$0.25±0.07^{b}$	$0.22±0.06^{b}$

^{a,ab,b,bc,c} *= Means in the same row but with different superscripts are statistically ($p<0.05$) significant; D1=Diet with 0.00% ASA and 0.25% NaCl; D2= Diet with 0.05% ASA and 0.50 % NaCl; D3 = Diet with 0.10% ASA ;and 0.75% NaCl; D4= Diet with 0.15% ASA ;and1.00% NaCl; ASA = Acetylsalicylic acid; NaCl = Sodium chloride.*

The average weekly ejaculate volume, though similar (p>0.05) when compared between the control and the ASA/NaCl treated groups, D2 gave the best statistic as far as this parameter is concerned. It showed that ASA when combined with NaCl at 0.05 and 0.50% of the diet would encourage maximum semen production. Though collected when these roosters were at a relatively young age (24-32 weeks), the figures still fell within the range of 0.2-0.5ml reported by Hafez and Hafez (2000)

The qualitative characteristics of the ejaculates of Isa White cocks fed dietary supplementation of varied levels of acetylsalicylic acid (ASA) and dietary inclusion of sodium chloride (NaCl) are as presented in Table 4.

Table 4: Qualitative characteristics of the ejaculates of Isa White cocks fed dietary supplementation of varied levels of acetylsalicylic acid (ASA) and dietary inclusion of Sodium chloride (NaCl).

Parameters	D1	D2	D3	D4
Seminal volume (ml)	0.30±0.10	0.27±0.07	0.27±0.07	0.20±0.07
Spermatocrit (%)	6.00±0.82^{a}	5.50±0.64^{a}	6.25±1.93^{a}	4.00±2.83^{b}
Seminal Plasma (%)	94.00±0.82	94.50±0.65	93.75±1.93	96.00±2.83
Sperm concentration ($\times10^{9}$)	6.83±0.41^{b}	6.64±0.34^{b}	8.55±0.88^{a}	4.35±2.57^{c}
TSE ($\times10^{9}$)	2.05±0.72^{a}	1.79±0.09^{a}	2.31±0.61^{a}	0.87±0.07^{b}
Sperm motility (%)	100.00±0.00^{a}	100.00±0.00^{a}	62.50±23.93^{b}	50.00±28.89^{b}
Live sperm concentration ($\times10^{9}$)	5.24±0.45^{a}	5.12±0.32^{a}	5.40±1.20^{a}	3.84±2.37^{b}
Dead sperm concentration ($\times10^{9}$)	1.59±0.19^{b}	1.45±0.15^{b}	3.16±1.50^{a}	1.07±0.64^{c}
% live sperm	76.50±3.43^{a}	76.98±1.70^{a}	65.22±14.04^{b}	43.32±25.40^{c}
% dead sperm	23.50±3.43^{b}	23.02±1.70^{b}	34.75±14.00^{b}	56.68±5.87^{a}
% abnormal sperm	18.50±2.40^{a}	17.75±3.84^{a}	20.23±4.18^{a}	13.00±7.90^{b}

^{a,b,c} *= Means in the same row but with different superscripts are statistically (p<0.05) significant; D1=Diet with 0.00% ASA and 0.25% NaCl; D2= Diet with 0.05% ASA and 0.50 % NaCl; D3= Diet with 0.10% ASA ;and 0.75% NaCl; D4= Diet with 0.15% ASA ;and1.00% NaCl; ASA = Acetylsalicylic acid; NaCl = Sodium chloride; TSE = Total sperm/ejaculate.*

All the ejaculate parameters varied significantly among the treatment means with the exception of seminal volume and seminal plasma. The spermatocrit, total sperm cells/ejaculate, live sperm concentration, percentage dead sperm and percentage abnormal sperm cells in D2 and D3 compared statistically (p>0.05) with values obtained in D1 while these values were significantly (p<0.05) depressed in D4. However, D1 and D2 had similar values in terms of sperm concentration, sperm motility, dead sperm concentration and percentage live sperm. The decrease in sperm motility was very obvious in D3 (62.50±23.93%) and D4 (50.00±28.89%) when compared with D1 (100.00±0.00%) and D2 (100.00±0.00%). Sperm motility and more importantly progressive motility is very crucial to the capacity of the sperm to fertilize the ovum. Therefore, using ASA and NaCl in combination above 0.05 and 0.50% of the diet respectively could compromise the reproductive capacity of Isa White roosters.

CONCLUSION AND RECOMMENDATION

The significant depression of most of the reproductive indices in D4 showed that as far as reproduction in male poultry species is concerned, caution should applied not to use ASA and NaCl in combination above 0.10 and 0.75% respectively in the diet.

THE INFLUENCE OF VARIED ACETYLSALICYLIC ACID AND SODIUM CHLORIDE LEVELS ON PERFORMANCE, CLOACAL AND AXILLARY TEMPERATURES OF ISA WHITE COCKS

Aro, S. O. & Onuoha, A. N.
Department of Animal Production and Health, Federal University of Technology, Akure, Nigeria
E-mail: soaro@futa.edu.ng

ABSTRACT
This experiment was conducted to investigate the combined influence of varied inclusion of sodium chloride (NaCl) and supplemental levels of acetylsalicylic acid (ASA) on performance, cloacal and axillary temperatures of Isa White cocks. Four diets with different NaCl and ASA levels of 0.25/0.00% (Diet 1 or D1), 0.50/0.05% (D2), 0.75/0.10% (D3) and 1.00/0.15% (D4) respectively were formulated. The D1 served as the control diet. These diets were fed to the cocks throughout the eight weeks of the experiment during which data on weight change, feed consumption, cloacal and axillary temperatures were taken. The ambient temperature and relative humidity in the mornings (6.00 hour) afternoons (12.00 hour) and evenings (18.00 hour) were recorded from which the respective temperature-humidity indices (THI) were calculated. The results showed significant differences in final live weight, weight change, feed intake and feed conversion ratio (FCR) among the different diets. The best FCR was observed in D3 while weight change was better enhanced in the D2 and D3 diets. The morning, afternoon and evening cloacal and axillary temperatures decreased ($p<0.05$) as the levels of NaCl and ASA increased in the diets. The respective THI for the mornings, afternoons and evenings were 18.36±0.53, 20.79±0.79 and 16.89±0.55. The decrease in the core body temperature of the birds showed that using 0.15% ASA and 1.00% NaCl in combination can help mitigate the harmful effects of high ambient temperature. Also, the combined effect of 0.10% ASA and 0.75% NaCl would optimally enhance feed consumption, feed efficiency and growth in Isa White breeder cocks.
Keywords: Acetylsalicylic acid, ambient temperature, heat stress, relative humidity, sodium chloride.

INTRODUCTION
Livestock production, especially in the tropics is faced with the problem of heat stress engendered by the twin effect of high environmental temperature and relative humidity (Aro *et al.,* 2018). This problem has continued to hamper livestock productivity in this torrid region of the world with its attendant decrease in feed intake, increased morbidity, reduced livability, drop in egg production, decreased milk yield and an overall erosion of the profit margin of the average livestock producer. Heat stress is also known to impart negatively on the physiology of livestock production through its disruption of hormonal balance, causation of heat stroke, heat prostration, respiratory alkalosis, disruption of acid-base homeostasis, impaired fertility, hatchability and general decline in the reproductive performance of livestock.

The urgent need to attenuate the ill effects of heat stress on our livestock to the barest minimum has necessitated series of research in diverse fields of science all with varied rates of success and the search is still on. For instance, the design of livestock houses in the tropics has been modified severally to ensure easy dissipation of heat, allow ample ventilation and reduce solar radiation. Several cooling systems with automation have been deployed towards warding off thermal stress within the animal houses with a view to improving the thermal welfare of livestock. Other intervention strategies that have been deployed against the menace of heat stress include dietary manipulation to help the animals decrease metabolic heat generation under prevailing high environmental temperature, the use of feed additives that will put to check the proliferation of the enteric methanogenic organisms and thus curtail the emission of the greenhouse gases among others. The use of ascorbic acid, potassium chloride, sodium chloride (NaCl), Vitamins A and E and pharmaceutical preparations like the sodium salicylates and acetylsalicylic acid (ASA) or Aspirin have been experimented with as possible antidotes to thermal stress in livestock production (Wu *et al*., 2016).

Currently, there is a renewed awareness in the use of acetylsalicylic acid as a possible elixir for combating thermal stress in livestock. This is predicated on the pharmaceutical importance of ASA as an antipyretic, anti-inflammatory and analgesic agent. The use of NaCl to ameliorate heat stress in livestock has also been reported but its predisposition to wet litter has discouraged its widespread acceptability. Recently, Aro *et al.* (2018) reported on the reduction in faecal moisture and

improvement in faecal consistency of layers fed supplemental levels of ASA. Also, the reduction in rectal and axillary temperatures of two breeds of laying chickens has earlier been reported by Aro *et al.* (2017). It is therefore expedient to experiment with dietary combination of varied levels of ASA and NaCl to unravel their synergistic or antagonistic role on reduction of heat stress, enhancement of growth and change in cloacal and axillary temperatures in Isa White breeder cocks.

MATERIALS AND METHOD

Experimental site: The experiment was carried out in the Student Project Block of the livestock section of Teaching and Research Farm, Federal University of Technology, Akure, Ondo State, Nigeria. Akure is located on Latitude7°1′N and Longitude 5°10”E with a bimodal rainfall pattern characteristic of the hot wet equatorial climate. The mean annual rainfall is about 1,500mm while the mean annual temperature is between 26-28°C.

Experimental birds and their management: Twenty Isa White cockerels with an average initial weight of 1.94kg at 16 weeks of age were purchased from a reliable source. Four experimental diets were formulated to meet the nutrient requirement of the cockerels. Acetylsalicylic acid and NaCl were respectively used at varied supplemental and inclusion levels of 0.00/0.25% (D1), 0.05/0.50% (D2), 0.10/0.75% (D3) and 0.15/1.00% (D4) of the diet. The 0.00/0.25% diet (D1) served as the control and four birds were randomly allotted to each treatment diet which was replicated four times with each bird serving as a replicate of its treatment diet. Table 1 gives the composition of the experimental diets.

Table 1: Gross composition (g/100g) of the experimental diet

Ingredients	D1	D2	D3	D4
Maize	55.10	55.10	55.10	55.10
Fish meal	1.00	1.00	1.00	1.00
Groundnut cake	9.00	9.00	9.00	9.00
Soybean meal	9.00	9.00	9.00	9.00
Wheat offal	21.00	20.75	20.50	20.25
Bone meal	2.75	2.75	2.75	2.75
Limestone	1.50	1.50	1.50	1.50
Salt (NaCl)	0.25	0.50	0.75	1.00
Premix	0.25	0.25	0.25	0.25
Lysine	0.10	0.10	0.10	0.10
Methionine	0.10	0.10	0.10	0.10
Total	**100.00**	**100.00**	**100.00**	**100.00**
ASA	0.00	0.05	0.10	0.15

DI = Diet with 0.00% of ASA and 0.25% NaCl; D2 = Diet with 0.05% ASA and 0.50% NaCl; D3 = Diet with 0.10% ASA and 0.75% NaCl; D4 = Diet with 0.15% ASA and 1.00% NaCl; ASA = Acetylsalicylic acid.

The experiment was carried out over a period of 8 weeks. The birds were fed with the experimental diets according to their respective treatments until the end of the experiment.

Data collection and analysis: Data were collected on feed intake and weight change from which feed conversion ratio was calculated. The ambient temperature and relative humidity were taken with a combined digital thermometer and hygrometer while the cloacal/rectal and axillary temperatures were taken with a digital thermometer. All these parameters were measured three times weekly (Tuesdays Thursdays and Saturdays at 6am, 12pm and 6pm) for eight weeks thus making a total of 72 observations. From these observations, the respective temperature-humidity indices (THI) for the morning, afternoon and evening readings were calculated according to the model of Marai *et al*. (2001) for non-sweating animals i.e. THI= t – [0.31-0.31 (RH/100)(t-14.4)], where: THI= Temperature humidity index, RH= Relative humidity; t= Dry bulb temperature (ambient temperature). Data collected were subjected to completely randomized design of one-way analysis of variance using SAS (2012), Version 9.2 Significant differences where appropriate were determined using Duncan multiple range test (DMRT) of the same statistical package.

RESULTS AND DISCUSSION

The results of the performance parameters of cockerels fed varied levels of dietary salt (NaCl) and supplemental acetylsalicylic acid (ASA) are as presented in Table 2 below. The final weight was higher ($p<0.05$) in D2 (2.60±0.37kg) and D3 (2.58±0.40kg) than in D1 (2.50±0.25kg) and D4 (2.53±0.37kg). The same trend was observed in the weight change over the entire period where both D2 and D3 recorded the same growth accretion of 0.65kg while D1 and D4 recorded 0.57kg and 0.60kg increase in growth respectively. The feed intake parameters were better ($p<0.05$) in the ASA supplemented and high salt diets than those in the D1 except for the D3 diet. The best feed conversion ratio (FCR) was however recorded in the D3 diet. Neither morbidity nor mortality was recorded during the course of the experiment. The higher growth accretion recorded in the high salt and ASA fed birds supports the report in literature of the role of dietary NaCl and ASA at enhancing the growth rate of livestock (Alagawany *et al*., 2017). This also explains why birds fed diets higher in NaCl and ASA had higher feed intake values than those on the control diet.

Table 2: Performance parameters of Isa White cockerels fed varied levels of dietary salt (NaCl) and supplemental acetylsalicylic acid (ASA)

Parameters	D1	D2	D3	D4
Initial weight (kg)	1.93±0.03	1.95±0.05	1.93±0.03	1.93±0.04
Final weight (kg)	2.50±0.25^{b}	2.60±0.37^{a}	2.58±0.40^{a}	2.53±0.37^{b}

Mortality	Nil	Nil	Nil	Nil
Morbidity	Nil	Nil	Nil	Nil

a,b = Means in the same row but with different superscripts are statistically ($p<0.05$) significant. DI = Diet with 0.00% of ASA and 0.25% NaCl; D2 = Diet with 0.05% ASA and 0.50% NaCl; D3 = Diet with 0.10% ASA and 0.75% NaCl; D4 = Diet with 0.15% ASA and 1.00% NaCl; ASA = Acetylsalicylic acid.

Table 3 shows the morning, afternoon and evening cloacal and axillary temperatures of Isa White cocks fed dietary supplementation of ASA and inclusion of NaCl under prevailing ambient temperature, relative humidity and their calculated temperature humidity indices. The average ambient temperature recorded in the mornings, afternoons and the evenings in the course of the experiments were 23.83± 0.58^{o}C, 28.27±0.51^{o}C and24.78±0.45^{o}C respectively. Of these three daily readings, only the morning and evening ambient temperatures fell within the 18-24°C thermo-neutral zone proposed for the tropical regions. The relative humidity data recorded for the corresponding periods of the day stood at 87.83±1.52%, 77.21±0.89% and 77.04±1.63% respectively. These are temperature and relative humidity values characteristic of the hot, wet equatorial climatic regions of the world with year-round high temperature and relative humidity - the two climatic variables that are the precursors of thermal stress in this torrid zone. The calculated temperature humidity indices (THI) for the mornings, afternoons and evenings (18.36±0.53, 20.79±0.79 and 16.89±0.55 respectively) showed that the birds were well within the comfort zone in the mornings and evenings but in the borderline of alert and danger zones in the afternoons. The implication of these is that the birds in the current study were only heat-stressed in the afternoons and any intervention strategy to reduce thermal stress on them should be directed at this period of the day.

There are well documented evidences of the decrease in the body temperature of livestock especially with dietary administration of ASA (Alagawany *et al*., 2017; Aro *et al*., 2017). The antipyretic role of ASA is thus evident in the significant reduction in both the cloacal and axillary temperatures of the birds thus helping them to cope better in their effort to maintain homeothermy when physiologically challenged with high air temperature. Furthermore, ASA was able to lower the birds' cloacal and axillary temperatures in the current experiment in combination with dietary increase in the levels of NaCl. This showed that ASA was able to work in synergy with NaCl to achieve this.

Table 3:Morning, afternoon and evening cloacal and axillary temperatures of Isa White cocks fed dietary supplementation of ASA and inclusion of NaCl under prevailing temperature, relative humidity and their calculated temperature humidity indices.

^{a,b,c,d}=Means in the same column but with different superscripts are statistically ($p<0.05$) significant. DI = Diet with 0.00% of ASA and 0.25% NaCl; D2 = Diet with 0.05% ASA and 0.50% NaCl; D3 = Diet with 0.10% ASA and 0.75% NaCl; D4 = Diet with 0.15% ASA and 1.00% NaCl; ASA = Acetylsalicylic acid; AMT = Ambient temperature; RH = Relative humidity; THI = Temperature humidity index; CT = Cloacal temperature; AXT = Axillary temperature.

CONCLUSION AND RECOMMENDATIONS

The decrease in the core body temperature as revealed by lower cloacal and axillary temperatures with incremental levels of both ASA and NaCl in the diets showed the synergy between these two additives at lowering the body temperature. Also, both ASA and NaCl will work optimally in favour of growth accretion when combined at 0.10 and 0.75% of the diet respectively. The THI as calculated in this study showed that the Isa White cocks were mostly heat-stressed in the afternoons. Therefore, any intervention strategy to mitigate heat stress at this particular location and in similar climes should be directed towards the afternoon period of the day.

ABSTRACT
Eighteen mature nulliparous rabbit does with initial body weight between 1600g-2500g were used to evaluate the effect of body weight at first mating on reproductive performance of rabbit does. These rabbits were assigned into three treatments, with T1, T2 and T3 weighing (1600-1900), (1901-2200) and (2201-2500) respectively. The study lasted for 5weeks. The does were mated with buck at ratio 1:3. The reproductive parameters evaluated were number of does that kindled, litter size at birth, breeding efficiency, litter size at weaning, pre-weaning loss. All data collected were subjected to descriptive statistical representation. The highest number of kindled does was 5 in T2 and T3; T1 had the lowest number (3). Breeding efficiency of 83.33% was recorded in T1 and T2 while T3 had 50.00%. T3 had highest average birth weight (49.51g) and T2 had the least (41.51g); litter size at birth and weaning ranged from 18 -28kits and 15-24kits respectively.T2 does recorded highest value in both parameters, T3 does recorded same value (28kits) for litter size at birth. Highest pre-weaning loss of 7kits was recorded from does in T3 while T1 and T2 recorded 4kits. It was therefore concluded that does with weight range 1901g – 2200g had better reproductive performance with highest breeding efficiency and lower pre-weaning loss.
Key words: Rabbit does, body weight, reproductive performance

INTRODUCTION
Rabbit farming is becoming more attractive to many animal breeders due to its high fecundity, high mothering ability, adaptability to a wide range of conditions, high genetic variability, high roughage utilization and low cost of production (Das and Yadav, 2007). Reproductive performance is the main factor which assures high productivity on rabbit farms. This requires that the management practices take into account the physiology and behaviour of the animals. For great profit a special attention must be focused on these traits, so studying factors that directly affect them are so important and must be taken into consideration during breeding of any productive species. Rabbit does experience a severe energy deficit during the first lactation; they tend to lose weight after their first litter until the kindling of second litter. This is due to the high energy needs of foetal growth combined with the drop in the feed intake during the last 10 days of gestation. This weight loss by first litter doe accounts for a drop in reproductive performance and a high replacement rate of young does (Rommers *et al*., 2002). Likewise does are often fed to appetite during rearing, and first mating is recommended at approximately 75 to 80% of mature body weight (Lebas *et al*., 1986). In modern management, young does are not mated at a fixed body weight but at a fixed age. Under *ad libitum* feeding conditions during rearing, heavy does can develop according to their growth potential, and body weight differences at first mating will be substantial. At the same age, heavy does can benefit from the extra amount of body weight at the end of rearing to withstand the energy deficit during first lactation. Rommers *et al*. (2002) reported that body weight did affect productive performance in the first parity. Although heavy does were heavier at first mating and remained heavier throughout the reproductive period, they followed a similar body weight curve after weaning the first litter as small and medium does. Hence, this study evaluated the effect of body weight at first mating on reproductive performance of rabbit does.

MATERIALS AND METHODS
Experimental Site
The experiment was carried out at the Rabbitry Unit, Teaching and Research Farm Development (TREFAD), College of Animal Science and Livestock Production Farm, Federal University of Agriculture Abeokuta. It falls within the rainforest vegetation zone of South West Nigeria on the latitude 7◦S 13’49.66’N and longitude 3◦ 26’11.98 E 76m above sea level (Google earth, 2018). The

climate is tropical humid with a mean annual rainfall of 1037mm, a temperature of 43◦C and a relative humidity of 82%.

Experimental Animals and Management

A total of 18 mature nulliparous rabbit does and 6 bucks (mixed breeds) were purchased from a reputable farm in Abeokuta, Ogun State. The does were distributed into three treatments, of six does per treatment. Each treatment was further subdivided into six replicates consisting of one does per replicate. On the arrival of the rabbits, they were given feed and water containing anti-stress (Maxiyield). The rabbits were allowed to acclimatize with the environment for one week (7 days) before the commencement of the experiment. The hutches and equipment that were used were thoroughly washed and disinfected with morigard before stocking the rabbits. The rabbits were kept in hutches equipped with concrete pots of feeders and drinkers. They were supplied with clean water in concrete drinkers and fed on commercial diet (Table 1) in concrete feeders and were also given *Tridax procumbens* twice a week. The droppings were swept off every day, and the rabbit were observed for any sign of illness.

Table 1: Nutrient Composition of the Commercial Feed (As Declared)

Parameter	**Value**
Crude Protein (%)	16.00
Fats and Oil (%)	5.00
Crude Fibre (%)	7.00
Calcium (%)	1.60
Available Phosphorus (%)	0.45
Lysine (%)	0.75
Methionine (%)	0.36
Salt (%)	0.30
Metabolizable Energy (kcal/kg)	2450

Experimental Procedure

The does were mated with a mating ratio of 1:3. The doe were hand mated in the morning and evening; the bucks were allowed to ride 3-4 times before the does were withdrawn. Pregnancy test was carried out on the does by palpating at the 14th and 20th day after mating. Clean and well disinfected kindling boxes were provided for the does to make nest of fur in preparation for birth. The rabbits were weighed on the day of kindling and subsequent weighing was done every week. Gloves were used for handling the kits.

Eexperimental treatments

Treatment 1: Does weighing between 1600 – 1900g
Treatment 2: Does weighing between 1900 – 2200g
Treatment 3: Does weighing between 2200 – 2500g

Data Collection

Data were collected on breeding efficiency (percentage of kindled does), litter size at birth (number of kits per doe at birth), litter size at weaning (number of kits per doe at weaning), average birth weight (weight of kits of a doe at birth divide by the total number of the kits), pre weaning loss (number of kits that died before weaning) and gestation length (difference between conception date and kindling date).

Statistical Analysis

All data obtained was analysed through the use of descriptive statistical tools.

RESULTS

The effect of body weight at first mating on reproductive performance of rabbit does are presented in Figure 1 and Figure 2 below. Figure 1 shows the effect of body weight at first mating on number of kindled does, gestation length and breeding efficiency. The number of does that kindled ranges from 3 to 5 with the does in T2 and T3 recording the highest breeding efficiency (83.33%) and does in T1 recording the lowest breeding efficiency (50.00%) respectively. The gestation length is longer in does in T1 and T3 with duration of 32days while the does in T2 recorded shorter with duration of 31days. The effect of body weight on average birth weight, litter size at birth, litter size at weaning and pre-weaning loss is presented in figure 2. The average birth weight of the kits ranged from 41.57g to 49.57g. Kits from does in T3 had highest (49.57g) while kits from T2 recorded the least (41.57g) average birth weight. Litter size at birth and weaning ranged from 18 to 28 and 15 to 24 respectively with the does from T2 recording the highest values for both parameters while does from T3 also recorded the same value (28) for litter size at birth. The highest pre-weaning loss of 7 was recorded from does in T3 while does in T1 and T2 recorded same pre weaning loss of 4 kits.

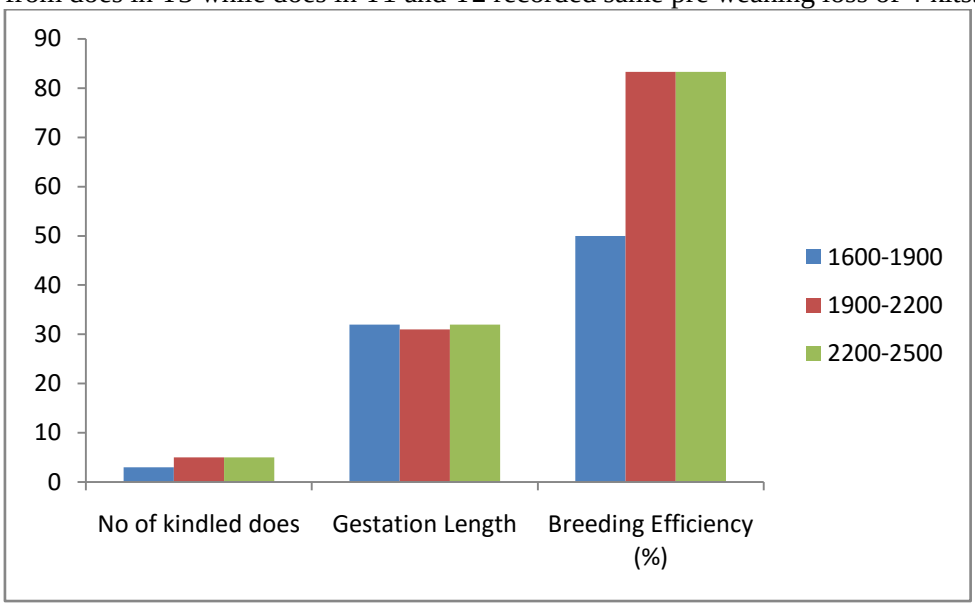

Figure 1: Effect of body weight at first mating on number of kindled does, gestation length and breeding efficiency.

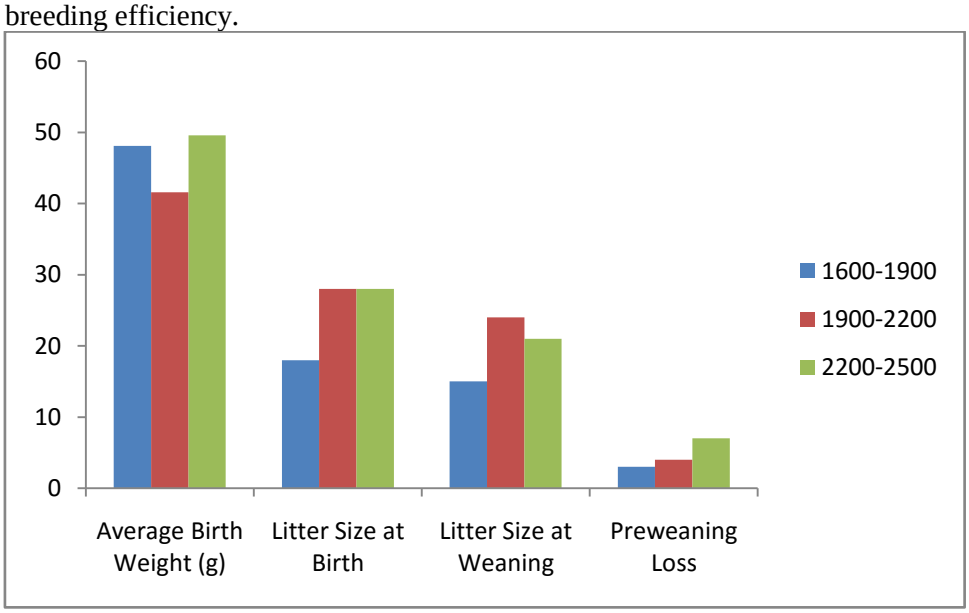

Figure 2: the effect of body weight on average birth weight, litter size at birth, litter size at weaning and pre-weaning loss.

DISCUSSION

The result obtained from does with weight between 1600-1900g having lower breeding efficiency, litter size at birth and litter size at weaning could be as a result of small body size and insufficient body reserve with a possible reduction in the milk production of the does and hence resulting in lower reproductive performance. This result is in line with the report of Szendrő *et al*., (2002) that the insemination of animals with lower body weight has been related to lower fertility and smaller litter size at first parturition (Rommers *et al*., 2001 and 2002). Rabbit does are susceptible to a severe energy deficit during first lactation (Xiccato, 1996), resulting in a decreased reproductive performance. Heavy does are more matured and have more body reserves (protein and fat tissue) which enable them to better resist energy deficit during first lactation, resulting in a better performance (Rommers *et al*., 2004).Gestation duration ranged from 31 to 32days gestation length in rabbit respectively is fixed and only varies within a very narrow gap as observed in this study; similar observation was made by Ajayi *et al*., (2005).The highest numerical value recorded for litter size at birth and weaning by does weighing between 1900 and 2200g shows that increased body weight improved reproductive performance at first parity. According to Inglis (1980), litter size and birth weight vary depending on the breed and size of the dam. Factors that increase litter size include the age at which the does are served and the optimum weight at service, which is an index of breed (Hafez and Hafez, 2000).

CONCLUSION

The study concluded that does with weight range 1901g – 2200g had better reproductive performance with highest breeding efficiency and lower pre-weaning loss.

ABSTRACT
A 150-day study was conducted to determine the performance and pregnancy rate of intensively managed West African dwarf goats to concentrate supplement containing varying levels of neem leaf meal (NLM). Twelve (12) West African Dwarf does with an average live weight of 11. 15.70 ± 0.81 kg were used in a Completely Randomized Design with animals grouped into three treatments of four replicates each balanced for weight. The animals were fed *Panicum maximum* in the morning with a daily supplementation of 350g concentrate diet containing varying levels of neem leaf meal at 0, 2.5, and 5%. Daily feed intake (1217.11g/day) of goats increased ($P < 0.05$) and daily weight gain (46.14g/day) of goats increased ($P > 0.05$) with inclusion of *A. indica.* However, the feed conversion ratio of the animals fed neem leaf meal increased significantly ($P < 0.05$) compared with the animals in the control. This study, however, concluded that neem leaf supplementation in reproducing traditionally managed WAD goats enhanced pregnancy development. Neem leaf inclusion at 2.5% in West African dwarf goat's diet had effects on the overall performance of the animals with a potential improvement in feed conversion ratio.

INTRODUCTION
Increase in global human population has introduced the challenge of providing quality animal protein for their feeding. In recent years, there has been growing interest in identifying potentially important feedstuffs to supplement the available low nutrient feeds (Tona *et al*., 2014) for ruminant feeding in the tropics. Goats constitute a very important part of the rural economy in Nigeria, with more than 95% of the rural households keeping goats (Ukpabi *et al.*, 2000). Goat rearing has been found equally rewarding under both intensive and semi-intensive systems of management (Shalander, 2007). The major problem being faced by developing countries especially Nigeria is the ever increasing population without a corresponding increase in animal protein production. Animal products contribute only 15 to 20% of the total protein intake of an average Nigerian contrary to 33% recommended by (FAO., 1987). This wide margin between the recommended protein intake and the average consumption rate has resulted in an ever-increasing demand for animal protein by the Nigerian populace. The neem plant (*Azadirachta indica*) is a non-leguminous multi-purpose tree which belongs to the family *Meliceae*. Its common English names include neem tree and margosa tree (Arbonnier, 2002). The neem tree is a drought tolerant plant and is known to do well in areas with long dry seasons, even with rainfall as low as 130mm per annum (Gowda and Sastry, 2000). It is also known to thrive in almost any type of soil and tolerate a wide soil pH range of between 4 and 10 (Arbonnier 2002; Girish and Shankara, 2008). The neem tree is therefore often used in afforestation programmes, especially in semi-arid regions. Neem leaves incorporation into ruminant feeds will help increase the utility of the plant and help alleviate the severe feed inadequacy experienced in the dry tropics during the dry season. Hence, this study was designed to evaluate the effect of neem meal leaf on growth performance of West African Dwarf (WAD) does during pregnancy.

MATERIALS AND METHODS

The experiment was carried out at the small ruminant unit of the Directorate of University Farms (DUFARMS), Federal University of Agriculture Abeokuta, Ogun state, Nigeria. Twelve (12) West African Dwarf (WAD) goats does, in their 2nd parity, aged 1-2 years, with an average weight of 11 were used in this study. The goats were housed intensively in well ventilated pens with concrete floors. The experiment was set up as a completely randomized design (CRD) with three levels of Neem Leaf Meal (0%, 2.5%, and 5.0%) added to the concentrate feed (maize (15%), cassava peel (15%), palm kernel cake (32%), wheat offal (24%), groundnut cake (10%), bone meal (3%) premix (0.5%) and salt (0.5%)). Each treatment was having four (4) replicates each. Concentrate was given to the animals at 5% of their body weight and *Panicum maximum* as basal diet, while clean water was provided *ad libitum* intake. The feeding trial lasted for 90days. Each goat was examined sonographically using a portable ultrasound machine with a 3.5 MHz curvilinear transducer (Kaixin KX 2000R, Xuzhou, China) at the Veterinary Teaching Hospital, FUNAAB. The machine was fitted with a 3.5MHz curvilinear and 7.0MHz linear transducers. Each transducer has four windows of frequency range. In addition, the machine was programmed with software for obstetric and cardiac calculations, as well as having a digital imaging and communication in medicine (DICOM) facility for image storage. Basic preparation included clipping of the hairs around the ventral abdomen and application of acoustic gel. Fresh neem leaf was harvested from neem trees found at Directorate of University Farms (DUFARMS). The leaves was separated from their twigs, air-dried and turned regularly for period of 14 days until the leaves was brittle and thoroughly dried. All the leaves were ground in a hammer mill (1-mm screen) to form the Neem Leaf Meal (NLM). The weights of the animals were taken at the commencement of the experiment and weekly for body weight change. Data collected included the following. The weights of the experimental animals were taken before the commencement of the experiment and it was done by using spring balance scale - 20kg capacity and the final weight of the goats were taken at the end of the experimental period of 12 weeks using spring balance scale 20kg capacity. The weight gain was determined by subtracting the initial weight of does from their final weight and the feed consumptionwas determined by taking the weight of total dietary concentrate fed to does daily and weight of concentrate refuse each day by the does throughout the experimental period. The difference between total concentrate refuse from total concentrate given daily gives the feed consume per day. The pregnancy rate was determined by counting the number of does that were confirmed pregnant in each treatment through scanning. Data collected during the experimental period was subjected to one way analysis of variance (ANOVA) in completely randomized design using SAS (1999) and the means separated using Duncan multiple range test of the same software at 5% level of significance.

RESULTS AND DISCUSSION

Approximately two (2) does from each treatment carried their pregnancy. Table 1 shows the performance characteristics of West African dwarf goats fed experimental diet. The initial weight, final weight, weight gain, daily weight gain, concentrate intake, and feed conversion ratio were not significantly ($P>0.05$) different. However, grass intake, total feed intake and daily feed intake were significantly ($P<0.05$) different. The animals showed an improvement in the final weight over the initial weight. The highest value (16.50kg) for weight gain was observed in the control diet and the least value (15.75kg) was observed in the diet with 5% neem leaf inclusion. Likewise, the highest value (46.14g) for daily weight gain was recorded in the treatment with 2.5% neem leaf inclusion and the lowest value (38.69) was observed in the diet with 5.0% neem leaf inclusion. Animal fed with the control diets were superior in their total feed intake and daily feed intake. The feed conversion ration ranged from 28.29-37.65. However, the result showed that T_2 had the best feed utilization of 28.29, while the poorest value (37.65) was observed in T_3.

Table 1: Performance characteristic of West African dwarf does fed experimental diets (%)

Parameters	Levels of inclusion of neem leaf meal g/kg				
	0	**2.5**	**5.0**	**SEM**	**P-VALUE**
Initial Weight (kg)	12.63	12.50	12.50	0.57	0.99
Final Weight (kg)	16.50	16.38	15.75	0.66	0.68
Weight gain (kg)	3.88	3.92	3.25	0.31	0.78
Daily weight gain (gday-1)	46.13	46.14	38.69	4.54	0.78
Concentrate intake (kg)	27.16	27.13	26.36	0.20	0.18
Grass intake (kg)	75.08[a]	74.24[ab]	73.48[b]	0.25	0.01
Total feed intake (kg)	102.24[a]	101.36[ab]	99.85[b]	0.43	0.02
Daily feed intake (gday-1)	1217.11[a]	1206.69[ab]	1188.63[b]	5.13	0.02
Feed Conversion Ratio	28.56	28.29	37.65	3.78	0.37
Pregnancy rate	50.00	50.00	50.00	4.62	0.47

[abc] Means on the same row having different superscripts are significantly different ($p<0.05$); T_1 = 100% concentrate; T_2 = 2.5% *neem leave meal* (NLM) + concentrate; T_3 = 5% *neem leave meal* (NLM). SEM – Standard error of means

The growth performance in this current study showed that the weight gain of the animals were not significantly different. Final weight obtained in this study is higher than the values (8.80 – 11.00kg) recorded by Anaeto *et al*. (2013) but fell within the values (10.42 – 17.25kg) recorded by Bawala *et al.* (2007). The result of this study on weight gain is in agreement with the report of Nkoku and Evbuomwan (2014) that efficient utilization of nutrients in diets that supply adequate energy and protein is required for optimum growth performance of ruminants. Final weight obtained in 2.5% inclusion level of neem leaf meal is higher than the result of (Hossain, 1994) who reported 3.33 and 3.70% for cattle fed neem leaves and neem seeds respectively in 28 days of treatment. The highest daily weight gain (46.14g/day) value recorded for animals fed 2.5% inclusion level of neem meal leave is close to the value of (52.0g/day) recorded by Paengkoum P, *et al*. (2010).

CONCLUSION AND RECOMMENDATIONS

From the results of this study, it can be concluded that the supplement containing up to 2.5% Neem leaf meal can be fed to West African Dwarf goat without any deleterious effect on pregnancy development while resulting in birth of viable kids of higher body weights. Neem leaf meal-based supplement can be used to achieve moderate growth in West African Dwarf goat in the dryseason. I recommend that supplement containing up to 2.50% neem leaf meal may be used to feed pregnant does in the dry season. Further research should be conducted to determine the effect of neem leaf meal on rumen microbial population and intestinal helminthes.

ABSTRACT
Considering the risk of epidemic diseases, *in-vitro* conservation is a strategic tool to secure genetic diversity. The present study is therefore aimed at evaluating the efficacy of different concentrations of glycerol and dimethlysulfoxide (DMSO) for successful cryopreservation of poultry semen extended with Tris coconut-water extender. Tris coconut water extender was prepared, DMSO and Glycerol were supplemented in it at different initial concentrations of; glycerol (4, 5, 6, 7 and 8 V/V) and DMSO (4, 5, 6, 7, 8 amd 9 V/V). Ejaculate Pooled semen from 10 roosters was collected and divided into 5 parts for glycero and 6 parts for DMSO. Semen was diluted with each extenders containing cryoprotectants at dilution ratio of 1:2 (semen:extender). Diluted semen was filled and sealed into 0.25ml straws and equilibrated for 4hrs period and later subjected to vapour freezing and finally immersed in liquid nitrogen container. After a period of 48hrs semen straws samples were brought out of the container for microscopic analysis. A Total of three trials were conducted. Percentage of motile, viable and membrane integrity (M.I) of post-thawed semen was significantly (P>0.05) higher in 7% (51.67±1.6, 62.62±3.8, 50.14±1.2) compared to other treatments although was statistical similar in motility (51.67±1.6) and HOST (45.15±1.1) to 8%. DMSO Post thaw motility, viability and M.I were also significantly (P>0.05) higher in 8% (46.67±9.2, 74.54.±5.9, 51.14±7.6%) and 9% (50.0± 0.0%, 67.81±6.7 %, 54.93±1.1%) than other treatments. Although, both where statistically similar to 7% concentration in motility (40.0±0.0) and M.I (47.38±1.1). It is therefore conclusive that 7-8% glycerol concentration and 8-9% DMSO concentrations is desirable for rooster semen cryopreservation.
Key words: Cryopreservation, Cryoprotectant, Semen, Coconut Water, Rooster

INTRODUCTION
More than 50% of the bird species are under extinction threats all over the world. Assisted reproductive techniques in livestock species have contributed to their conservation and sustainable use. Cryopreservation in -196°C (liquid nitrogen) is a method that makes long term storage of spermatozoa possible (Hammerstedt *et al.*, 1999). However subjecting poultry spermatozoa to ultra low temperature like -196°C usually predispose the sperm to cryopreservation stress which may eventually leads to damage or death of entire spermotozoas contained in the semen, and consequently result into low or zero fertility of inseminated birds and limit is on-farm use. This on the other hand has also limit the effective use of line breeding in poultry breeding farms. An efficient approach for long-term poultry semen storage is thus necessary for future use.
Various semen freezing cryoprotectants and protocols have also been implemented for poultry semen freezing regardless of the physiological differences between species (Awad, 2011; Purdy *et al.*, 2009; Polge *et al.*, 1949). Moreover, there are different types of Cryoprotectants and are usually classified based on their molecular weight, toxicity, temperature and degree of permeability. Glycerol and DMSO cryoprotectants have been formerly used for poultry semen cryopreservation (Tselutin *et al.*, 1995; Polge *et al.*, 1949), but with low and unstable fertility success. It is however deemed that standardizing this two fast permeating cryoprotectants concentration for poultry semen freezing may be an efficient approach. This study therefore aimed at evaluating effects of different glycerol and DMSO concentrations for poultry semen cryopreservation.

MATERIALS AND METHODS
Tris buffer was prepared by adding 3.785g of tris to distilled water, and the pH was adjusted to 7.2. Coconut fruits were purchased from the market, the shell was pierced and water was drained from it into a beaker, it was decanted and filtered. Coconut-water was kept at -20°C for further use. Coconut-water was thawed, added to tris buffer at different concentration of 50%. Different concentrations of

glycerol (4, 5, 6, 7 and 8 V/V) and DMSO (4, 5, 6, 7, 8 and 9 V/V) were prepared in TCWE. Ejaculate of Pooled semen from 10 roosters was collected and divided into 5 parts for glycerol comprising 4% (T1), 5% (T2), 6% (T3), 7% (T4) 8% (T5) and 6 parts for DMSO; 4% (T1), 5% (T2), 6% (T3), 7% (T4) 8% (T5), 9% (T6). Semen and extender was maintained at 37°C before dilution. Semen was diluted with each extenders containing cryoprotectants at dilution ratio of 1:2 (semen : extender), and was processed for chilling in respective extender to get a final concentration of 200 x 10^6 spermatozoa /ml. Extended semen was filled and sealed in 0.25ml straws by manual filling and sealing method. Straws were kept at 4^0C for 4hrs in cold handling cabinet for equilibration. Straws racked in floating rack, equilibrated for 4 hrs were kept in LN_2 vapors in a manual freezer (minitube) for 12 min before plunging into liquid nitrogen. Semen was thawed after 48 hrs at 4°C for 1min and analyzed for motility, viability and membrane integrity. A Total of three trials were conducted, all data collected were subjected to analysis of variance and means were separated with Ducan multiple range test.

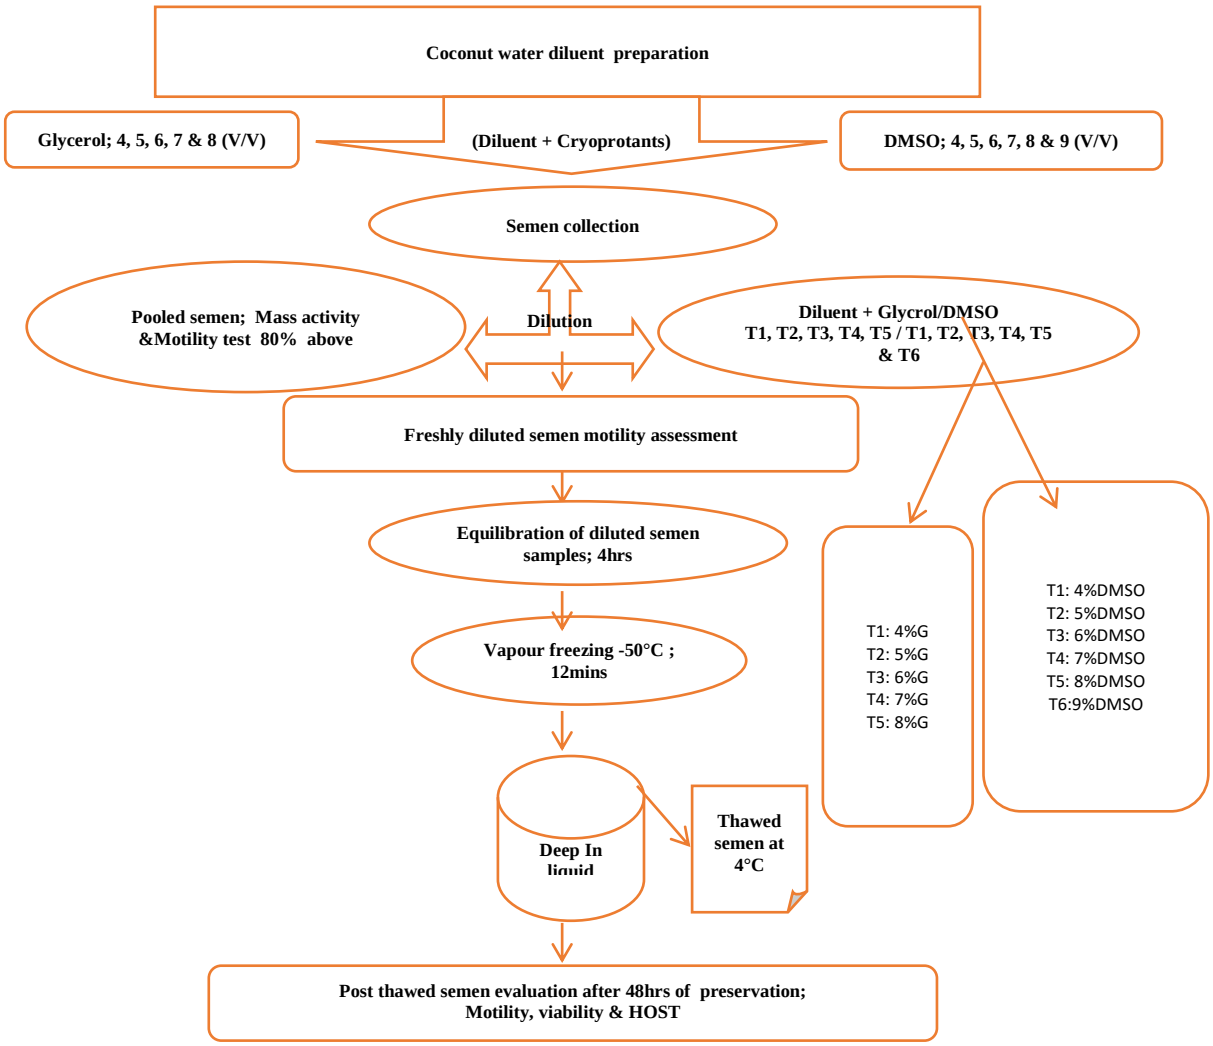

Fig1: Flow Chart of Glycerol and DMSO Concentrations Standardization for Rooster Semen Cryopreservation

RESULT AND DISCUSSION

Effects of different concentrations of glycerol in TCW extender on sperm attributes of post thawed semen are presented in (Table 1). Chickens were the first animals to be produced from frozen sperm using glycerol as a cryoprotectant (Donoghue and Wishart 2000). Percentage of motile, viable and HOS positive spermatozoa in post-thawed semen was significantly (p>0.05) higher in T4 (51.67±1.6, 62.62±3.8 and 50.14±1.2)) than other treatments, T1 (23.33±3.3, 25.08±5.6, 22.70±6.4), T2 (28.33±3.3, 33.50±5.0, 27.47±3.2) and T3 (33.33±3.3, 43.56±1.1, 34.67±4.9) extender. However, Motility and membrane integrity of post thawed semen cryopreserved in T5 (51.67±1.6%, 45.15±4.1%) extender were statistical similar (P>0.05) to T4. Our findings revealed 7% glycerol as optimum concentraton for successful cryopreservation of rooster's semen. In consonance with our observation, (Bearden *et al* 2004) reported that glycerol penetrates the sperm cell and dehydrates the cell partially, thereby reducing the risk of water crystallization. Moreover, motility score of sperm cryopreserved with 7% glycerol is above average. Since motility is one of the many important attributes of a fertile spermatozoon, in agreement with our study (Peña Martinez 2004), also reported 7-8% glycerol is deemed to be sufficient for poultry semen freezing and further reported that the concentration of glycerol to be used is semen diluents dependent. Reda Ibrahim El-Sheshtawy *et al* (2017) reported that CW extender with glycerol 4%, 6% and 8% improved sperm membrane integrity of cooled semen and the superior result was obtained in CW with 4% glycerol. In addition, Silva *et al* (2004) and Cardoso *et al* (2006) also concluded that CW containing glycerol is recommended to achieve satisfactory post freezing quality of boar semen. However, glycerol has a contraceptive effect in poultry (Long and Kulkarin 2004).

Table 1: Effects of different concentrations of glycerol in Tris coconut water extender on post thawed roosters semen

	Glycerol Concentrations				
Parameters	T1 (4%)	T2 (5%)	T3 (6%)	T4 (7%)	T5 (8%)
Motility (%)	23.33^{c}±3.3	28.33^{bc}±3.3	33.33^{b}±3.3	51.67^{a}±1.6	51.67^{a}±1.6
Viability (%)	25.08^{c}±5.6	33.50^{bc}±5.0	43.56^{b}±1.1	62.62^{a}±3.8	43.56^{b}±4.1
Host (%)	22.70^{c}±6.4	27.47^{bc}±3.2	34.67^{ab}±4.9	50.14^{a}±1.2	45.15^{ab}±11.1

Superscripts indicate significant difference at 5 % level with in the columns (a – c)

Effects of different concentrations of DMSO in Tris coconut water extender on post thawed of rooster's semen are presented in (Table 2). Post thaw motility, viability and M.I were also significantly (P>0.05) higher in 8% (46.67±9.2, 74.54.±5.9, 51.14±7.6%) and 9% (50.0± 0.0%, 67.81±6.7 %, 54.93±1.1%) than other treatments. Although, both where statistically similar to 7% concentration in motility (40.0±0.0) and M.I (47.38±1.1). This result revealed that 8%-9% DMSO concentration may be considered as optimum level for cryopreservation of rooster's semen. Moreover, Rosato and Laffaldano (2013) explained that intra-cellular cryoprotective agents are needed to increase membrane fluidity and to prevent dehydrating the cell. Donoghue and Wishart (2000) reported that the DMSO is a standard cryoprotectant for poultry sperm cryopreservation and gives higher sperm motility recovery rate. DMSO has also been proven to be the best cryoprotectant in other avian studies with higher fertility and recovery motility (Sontakke *et al* 2004).

Table 2: Effects of different concentrations of dimethlysulfoxide in Tris Coconut Water extender on post thawed Semen.

	Dimethlysulfoxide Concentrations					
Parameters	T1 (4%)	T2 (5%)	T3 (6%)	T4 (7%)	T5 (8%)	T6 (9%)
Motility (%)	21.67^{c}±1.6	26.67^{c}±1.6	31.67^{bc}±1.6	40.00^{ab}±0.0	46.67^{a}±9.2	50.00^{a}±0.0
Viability (%)	43.36^{c}±0.4	44.73^{c}±0.3	53.25^{bc}±0.3	40.04^{c}±4.3	74.54^{a}±5.9	67.81^{ab}±6.7
Host (%)	20.75^{c}±3.1	26.51^{bc}±1.2	35.76^{b}±2.0	47.38^{a}±1.1	51.14^{a}±7.6	54.93^{a}±1.1

Superscripts indicate significant difference at 5 % level with in the columns (a – c)

CONCLUSION AND RECCOMENDATION

It is therefore conclusive that 7-8% glycerol concentration and 8-9% DMSO concentrations is desirable for rooster semen cryopreservation. However, glycerol usage should not exceed 8% initial concentration while DMSO usage should not exceed 9% concentration when used in poultry. Evaluation of Different freezing, thawing and pre-freezing procedure is also recommended for better post thawed poultry semen quality.

ABSTRACT
Dilution of neat semen is advantageous, as more hens can be inseminated from a single ejaculate semen sample. This study was conducted to evaluate the optimum dilution rate of marshal and Isa brown cocks semen diluted with Tris Egg-yolk Orange Juice extender Preparation of TEY-O extender was done, and maintained at 37°C. Ten marshal and Isa brown of 30-40 weeks of age from Obasanjo farms limited were used. Pooled ejaculates of 10 cocks from each strains were collected into glass funnel per trials. Blood stained and contaminated semen was discarded. Semen was examined for individual progressive motility. The extender and semen were kept at 37°c 5-10 mins before dilution. Pooled semen with motility > 80% was processed for dilution. Ejaculated pooled Semen from each strains were divided into four equal parts consisting of eight treatments and diluted at different ratio with TEY-O extender; undiluted semen, diluted Marshal (1:2, 1:3 and 1:4) and Isa brown (1:2, 1:3 and 1:4) cocks semen. Diluted and undiluted semen samples were evaluated for motility, viability, membrane and acrosome integrity. A total of three trials were conducted. The Freshly diluted semen samples showed no significant difference (P<0.05) in all parameters evaluated. However, in marshal extended semen three folds dilution (1:2) had highest value, while in Isa brown, four folds dilution had highest value in most paramters. It is therefore concluded that semen dilution rate does not have significant influence on strains variability (heavy and light) and that both strains respond similarly to the different dilution rate.
Key words: Extender, Semen, Dilution, Egg-yolk, Strains

INTRODUCTION
The technique of Artificial Insemination is getting popular in other poultry species other than turkey. Since last few decades, more farms in Nigeria now rely on A.I for their broiler breeders. For example, fertility in the broiler breeds continues to decline as males are selected for growth, A.I may become cost effective in broiler breeder management (Reddy, 1995). A.I in poultry expresses better fertility than natural mating (Saeki and Nagomi, 1964). Even when under natural mating 80–85% of eggs are fertile, fertility can be further increase by 5–10% simply through augmentation with A.I to the propagation program (Gee *et al.*, 2004). Semen dilution with an extender for poultry is important because poultry semen is viscous and highly concentrated, containing approximately six to twelve billion spermatozoa per ml for roosters and toms, respectively (Donoghue and Wishart, 2000). Dilution of neat semen irrespective of the strains variability (meat/egg) laying type is therefore advantageous in that more hens can be inseminated from a single ejaculate semen samples. However, Choice of semen extender is an important aspect of semen processing for A.I (Peterson *et al*., 2007).
Several investigators have compared the composition of various diluents and summarized fertility data across studies (Howarth 1983; Bakst 1990; Bootswala and Miles, 1992). But, no standard diluent for poultry semen yet, and studies are so variable in experimental design which includes species and strains response, dilution rate, time of insemination, vaginal depth and frequency of AI, Storage period and number of spermatozoa inseminated and duration of fertility analyzed that discerning the benefits of different diluents is difficult. Glutamic acid is believed to be the most important chemical constituent of avian seminal plasma and it has become a standard component of extenders (Siudzinska and Lukaszewicz, 2008). Egg-yolk known to contain a considerable amount of glutamic acid, and vitamine E, an evident for it antioxidant potentials has been a major component of cattle and some other farm animal species diluent. Moreover, optimizing the potentials of egg-yolk by supplementing it with orange juice as a conjugate antioxidant source has been reported to enhance semen quality *in-vitro* and *in-vivo* and subsequently egg fertility percentage (Balogun, 2019).
Penfold *et al.* (2001) also reported a significant advantage of diluting freshly collected spermatozoa 1:1 in BPSE on sperm motility and progressive status regardless of temperature (24°C versus 4°C) while further dilution in BPSE (1:10 or 1:100) caused a transient increase and a rapid decrease in progressive motility. Thus, maintaining the quality of poultry sperm *in vitro* shortly before and during

insemination has been observed to require suspending it in a solution capable of preserving it fertilizing ability till the sperm is inseminated and probably in the hen oviduct. Thus, identifying the appropriate and optimum dilution ratio ditto strains response is paramount and may be an important step in achieving better diluted semen quality and subsequently good fertility.

MATERIALS AND METHODS

This study was conducted at Oyo State College of Agriculture and Technology, in Collaboration with Obasanjo farm Nigeria limited (OFN) at Igboora. Tris buffer was prepared by adding 3.785g of tris to distilled water, and the pH was adjusted to 7.2. Fresh domestic fowl eggs were collected from the farm and disinfected, the shell was broken and yolk was separated from albumen. 20% egg-yolk was vigorously mixed with Tris buffer in the beaker and finally 10% orange juice was supplemented into it and mixed very well. TEY-O extender was kept in the freezer for further use. Ten Marshal and Isa cock birds were used from Obasanjo Farm Nigeria limited. Pooled semen with motility > 80% from each strains were separately simultaneously processed for dilution. Ejaculated pooled Semen from each strains were divided into four equal parts consisting of eight treatments and diluted at different ratio with TEY-O extender; undiluted semen, diluted Marshal (1:2, 1:3 and 1:4) and Isa brown (1:2, 1:3 and 1:4) cocks semen. The diluted and undiluted semen samples were evaluated for motility, viability, membrane and acrosome integrity. A Total of three trials were conducted, all data collected were subjected to analysis of variance and means were separated with Ducan multiple range test.

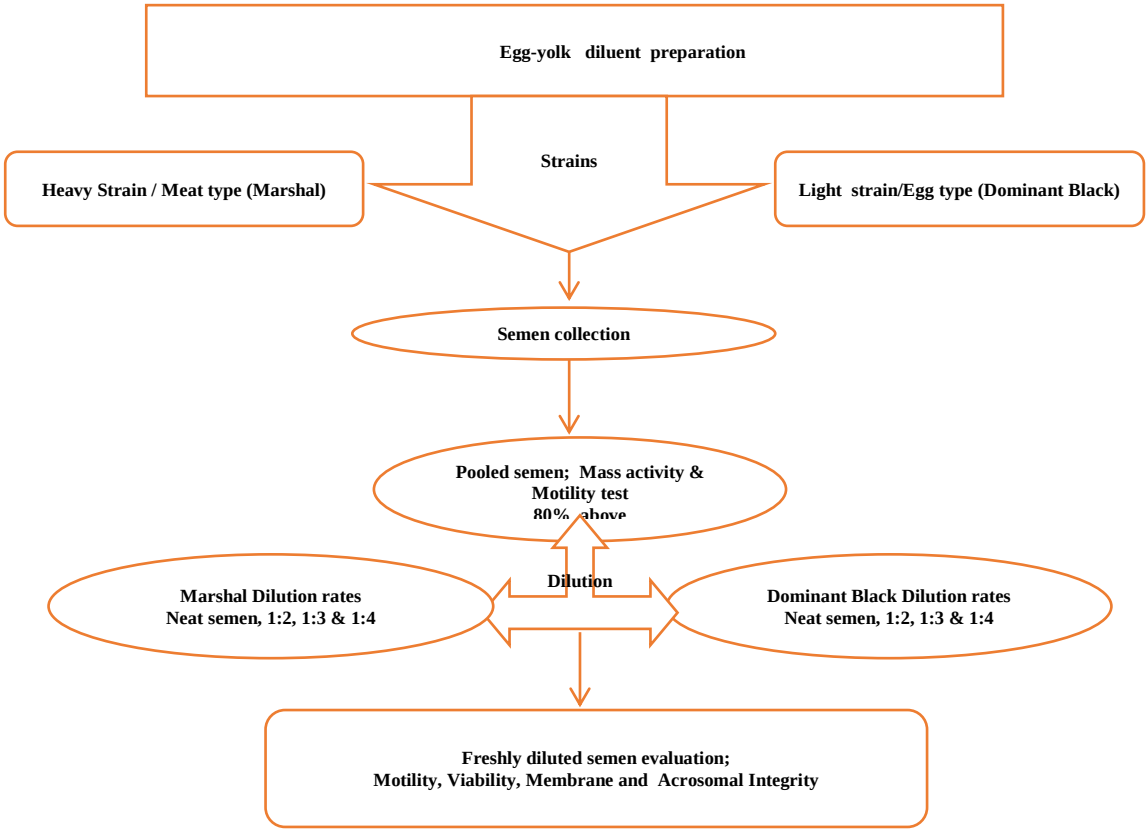

Fig1: Flow Showing Standardization of Semen Dilution Rate of Heavy and Light Strains Domestic Fowl With Tris Egg-Yolk Orange Juice Extender

Result and Discussion

Microscopic semen quality parameters of neat rooster semen extended with Tris egg-yolk orange juice extender is presented in (Table1). Freshly diluted semen samples showed no significant difference ($P<0.05$) in most parameters evaluated such as percentage motility, viability, membrane integrity and acrosome integrity. However, in marshal extended semen, three folds dilution (1:2) had highest value in most parameters such as motility (93.33%), viability (95.00%) and membrane integrity (93.47%) while in Isa brown, four folds dilution (1:3) had highest value in most parameters; motility (91.67%),

viability (94.33%) and membrane integrity (93.33%). This result revealed that most microscopic semen parameters are not significantly affected by dilution rate with TEY-O extender on semen of both heavy and light strain cocks. Moreover, extender do not had adverse effects on immediate dilution with neat semen irrespective of the dilution rate up to four dilution folds.Similar results were reported by (Balogun et al., 2017a, Balogun 2019) on standardization of egg-yolk concentrations for rooster semen dilution and preservation. Also, the result obtained is in agreement with the previous studies in turkey semen (Iaffaldano *et al.,* 2010; Venkatesh 2005).However, Iaffaldano *et al.,* 2010 also reported superior spermatozoa motility with BPSE and IMV diluents at lower dilution (1:2 and 1:3), in which we also recorded highest values in our present experiment. Furthermore,Keerthy *et al.* (2016) buttress the result of our present study by observing that dilution rate did not showed any significant difference even between storage periods irrespective of the extenders and the guinea fowl varieties.

SEM : Standard Error of Mean

CONCLUSION AND RECOMMENDATION

It is therefore concluded that semen dilution rate does not have significant influence on strains variability and that both heavy and light strains cock semen responds similarly to different dilution rate with Tris egg-yolk diluents and can be diluted up to five folds for immediate artificial insemination use without exposing the sperm cells to any deleterious effects.

FERTILITY AND DURATION OF FERTILE PERIOD IN BROILER BREEDER HENS INSEMINATED WITH VARIED SEMEN DOSES

Bolarinwa, A. O., Adebisi, K. A & Ewuola E. O
Animal Physiology and Bioclimatology unit,
Department of Animal Science, University of Ibadan, Ibadan, Nigeria

ABSTRACT
One hundred and twenty Marshall broiler breeder hens aged 32 weeks were used to assess the effect of varying insemination doses on egg fertility and duration of fertile period. The hens were randomly allotted into five treatments of twenty four hens each in a completely randomized design. Semen was harvested from 10 cocks, using abdominal message technique, pooled and evaluated for semen quality. Hens in T1 were inseminated with 0.02 mL semen (containing $5x10^6$ motile spermatozoa), hens in T2, T3, and T4 were inseminated with 0.04, 0.06 and 0.08 mL of semen, respectively, while hens on T5 were exposed to natural mating at a ratio of one cock to four hens. Both mating processes were repeated for two successive days. Eggs were collected daily and incubated weekly for four weeks to determine egg fertility as influenced by semen doses and oviductal sperm age. Data were analysed using descriptive statistics and ANOVA at $\alpha_{0.05}$. At the first week, fertility in T1 (94.3±1.9%), T2 (94.5±3.2%), T3 (95.2±1.9%) and T4 (97.1±2.9%) were significantly higher than T5 (76.9±3.0%). Fertility up till 7 days of oviductal sperm age in inseminated hens was above 90%, but reduced to 87.0±4.7% and 74.2±9.3% at days 8 and 9, respectively and declined to zero fertility in day 22. It could be concluded in this study that semen insemination dose of 0.02 mL is lease economic dose with optimum fertility in broiler breeder hens. The maximum duration of fertility period in broiler breeder hens was 21days, while efficiency in fertility reduced after 8days.
Keywords: Artificial insemination, fertile period, insemination dosage, egg fertility

INTRODUCTION
Broiler breeder production is one of the profitable business in Nigeria due to the ban in the importation of frozen chickens. This recent development by the government has led to an increase in the demand of day old chicks for production of broiler chickens.

Interestingly, most broiler breeder farms in Nigeria still widely employ the natural mating system in the production of fertile eggs that will yield day old chicks. This system however, is marred with associated problems which includes transfer of disease from male to female, incomplete successful mating leading to reduced fertility due to body weight gain of cocks during natural mating (Attia *et al*., 1993) and higher number of cock to hen ratio. Also, during natural mating a single cock deposit much more semen than what is needed to fertilize an egg which leads to semen wastage and economic loss at large to farmers.

Fertility is of major concern to broiler breeder farmers. To increase fertility in poultry, adoption of artificial insemination (AI) is of paramount importance since AI is attributed with several advantages compared to natural mating (Penfold *et al* 2000). The merit of A.I among others includes increase in number of settable eggs, best overall fertility and hatchability, thus reducing the cost of production of day old chicks (Brillard, 2003). Artificial insemination has been used in poultry industry in the developed countries (Surai and Wishart 1996), However in Nigeria measures have not been put in place in poultry industry to regulate artificial insemination protocol and practices. Artificial insemination technology in poultry has been hypothesized to lengthen insemination interval with lesser semen dose for insemination (froman *et al.*, 2011). Despite the promising of AI in poultry industry in Nigeria, there still indiscriminate use of semen in broiler chicken breeding programs, thus leading to semen wastage.

This is because the management technology and other useful information on insemination dosage in broiler breeder hens are not readily available to the farmers and even the commercial farmers depend on their past experiences.

Researches that have been carried out on A.I in broiler breeders chickens mostly were in temperate regions which may not be directly adoptable by tropical farmers Burrow and Quinn (1937) reported insemination dose of 0.05 mL of undiluted semen; Dose containing 5.5 $x10^6$ spermatozoa have been reported to increase fertility (Lake and Ravie, 1988). There is therefore dearth of information on

insemination schedule in broiler breeder chickens in Nigeria. Also, proper documentation on insemination schedule particularly on least viable semen dose for optimum fertility under Nigeria condition is lacking. Therefore, this study was aimed at investigating the appropriate semen dosage, for optimal fertility in broiler breeder hens.

MATERIALS AND METHODS

Experimental location

The experiment was conducted at the poultry unit of the Teaching and Research farm and the Animal Physiology Laboratory of the Department of Animal Science, University of Ibadan, Nigeria.

Experimental animal management and semen collection

One hundred and twenty Marshall broiler breeder hens aged 32 weeks were randomly allotted into five treatments (T1-T5) of twenty- four hens each in a completely randomized design. Semen was harvested from 10 cocks, using abdominal message technique (Burrow and Quinn 1937), pooled and evaluated for semen quality.

Insemination, data collection and analysis

Hens in T1 were inseminated with 0.02 mL semen (containing $5x10^6$ motile spermatozoa). Hens in T2, T3, and T4 were inseminated with 0.04, 0.06 and 0.08 mL semen, respectively while hens on T5 were exposed to supervised natural mating at a ratio of one cock to four hens and each hen was allowed to be mated once per day. Both mating processes were repeated for two successive days. Eggs were collected daily and incubated weekly for four weeks to determine egg fertility and duration of fertile period as affected by semen doses and oviductal sperm storage. Analysis was done on square root transformed data using general linear model of SAS (2003) while means where significant were separated using Duncan's Multiple Range Test of the same software.

RESULTS

Spermatozoa characteristics in pooled semen inseminated for the two days are shown in Table 1. Average sperm concentration, liveability and sperm motility were 0.28 $x10^9$ cells/ml, 96.8% and 90%, respectively.

Table 1: Characteristics of pooled semen administered to the hens

Semen parameters	Mean values (± Standard deviation)
Sperm concentration (x 10^9 cells/mL)	0.28±0.13
Liveability (%)	96.8±3.7
Sperm motility (%)	90.0±0.0

Table 2. Shows the effect of different semen insemination dosage and natural mating on fertility of hens. Fertility result for the first week ranges from 94.29±1.91% to 95.17±1.91% in the inseminated groups and was significantly ($p<0.05$) higher than that of the natural mating groups (76.89±2.95%). Fertility in week two and three was not significantly different ($p<0.05$) among the treatments. Though drops to zero in all the treatments at weeks four.

Table 2: Egg fertility (%) in broiler breeder hens inseminated with varied semen doses for four weeks

Weeks after insemination	Semen dose inseminated (mL)				
	0.02 (T1)	0.04 (T2)	0.06 (T3)	0.08 (T4)	Natural mating (T5)
1	94.29±1.91[a]	94.53±3.23[a]	95.17±1.91[a]	95.17±1.91[a]	76.89±2.95[b]
2	66.60±9.01	56.03±4.41	55.17±7.54	47.01±9.32	41.89±8.52
3	15.50±6.32	12.89±4.50	9.37±4.40	10.42±3.79	6.22±2.17
4	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00	0.00±0.00

[ab] Means of treatments along a row with different superscripts differed significantly ($p<0.05$). SE-standard error.

The duration of fertile period and oviductal spermatozoa age effect on fertility of the inseminated groups of hens are presented in Fig 1. Fertility was at maximum at the first week after insemination with 95.3% but there was a steady and significant drop in fertility on a daily basis to about 25% at 14th day, after which it declined till it finally reached 0% at 22 days.

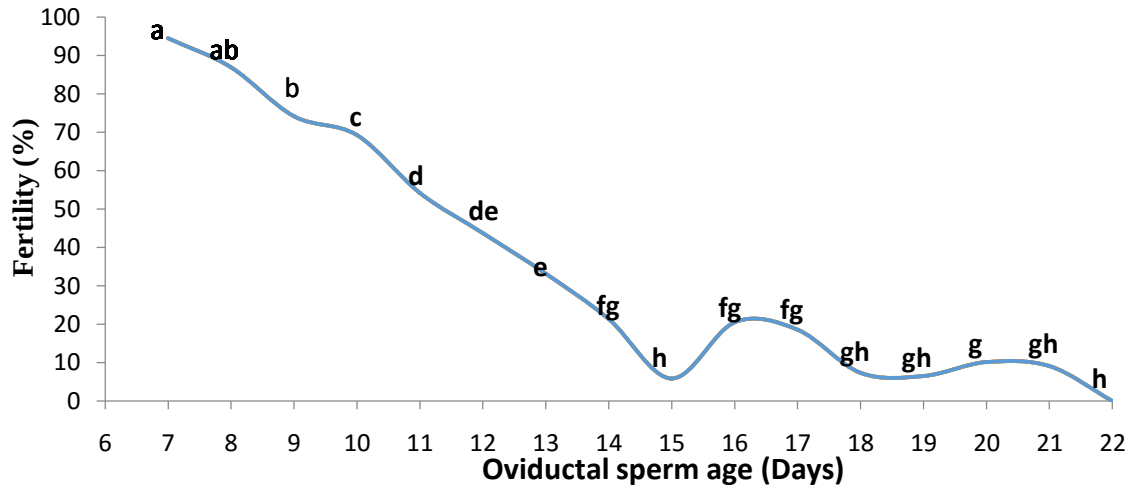

Figure 1: Duration of fertile period in inseminated broiler breeder hens

DISCUSSION

The mean values of sperm concentration observed was 0.28±0.13 ($x10^9$ /ml). The values for sperm concentration was $5.5x10^6$ /ml reported by Lake and Ravie (1988) for breeder cocks. This suggests that the concentration of sperm cells in the semen was high and thus sufficient for the intended purpose. Liu *et al.* (2009) noted that semen quality parameters such as concentration, liveability and morphology are good predictors of the fertilizing ability of sperm cells.

The result of the semen evaluation for 0.02, 0.04, 0.06 and 0.08mL of raw semen contained approximately, 5 $x10^6$, 10 $x10^6$, 15 $x10^6$ and 20 $x10^6$ motile sperm cell respectively. Brillard and Bakst (1990) reported that the length of fertile period in chickens is determined by the number of spermatozoa that enters the sperm storage tubules (SST). This Suggest that an increase in the number of spermatozoa inseminated may maintain a high level of fertility for an extended period. Contrarily, Campton and van krey (1979) suggest that only a finite number of sperm cells are capable of entering the sperm storage tubules within a given period. The suggestion supports the observation from this

study as increasing administration of semen dose across treatment groups did not translate to increase in fertility. Thus, suggesting that insemination dose above 0.02mL (approximately 5 $x10^6$ motile sperm cell) is in excess of the maximum number of spermatozoa which can be accommodated by the SST at a given period.Also, by inseminating a semen dose of 0.02mL would mean that more hens will be inseminated. Semen wastage will be reduced and cost of production will be lowered. The fertility rate of hens on natural mating was observed to be lower throughout the trail compared to the inseminated groups. This could probably be that the volume of semen ejaculated for the two consecutive mating days did not contain enough sperm cells that was sufficient to fill the sperm SST probably due to wastage as a result of inadequate contact during natural mating.

Fertility significantly decreases with increasing oviductal sperm age up to 21 days. However, optimum fertility level was observed in inseminated groups which was obtained within first 7days post-insemination. At days 8 and 9 fertility ranged from 86.98 to 74.1% and slightly decreased to 69.2% at day 10. There was a sharp reduction on day 15 (5.83%) which later increased to (20.52%) at day 16 and subsequently 0% fertility was attained at day 22 post - insemination. This observation was in line with the work of Tabatabaei *et al.,* (2009) where optimum fertility was obtained at days 1 to 7, while fertility drops to zero at day 19 in indigenous chickens and day 17 for Ross chickens. The duration of fertile period in chicken was reported as 21days by Brillard (1993); while Bramwell (2002) reported 22 days for broiler breeder hens which corroborated this finding in the tropics.

CONCLUSION AND RECOMMENDATION

In the adoption of artificial insemination in broiler breeder hen, Semen insemination dose of 0.02mL containing $5x10^6$ motile spermatozoa is recommended as an economic dose using undiluted semen. The duration of fertile period in broiler breeder hens is 21days while efficiency in fertility reduces after 8 days.

ABSTRACT

The study was carried out to evaluate the effects of supplemental biotin on yolk, albumen and external quality parameters of Noiler hen eggs. A total of one hundred and twenty Noiler hens were purchased from the bauchi state agricultural development project, they were housed in the poultry unit of Abubakar Tafawa Balewa University Teaching and Research Farm and were further designated into five treatments with each treatment having 24 hens. Five graded levels of supplemental biotin (0.00, 0.50, 1.00, 1.50, 2.00g) were administered to each treatment in drinking water. The results for yolk quality parameters indicate that there was significant difference ($p<0.05$) among different levels of biotin tested, it was also deduced that treatment 4 with biotin level of 2.0g performed best, which was closely followed by treatment three with biotin level of 1.5g. The results also shows that albumen quality was significantly affected ($p<0.05$) by treatment 4 (2.0g) which had the highest influence on the parameters. Results for effects of biotin on external egg quality parameters indicates that there was significant difference ($p<0.05$) among the treatments with treatment 4 (2.0g) showing superior performance. From the results of this research it was concluded that biotin improved the performance of Noiler hens in all parameters studied. Therefore it is recommended that supplemental biotin should be administered at either 1.5g or 2.0g. Further research is also recommended so as to widen the use of biotin in poultry science.

Keywords: Biotin, Noiler, Albumen, Yolk.

INTRODUCTION

The chicken egg is naturally designed for reproduction, it is a veritable source of protein affordable to all classes of people. In addition to protein, the chicken egg also contains carbohydrate, vitamins and other nutrients. Among the economically important traits in egg production enterprise are egg size, shell thickness and internal qualities of egg as well as hatchability. The quality of chicken egg is influenced by age, breed and strain of the chicken, as well as nutrition. Thus, the internal and external egg quality traits are of major importance to the egg industry worldwide (Ahmadi and Rahimi, 2011). It has been reported that the quality of the chicken egg is influenced by genetic and non-genetic factors such as season, environment and feed intake (Ahmadi and Rahimi, 2011; Ojedapo, 2013; Burra, 2014). Egg quality traits had been reported to influence embryo development, hatchability, and growth performance of chicks (Khan et al., 2004; Onagbesan et al., 2007; Huwaida et al., 2015). The Noiler chicken breed is a hybrid developed in Nigeria which is rugged and can adapt to harsh conditions like local chickens, they have an excellent survival rate that matches that of local chicken they also grow faster and have better egg laying performance. Management practices, high stocking density and harsh climatic conditions result in poor egg quality such as thin egg shell, shell-less egg, low albumen and yolk quality which impacts negatively on the poultry industry. Biotin (vitamin H) which is also called vitamin B7 or B8 is a water soluble B-vitamin and an essential coenzyme that contributes an integral part of embryonic development. Its physiologically active form is linked to biotin-dependent enzymes (Chen *et al.*, 1994). Thus, it contributes to growth, bone development, reproduction, improving feed conversion in animals (McMahon, 2002) and improving the performance of breeder hens and chicks (Arends *et al.*, 1971; Watkins andKratzer, 1987; Kruger and Brown, 1987and Robel, 1989 & 1991). Birds do not have the capability to synthesize biotin, which is provided, under physiological conditions, by microbial synthesis of gut flora. Egg biotin is positively related to dietary biotin. Egg biotin content increases with incremental dietary biotin levels (Frigg *et al.*, 1984 andRobel, 1991). Hence the objective of the research was to determine the effects of biotin on yolk, albumen and external quality parameters of Noiler hen eggs.

MATERIALS AND METHODS

The study was conducted at Abubakar Tafawa Balewa University Teaching and Research Farm Bauchi, Bauchi state it is located in the north eastern part of Nigeria and has a tropical climate. One hundred and twenty Noiler hens were purchased from the Bauchi State Agricultural Development Project, they were designated to five treatments in a complete randomized design with each treatment having 24 hens. Biotin was administered orally in drinking water. The research work lasted a period of twelve weeks.

Treatment layout

Control (0.00)
Treatment 1 (0.5g)
Treatment 2 (1.0g)
Treatment 3 (1.5g)
Treatment 4 (2.0g)

Egg and shell weight

The eggs were collected within four hours of lay and weighted using a digital weighing scale and weights were recorded to the nearest 0.1mm.

Egg length and width

The egg length and width were measured with a vernier calliper to the nearest 0.1mm.

Egg shell thickness

The thickness of the shell with intact membrane were measured at three different points and the average of the broad, sharp and middle parts of the egg shell were obtained using micro screw gauge.

Albumen length, width and height

Albumen length, width and height were measured using vernier calliper to the nearest 0.1mm.

Yolk length, width and height

Yolk length, width and height were measured using vernier calliper to the nearest 0.1mm

Yolk colour

Yolk colour was measured using Roche Colour Chart.

Yolk and albumen weight

Yolk and albumen weight were measured using a digital weighing scale

Data analysis

Data obtained were analysed using General Linear Model Procedure of SAS (2015) and significant ($p<0.05$) means differences among treatment means were compared using Duncan's Multiple Range Test (Duncan, 1995) of the SAS package.

RESULTS AND DISCUSSION

Table 1: Effects of Biotin on yolk quality parameters

Parameters	Yolk Length (mm)	Yolk Width (mm)	Yolk Height (mm)	Yolk Weight (g)	Yolk Colour
Treatments					
CC (0.0g)	3.98^{b}	3.98^{ab}	1.51^{c}	14.96^{c}	4.62^{b}
T1 (0.5g)	3.98^{b}	3.10^{c}	1.52^{bc}	15.02^{c}	4.71^{a}
T2 (1.0g)	4.04^{b}	4.02^{a}	1.54^{b}	15.56^{b}	4.74^{a}
T3 (1.5g)	4.06^{a}	4.05^{a}	1.55^{b}	15.78^{b}	4.47^{c}
T4 (2.0g)	4.05^{a}	4.05^{a}	1.71^{a}	16.47^{a}	4.76^{a}

Means within columns having different superscript are significantly different ($P<0.05$)

The results for effects of biotin on yolk quality parameters are shown in table 1. The results shows that there exist significant difference ($p<0.05$) among the treatments in all the parameters studied. It was also deduced that treatment 4 with biotin level of 2.0g performed best, which was closely followed by treatment three with biotin level of 1.5g.

Table 2: Effects of Biotin on albumen quality parameters

Parameters	Albumen Length (mm)	Albumen Width (mm)	Albumen Height (mm)	Albumen Weight (g)
Treatments				
Cc (0.0)	6.48^{bc}	4.42^{d}	0.60^{c}	22.44^{d}
T1 (0.5g)	6.38^{c}	4.72^{c}	0.60^{c}	23.84^{c}
T2 (1.0g)	6.59^{b}	4.75^{c}	0.66^{b}	24.76^{bc}
T3 (1.5g)	7.08^{a}	5.21^{b}	0.66^{b}	25.27^{b}
T4 (2.0g)	7.38^{a}	5.30^{a}	0.72^{a}	27.83^{a}

Means within columns having different superscript are significantly different ($P<0.05$)

The results for effects of biotin on albumen quality parameters are shown in table 2. The results shows that there was significant difference ($p<0.05$) among the treatments with treatment 1(0.5g) having the lowest influence on the parameters while treatment 4 (2.0g) having the highest influence on the parameters.

Table 3: Effects of biotin on external egg quality parameters

Parameters	Egg Weight (g)	Egg Length (mm)	Egg Width (mm)	Shell Weight (g)	Shell Thickness (mm)
Treatments					
CC (0.0)	50.24^{d}	5.27^{d}	4.07^{c}	5.73^{b}	0.37^{b}
T1 (0.5g)	51.40^{cd}	5.24^{e}	4.11^{bc}	5.84^{b}	0.38^{ab}
T2 (1.0g)	52.51^{c}	5.42^{c}	4.13^{ab}	5.79^{b}	0.38^{ab}
T3 (1.5g)	56.63^{b}	5.83^{b}	4.14^{ab}	5.89^{b}	0.38^{ab}
T4 (2.0g)	58.88^{a}	6.04^{a}	4.18^{a}	6.40^{a}	0.40^{a}

Means within column having different superscript are significantly different ($P<0.05$)

The results for effects of biotin on external egg quality parameters are shown in table 2. The results indicates that there was significant difference ($p<0.05$) among the treatments with treatment 4 (2.0g) showing superior performance.

CONCLUSION AND RECOMMENDATIONS

From the results of this research it was concluded that biotin improved the performance of Noiler hens in all parameters studied. Therefore it is recommended that supplemental biotin should be administered at either 1.5g or 2.0g, further research is also recommended so as to widen the use of biotin in poultry science.

ABSTRACT

A study was conducted to determine the effects of Noiler hen strains on yolk, albumen and external egg quality parameters. A total of one hundred and twenty Noiler hens were divided into three treatments at the Bauchi State Agricultural Development Project. The hens were housed in a two tier battery cage, they were further divided into three treatments of forty hens each comprising three strains namely Brown, Black and Spotted. The results obtained from the study shows that strains did not significantly affect ($p<0.05$) yolk lenght, yolk width, youlk height, yolk weight and yolk colour. The results also indicates that ($p<0.05$) there were no significant difference in albumen length, albumen width and albumen height but it was observed that there was significant difference in albumen weight with Black (25.46g) and Spotted (25.40g) performing better than Brown (23.92g). Furthermore the results for external egg quality parameters showed that there was no significant difference ($p<0.05$) among the strains tested, this implies that strains did not affect egg weight, egg lenght, egg width, shell weigth and shell thickness. From the finding of this research it was therefore concluded that the strains studied did not influence yolk quality parameters and external egg quality parameters but significantly influenced albumen weight. It is recomended that either black, spotted or a combination of the two strains should be used by local farmer.

Keywords: Noiler, Strain, Yolk, Albumen

INTRODUCTION

Noiler chicken breed is one of the breeds of poultry birds with with a great prospect, raising Noiler hens is comparatively cheaper than other chickens. The demand for animal protein has globally increased, in the last five years meat consumption has gone up sactifactorily, with Noiler chiken breed, the production of animal protein is cheaper and sustainable. The Noiler chiken is a dual-purpose breed of chicken developed in Nigeria.Noilers are suitable for rural communities and smallholder farmers and can address the challenges of animal food insecurity (justagric.com, 2019). Noiler hens come in different strains such as black, brown, spotted etc, these strains affect the quality of the eggs produced by the hens such as yolk, albumen and external quality parameters which in turn influence the marketability of the eggs and also the quality of chiks obtained from the eggs after hatching. This research was therefore conducted to evaluate the effects of some selected Noiler strains (brown, black and spotted) on yolk, albumen and external egg quality parameters of eggs.

MATERIALS AND METHODS

The study was conducted at the Bauchi State Agricultural Development Project (BSADP) Bauchi State, Nigeria. It lies between latitude 9.30° and 12.3° North of the equator, and Latitude 8.48° and 11° East of the Greenwich meridian. One hundred and twenty Noiler hens were purchased from the bauchi state agricultural development project and housed in two tier battery cages, they were allotted to three treatments in a complete randomized design with each treatment having 40 hens. The research work lasted a period of twelve weeks.

Egg and shell weight

The eggs were collected within four hours of lay and weighted using a digital weighing scale and weights were recorded to the nearest 0.1mm.

Egg lenth And width

The egg lenght and width were measred with a vernier calliper to the nearest 0.1mm.

Egg shell thickness

The thicness of the shell with intact membrane were measured at three different points and the average of the broad, sharp and middle parts of the egg shell were obtained using micro srew guage.

Albumen lenght, width and height

Albumen lenght, width and height were measued using vernier calliper to the nearest 0.1mm.

Yolk lenght, width and height

Yolk lenght, width and height were measued using vernier calliper to the nearest 0.1mm

Yolk colour

Yolk colour was measured using Roche Colour Chart.

Yolk and albumen weight

Yolk and albumen weight were measured using a digital weighing scale

Data analysis

Data obtained were analysed using General Linear Model Precedure of SAS (2015) and significant ($p<0.05$) means differences among treatment means were compared using Duncan's Multiple Range Test (Duncan, 1995) of the SAS package.

RESULTS AND DISCUSSION

Table 1: Effects of strain on yolk quality parameters

Parameters	Yolk Length (mm)	Yolk Width (mm)	Yolk Height (mm)	Yolk Weight (g)	Yolk Colour
Strains					
Brown	4.02[a]	4.01 [a]	1.56 [a]	15.61 [a]	4.59 [a]
Black	4.03 [a]	4.03 [a]	1.59 [a]	15.53 [a]	4.71 [a]
Spotted	4.03 [a]	4.03 [a]	1.56 [a]	15.50 [a]	4.70 [a]

Means within column having different superscript are significantly different ($P<0.05$)

The results for effects of strain on yolk quality parameters is outlined in table 1. The results showed that ($p<0.05$) there was no significant difference in all the parameters tested, this implies that the strains did not influence the out come of yolk lenght, yolk width, youlk height, yolk weight and yolk colour.

Table 2: Effects of strain on albumen quality parameters

Parameters	Albumen Length (mm)	Albumen Width (mm)	Albumen Height (mm)	Albumen Weight (g)
Strains				
Brown	6.80 [a]	4.88 [a]	0.63 [a]	23.92[b]
Black	6.80 [a]	4.92 [a]	0.65 [a]	25.46[a]
Spotted	6.72 [a]	4.82 [a]	0.63 [a]	25.40[a]

Means within column having different superscript are significantly different ($P<0.05$)

The results for effects of strain on albumen quality parameters is outlined in table 2. The results obtained in table two indicates that ($p<0.05$) there were no significant difference in albumen length, albumen width and albumen height but it was also observed that there was significant difference in albumen weight with Black (25.46g) and Spotted (25.40g) performing better than Brown (23.92g).

Table 3: Effects of strain on external egg quality parameters

Parameters	Egg Weight (g)	Egg Length (mm)	Egg Width (mm)	Shell Weight (g)	Shell Thickness (mm)
Strains					
Brown	54.43[a]	5.59[a]	4.12[a]	6.09 [a]	0.38 [a]
Black	53.74[a]	5.56 [a]	4.13 [a]	5.84[a]	0.38 [a]
Spotted	53.31[a]	5.51 [a]	4.12 [a]	5.80[a]	0.38 [a]

Means within column having the same superscript are not significantly different ($P<0.05$)

The results for external egg quality parameters are outlined in table 3. The results indicates that there was no significant difference among the parameters tested, this shows that strains did not affect egg weight, egg lenght, egg width, shell weigth and shell thickness.

CONCLUSION AND RECOMMENDATIONS

From the finding of this research it was therefore concluded that the strains studied did not influence yolk quality parameters and external egg quality parameters but significantly influenced albumen weight. It is recomended that either black, spotted or a combination of the two strains should be used by local farmers.

UNILATERAL TESTICULAR DEGENERATION IN DOGS ADVERSELY AFFECTS SPERMATOZOA CHARACTERISTICS IN THE TESTIS AND EPIDIDYMIS

ABSTRACT
Testicular degeneration (TD) is associated with poor fertility in affected dogs. The study investigated the specific effects of unilateral testicular degeneration (UTD) on spermatozoal parameters in the testes and epididymides of dogs. Ten sexually mature (7-12 months old) Nigerian indigenous breed of dogs comprising 5 normal dogs (N; both testes normal and present in the scrotum) and 5 dogs with UTD (one normal scrotal testis and one degenerated scrotal testis) were used for the study.The testes and epididymides were removed via orchidectomy and sperm analyses (total and progressive motility, vitality, total abnormalities and concentration) were performed. The samples were grouped as N1 (right normal testis); N2 (left normal testis); UTD-N (normal testis in dogs with UTD); UTD-D (degenerated testis in dogs with UTD). Data were analysed using one-way ANOVA. The UTD-D group had significantly lower ($p<0.001$) epididymal sperm total and progressive motility, vitality and concentration, higher total sperm abnormalities ($p<0.001$) and lower testicular sperm concentration ($p<0.01$) compared to the contralateral UTD-N and the N testes. The UTD-N group also had significantly lower epididymal sperm total motility ($p<0.01$) and progressive motility ($p < 0.05$), and higher total abnormalities ($p<0.05$) compared to the N groups. Our study demonstrated that UTD in dogs adversely affected spermatozoa in the affected testis and epididymis. There was also evidence of compromised spermatozoa in the testis and epididymis contralateral to the degenerated testis. Taken together, these sperm abnormalities are likely to have adverse effect on the fertility of affected dogs.

INTRODUCTION
Dogs are mainly bred for companionship, security and hunting, and to provide valuable source of income for breeders. In addition, the slaughter and consumption of dog meat is popular in many countries worldwide including Nigeria (Podberscek, 2009; Ehimiyein *et al*., 2014). Therefore, infertility is likely to cause significant economic losses in canine breeding.

The testis is the primary organ of reproduction in male animals and functions in spermatogenesis (sperm production) and steroidogenesis (testosterone production). Testicular degeneration (TD) is considered as one of the most common causes of poor semen quality and acquired infertility in male dogs (Fontbonne, 2011; Domingos and Salomão, 2011) with a prevalence of 15-58% in dogs (Ortega-Pacheco *et al.*, 2006; Câmara *et al*., 2014). TD involves deterioration in the structure of the testis with a consequent loss of testicular function (Turner, 2007). It may affect one (unilateral) or both (bilateral) testes, involving parts of the testis or the whole testis. Acute TD can result secondary to a known insult such as exposure of the testes to toxins, radiation, extreme scrotal temperature, scrotal trauma, autoimmune disease, certain nutritional deficiencies, and infection with pathogenic organisms (Turner, 2007; Obi *et al*., 2013). Idiopathic TD has no identifiable underlying cause and has also been reported in dogs (Rehm, 2000; Fontbonne, 2011).

Spermatozoa can be recovered from the cauda epididymides of dogs by percutaneous epididymal aspiration, following castration or at post mortem, for use in the investigation of sperm quality and spermatozoal characteristics (Varesi *et al*, 2013; Chima *et al*., 2017; Bhanmeechao *et al*., 2018) and for artificial breeding of bitches (Wydooghe *et al*., 2016). Ejaculated semen comprises sperm from both testes and also secretions of the accessory sex glands. Thus while evaluation of the ejaculate is used to assess semen for fertility potential, it precludes the investigation of specific effects of testicular disorders and their impact on spermatozoa. Moreover, there is little available information on the effect of TD on epididymal or testicular spermatozoa in dogs. Therefore, the aim of the study was to investigate the specific effects of unilateral testicular degeneration (UTD) on spermatozoal parameters in the testes and epididymides of affected dogs. The specific objectives were to evaluate the effects of UTD on epididymal sperm motility, vitality, morphological abnormalities and concentration, and testicular sperm concentration.

MATERIALS AND METHODS

Animals

Ten sexually mature (7-12 months old) apparently healthy Nigerian indigenous breed of dogs comprising 5 normal dogs (N; both testes normal and present in the scrotum) and 5 dogs with UTD (one normal scrotal testis and one degenerated scrotal testis) were used for the study. Only dogs with a history of progressive unilateral scrotal testicular atrophy were selected and UTD was confirmed retrospectively following testicular histopathology. Animal welfare was observed in accordance with the National Research Council's Guide for the Care and Use of Laboratory Animals (2011) and the protocol was approved by the Research Ethics Committee of the Faculty of Veterinary Medicine (2016/10-173537). Orchidectomy (open castration) was performed following standard surgical procedure as previously described (Hassan and Hassan, 2003) and the testes and epididymides were dissected, and then used for sperm analyses.

Epididymal and testicular sperm analyses

Sperm evaluation was performed as previously described (Seed *et al*., 1996; Cooper, 2010). Sperm motility was determined using the sperm diffusion in phosphate buffered saline (PBS; pH 7.4, 37 °C) from sectioned cauda epididymis. Sperm motility (%) was determined at ×400 using a phase-contrast microscope (Motic B3; Motic, Carlsbad, CA, USA) equipped with a stage slide warmer (TCS-100; Amscope, Ivrine, CA, USA) set at 37 °C. Sperm vitality (%) was evaluated using eosin-nigrosin vital staining method. Sperm morphological abnormalities were evaluated using eosin-nigrosin staining and phase-contrast microscopy. All values in percentage were determined by examining 200 sperm cells in duplicates. Cauda epididymal and testicular sperm concentrations were determined following cauda epididymal/testicular tissue homogenization in PBS and sperm cells were counted using a haemocytometer (Weber, England). Total sperm count was expressed as number of sperm per gram cauda epididymis and per gram testis, respectively.

Data analysis

Data were analyzed using One-way analysis of variance (ANOVA) built in SPSS, version 20 (IBM Corp, Armonk, NY, USA). Significant differences between means were confirmed using Tukey's honestly significant difference post hoc test. Results were considered significant when $p < 0.05$.

RESULTS

The results of the sperm analysis in normal dogs and dogs with UTD are shown in Table 1. There were no significant differences ($p > 0.05$) in all the spermiogram parameters between the two normal testes (N1 and N2) in the normal dogs. Both N groups also did not differ from the normal testes (UTD-N) in dogs with UTD with respect to epididymal sperm vitality and concentration and testicular sperm concentration. However, UTD-N group had significantly lower epididymal sperm total motility ($p < 0.01$) and progressive motility ($p < 0.05$) and higher total abnormalities ($p < 0.05$) compared to the N groups. The predominant sperm abnormalities observed included presence of cytoplasmic droplets, bent tails and coiled tails. On the other hand, there were significant differences in all the spermiogram parameters in the degenerated testes (UTD-D) when compared to the contralateral normal testes (UTD-N) in dogs with UTD and also when compared to the two normal testes (N1 and N2) in the normal dogs. The UTD-D group had significantly lower epididymal sperm total and progressive motility, vitality and concentration ($p < 0.001$) and higher total abnormalities ($p < 0.001$) compared to the contralateral UTD-N and the N testes. The predominant sperm abnormalities observed included presence of detached head, bent midpiece, coiled midpiece (dag defect) and coiled tails. Moreover, testicular sperm concentration was significantly decreased in the UTD-D testes when compared to the contralateral UTD-N testes ($p < 0.01$) and the N testes in normal dogs ($p < 0.001$).

Table 1. Epididymal and testicular spermatozoal parameters in dogs with normal testes and unilateral testicular degeneration

Sperm parameters	N1	N2	UTD-N	UTD-D
Epididymal sperm total motility (%)	83.6 ± 2.7^a	84.8 ± 3.0^a	71.2 ± 5.8^b	8.4 ± 5.1^c
Epididymal sperm progressive motility (%)	74.4 ± 4.7^a	71.2 ± 5.0^a	60.2 ± 7.8^b	3.6 ± 4.2^c
Epididymal sperm vitality (%)	94.6 ± 2.3^a	94.2 ± 2.8^a	87.6 ± 4.8^a	27.2 ± 8.3^b
Epididymal sperm total abnormalities (%)	28.0 ± 2.7^a	27.2 ± 3.1^a	39.0 ± 3.2^b	66.4 ± 8.7^c
Epididymal sperm concentration ($x10^6$/g epididymis)	926.0 ± 23.9^a	912.4 ± 19.1^a	874.0 ± 78.7^a	3.29 ± 2.1^b
Testicular sperm concentration ($x10^6$/g testis)	31.6 ± 5.7^a	29.3 ± 4.8^a	23.2 ± 9.3^a	5.81 ± 2.9^b

N1 (right normal testis); N2 (left normal testis); UTD-N (normal testis in dogs with UTD); UTD-D (degenerated testis in dogs with UTD). Values represent mean ± SD. Rows with different superscripts indicate significant differences ($p < 0.05$).

DISCUSSION

The study provided evidence that UTD adversely affected spermatozoa parameters in the testes and epididymides of dogs. UTD decreased epididymal sperm total and progressive motility. A low % of progressively motile sperm has also been reported in the semen of stallions with TD (Blanchard *et al*., 2000). Decreased sperm motility may be related to abnormal sperm formation and the observed increase in dead sperm and sperm with morphologic abnormalities. There was also increased % of dead epididymal sperm (decreased sperm vitality) in dogs with UTD. This may be related to a disruption of the normal processes in spermatogenesis and sperm epididymal maturation consequent upon the testicular insult. A significantly higher percentage of morphologically abnormal sperm was observed herein in the dogs with UTD. Câmara *et al*. (2014) similarly reported high sperm abnormality in dogs with severe TD. Interestingly, our study observed a higher % of sperm total abnormalities in dogs with UTD compared to the previous study. This may be due to differences in the source of sperm sample. Herein, sperm was harvested from the cauda epididymis whereas the previous study utilized sperm from the vas deferens. In addition, a higher % of detached head, bent midpiece and dag defect were observed in the UTD-D group, which are known to have significant negative effect on fertility (Kolster, 2018).

In this study, TD also decreased the testicular and epididymal sperm concentration. This may be a consequence of atrophy of the testicular parenchyma, degeneration of seminiferous tubules and decreased spermatogenesis (spermatogenic arrest). Since the cauda epididymis is site of sperm storage, the lowered epididymal sperm concentration may reflect a decrease in sperm production in the testis. Similarly, there was lowered daily sperm production per milliliter of testis and decreased sperm concentration in stallions with TD (Blanchard *et al*., 2001). Azoospermia has also been reported in the semen and vas deferens fluid of dogs with TD (Fontbonne, 2011; Câmara *et al*., 2014). Moreover, the findings suggest that TD in one testis can impair spermatozoa in the contralateral testis and epididymis. However, the mechanism for this effect (whether direct or indirect) was unclear due to the unknown underlying aetiology of UTD in the affected dogs. Some spermatozoal parameters (vitality and concentration) were not significantly different between the testes in normal dogs and the contralateral testes in UTD dogs. However, it is likely that the overall fertility outcome in dogs with UTD will depend on the progression and severity of TD. Taken together, lowered epididymal sperm motility, vitality and concentration, increased epididymal sperm abnormalities, and decreased testicular sperm concentration can have adverse effect on the fertility of affected dogs (Johnston *et al*., 2001; Robert *et al*., 2016; Kolster, 2018).

In summary, our study demonstrated that UTD in dogs adversely affected spermatozoa in the testis and epididymis and also showed evidence of compromised spermatozoa in the contralateral testis and epididymis. Our findings provide more information on alterations in sperm quality in relation to UTD. Although sperm cells may be recovered from the cauda epididymides of affected dogs for application in assisted reproductive technologies, further studies could investigate the functional capacity and fertilizing potential of such recovered spermatozoa.

ABSTRACT
This study was conducted to assess the effect of breed and sex on body condition score (BCS) of some sheep raised at Federal College of Education, Pankshin Research Farm in Plateau state. The BCS data were obtained from two hundred and twenty (220) sheep comprising 46 Balami (26 females: 20 males), 44 Uda (21 females: 23 males), 63 WAD (33 females: 30 males) and 67 Yankasa (32 females: 35 males) at the age of 1 year based on the BCS scale of 0 - 5. Data were analyzed with statistical package for social science version 22.0. Results indicated that WAD and Yankasa had higher ($p<0.05$) BCS than Balami and Uda, while males were superior ($p<0.05$) to females. It is concluded that breed and sex influence BCS of sheep.
Keywords: Sheep, Breed, Sex, BCS, Nigeria

INTRODUCTION
Body condition score (BCS), an estimate of the muscle and fat cover of an animal by palpation of different regions of the body, was originally described by Jefferies (1961) in Scotland sheep. It consists of a scale of six scores, from 0 to 5, based on the concept that subjectively assessed condition score is closely related to the amount of chemically determined fat in sheep (Russel *et al.,* 1969). It is an estimate of body reserves (Edea, 2008). The BCS method has been applied on various sheep breeds such as Avagonesa (Purroy, 1997), Bermagasia (Susmel *et al.,* 1995), Awassi (Treacher and Filo, 1995), Sarda (Ligios *et al.,* 1995) and Lacaune (Bocquier *et al.,* 1999). Body condition scores have been widely adopted for managing the nutrition of flock, especially on grazing, and for selecting lambs for purchase and slaughter (Jalilian and Moeini, 2007). In most studies, BCS provides a better prediction of body composition than live weight (Russel *et al.,* 1969; Sanson *et al.,* 1993).
Stockmen in several countries usually appraise animal condition in verbal terms such as "fair, bad, good, lean, fat" which are often ambiguous (Woldemariam, 2005). Over the years, several attempts have been made to formalize body condition scores using numerical values. A system based on six points scale was described by Boden (1991).Russel *et al.* (1969) showed that subjective body condition scores were closely related to the amount of chemically determined fat in sheep and could provide acceptable and useful means of estimating the proportion of fat in the body. In recent years, the system has been improved with better guidelines. According to Boden (1991);

i. An assessment is made of the prominence (the degree of sharpness or roundness) of the spinous process of the lumbar vertebrae.
ii. The prominence and the degree of fat cover of the transverse process of the vertebrae were also assessed.
iii. The extent of the muscular and fatty tissues below the transverse process were judged by the ease with which the fingers pass under the ends of the bones.
iv. The fullness of the muscle area and degree of fat cover in the angle between the spinous and transverse process estimated.

The purpose of this study is to determine the effect of breed and sex on body condition score of some Nigerian sheep.

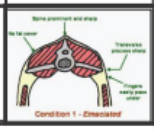
MATERIALS AND METHOD
Location and climate
The research was carried out in Pankshin town, Jos Plateau. The Jos Plateau has been described by PADP (2000), WWF (2001) and Plateau State Government Organization (2004). It is a pear-shaped upland located in the middle of Nigeria between latitude $8^{o}$and 10^{0}north and longitudes 7^{0} and 11^{0} east, at an average attitude of 1,200m above sea level and reaches the highest peak in the Shere Hills where it stands at 1,766m.

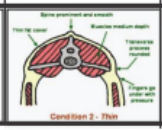
Sheep used and management

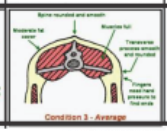
The study sheep comprised 220 sheep (46 Balami, 44 Uda, 63 West African Dwarf sheep and 67 Yankasa) reared at Federal College of Education, Pankshin Research Farm. sheep were managed under the traditional free-range in the dry season. In the rainy season when arable crops were growing, animals were kept under semi-intensive management. Under this system, sheep were taken out for grazing by a shepherd from late morning till evening. Sometimes supplementary feeds (hay and household waste) were fed.

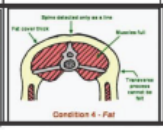
Body condition scores

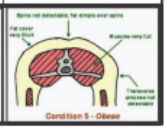
The body condition scores (BCS) were assessed by combining palpation of the sheep in the lumber region and around the backbone in the loin area immediately behind the last rib, as suggested by Boden (1991) and the guidelines (Figure 1). The scores used in the study were 1.0, 2.0, 3.0, 4.0 and 5.0 for emaciated, thin, average, fat and obese respectively. Cases which did not fit these categories properly, i.e fell between whole numbers were assigned half scores as recommended by Thompson and Meyer (1994) and additional scores of 1.5, 2.5 and 3.5 were therefore used.











Spines	Individually clearly felt, sharp, obvious	Forms a smooth line with smooth undulations	Only slightly detectable undulations	Only detectable with firm pressure	Not detectable
Transverse Process	Fingers easily pass underneath	Smooth round edges	Well covered, have to push firmly to get fingers underneath	Cannot be felt at all	
Muscle	Very little concave	Concave	Not concave, Not convex	Minimally developed convex	
Fat Layer	No	Very thin	Moderate	Thick	very thick to form a dp along top midline
Condition score					

Figure 1: Body condition scoring of sheep Source: Woldemariam, 2005.

Statistical analysis

Data generated were analyzed using the General Linear Model (GLM) of SPSS (Statistical Packages for Social Sciences, 2013) version 22.0, differences between breed and sex in BCS were determined. Ryan-Einot-Gabriel-Welsch post hoc-test was performed to separate means of breeds that were statistically different. The final model used is as follows

$$Y_{ij} = \mu + B_i + S_j + E_{ij}$$

Where:

Y_{ij} = individual observation on the animal for the ith breed and j^{th} sex

μ=overall mean

B_i=effect of the ith breed (i=1,2,3,4)

S_j = effect of the jth sex (j=1,2)

$$E_{IJ} = random\ error$$

RESULTS AND DISCUSSION

Table 1 shows BCS of sheep by breed and sex. Breed had significant ($p<0.01$) effect on BCS. West African Dwarf Sheep (WAD) and Yankasa with respective mean BCS of 3.21 and 3.20 did not significantly differ but were superior to Balami and Uda which had BCS of 2.67 and 2.79, respectively. However, Balami and Uda did not differ in BCS. Male sheep had mean BCS of 3.56 which was significantly ($p<0.01$) higher than the 2.56 in females.

In the present study, WAD and Yankasa had higher BCS's than the larger breeds (Uda and Balami). This is similar to some previous reports. Edea (2008) recorded higher BCS (3.23) in Horro than (2.71) in Bonga. Frutos *et al*. (1995) found higher internal fats and BCS in Churra than Merino. They further stated that the distribution of internal fat varied between the two breeds; the Churra breed had higher omental but lower mesenteric fat. Similarly, in a comparison between Sarda and Lacaune breeds to using BCS scores between 1 and 3.5, Ronchi *et al.* (1993) found that 60% of the former had BCS higher than 2.3 while only 40% of the latter had values higher than 2.3. Gizau *et al.* (2013) found higher overall mean BCS (2.04±0.04) in Afar than Menz breed (1.9±0.03). Laxta breed had also been found to have lower BCS (2.66) than Gallega (2.76) (Osoro *et al.,* 2002). Olthoff and Dickerson (1989) asserted that genetic differences exist in distribution of body scores in sheep. Purroy (1997) also observed that the range of BCS variation depends on the breed, due to difference in skeletal proportion, rating among muscle and fat and, the type of deposits.

In the present study, male sheep had higher BCS than female. This corroborates the report of Gizau *et al.* (2013) in each of Afar and Menz breeds. However, Ma'aruf *et al.* (2018) reported non-significant effect of sex on BCS of Yankasa sheep in Kano. The higher BCS in WAD and Yankasa despite higher than Uda and Balami, is an indication that these breeds are better adapted to the environment.

CONCLUSION

It is concluded that West African Dwarf and Yankasa sheep have similar BCS which were higher than those of Balami and Uda sheep. Male sheep have higher BCS than females.

Table 1: Body condition scores of sheep by breed and sex

	Body condition score **Means ± standard error**
Breed	
Balami	2.67 ± 1.73^{a}
Uda	2.79 ± 1.69^{a}
WAD	$3.21+1.23^{b}$
Yankasa	3.20 ± 1.41^{b}
Sex	
Male	3.56 ± 1.20^{a}
Female	2.56 ± 1.62^{b}

Means in the same column with different superscripts differ significantly, ($p<0.01$)

ABSTRACT
This study investigated the haemoglobin genotype of Nigerian sheep. Two hundred animals comprising 46 Balami (20 males vs 26 females), 44 Uda (23 males vs 21 females), 63 West African Dwarf (30 males vs 33 females) and 67 Yankasa (35 males vs 32 females) reared at the Teaching and Research Farm of Federal College of Education, Pankshin were used for this study. Five millilitres of blood was obtained from each animals by jugular venipuncture and dispensed into bottles containing Ethylene Diamine Tetra Acetic Acid and analysed using cellulose acetate paper electrophoresis. Only a single band was observed and designated as AA based on the comparison with existing control giving rise to HbAA genotype and HbA gene frequency of 1.0 each. It is concluded that all the sheep breeds studied were homozygous for haemoglobin allele Hb A. The haemoglobin phenotype could therefore not be used as basis for selection.
Keywords: Sheep, breed, sex, haemoglobin, genotype

INTRODUCTION
Haemoglobin polymorphism in sheep was first described in 1955 (Cabannes and Serain, 1955; Harris and Warren, 1955). The characteristics of blood groups and biochemical polymorphism of blood protein in farm animals have been attracting geneticists interest in obtaining data for analysing genetic differences between gene pools (Darcan and Guney, 2001). Subsequent studies of Tucker (1971) and Agar *et al.* (1972) confirmed the different variants. Electrophoretic study of sheep haemoglobin showed that there are three main genotypes; HbAA, HbBB and HbAB (Miresan, 2003; Tapio *et al.*, 2003: Salako *et al*., 2007; Akinyemi, 2010). Haemoglobin types are genetically determined in a simple Mendelian manner, none being dominant (Evans *et al.,* 1958).
The alleles vary with breed (Harris and Warren, 1955; Evans *et al.,* 1958; Stormont *et al*., 1968). The Hb C appeared in anaemic sheep (Van Vliet and Huisman, 1964). A fourth allele, Hb D with electrophoretic mobility faster than Hb A, B and C was found to be characteristic of some Yugoslavian sheep (Vaskov and Efremov. 1967). Specific foetal haemoglobins, designated as Hb F have also been identified (Helm *et al*., 1958).
Akinyemi (2010) obtained a high frequency of Hb A in populations of Balami, Uda and Yankasa reared in the Northern Guinea Savannah zone of Nigeria, while Salako *et al*. (2007) reported a higher value of HbB in population of West African Dwarf sheep at low altitude in South-West Nigeria.
The discovery of genetic polymorphism demonstrated by proteins that differ electrophoretically furnishes information for the study of the genetics of the organism at all levels, i. e. molecular, cellular, or the entire organism. The knowledge obtained from the determination of genetic polymorphism from protein differences permits the study of protein evolution and thus the evolution of the organism. Qualitative genetic traits enable man to examine the effects of breeding systems on the frequencies of alleles where inbreeding and selection are practiced. It is assumed that the genes for quantitative traits behave in the same manner as the qualitative genes and thereby allow a monitoring of the shifts in gene frequencies of all genes where various breeding systems are used. The discovery of a qualitative gene trait that may serve as a genetic marker for a desirable combination of quantitative genes which will make for better animal production is possible as well as desirable. The objective of this study is to validate or otherwise previous findings (Salako *et al.,* 2007; Agaviezor *et al.*, 2013; Dafur *et al*., 2019) on Nigerian sheep haemoglobin as demonstrated by electrophorentic pattern. Study like this may not only add to store of knowledge but may provoke further studies on sheep selection and breeding.

MATERIALS AND METHOD

Location and climate

The research was carried out in Pankshin town (Figure 9), Jos Plateau. The Jos Plateau has been described by PADP (2000), WWF (2001) and Plateau State Government Organization (2004). It is a pear-shaped upland located in the middle of Nigeria between latitude $8^{o}$and 10^{0}north and longitudes 7^{0} and 11^{0} east, at an average attitude of 1,200m above sea level and reaches the highest peak in the Shere Hills where it stands at 1,766m.

Sheep used and management

The study sheep comprised 220 sheep (46 Balami, 44 Uda, 63 West African Dwarf sheep and 67 Yankasa) reared at Federal College of Education, Pankshin Research Farm. sheep were managed under the traditional free-range in the dry season. In the rainy season when arable crops were growing, animals were kept under semi-intensive management. Under this system, sheep were taken out for grazing by a shepherd from late morning till evening. Sometimes supplementary feeds (hay and household waste) were fed. In both systems, extensive and semi-intensive, no specialized form of housing was provided but their owner's compound or homestead and veterinary care was generally not provided.

Blood sample collection and analysis

Blood (5ml) was collected from each sheep by jugular venipuncture and dispensed into each of the sample bottles with ethylene diamine tetra-acetic acid (EDTA) for electrophoresis to determine haemoglobin genotype. Electrophoresis was carried out at the Central diagnostic laboratory of NVRI Vom. Two millilitres of blood sample were placed into a clean test tube, 5ml of cold saline was added and the diluents centrifuged at 4000 rpm for 10 – 15 minutes. The supernatant was discarded and the sample washed again three times. The sediment was re-suspended using 2ml of cold distilled water. When the lysate was well separated after standing, it was stored at refrigeration temperature until electrophoresis. The red cell lysate was then impregnated on a cellulose acetate paper which was placed in the electrophoresis tank using forceps and subjected to electrophoresis according to standard procedure described by Evans (1971). The tank was powered with the lid closed and sampled allowed to separate for about 10 – 15 minutes. The identification of the haemoglobin type was achieved by the position of bands along the electrophoretic substratum using Ponceau-S which was later washed with glacial acetic acid.

Data Analysis

Because only one allele (A) was detected, the haemoglobin genotype and gene frequencies was estimated thus; the genotype frequency AA = number of AA/total number x 100, while gene frequency = number of AA x 2/100.

RESULTS AND DISCUSSION

Table 1 depicts the genotype and gene frequency of sheep by breed and sex. At electrophoresis, only a single band was observed and designated as AA by comparison with existing control. This implied that all the sheep breeds (Balami, Uda, West African Dwarf and Yankasa) studied were homozygous for haemoglobin allele HbA. This gave rise to Hb AA genotype and HbA gene frequency of 1.0 each.

Only HbAA genotype was observed in sheep used for this study. This is in agreement with the report of Chuku and Uwakwe (2012) who also found only HbAA genotype in sheep in Port Harcourt, Nigeria and Dafur *et al.* (2019) who similarly reported only the Hb AA in all sheep breeds on the Jos Plateau. However, these findings contradict that of Salako *et al* (2007) who showed that HbBB predominates followed by HbAA and HbAB in both male and female sheep. The existence of only HbAA in this study could be an adaptive survivability feature. Different genotypes have been reported to exhibit selective advantages in different geographical regions (Ndamukong, 1995). This might have led to the fixation of HbAA in sheep of present study. FAO (1988) reported that carriers of HbAA demonstrated significant resistance against helminth infections. According to Distasio (1997), this could be due to better functional properties such as greater affinity to oxygen, higher Hb concentration and packed cell volume. Conversely, Mwacharo *et al.* (2002) found HbBB alleles fixed in Kwale, Makueni and Siaya sheep breeds of Kenya. Agaviezor *et al.* (2013) stated that there is indication that vegetation or climate changes affect Hb type. With homozygosity at the Hb locus, selection for improvement cannot be based on sheep genotype.

Table 1: Haemoglobin types and gene frequencies of four Nigerian Sheep Breed

Breed	N	Genotype frequency			Gene frequency	
		AA	AB	BB	A	B
Balami	46	46(1.00)	0(0)	0(0)	92(1.00)	0(0)
Female	26	26(1.00)	0(0)	0(0)	52(1.00)	0(0)
Male	20	20(1.00)	0(0)	0(0)	40 (1.00)	0(0)
Uda	44	44(1.00)	0(0)	0(0)	88(1.00)	0(0)
Female	21	21(1.00)	0(0)	0(0)	42(1.00)	0(0)
Male	23	23(1.00)	0(0)	0(0)	46(1.00)	0(0)
West African Dwarf	63	63(1.00)	0(0)	0(0)	126(1.00)	0(0)
Female	33	33(1.00)	0(0)	0(0)	66(1.00)	0(0)
Male	30	30(1.00)	0(0)	0(0)	60(1.00)	0(0)
Yankasa	67	67(1.00)	0(0)	0(0)	134(1.00)	0(0)
Female	32	22(1.00)	0(0)	0(0)	44(1.00)	0(0)
Male	35	35(1.00)	0(0)	0(0)	70(1.00)	0(0)

CONCLUSION AND APPLICATIONS

It is concluded that on the Hb AA genotype is exhibited in the Nigerian sheep used for the study, therefore, haemoglobin genotype cannot be used as the basis for selection of sheep for improvement.

INFLUENCE OF PERIOD EGG PRODUCTION PERFORMANCE OF NOILER CHICKENS

[1]Dogara, M. U., [1]Kalla, D. J. U., [1]Mancha, Y. P.

[1]Department of Animal Production Faculty of Agriculture anad Agricultural Technology, Abubakar Tafawa Balewa University, Bauchi, Nigeria

[2]Department of Animal Science Faculty of Agriculture, Federal University of Kashere, Gombe State, Nigeria

ABSTRACT

The study was conducted at Poultry unit of Bauchi State Agricultural Programme (BSADP) from July to September, 2018 to determine the influence of period on egg production performance of noiler chickens. A total of 135 adult noiler hens were used for the study out of which 63 were black strain, 52 brown and 20 spotted. Specifically, egg weight, egg mass, hen day production (HDP) and hen house production (HHP) were assessed. Data generated were subjected to analysis of variance using SPSS version 22. Period had significant effect on all the variable recorded and that these traits increases with increment in production cycle. Thus, selective improvement of these birds on these traits should be emphasised at peak laying.

Keywords: Noiler chicken, egg production and period

INRODUCTION

Poultry eggs constitute one of the most valuable sources of animal protein recommended for human consumption and offer means of solving the problems of animal protein shortage (Olawoyin, 2006). The need to produce more animal protein in the country has become increasingly urgent in view of the ever rising population. The human population in Nigeria is projected to grow at an annual rate of 2-5% to the year 2025 (Adebambo, 1999). Population growth has surpassed food production and at the moment it is estimated that about one quarter of the population are already facing chronic food insecurity. Poultry meat and eggs have been recommended among the livestock to bridge this protein gap, because of short generation interval, high rate of productivity, quick turnover rate, higher feed efficiency and low labour and land requirement (Ojedapo *et al.,* 2008). Adequate information on growth potentials of existing commercial layers in the country is essential to poultry farmers so as to guide or assist in the choice of stock. However, because these commercial layers vary in production indices, it is therefore imperative to assess them as a measure of their performance in the environment (Piper and Latter, 1974). Most commercial laying birds are bred in developed countries of Europe and America by International breeding companies and supplied to enfranchised companies locally from whom many farmers purchase their chicks (Oluyemi, 1978).

MATERIALS AND METHODS

Location of the study area

The experiment was conducted at the poultry unit of Bauchi State Agricultural Development Programme (BSADP) Headquarters Bauchi, Bauchi State, Nigeria. Bauchi State is located between latitudes 9° 3' and 12° 3' north, longititudes 8° 50' and 11° east of the equator, at an elevation of 537 meters above sea level. The land area is 49,119 km^2 representing 5.3% of Nigeria's total land mass. The area is primarily agrarian contributing 75% to the State's economy. The climate is characterized by two well defined seasons: The rainy season (May to October) and the dry season (November to April). The mean annual rainfall and temperature range are 905.33 mm and 11 - 41 ^{o}C, respectively (IAR/BSADP, 1996).

Experimental Design

A total of 135 noiler chickens of 8 weeks purchased from Bauchi State Agricultural Development Programme (BSADP) were used for the present study. It comprises of 63 Black, 52 Brown and 20 Spotted noiler chickens. The experimental design employed was (CRD) and the experiment lasted for three (3) months.

Experimental diets

From time of purchase to commencement of laying, the birds were fedwithcommercial growers' feed (CP = 14 %, Fat = 7 %, Crude Fibre = 10 %, Calcium=1.0 % and Available Phosphorous = 0.35 %). At 5% of laying, the feed was changed to commercial layers ration (CP = 16.5 %, Fat = 5 %, Crude Fibre = 10 %, Calcium = 3.50 % and Available Phosphorous = 0.40 %) feed. feed and water was supplied *ad-libitum*.

Data Collection

Data on egg weight, hen day egg production (HDEP), hen housed production (HHP) and average egg mass (AEM) was recorded in three strains of chicken. Egg weights were recorded individually to the nearest gramme using an electronic scale (Professional scale), while HDEP, HHP and AEM were obtained using the following formulas.

$$\text{HDEP} = \frac{Total\ number\ of\ eggs\ produced\ in\ a\ day}{Total\ number\ of\ hens\ present} \times 100$$

$$\text{HHP} = \frac{Total\ number\ of\ eggs\ produced\ in\ a\ day}{Total\ number\ of\ hens\ at\ begining\ of\ laying} \times 100$$

Average egg mass = per cent HDEP × Average egg weight (g)

Data Analysis

The data generated were subjected to analysis of variance (ANOVA) using the General Linear Procedure (GLM) of SPSS, version 22 (2014). Significantly different means were compared using the Least Significant Difference (LSD). The model utilized was as follows:

$\mathbf{Y}_i = \mathbf{U} + \mathbf{W}_i + \mathbf{e}_i$

Where:

$\mathbf{Y}_i$ = Dependent variable (egg production performance)

$\mathbf{U}$ = Overall mean

$\mathbf{W}_i$ = Effect of ith week of lay

$\mathbf{e}_i$ = Residual error

Table 1: Weekly Egg production of noiler birds

Week of production	Age of bird in days	Age of bird in weeks	Hen day production (%)	Egg weight (g)	Egg mass
1	154	22	2.82^{e}	44.15^{c}	1.25^{d}
2	161	23	17.15^{d}	43.48^{c}	7.46^{c}

Overall mean	-	-	59.37	51.36	35.72

Means in the same column with different superscript are significant ($P<0.05$)

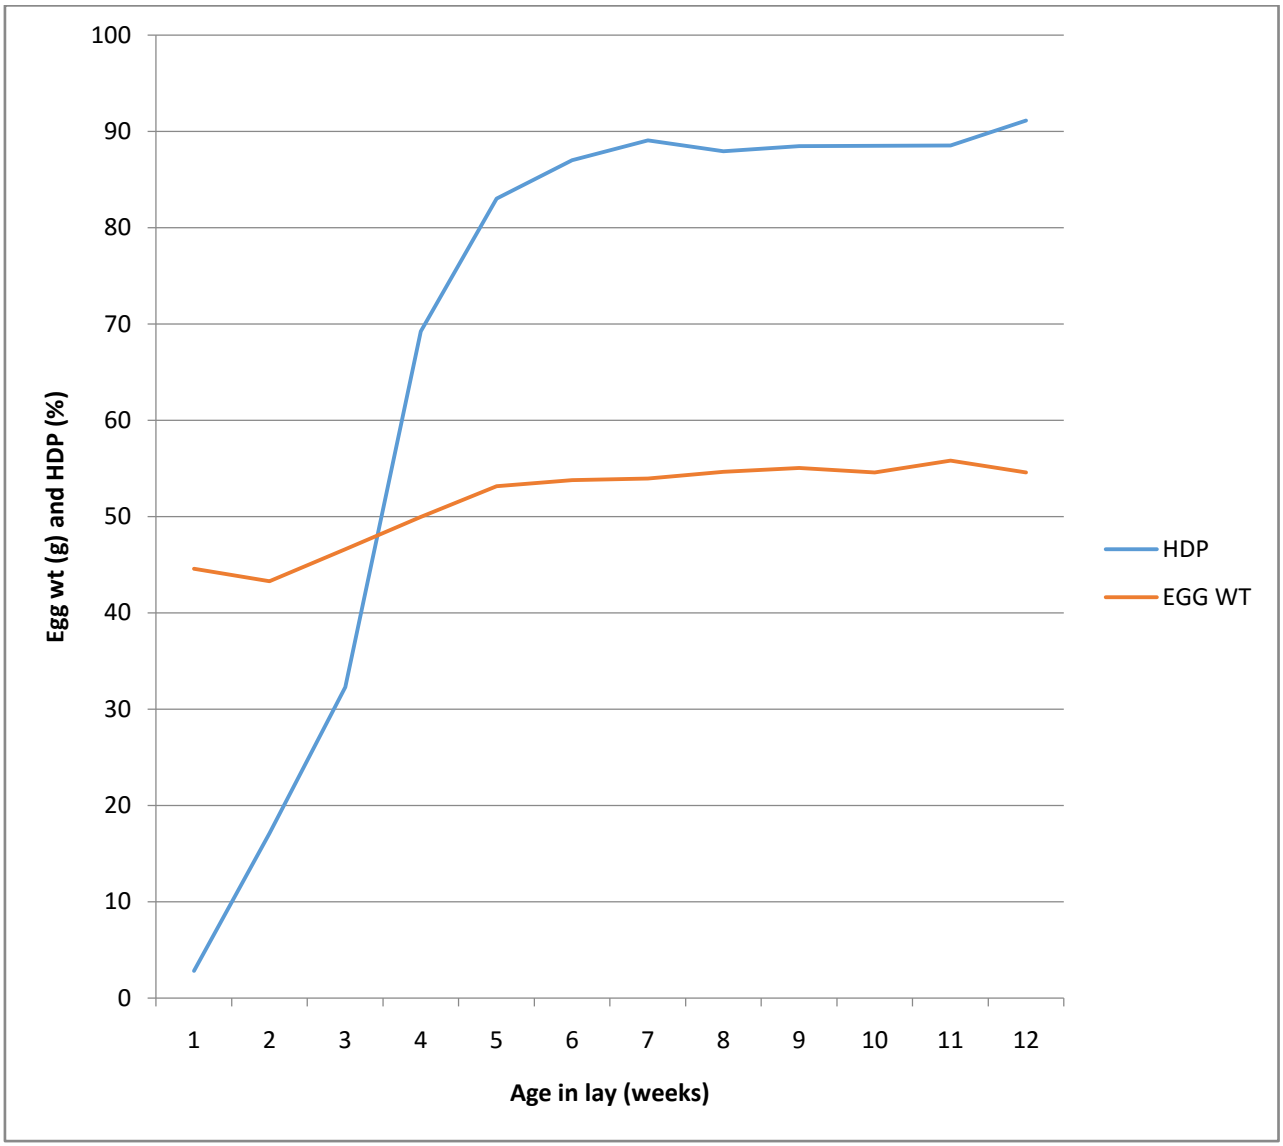

Figure 1: Egg production pattern of Noiler chicken

RESULTS AND DISCUSSION

Averages of hen day production (HDP), egg weight and egg mass according to week of production are presented in Table 1. Significant influence ($P<0.05$) of week of production was observed in these traits. This is line with the work of Padhi *et al*. (2013) who observed that egg quality traits of commercial layer bird increases significantly from 28 weeks of age to 72. However, the authors revealed that egg weight at 52, 64 and 72 weeks of age did not differ significantly indicating that in early period there was gain in this trait and thereafter, it remain static. Similar observation was reported by Suk and Park (2001). Tumova and Gous (2012) also reported non-significant effect of age on egg shape index in broiler breeder and laying hen. Usman *et al*. (2017) reported significantly higher egg production in first laying cycle than second and third among Aseel chicken native to Pakistan and attributed it to low level of fat deposition on the reproductive organs in the younger birds. They further explained that fat deposition on the ovary increases with increasing age. Usman *et al*. (2013) also stressed that egg production of commercial layer birds decreased with age advancement. Regarding egg mass, chicken in the first cycle production had significantly larger egg mass which could be as a result higher number of egg produced compared to the second and third cycles (Usman *et al*., 2013). Similar to the present result, the earlier work of Haq *et al*. (1997) showed that feed conversion ratio (FCR) values of layers during the first production cycle were better than in the second production cycle. However, Vargas *et al*. (2009) reported that FCR is not influenced by

age. Regarding egg parameters, Vargas *et al*. (2009) reported higher mean in third laying cycle compared to second and first and could be due to the weight and size of egg laid by birds of this age group. In another study, higher egg breadth in older birds has been reported which is positively correlated to the size of the oviduct (Johnston and Gouys, 2007). Contradictory statement has been reported by Sohail *et al.* (2013) who observed non-significant effect of age on egg surface area. In figure 1, HDP and egg are presented. The result revealed that HDP increases with age advancement and peaked at 6 to 7 weeks of production. Thereafter, the production is maintained. For egg weight, the deviation from the initial weight was insignificant.

CONCLUSION

The study therefore revealed that both egg mass and HDP increases with increase in weeks of production, while the changes observed in egg weight was insignificant.

ABSTRACT

A total of nine hundred (900) goats comprising of three hundred Sahel goats from Borno state, three hundred Red Sokoto goats from Sokoto state and three hundred West African Dwarf goats from Ogun state were used for the study. Each breed consisted of three hundred goats each, made up of fifty males and fifty females distributed in the following age groups <1, 1-2 and 2-3 years. These were evaluated for morphometric characteristics. The pairs of permanent incisors in the dentition of the goat were used to determine age. The effects of age, breed, and sex on linear measurement were estimated using the GLM procedure of the statistics analysis software package. These were computed on the basis of interaction with age groups. Means were separated within age groups using Duncan multiple range test. The result of this study indicated that the Sahelian breed was superior to other breeds across all age groups in body weight, while the red Sokoto was intermediate followed by the West African Dwarf.

INTRODUCTION

Goats are the largest in number among ruminant livestock in Nigeria totaling about 58.3 million (FAOSTAT, 2008). Goats, predominantly are kept by the rural household and ownership is spread across all human age groups and sexes (Akpa,1999).The importance of goat stem from its ability to convert forages and household by-product into high quality human food and their role as locally available source of food, fibre, power and other products to suit local community needs. The indigenous breeds found in Nigeria are, Red Sokoto, Sahel, and West African Dwarf (WAD) goat (Adu and Ngere, 1979). These differ considerably in size, coat colour, horn length, etc. Their broad genetic variability enables them to survive under stressful environmental condition including high disease incidence, poor nutrition which may increase animal susceptibility to disease, high temperature, and traditional husbandry system.

MATERIALS AND METHODS

The study was carried out in Borno, Sokoto and Ogun States. These states were selected because they are locations having close to pure breeds of the goats. Animals used for this study were sampled in the abattoir, of Borno, Sokoto and Ogun states when brought for slaughter either by the owner or by the slaughter man. It is believed that all animals find their way into the abattoir from villages and local markets, where they are kept in small numbers by local farmers; they are raised under the extensive system of management. A total of nine hundred (900) goats comprising of three hundred Sahel goats from Borno state, three hundred Red Sokoto goats from Sokoto state and three hundred West African Dwarf goats from Ogun state were used for the study. Each breed consisted of three hundred goats each, made up of fifty males and fifty females distributed in the following age groups <1, 1-2 and 2-3 years. These were evaluated for morphometric characteristics. The pairs of permanent incisors in the dentition of the goat were used to determine age.

The following metric characters were measured on each animal: Body Weight (BW), Age, Horn Length (HL), Ear length (EL), Shoulder width (SW), Neck circumference (NC), body length (BL), Withers Height (WH), Heart Girth (HG), Pouch Girth (PG), Tail Length (TL) and Scrotal circumference (SC). Weights of the animals were taken using a spring balance and Walk-in weighing scale. Flexible measuring tape was used to take the body measurement. During body measurement, animals were made to stand upright and restrained by two assistants in such a way that their heads,

necks, and chest were stretched almost in a straight line. Each measurement was taken at least three times and the mean recorded to the nearest centimeter or kilogram. Reference marks used for body measurement according to the method of and Salako and Ngere (2002).

Data analysis

The effects of age, breed, and sex on linear measurement were estimated using the GLM procedure of the statistics analysis software (SAS, 1990) package. These were computed on the basis of interaction with age groups. Means were separated within age groups using Duncan multiple range test.

RESULTS AND DISCUSSIONS

Mean body weight in Red Sokoto, Sahel and West African Dwarf goats less than one year are presented in Table 1. The Sahel breed is superior to the other breeds with a body weight of 13.56±0.56Kg and 14.94±0.52Kg in does and bucks respectively. Within the Red Sokoto population, body weight in doe and buck was 13.73±0.51Kg and 12.86±0.42Kg respectively while in West African Dwarf, 10.44Kg±0.22 and 10.62±0.21Kg for does and bucks. Coefficient of variation ranges between 13.98% and 29.40% suggesting the influence of major genes on this trait.

Summarized in Table 2 are Sahel goats had a mean weight of 17.13±0.43Kg and 16.86±0.49Kg followed by West African Dwarf goats with 15.45Kg±0.54 and 17.65±0.44Kg for does and bucks respectively. Red Sokoto goats weighed 13.60±0.46Kg (does) and 13.51±0.43Kg (bucks).

Live weight is important for assessing the condition of the animal and represents a criterion of selection. Mean live weight of 13.73 Kg, 13.56 Kg, 10.44 Kg and 12.86 Kg, 14.94 Kg and 10.44 Kg for does and bucks for the three breeds respectively for age less than one year are within the range of 12-18 Kg reported by Katongole *et al*. (1996) for indigenous goats in Kenya. Mean live weight of 13.60 Kg, 17.13 Kg, 15.45 Kg and 13.51 Kg, 16.84 Kg and 17.65 Kg for does and bucks between the age one through two years are lower than values of 20-40kg reported by several authors (Akpa *et al*., 1998, Otoikhan *et al*., 2008 and Salako *et al*., 2006) in different breeds of goat. Mean live weight of 18.95 Kg, 23.60 Kg, 19.13 Kg and 19.21, 25.12 Kg and 19.35 Kg for does and bucks above two years are closer to the range reported by several authors (Akpa *et al*., 1998, Osuhor *et al*., 2002 and Otoikhan *et al*., 2008), with Sahel breed fell within the specified range of 20-40 Kg. The average body weight at different ages fell within the range of 16-30 Kg specified by Hassan and Ciroma (1990) for both does and bucks from age 1-5 years in different breeds of goats.

CONCLUSION

Present results showed that age has strong influence, as there were consistent increases in all the traits studied as the animals aged. The scenario is however not surprising since the size and shape of the animal is expected to increase as the animal is growing with age. There was wide variability as the age of the animals increased most particularly in the bodyweight. This was in consonance with the report of Orheruata and Olutogun, (1984) in cattle.

ABSTRACT

This paper discusses the influence of road transport stress on cattle heart rate and beef quality. The demand for beef and beef products has resulted in increased road transport of cattle which is the predominant means of cattle transport especially in developing parts of the world. Stress due to road transport exposes cattle to physical, psychological, and climatic factors that affect the animals with different intensities and duration. The most dominant stress factors associated with road transport of cattle include loading and unloading, bad handling, inappropriate driving, poor road conditions, too hot or too cold climate, insufficient ventilation, high stocking densities, mixing of unfamiliar groups, water and food deprivation, vibration, vehicle motion and length of the journey. These stress factors result in an increased heart rate which distort homeostatic balance of the animal, thus leading to induced changes in the secretion of pituitary hormones, altered metabolism, immune competence and behaviour which result in Dark Firm Dry (DFD) and Pale Soft Exudative (PSE) beef products which are unattractive and unpalatable to consumers. It is concluded that road transport is a source of stress for cattle. Road transport conditions are very essential factors which affect heart rate of the animal, this directly impacts the physiological wellbeing of the animal with direct influence on the quality of beef produced. Therefore it is recommended that all stake holders in the road transport sector should be trained on the techniques of handling cattle during transport. Specialized vehicles should be designed for road transport of cattle.

Keywords: Transport, Heart Rate, Stress, Road, Cattle, Beef, Cortisol

INTRODUCTION

Stress can be defined as a biological response elicited when an animal perceives threat to its homeostasis (Mob erg, 2000). There is increasing transport of livestock through long distances, as demand for meat products increases freight opportunities grow and trade barriers are reduced (Phillips, 2015). Most of this transport is by road. The physiological responses of animals to adverse conditions such as those which they may encounter during handling and transport will be affected by the anatomical and physiological constitution of the animal. Cattle transport produces physical, psychological, and climatic stressors that affect animals with different intensities and duration (Earley, 2010). There is no doubt that long transport is an unknown procedure for cattle which can be irritating and aversive (Hartung, 2003). This will lead to a persistent increase in heart rate of the animal which will cause an increased level of cortisol and other stress hormones that will affect beef quality. Warriss (2000) defined meat quality on the basis of their functional or conformational qualities. Functional qualities were referred to as the desirable attributes in a product while conformance qualities encompass producing a product that meets consumer's specification exactly. Yield and gross composition, palatability, wholesomeness and ethical quality are the components of meat quality (Warriss, 1996). Therefore this review elaborates the influence of road transport stress on cattle heart rate and beef quality.

Factors Causing Transport Stress

The most pervasive factors with cattle transport include loading and unloading, bad handling, inappropriate driving, poor road conditions, too hot or too cold climate, insufficient ventilation, high stocking densities, mixing of unfamiliar groups, deck height, water and food deprivation, vibration, vehicle motion and length of the journey (Hartung, 2003). The duration of the journey has a greater impact than the distance (Von Borell, 2005). The main critical issues resulting in stress during transport are due to factors like inadequate road vehicles, illegal route plan and non-compliance with travelling speed limit, negligence and poor handling of animals, transport of unfit cattle, inadequate ventilation, over loading and difficulty in checking that vehicles were authorized to transport cattle (Singh, 2012). Some other stress inducing factors during transport are the attitudes of stakeholders and their driving skills, laws and codes of practice, genetic differences between breeds, design of vehicle for transport and design of equipments used for loading, payment of persons working with animals (Broom, 2003).

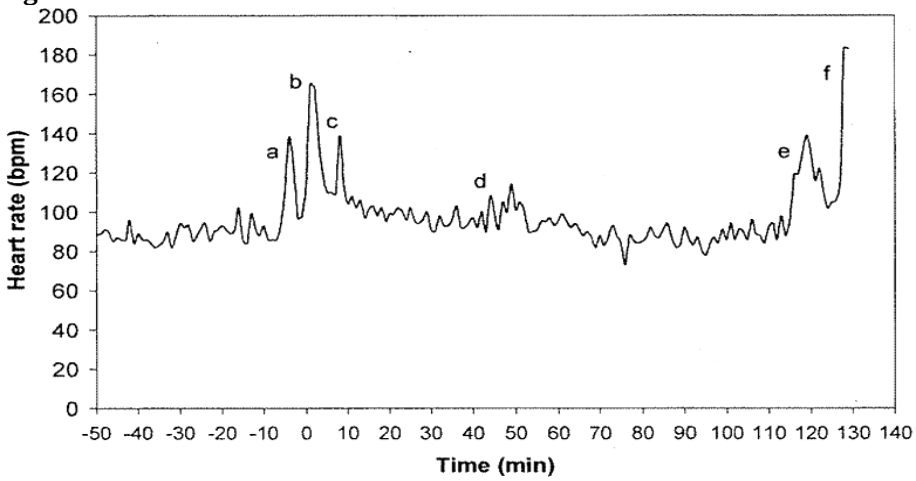

Table 1: Stressors in cattle transportation

Stress	Stressor	Effect
Behavioural	Novelty, restraint, noise	Fear
	Mixing, overcrowding	Aggressive interaction
Nutritional	Fasting	Dehydration and hunger
Physical	Mixing & overcrowding	Bruising and injury
	road conditions	Bruising and injury
	driving technique& horns	Bruising and injury
	Weather extremes	Hyper/hypothermia
Infectious	Dust exposure	Respiratory disease

(Ashenafi, 2018)

Influence of road transport stress on cattle heart rate

Figure 1. Curve of measured heart rate from a bull.

(Gebresenbet, 2005)

a) Animal near experimental animal is loaded
b) Loading
c) The vehicle starts to drive
d) Loading of new animals
e) Unloading at abattoir
f) In the stunning box

X-axis represents time in minutes where 0 represent loading, negative time is before loading and positive after loading.

A typical heart rate curve is shown in figure 1. The first peak occurred when an animal near the experimental animal was loaded, the second peak at loading, the third peak when the vehicle started to drive, the forth small peak occurred when new animal was loaded to the vehicle, and the fifth and sixth peak when the bull was unloaded and then forced to go into the stunning box (Gebresenbet, 2005).

Effects of increased heart rate on hormones

Increased heart rate as a result of transport stress triggers an increase in activity of thyroid and adrenal function in cattle which continues to increase after long distance transport (Fazio, 2005). Physiological changes encountered during road transport induced heart rate increase include plasma cortisol levels, breathing rate, extent of muscle tremor, foaming at the mouth, changes in adrenaline and noradrenaline (i.e., epinephrine and nor epinephrine), plasma or saliva glucocorticoid levels, saliva cortical levels, increases/decreases in body temperature, physical signs of nausea or motion

sickness, plasma vasopressin levels, plasma ß-endorphin levels, plasma Adrenocorticotropic hormone (ACTH) levels, plasma creatinine levels, plasma lactate dehydrogenate levels (Ashenafi, 2018). Cortical concentrations are used extensively as an indicator of stress because cortisol is released during the activation of the Hypothalamus, Pituitary and Adrenal glands (HPA) axis in response to stressful stimuli (Swanson, 2001). It has been widely documented that increased heart rate in response to transportation in the bull, cow and calf elicit an elevation in plasma cortisol levels which result in high levels of plasma urea and glucose (Guardia, 2009; Averos, 2008).

Effects of increased heart rate on beef quality

Elevated heart rate levels have a direct impact on cortisol. This influences other blood physiological parameters such as depletion of glycogen reserves which lead to a decrease in post-mortem lactic acid production (Coldit *et al*.2006; Mounier *et al*. 2006). This lead to two major conditions namely Pale Soft Exudative (PSE) and Dark Firm Dry (DFD) beef. Pale soft exudative and dark firm dry beef are very important beef quality problems that continuous to bedevil the beef industry, PSE and DFD beef are unattractive and more likely to face discrimination by consumers (Viljoena *et al*., 2002). Pale soft exudative beef looks pale, lean, has soft texture and low water holding capacity and poor functional attributes. Dark firm dry beef looks dark, variations in tenderness, poor functional attributes and prone to spoilage. Detailed description of pale soft exudative and dark firm dry beef can be found in Adzitey and Nurul (2010).

CONCLUSIONS

There is clear indication that road transport represent a source of stress for cattle. Transport conditions are very essential factors which affect heart rate of the animal. This directly impacts the physiological wellbeing of the animal which has direct influence on the quality of beef produced.

Transport stress ⟶ Elevated heart rate ⟶ physiological changes ⟶ PSE & DFD Beef

RECOMMENDATIONS

All stake holders in the road transport sector should be trained on the techniques of handling cattle during transport. Specialized vehicles should be designed for road transport of cattle. Private investors should be encouraged to invest in modular abattoirs so as to reduce distance and duration of road transport for cattle.

EFFECTS OF TOMATO LYCOPENE ON SEMEN CHARACTERISTICS AND LIBIDO OF RABBIT BUCKS

***Ebule K., D.J.U Kalla & Y.P Mancha**

Department of Animal Production, Abubakar Tafawa Balewa University Bauchi, Bauchi State Nigeria

**Corresponding author: ebulekenneth@gmail.com Mobile No: 08024263740*

ABSTRACT

A total of 15 mature mongrel rabbit Bucks were randomly divided into five treatments at the Abubakar Tafawa Balewa University Farm, Bauchi, Nigeria. The experiment lasted for a period of 16 weeks. The Bucks were allowed 4 weeks for stabilization and acclimatization, 4 weeks for training with a teaser doe and 8 weeks for oral administration of graded levels of tomato lycopene (0.00g, 0.25g, 0.50g, 0.75g, and 1.00g). Semen was collected once a week from all 15 Bucks and analyzed. The result showed that while lycopene doses at 0.75g and 1.00g significantly reduced ($P<0.01$) reaction time (seconds) it also resulted in greater ($P<0.01$) semen volume (ml), sperm cell concentration/ml ($n\times10^7$), total sperm Count ($n\times10^7$) and libido score (mounts/minute) while live sperm cells (%) was not significantly affected by all doses of lycopene administered. The result also showed significant improvement ($P<0.05$) for Sperm motility (%)of Bucks administered 0.50g and 0.75g lycopene. From the finding of this study it was concluded that lycopene significantly influenced semen characteristics and libido of rabbit bucks. This study therefore recommends that lycopene at 0.75 grams per day for eight weeks should be used to improve the semen quality and libido of rabbit Bucks used for breeding. Further research should be carried out so as to widen the scope and utilization of lycopene in animal science.

Keywords: Lycopene, Tomato, Semen, Sperm, Libido

INTRODUCTION

Rabbit farming is becoming more attractive to many animal breeders due to its high fecundity, high mothering ability, adaptability to a wide range of conditions, high genetic variability, high roughage utilization and low cost of production (Das, S.K *et al.*,2007; Zarrouki, N *et al.*,2004). The economic efficiency of a rabbitry depends mainly upon the reproductive performance of the doe, which in turn is affected by fertility of the buck (Castellini C *et al.*,2003). Male rabbits are undoubtedly the basis of reproductive success, given that farm profitability depends not only on the female's fertility but also upon the buck. Male fertility is also an interesting trait in rabbit breeding, because together with the doe it determines reproductive and productive success. Moreover, due to the fertilising capacity of semen, the male can influence not only fertility and conception but also the productivity of the does (Berchiche *et al.*, 2000; Zerrouki *et al.*, 2005a). Lycopene has antioxidant properties and imparts the red-coloured pigment in both fruits and vegetables. Poor semen production is a factor that hinders efficient reproductive performance in rabbit Bucks. In the tropics, male rabbits are used for breeding purposes from about 6 months of age and expected to produce semen consistently from this age (Wang *et al*., 2010). This is not so in many tropical breeds and their crosses as a result of the extreme conditions in the tropics which causes oxidative stress even in period of abundant feed supply. Antioxidants, especially lycopene which is an antioxidant carotenoid compound have not been widely used to improve rabbit semen. This study was therefore designed to evaluate the influence of lycopene on semen characteristics of rabbit Bucks.

MATERIALS AND METHODS

This study was carried out at Abubakar Tafawa Balewa University Teaching and Research Farm, Bauchi, Bauchi state, Nigeria. It is located in the north eastern part of the country and has a tropical climate. Lycopene used for this experiment was obtained by extraction from tomato. Fifteen Mature mongrel rabbit Bucks of breeding status were randomly assigned to different treatments in a complete randomized design. The experiment lasted for a period of 16 weeks comprising 4 weeks of stabilization and acclimatization, 4 weeks of training with a teaser doe and 8 weeks for oral administration of graded levels of tomato lycopene.

Reaction Time

A teaser doe was introduced to each buck every week to measure reaction time. This was the time it takes the rabbit buck to sniff, groom and mount the doe and it was recorded with a stop watch.

Libido Score

A teaser doe was introduced every week to measure sex drive, this was the number of time each buck attempted to mount the doe in a minute.

Semen Collection

Semen was collected from the Bucks with the aid of an artificial vagina (AV) as described by Herbert and Adejumo (1995). Prior to semen collection the AV was warmed for a few minutes in warm water at a temperature slightly above body temperature and thereafter drained. The semen was collected between 8:00am and 9:00 am, this was to ensure that good quality semen was obtained.

Semen Colour and Semen Volume

Semen colour was noted visually immediately after collection. The volume of semen collected was measured using graduated collection tube.

Sperm Motility

To determine the motility of the sperm cells, a drop of undiluted semen mixed with a drop of slightly warmed diluents (sodium citrate) was placed on a sterile slide, covered with a cover slip and observed under the microscope at ×400 magnification and scored within a rating of 0-100% as described by Ewuola and Egbunike (2010).

Sperm Cell Concentration (per ml)

Sperm cell concentration per ml of semen was evaluated by visual count under the microscope using the improved Neubauer haemocytometer. A mixture of sodium bicarbonate (5g), formalin (1ml) and distilled water (100ml) was used as diluents to arrest the activity of sperm cells in the sample. The mixture was uniformly mixed and through capillary action allowed to run under the cover slide placed on the haemocytometer. After few minutes the sperm cells were counted within the five smaller squares. The total count was obtained by adding the counts from the five smaller squares multiplied by the dilution factor and the multiplication factor.

Live Sperm Cells Count

Live sperm cells determination was done by placing a drop of semen on a glass slide, mixed with one drop of eosin negrosin, smeared and observed under the microscope. The unstained cells represented the live cells while the stained cells are the dead ones.

Total Sperm Count

The total sperm count was obtained by multiplying the sperm concentration by the volume of semen per ejaculate.

Statistical Analysis

All data obtained were subjected to analysis of variance (ANOVA). Treatment means were separated and compared with the control using Least Significant Difference (LSD).

RESULTS AND DISCUSSION

Results for semen characteristics and libido score are elaborated in table 1

Reaction Time

From the result of this study it can be observed that animals in treatment 4 (0.75g) and 5 (1.00g) had lower reaction time (3.62 and 3.65 seconds) this implies that for Bucks in this group it will only take 3.62 or 3.65 seconds to realize that a doe has been brought to them and attempt to mount.

Libido score

The result from this study indicate that animals in treatment 4 (0.75g) and 5 (1.00g) attempted to mount the doe more times in a minute than animals in treatment 2 (0.25g), 3 (0.50g) and the control (0.00g). It is also noteworthy to state that from the results obtained it was noticed that reaction time and libido score are inversely related, the lower the reaction time the higher the libido score.

Semen colour and Semen Volume

Semen colour for all the treatments and the control were observed to be milky. Semen volume was significantly influenced by lycopene in treatment 4 (0.87ml) and 5 (0.90ml) this was a significant improvement when compared with the control in treatment 1 (0.47ml). With this improvement it is therefore safe to say that lycopene at 0.75g and 1g will improve semen volume significantly.

Sperm Motility

Motility which is best described as the progressive forward movement of sperm cells is important for the transport of spermatozoa in the reproductive tract and oocyte penetration (Holt and Van Look, 2004). The result obtained from this study indicates that the most motile sperm cells were observed in treatment 3 (79.50%) and treatment 4 (78.63%), it is therefore note worthy to mention that as the level of lycopene increased in treatment 5 (1.00g) the motility of sperm cells reduced.

Sperm Cell Concentration (per ml) and Total Sperm Count

The high percentage of live sperm cells observed in this study is an indication of the viability of sperm cells with possibly higher fertilizing capacity. Sperm concentration was significantly influenced by lycopene in treatment 4 (38.88×10^7 /ml) and 5 (48.13×10^7 /ml). Although testosterone was not a parameter in this study, the result of this study suggests that lycopene has a positive influence on testosterone since it increased sperm concentration. The total sperm count was also observed to be significantly affected by treatment 4 (31.54×10^7 /ml) and 5 (46.30×10^7 /ml) which were the highest observed in this study. ***Live Sperm Cells***

The result from this study revealed that lycopene did not affect or influence the percentage of live sperm cells in the semen, this also indicate that the volume of semen did not influence the percentage of live sperm cells but influenced the total number of sperm cells as semen of higher volume resulted in higher sperm cells, this is further authenticated by the fact that all semen collected demonstrated a consistent colour.

Table 1: Semen characteristics and libido score of rabbit Bucks administered graded levels of lycopene

	Lycopene						
Parameters	T1 (0.00)	T2 (0.25)	T3 (0.50)	T4 (0.75)	T5 (1.00)	LSD	LOS

CONCLUSION AND RECOMMENDATIONS

Based on the findings of this study Lycopene up to 0.75g and 1.00g improved semen quality and libido of rabbit Bucks. Lycopene up to 0.75g administered every day for eight weeks (56 days) should be used to boost semen quality and libido of rabbit Bucks used for breeding. Further research should be carried out so as to widen the scope and utilization of lycopene in animal science.

ABSTRACT
Lycopene is an antioxidant carotenoid compound occurring in plants and is responsible for the red coloured pigment of tomato, watermelon and other fruits mostly red coloured. In this study lycopene was extracted from tomato using acetone and dichloromethane as extraction solvents. Identification of lycopene was carried out using UV-Visible spectrophotometer. It was further fed to 15 mongrel rabbit Bucks in five graded levels at 0.00, 0.25, 0.50, 0.75 and 1 gram using a completely randomized design for a period of 8 weeks (56days) to determine its effects on electrolyte balance (sodium, potassium, chloride and bicarbonate), kidney function (uric acid, urea nitrogen and creatinine) and liverfunction (total protein, albumin, total bilirubin, alkaline phosphatase, aspartate aminotransferase and alanine aminotransferase). The results showed that the peaks of lycopene in UV-Visible spectrophotometer were found at 475nm and 470.5nm in chloroform and hexane respectively. Also, all parameters tested for electrolyte balance, kidney and liver function were within the normal range. From the results of this study it was concluded that lycopene did not have any adverse effects on electrolyte balance, kidney and liver function but it was well tolerated by these delicate organs. This study therefore recommends that lycopene can be used an antioxidant in rabbit Bucks to reduce oxidative stress.
Keywords: Lycopene, Tomato, Antioxidant, Electrolyte, Kidney, Liver

INTRODUCTION
Rabbits have an important role in the supply of animal protein for humans. Rabbit occupies a vital midway position between ruminants and non-ruminant animals and can effectively utilise feed in rations containing less than 20% grain (Saleh *et al.*, 2010). Male rabbits are undoubtedly the basis of reproductive success, given that farm profiability depends not only on the female's fertility but also upon the welfare of the buck which is subject to stress factors such as oxidative stress. Reactive oxygen species (ROS) are the major cause of oxidative stress and are continuously produced during metabolism.Indeed, when produced in excess and not tightly kept under control by the antioxidant "detoxifying" systems, ROS can potentially damage all components of the cell (Jean, 2012). Lycopene is a carotenoid that has antioxidant properties and imparts the red-colored pigment in both fruits and vegetables, it is a fat soluble substance. Epidemiological research studies have demonstrated positive benefits in consuming lycopene. Fruits and vegetables that are high in lycopene include tomatoes, watermelon, pink guava and red pepper. The lycopene in tomato is considered to possess the highest antioxidant activity. The antioxidant property of lycopene is highlighted by its capacity to sequester and its ability to trap reactive oxygen species (ROS) (Amany *et al.*, 2009). This study was therefore designed to determine the safety of lycopene administered to rabbit Bucks by evaluating its effects on electrolytes balance, kidney and liver function.

MATERIALS AND METHODS
This study was carried out at Abubakar Tafawa Balewa University Teaching and Research Farm, Bauchi, Bauchi state, Nigeria. It is located in the north eastern part of the country and has a tropical climate. Lycopene used for this experiment was obtained by extraction from tomato which was procured from an established market in Bauchi metropolis. Fifteen mature mongrel rabbit Buckswere randomly assigned to different treatments in a complete randomized design. The experiment lasted for a period of 12 weeks comprising 4 weeks of stabilization and acclimatization and 8 weeks for oral administration of graded levels of tomato lycopene.

Extraction and packaging of Lycopene from Tomato
Lycopene was extracted using Acetone and Methylene chloride (Dichloromethane) following the method of Gordon *et al* (2007) with some slight modifications.
The following steps were followed:-

- Tomato was washed in a basket with running water only
- It was milled into paste with the aid of a petrol powered 5.5 horse power grinding mill, it was heated and allowed to simmer for five minutes.

- After simmering for five minutes it was poured into a cheese cloth which was suspended above ground level and allowed to drain until 10 percent of the initial weight was attained.
- Tomato paste was processed in batches of 1kg at a time in 1.4 litre of acetone (This was done to dehydrate the tomato paste)
- It was stirred until no longer gummy and then Filtered using a cheese cloth
- The resultant solid material was Placed in 1 litre of Methylene Chloride and then
- Filtered with the aid of 110mmØ whatman paper
- The filtrate was allowed to evaporate at room temperature leaving behind lycopene at the base of the beaker.
- It was then subjected to light spectrophotometric authentication in selected solvents such as Hexane and chloroform
- It was further graded into 0.25gram, 0.50gram, 0.75gram and 1gram
- Wheat flour was used as excipient which was mixed thoroughly with lycopene and finally packaged in capsules.

Blood Collection

Blood was collected from each buck through the marginal ear vein (ear veinipuncture) every fortnight (two weeks) to examine major electrolytes, liver and kidney function.

RESULTS AND DISCUSSION

Figure1 and 2 below shows that the maximum absorbance of lycopene in chloroform and hexane was at 475nm and 470.5nm respectively, this very closely coincides with the three peaks characteristics of Lycopene at λ = 446nm, 472nm and 505nm (Monica, 2011).

Electrolytes Balance

The role of balanced electrolytes in male animals cannot be overemphasised. In this study sodium, potassium, chloride and bicarbonate were tested. The results in table 1 shows that all the electrolytes were within the normal range except for bicarbonate in treatment one (T1) which is the control group with no lycopene administered. This indicates that lycopene helped to maintain electrolytes balance.

Table 1: Electrolyte balance of rabbit Bucks administered graded levels of lycopene

Parameters	T1(0.00)	T2(0.25)	T3(0.50)	T4(0.75)	T5(1.00)
	Lycopene				
Sodium (140-160 mmol/L)	153.91±0.88	152.67±3.06	155.58±5.78	154.92±3.79	152.17±2.31
Potassium (4.3-5.8 mmol/L)	4.88±0.06	5.15±0.1	4.9±0.53	4.87±0.32	4.91±0.68
Chloride (90-110 mmol/L)	105±0.47	101.42±1.73	97.67±8.50	98.83±6.24	105.67±4.73
Bicarbonate (16-32 mmol/L)	33.66±3.95#	24.67±5.03	22.33±5.29	27.83±4.04	20.00±2.08

Means that it is outside the normal range

(mmol/L) Millimoles Per Litre

Liver Function

A loss of liver function will result in retaining waste metabolites in the body, there by affecting performance, in view of this, total protein, albumin, total bilirubin, alkaline phosphatase (ALP), aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were examined to determine the effect of lycopene on the functionality of the liver. The result in table 2 showed that lycopene did not affect liver function as all the parameters tested were within the normal range. This is also an indication that lycopene was well tolerated and metabolised by the liver without affecting its functionality.

Kidney Function

The kidneys are responsible for maintenance of homeostasis which directly impacts performance of rabbit Bucks, in this study parameters such as uric acid, urea nitrogen and creatinine were examined. Table 3 shows that all parameters tested were within the normal range at all lycopene levels. From the results therefore, it can be deduced that lycopene did not adversely affect the kidneys but rather maintained the functionality of the kidneys.

Table 2: Liver function of rabbit Bucks administered graded levels of lycopene

Parameters	T1(0.00)	T2(0.25)	T3(0.50)	T4(0.75)	T5(1.00)
	lycopene				
Total Protein (5.4-7.3g/dl)	6.12±0.75	5.77±0.26	6.34±0.29	6.14±0.15	6.40±0.60

Creatinine (0.5-2.2 mg/dl)	1.24±0.56	1.63±0.15	1.73±0.26	1.51±0.61	1.35±0.31

(mg/dl) milligrams per decilitre

CONCLUSION AND RECOMMENDATIONS

This study has shown that lycopene does not have any adverse effect on the electrolyte balance, kidney and liver function of rabbit Bucks. This is an indication that lycopene up to 1gram is safe to use as an antioxidant to combat oxidative stress and improve overall performance of rabbit Bucks.

ABSTRACT
This study was designed to compare the egg quality of three poultry species (turkey, chicken and guinea fowl) under two storage methods (refrigeration and room temperature) over 28 days storage period. A total of 72 eggs comprising 24 eggs from each species, were assessed for exterior and interior quality at 0, 7, 14, 21 and 28 days of storage as well as the determination of chemical composition at 0 day of age using the 3 x 2 factorial design. Results obtained showed that the average weight of fresh turkey eggs was 69.13 g; chicken eggs, 60.13 g and guinea fowl eggs, 38.50 g .However, there was significant decline in haugh unit due to species and method of storage, but the decline in guinea fowl eggs was relatively faster from 21st day of storage. These are important issues in egg handling, transportation, processing and consumption.
Keywords: Storage; Percentage yolk index; Haugh unit; three species of poultry eggs.

INRODUCTION
All living organisms need protein because it is the basic structural material from which all body tissues are formed such as muscles, skin, nerves, blood cells, hair, hooves, bone, etc. (Esonu, 2006) No other nutrient can replace protein in the ration, because, in addition to its importance as a structural component, all enzymes and many hormones are proteins (Esonu, 2006). Because of the animal's numerous needs for protein and its irreplaceable nature, there is a certain minimum dietary level recommended for each class of animal, depending on physiological age and type of production (Esonu, 2000). Animal products being one of the most important constituents of human diet which aid in proper development of the body are in short or limited supply. The husbandry system coupled with the hot and humid tropical climate adversely affect product quality. Although eggs are less perishable compared with meat and milk, evidence exist nonetheless showing that chicken egg quality depreciates significantly after one week of storage under ambient condition. Presently, there is scare information on the effect of storage on the quality of poultry eggs of various species and storage temperatures. Turkey eggs and more importantly guinea fowl eggs are consumed in large numbers in Nigeria, and interestingly little are known about changes in exterior, interior and chemical quality parameters during handling and storage. Research in this area is justified because of the immense importance of poultry eggs in human diet, and losses that may be incurred during storage.

MATERIAL AND METHOD
A total of 72 eggs comprising 24 eggs each from turkey, chicken and guinea fowl were used in this study. Fresh turkey and chicken eggs were obtained from a commercial farm at Isuofia in Aguata Local Government Area of Anambra State. Fresh guinea fowl eggs were obtained from dealers in Awka, Anambra State because of wild nature of guinea fowl.
The 24 eggs from each species were divided into two groups of 12 eggs and kept in the refrigerator at 4° C while the second 12 eggs were kept under the ambient temperature of 26 ^{0}C - 30 ^{0}C (room temperature) on a plastic egg crate respectively. The 12 eggs from each group were further sub divided into four of three eggs for each sub groups. Three eggs from each group were cracked for interior and exterior quality measurement at seven days intervals. The albumen height and width were measured using venier caliper. The egg was broken out on a flat plate, and readings were taken in millimeters. Then the albumen was separated from the yolk and poured in a petri dish. The albumen weight was taken. The yolk was separated from the albumen using a spoon and the weight measured on the sensitive electronic balance. The yolk height and width were measured with the pin end of venier caliper. The haugh unit was calculated using the formula derived by Haugh (1937):

$$HU = 100Log (H+7.57 – 1.7W^{0.37})$$

Where H = Observed albumen height (mm) and

W = Observed weight of eggs (g)

The ratio of yolk height to average of the width was taken as the yolk index while the ratio of the albumen height to average albumen width was also taken as the albumen index.

Statistical analyses were carried out using the 3 x 2 factorial designs. Factors were 3 poultry species (turkey, chicken and guinea fowl) and 2 storage methods (refrigeration and room storage). Data analysis was executed using the analysis of variance for completely randomized design. Egg quality parameters were regressed on shell thickness / percentage weight loss, and the correlation coefficients tested for significance. Means having significant differences were separated using the least significant difference (LSD) method as describe by Snedecor and Cochram (1983). Statistical analysis was performed using SAS (1999) computer application software.

RESULTS AND DISCUSSION

The effect of species by storage method interaction is shown in table 4.8. Generally and in few exceptions yolk index was highest in guinea fowl eggs throughout the four storage periods in both refrigerated and room temperature stored eggs (P>0.05). After the 7th day of storage, yolk indices of guinea fowl and chicken eggs stored under refrigeration were similar to yolk indices of counterparts stored under room temperature, whereas for turkey eggs room temperature stored eggs were significantly lower in yolk index than those stored under refrigeration (P<0.05). After the 28th day of storage, species related differences in yolk index among eggs stored under refrigeration were not significant (P>0.05) whereas under room temperature storage, guinea fowl and turkey eggs were similar in yolk index, while chicken eggs were significantly lower in yolk index than eggs from the other two species (P<0.05).

These results suggests that based on the yolk index, guinea fowl eggs would have longer shelf life than turkey or chicken eggs. This observation is supported by the lower weight loss suffered by guinea fowl eggs during storage compared with turkey and chicken eggs (Tables 4.2 and 4.3). However, this is contradicted by the higher haugh unit value recorded by turkey eggs during storage compared with guinea fowl eggs (Table 4.4). Although the haugh unit and yolk index are considered to be the best indicators of interior egg quality (Ogunwole *et al.,2017*), the yolk index may be better than the haugh unit when comparisons across different species are undertaken.

The effect of length of storage on haugh unit of turkey, chicken and guinea fowl eggs are presented in Table 4.4. Although, fresh guinea fowl eggs were significantly higher (P<0.05) in haugh unit than turkey and chicken eggs, this was not the case during storage. By the 7th and 28th days of storage, turkey eggs were significantly higher (P<0.05) in haugh unit than chicken and guinea fowl eggs, whereas chicken eggs were higher (P < 0.05) in haugh unit than the eggs from the other two species by the 21st day of storage. Differences in haugh unit between the three poultry species were not significant (P>0.05) by the 14th day of storage. These results indicate that no clear trend could be established in the differences in haugh unit between these species during a storage period of 28 days. However, in all the poultry species and for all the storage periods, eggs stored in the refrigerator were consistently higher in haugh unit (P<0.05) than eggs stored under room temperature. This was in support with Akinola, and Iyomo,(2018). Species by storage interaction effect was not significant (P>0.05) in any of the storage period.

ABSTRACT
Growth performance and haemoglobin polymorphisms in relation to the Ghrelin Genotypes present in three Yoruba ecotype chicken strains were evaluated. Blood sample was collected from 45 Yoruba Ecotype chicken strains: Frizzled Feathered (FF), Naked Neck (NN) and Normal Feathered (NF) for ghrelin genotyping via electrophoresis using standard procedures. Growth performance data were generated for 18 weeks: Initial and Final Body Weight, Body weight gain, Feed Intake, Feed conversion Ratio (FCR) and the mortality rate. Data were subjected to ANOVA and means were separated using the Duncan Multiple Range Test. Ghrelin genotyping of the three Yoruba ecotype chicken strains for 18 weeks showed that genotypes AA and AB were observed, while genotype BB was absent among the chicken strains. Results revealed that ghrelin genotypes had significant effects ($p<0.05$) on Final Weight, Body weight gain, Feed Intake, FCR and the mortality rate. The highest final body weight was recorded in the NN genotype (888.08±0.12g), while the lowest final weight gain was recorded in the NF genotype with (805.10±0.12g). The highest body weight gain was also recorded in the NN genotype with (858.61±0.14g) and the least body weight gain was recorded in the NF genotype (775.67±0.14g).The lowest feed intake was recorded in the NN genotype (5538.46±7.09g) while the highest feed intake was recorded in the NF genotype (5752.46±7.09g).The highest FCR was recorded in the NF genotype (7.42±0.01g) while the lowest FCR was recorded in the NN genotype (6.45±0.01g). The picture of the ghrelin genotypes during electrophoresis showed the genotypes A and B. The base pairs (bp) of 300 and 400 indicated the genotype AA while the base pairs (bp) of 300,400,500,700,900 up to 1000 indicated the BBgenotypes. It was concluded that Naked Neck chicken with the ghrelin genotypes AA and AB had the lowest feed intake and FCR, which indicated that Naked Neck ghrelin genotypes AA and AB favoured better growth performance.

INTRODUCTION
The indigenous chickens or native chicken populations was about 103 million in Nigeria (RIM, 1992), with the largest percentage in the Northern part. These birds among others inherent advantages over their exotic counterparts are hardy can adapt to rural environment, survive on little inputs and is better in both fertility and hatchability of egg (Ige *et al*., 2012). Nevertheless, these birds are important reservoirs of useful (major) genes and possess a number of adaptive traits. Among the major genes that have been found potentially useful to the tropical environment are Naked neck (*Na*) and Frizzle (*f*) genes. These genes have been associated with heat stress (Horst, 1989). Thus, they serve as a good pool for genetic improvements (Mengesha and Tsega, 2011).

Variation in haemoglobin has been reported to cause depression in percentage egg production in mutant haemoglobin type compared with normal or heterozygous haemoglobin (Lowe and Washburn, 2007).

Haemoglobin polymorphism is a term used in genetics to describe the multiple forms of a single gene that exists in an individual or among a group of individuals. (Williams *et al*.,1990).

In animal industry, growth traits of animals are always of primary concern during breeding for its determinant economic value (Zhang *et al.,* 2008).

The growth traits are complex traits involving multiple genes, loci and interactions (Hua *et al.,* 2009).

Ghrelin is a circulatory hormone produced by the entero endocrine cell of the gastro intestinal tract especially the stomach and it is often called a "Hunger Hormone" because it increases food intake. (kojima *et al.,* 1999). Ghrelin is a 28- amino acid peptide in a monogastric species (Dickin*et al.,* 2004).

It is primarily produced by oxyntic cells in the stomach or abomasum with smaller amounts produced by the intestine and pancreas (Hosoda *et al.,* 2006). Ghrelin stimulates the secretion of GH, increases

food intake and in turn produces gain in weight (Solomis *et al.*, 2014) . Ghrelin is the only known peripherally produced and centrally active orexigenic hormone that is considered to be an important gut-brain signal for appetite control and energy balance (Solomis *et al.*, 2014).

The objectives of these investigations were therefore to evaluate the growth performance of three Yoruba ecotype chicken strains in relation to ghrelin genotypes. And also to determine ghrelin haemoglobin polymorphisms among three Yoruba ecotype chicken strains.

MATERIALS AND METHODS

The study was carried out at the Poultry Unit of the Federal College of Animal Health, I.A.R&T, Ibadan, Nigeria and the experiment lasted for 18weeks

Data Collection

From day one, growth performance indices were recorded for the Yoruba ecotype chickens (FF, NN and NF) and at the eighteenth week, 2-5 mLs of blood was sampled through the jugular vein into EDTA bottles. The blood samples were then placed in a cooler containing iced block to maintain the stability of the blood and then taken to Biotechnology Laboratory, Abeokuta, Ogun state for genotyping.

DNA Extraction and Electrophoresis

DNA Extraction is a routine procedure used to isolate DNA from the nucleus of cells. The extraction was carried out using Blood-Plant Animal DNA preparation kit following standard procedures.

Data Analysis

Data were subjected to analysis of variance (ANOVA) according to SAS (2004) and means were separated using Duncan multiple range test.

RESULTS

Table 2: Growth performance and Ghrelin genotypes of three Yoruba ecotype chicken strains at week 18

	Strains			
Parameters	FF	NF	NN	SEM±
Ghrelin Genotypes	(AA, AB)	(AA, AB)	(AA, AB)	
Initial Weight(g/b)	29.38	29.43	29.48	0.05
Final Weight(g/b)	839.42^{b}	805.10^{c}	888.08^{a}	0.12
BWG (g/b)	810.05^{b}	775.67^{c}	858.61^{a}	0.14
Feed Intake (g/b)	5590.44^{b}	5752.06^{a}	5538.46^{c}	7.09
FCR	6.90^{b}	7.42^{a}	6.45^{c}	0.01
Mortality (%)	1.92^{b}	2.25^{a}	1.91^{c}	0.00

^{a,b,c}means along the same row with different superscripts are significantly different ($p<0.05$). Feed intake (FI), Body weight gain (BWG), Feed conversion ratio (FCR).

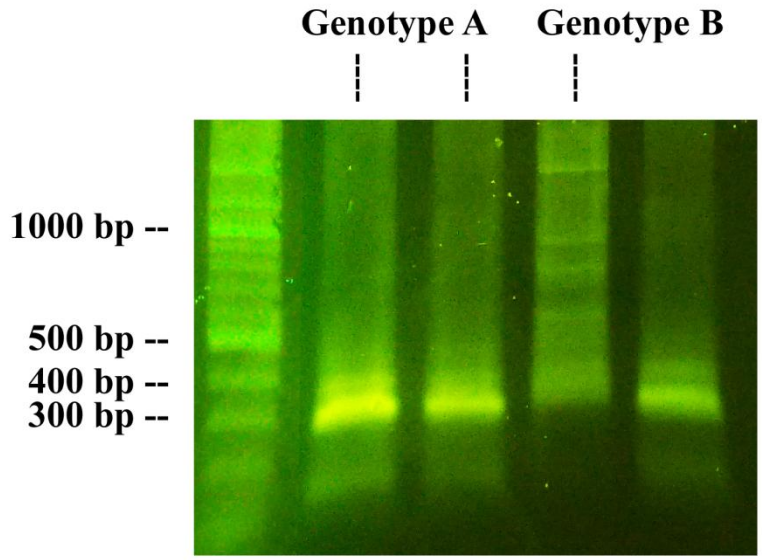

Figure 1: Shows the picture of Ghrelin genotype bands during Electrophoresis. Bp (base pairs)

DISCUSSION

The Growth performance and Ghrelin genotypes of the three Yoruba Ecotype chicken strains at 18 weeks showed that the Naked Neck with Ghrelin genotypes AA and AB had highest value for body weight gain (858.61±0.14g) with the lowest feed intake (5538.46±7.09g) and the lowest Feed conversion ratio (6.45±0.01g). This corroborates the findings of Nakazeto *et al.,* 2001, which states that Ghrelin influences energy metabolism and body composition. The result of the Ghrelin haemoglobin polymorphisms of the three Yoruba ecotype chicken strains showed that there was remarkable variation in the Yoruba ecotype chicken as two haemoglobin variants AA and AB alleles were identified with corresponding detectable genotype HbAA and HbAB. This showed that the population of this Yoruba ecotype chicken is Homozygous. This does not agree with the findings of (Ibe, 1990) who observed three haemoglobin variants AA, AB and BB alleles with corresponding detectable genotypes HbAA, HbAB and HbBB which showed that the population of the indigenous chicken is Heterozygous, which may be as a result of crossbreeding of indigenous chicken with the exotic strains or may be due to the larger sample size used. The report of (Washburn *et al.,* 1971) showed that chicken of the homozygous haemoglobin genotypes as observed in this study are approximately 20% less susceptible to Marek's disease. The Homozygous genotypes observed in this study could be an added advantage in conferring resistance to this disease. The picture of the Ghrelin Genotype bands during Electrophoresis showed the Genotypes A and B. The first band which is the ladder serves as a guide to measure the Ghrelin levels and Genotypes. Genotype AA had a base pair of 300 and 400 while genotype AB had the base pair of 300,400,500,700,900 up to 1000. The more the bands, the more the variations among the ghrelin genotypes which is an indication of wider heterozygosity. From the results of this study, chicken strains with the Ghrelin genotypes A and B are more distant from one another as a result of variation among the population samples

CONCLUSION AND RECOMMENDATION

It is concluded that Naked neck strains with ghrelin genotypes AA and AB had a better Feed Conversion Ratio with a consequential enhanced growth performance.

It is also concluded that proper evaluation of ghrelin genotypes and other genes in chicken genome as they affect feed intake, weight gains and overall animal protein food security is important.

RECOMMENDATION

Also, since the Naked Neck strain has the highest final and body weight gains, therefore naked neck chicken should be selected and improved upon for their growth performance as this will contribute to availability and affordability of meat and its products for the masses**,** particularly in the rural communities.

ABSTRACT

The study was conducted in Maigatari Local Government Area of Jigawa State. A total of 250 goats (187 Red Sokoto and 63 Sahel) of mixed sex and age were used to obtain the following parameters; body weight (BW), body condition score (BCS), body length (BL), heart girth (HG), wither height (WH), udder length (UL), udder circumference (UC), testicular length (TL) and testicular circumference (TC). The animals were sampled from Maigatari main livestock market. Data generated were subjected to analysis of variance, Pearson's correlation analysis and stepwise linear regression. Red Sokoto had mean BW, BCS, BL, HG, WH, UL, UC, TL and TC of 20.58 kg, 3.20, 22.45 cm, 25.28 cm, 22.93 cm, 3.48 cm, 5.99 cm, 4.97 cm and 7.88 cm, respectively. The corresponding values for Sahel were 22.91 kg, 3.00, 23.58 cm, 25.07 cm, 24.55 cm, 4.14 cm, 7.06 cm, 4.75 cm and 7.52 cm. Sahel goats had significantly higher BL (P<0.01) and WH (P<0.001). Female goats were heavier than male and had longer body, wider chest and higher height at wither. Except TC, goats of 36 - 48 months had the highest for all the significantly affected traits (BW, BCS, BL, HG and WH; P<0.001). The correlation coefficients observed among the morphometric traits were in general high, positive and significant, while the accuracy of the predictive equation when HG and in combination with BL were used to predict live weight was also high. This study indicated that breed had no effect on most body characters and that live weight can best be predicted using HG.

Key words: Morphometrics traits, breed, sex, age, goat.

INTRODUCTION

Small ruminants are important genetic resources and play apredominant role in the sustenance of the livelihoods of impoverished families especially inthe rural areas of tropical countries. Caprine species specifically goats play animportant role in the social life of many Africans and supply human population withmeat, milk, skin, manure and other products. The Red Sokoto goat (RSG) or Maradi is the most predominant breed and accountsfor about 70% of Nigeria's total goat population (Ademosun, 1994). It is commonly found with the agro pastoralist mainly within thenorthern sub-humid and semi-arid zones of the country (Akpa *et al.,* 2001). The Sahel goat is an extant meat and milk type goat in Nigeria (Otoikhian and Orheruata, 2010). It is large in size, predominantly white colour, pied with black or white and brown spots around the ear, nose and udder. This breed is found alongthe northern border of Nigeria, particularly Borno State, where it is often known as"Balami, although this name has not been adopted as it would lead to confusion with thebetter known sheep breed Balami. Morphometric characteristics are important in breed identification and classification. Gizaw *et al.* (2007) stated that morphostructural description of traits remained essential component of characterization that can be used to physically identify, describe and recognize a breed. It also helps in the classification of livestock breeds. The knowledge of morphometric traits aids in appropriate breeding design, feeding and health management (Thiruvenkadan, 2005).

MATERIALS AND METHODS

Study Location

The study was conducted at Maigatari Local Area of Jigawa State. Maigatari is located between longitude 48.26^0 12' N and latitude 25.50^0 9'E and is 352m above sea level (Encarta Encyclopedia, 2009 PC version). It has an average annual rainfall of 418 mm per annum, which starts from late April or early May and ends in mid-October.

Experimental Animal and Management

A total of 250 goats (180 Red Sokoto and 70 Sahel) of mixed sexes and ages(1 year = 1PPI, 2 years = 2PPI, < 2-3 years = 3PPI and 3.5-4 years above = 4PPI) were used for the study. The animals were randomly selected from Maigatari main livestock market.

Data Collection

Body weight and seven linear body measurements were recorded. They include; body length (BL), heart girth (HG), wither height (WH), testicular length (TL), testicular circumference (TC), udder length (UL) and udder circumference (UC). The measurement was done using a flexible tailors tape, while the wither height was accessed with a measuring stick.

Body Condition Score

Body condition score (BCS) was achieved through palpation of visible bone structure. Animals were palpated over the back bone, loin and rump. Fat condition was smooth to palpate while bone structure with little or no fat cover felt rough to touch. These general assessments were used to place each goat in a category of body condition (very thin = 1, thin = 2, moderate = 3, fat = 4 and obese = 5).

Data Analysis

Data generated were subjected to general linear model (GLM) procedure of SPSS, version 22 (2013). Significantly different means were compared using the least significant differences (LSD). The model utilized was as follow:

$Y_{ijk} = \mathbf{U} + \mathbf{B}_i + \mathbf{S}_j + A_k + \mathbf{e}_{ijk}$

$\mathbf{Y}_{ijk}$ = Observation on dependent variables

U = Common Mean

$\mathbf{B}_i$ = effect of ith breed (1, 2)

$\mathbf{S}_j$ = effect of jth sex (1, 2)

$\mathbf{A}_k$ = effect of kth age (1, 2, 3, 4)

$\mathbf{e}_{ijk}$ = random error term

The relationships among the linear body measurements and body weight were estimated using Pearson's correlation analysis. Stepwise regression procedure was used to find the best linear combination of morphometric traits that can predict body weight. This was performed for male, female and the pooled data. The following linear and multiple regression models were applied:

$Y_1 = a + bx$ - - - - - - (2) simple regression model

$Y_1 = a + b_1x_1 + b_2x_2 + \ldots + b_kx_k$ - - - -(3) multiple regression model

Where Y = dependent variable

a = the Intercept, bs = the slopes and x = independent variable.

RESULTS

Average morphometric traits according to breed, sex and age are presented in Table 1. There was significant effect of breed on BL ($P<0.001$) and WH ($P<0.01$). Sahel goats had lengthier body and higher wither height than Red Sokoto (23.88±0.43 and 24.55±0.41 cm vs 22.45±0.50 and 22.93±0.44 cm). However, non-significant effect of breed on BW, BCS, HG, UL, UC, TL and TC was observed. Significant effect of sex on BW, BL, HG ($P<0.001$) and HG ($P<0.05$) was observed. Females were heavier and had longer body, wider chest and higher wither height than males (25.28±1.00 kg, 24.54±0.41 cm, 26.48±0.40 cm and 24.25±0.38 cm vs 18.51±1.34 kg, 21.80±0.55 cm, 24.47±0.53 cm and 23.24±0.50 cm). Non-significant influence of sex on BSC was however evident. Significant influence of age on BW, BCS, BL, HG, WH ($P<0.001$) and TC ($P<0.01$) was observed. Except TC, goats of 36 - 48 months had the highest for all the significantly affected traits. The correlation coefficients for separate and both sexes are presented in Table 2, 3 and 4. The coefficients observed were in general high, positive and significant except between WH and TL in male and between BW and UC, BCS and BL, WH, UL and UC in females.

Predictive equations of body weight from linear body measurements are shown in Table 5. Of all the body traits recorded, heart girth was observed to have the highest coefficient of determination, while subsequent inclusion of body length in females and pooled data of both sexes yielded better result.

Table 1: Average morphometric traits according to breed, sex and age

	BW = - 37.81 + 1.50HG + 0.96BL	0.88

BW = Bodyweight, BL= Body length, HG = heart girth. R^2 = Coefficient of determination

DISCUSSION

The facts that breed had effect on BL and WH as observed in the present study agrees with the findings of Guifen *et al*. (2014) who reported a significant variation in morphometric and carcass traits of different genotypes of goats. Similarly, the work of Sanni *et al*. (2018) on different breeds of goats (Kalahari and Sokoto reds, Sahel and WAD) native to Africa also detected a significant variation on morphostructural traits and it has been suggested that the wide variation observed between Sahel and WAD goats could lead to heterotic gain (Zaharaddeen *et al*., 2008). Some authors (Gizaw *et al*., 2007; Agaviezor *et al*., 2012) attributed this variation to inherent genetic potential of each breed, geographical isolation and ecological variation. The significantly higher BSC observed in Red Sokoto goats contradicts the work of Brown and Swan (2012). The results obtained in the present study indicated that morphometric characteristic of Red Sokoto goats was sexually dimorphic in favour of females. This agrees with the work of Ma'aruf *et al*. (2018) in Yankasa sheep breed. Contrary to the present observation, Sowande *et al*. (2008) showed that male sheep were superior to female in live weight and most body measurements. They attributed this differences to genes linked with sex chromosomes. Shuaibu *et al*. (2018 and 2019) also made similar assertion in Yankasa sheep that males had higher values for morphometric traits than females.

The effect of age on live weight and linear body measurements observed in this study agrees with the work of some investigators (Afolayan *et al*., 2006; Mavoule *et al*., 2013) who reported that adult sheep were heavier than the younger ones and had higher values for linear body measurements. Similarly, Mekuriawa *et al*. (2013) reported higher values for morphometric traits in adult sheep compared to the younger and yearling ones and suggested that selective improvement of body weight and conformation traits should be emphasized at this stage (adult). The correlation coefficients observed among the morphometric traits were high, positive and significant. This is in line with the work of Afolayan *et al*. (2006) who reported that live weight was highly correlated with body dimensional traits. The finding of Shuaibu *et al*. (2018) on Yankasa sheep also indicated that the relationship between live weight and linear body measurements were mostly moderate to high which shows that they can predict each other. Working on dairy goat (Saneen), Pesmen and Yerminci (2008) however reported low to moderate relationships among these traits. The highest R^2 observed in this study when BW is predicted from HG conform the report of Tsegaye *et al*. (2013) that this trait (HG) is positively correlated with live weight (LW) and can indicate it with high precision (R^2 = 0.94). Similar report by Tadesse and Gebremariam (2010) in sheep also showed that heart girth predicted LW with higher accuracy of 0.69. Yakubu (2010) attributed this relationship to pleiotropic gene action that exist between the two traits. In the present finding, subsequent inclusion of body length in females and in pooled data of both sexes yielded better values, this agrees with the report of Tadesse and Gebremariam (2010) who observed higher R^2 when BL and WH are included in the predictive equation of BW from HG.

CONCLUSION

I. The results of this study showed that breed had no influence on body weight and most linear body measurements, however, significant effect of sex and age was observed.
II. The correlation coefficients observed among the morphometric traits were in general high, positive and significant.
III. The coefficient of determination observed in the prediction of body weight from height girth was high, but subsequent inclusion of body length in female and the pooled data of sexes yielded better result.
IV. Heart girth predicted body weight with highest precision.

ABSTRACT
The experiment was conducted to determine the effects of sex on haematological values, blood chemistry and carcass characteristics of Noiler chicken. A total of one hundred and thirty-six (136) eight weeks old Noilers birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system. The experiment lasted for three months. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum. The result showed that cocks and hens haemoglobin (Hb) and packed cell volume (pcv) values were significantly the same ($P<0.05$). The result of PCV (Packed Cell Volume) showed that the PCV values were ($P<0.05$) significantly the same (32.00 and 32.60) for the cocks and hens respectively. This shows that Hb and PCV were not influenced by androgen, which is a hormone that plays a major role in male traits and reproductive activities. The percentage of lymphocytes, neutrophyl, basophyl and eosinophyl were also not significantly different between cocks and hens. The result for biochemical values shows that that there was no significant difference between Noiler cocks and hens in all the parameters tested. From the result it was deduced that dressing percentage was affected by sex, which showed that cocks had higher dressing percentage (77.54) than hens (69.65). From the finding of this study it was concluded that there were no significant differences in haematological and biochemical values between sexes, however cocks showed superior dressing percentage.
Keywords: Sex, Carcass, Noiler, Haematological

INTRODUCTION
Globally, animal protein consumption has steadily increased in the last five years, this is as a result of increased beef consumption. Pork is the number one animal protein consumed around the world, however, the Food and Agriculture Organization (FAO, 2011) predicts chicken will overtake pork as the most consumed animal protein by the year 2020. Consumption is driven by poultry's lower cost and demographic interest that fit with their meat. Inadequate consumption of animal protein by an average Nigerian is on the increase due to the increase in population which has resulted in the demand for protein of animal origin to surpass its supply. Food and Agricultural Organization (2006) reported that an average Nigerian takes about 5.5g of animal protein per day which is very low compared to the recommended 77g per day. The solution to the problem of inadequate consumption of animal protein by an average Nigerian is to increase the production of highly productive animals with short generation interval such as rabbits, pigs and poultry (Ani and Adiegwu, 2005). The development of indigenous breeds with improved meat and egg production is also a solution to the problem of poor consumption of animal protein. Recently the development of NOILER chicken by Amofarm Siebere Hatchery in Nigeria is a step in the right direction becausese Noiler chicken is a natural cross breed between broilers, layers and indigenous local chicken. There is little information about the bird focusing on the haematological and carcass characteristics of Noiler chicken. This research is expected to generate information on the Carcass yield, Gut and Organ characteristics and haematological values of male and female Noiler chicken.

MATERIALS AND METHODS
The experiment was conducted at the poultry section of the Bauchi State Agricultural Development Programme (BSADP) along Yelwan Makaranta Dass Road, Bauchi State. A total of one hundred and thirty-six (136) eight weeks old Noilers birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system and were randomly distributed into 3 treatment groups based on strain using a Completely Randomized Design (CRD). The experiment lasted for three months. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum.

Data Collection and Analysis

At 34 weeks, twenty four (24) birds were randomly selected from each of the three strains with each strain having twelve (12) cocks and hens respectively for haematology and biochemical analysis. 3ml of blood samples were collected from the basillic vein of the birds into a well labelled sterile bottle containing anticoagulants. These were used to determine packed cell volume, hemoglobin (hb), white blood cell count (WBC), and the differential counts which are Neutrophils, lymphocites, monocites, Eosinophil and Basophils. Another 3ml sample of blood was collected into sterile labelled bottles without anticoagulants to determine the serum biochemical metabolites as follows: total protein, cholesterol, Glucose, Albumin, calcium, phosphorus, uric acid.

Hematological technique

Total red blood cell count and Total white blood cell count were determined by a manual method using hematocytometer (Campbell, 1995). Differential counts were made on monolayer blood films, fixed and stained with leishman – stain. Packed cell volume was measured by a standard manual technique using micro hematocrit capillary tubes and hematocrit reader. Haemoglobin concentration was measured by cyanhemoglobin method (Ritchie *et al.,* 1994).

Biochemical technique

Total protein, glucose, calcium, phosphorus, cholesterol, and uric acid, were determined by automatic analyzer.

Gut and Carcass Analysis

At the end of the experiment, nineteen (19) birds were randomly selected from each of the three strains with each strain having ten (10) hens and nine (9) cocks. They were deprived of feed for twelve hours but provided with drinking water. The chickens were weighed and slaughtered. Slaughtered birds were scalded in hot water (about 50^0c) for 1 minute and plucked manually, offal were then eviscerated for carcass yield and organ weight determination. The carcass yield and organ weight were calculated as percentage of the live weight. Dressing percentage was calculated using the relationships: -

$$\text{Dressing percentage} = \frac{\text{carcass weight}}{\text{live weight}} \times 100$$

Statistical Analysis

Analysis of variance was carried out on data collected using the general linear model of SPSS (2011). Where means differed, Duncan multiple range test (DMRT) was used to separate them (Duncan, 1955).

RESULTS AND DISCUSSION

The result for the effects of sex on haematological values of Noiler chickens is shown in Table 1.The result showed that cocks and hens haemoglobin (Hb) and packed cell volume (pcv) values were ($P<0.05$) significantly the same. The result disagrees with the study conducted by Addass et al., (2012) on indigenous chickens where they observed that cocks generally have higher hb value than the hens. PCV values were ($P<0.05$) significantly the same (32.00 and 32.60) for the cocks and hens respectively. The percentage of lymphocytes, neutrophyl, basophyl and eosinophyl were also not significantly different ($P<0.05$) between cocks and hens.

The result for the effects of sex on biochemical values of Noiler chicken is shown in Table 2. The result obtained indicates that there was no significant difference between Noiler cocks and hens in all the parameters tested.

Table 1: Effects of Sex on Haematological Values of Noiler Chickens

	Sex		
Parameters	**Cocks**	**Hens**	**SEM**
Heamoglobin (gldl)	11.47	10.90	0.39NS
Parked cell volume %	32.00	32.60	1.19NS
White blood cell %	3.62	4.54	0.54NS
Neutrophil %	39.04	38.28	0.73NS
Lymphocytes%	50.80	55.94	0.87NS
Monocytes%	2.23	3.66	0.17NS
Basophils%	0.00	0.00	0.00NS
Eosinophils%	0.00	0.20	0.00NS

SEM=standard error of mean, NS= Not significant

Table2: Effects of Sex on Biochemical Values Noiler Chicken

	Sex		
Parameters	**Cocks**	**Hens**	**SEM**
Total protein(gl)	63.92	57.98	1.19NS
Albumin (mmol/l)	22.61	23.94	0.46NS
Glucose (mmol/l)	4.29	1.38	0.23NS
Cholesterol (mmol/l)	2.46	5.41	1.74NS
Calcium (mmol/l)	3.31	2.36	0.59NS
Phosphorus (mmol/l)	1.23	2.58	1.01NS

SEM-standard error of mean, NS= Not significant

The result for effects of sex on effects of sex on carcass and gut characteristics Noiler chickens is shown in Table 3. From the result it was deduced that only dressing percentage was affected by sex. The cocks have higher dressing percentage (77.54) than the hens (69.65). Dressing percentage is the proportion of live weight that is obtained as a carcass. The dressing percentage indicates the quantity of meat that could be obtained from the animal. Report by Jones et al. (1994), who reported a higher dressing percentage for cocks agrees with the finding of this research. However the dressing percentage of the Noiler hen indicated that it can also be used as a meat animal thereby qualifying the Noiler as a dual purpose breed.

Table 3: Effects of Sex on Carcass and Gut characteristics Noiler Chickens

Parameters	Sex			
	Cocks	**Hens**	**SEM**	**LS**
Live weight	2.48	3.61	0.108	NS
Plucked weight	2.2	3.36	0.104	NS

ABSTRACT
In poultry, body weight is an important trait when selecting for breeding flock performance, hence Sasso cock could be notable in any breeding program. But the size may not be convenient for massage technique during semen collection. As a result, this study was aimed at using teaser hens to ease semen collection in Sasso cocks without massaging. Twelve Sasso cocks with 4 each in Control (T1): massage technique, use of Sasso hen as a teaser (T2) and use of local hen as a teaser (T3). Another set of 4 each of Sasso hens and local hens were used as teasers in T2 and T3, respectively. In T1, gentle massage on the back and the abdominal regions of the cocks was done to collect semen. While in T2 and T3, Sasso and local hens were used as teasers for semen collection (without massage). Capillary tubes were used in the collection of semen that was promptly processed for semen quality and spermatozoa characteristics determinations. It was observed that only a cock (representing 25%) responded to semen collection when local hen was used as a teaser, whereas all the cocks (100%) responded to massage technique and use of Sasso hen as a teaser. The semen volume ranged from 0.12ml (T3) to 0.22ml (Control) and the total spermatozoa count was similar (405 – 459 x 10^6/ml) across the treatments. Since the Sasso cocks responded to use of teaser hens in semen collection and the semen quality as well as spermatozoa characteristics were apparently not compromised, use of teasers in semen collection could be an alternative technique in poultry.
Keywords: ACGG-Nigeria, artificial insemination, poultry species, spermatozoa quality

INTRODUCTION
It has been established that assessment of semen quality in poultry species, gives an excellent indication of the reproductive potential and it was stated to be a major determinant of fertility and hatchability of eggs, which in turn determines hatchery enterprise profitability (Islam *et al*., 2002). Poultry semen quality as reported by Tarif *et al.* (2013) includes semen volume, glucose level and pH as well as spermatozoa concentration and motility.
According to Ganpule (2018), Sasso is the premium quality coloured broiler breeder that was exclusively bred from original parent breeding stocks in France. It was stated that it has been proven to be hardy, easy to manage and was regarded to as a multipurpose bird, hence its international popularity. These attributes make Sasso cock a reputable strain and may be a suitable research bird for demonstration of artificial insemination technique in breeding programs.
Unfortunately, the weight may not be convenient for the usual massage method of semen collection, as a result of possible injuries and discomfort during massage for semen collection in large poultry species. This has often times resulted in frequent administration of antibiotics and anti-stress medications, which could be detrimental. Therefore, use of teasers as being practiced to collect semen in rabbits, swine and ruminants (Barszcz *et al*., 2012; Dominiek *et al*., 2011; Naughton *et al*., 2003), could be a veritable alternative to the usual massage technique in poultry species.

MATERIALS AND METHODS
Experimental birds and welfare
From a large stock of Sasso birds reared in deep litter system, by African Chicken Genetic Gains Research Group at the Teaching and Research Farm, Nasarawa State University, Keffi, Shabu-Lafia Campus. Twelve cocks at 24 weeks old were randomly selected, weighed, housed individually and acclimatized for two weeks. Breeders' mash as well as cool clean drinking water was offered *ad libitum.* The twelve Sasso cocks were distributed 4 each to Control (T1): massage technique, use of Sasso hen as a teaser (T2) and use of local hen as a teaser (T3). Another set of 4 each of Sasso hens and local hens were kept separately and used as teasers to arouse the Sasso cocks in T2 and T3, to ease semen collection without massage. During the acclimatization period, teasers were introduced only to the cocks in T2 and T3 twice daily, but were not allowed to mount.

Semen collection techniques

Massage technique

Gentle "to and fro" stroke on the back feather using one hand accompanied with abdominal massage toward the tail with the other hand to stimulate the copulatory appendage was done to cause the ejaculatory papillae to swell. Upon eventual secretion of semen on the swollen ejaculatory papillae, capillary tube was used in the semen collection as described by Burrows and Quinn (1937).

Use of teaser technique

A teaser hen was introduced one at a time to the Sasso cocks individually. Immediately the cock advances to mount the teaser, it was allowed a short time and then picked up at the point of ejaculation. Without any massage, semen was secreted on the swollen ejaculatory papillae and capillary tube was used in the collection as described by Burrows and Quinn (1937).

Data collection and statistical analysis

Body weight of the Sasso cocks, number of cocks that responded to semen collection technique, response time to semen collection, semen volume and pH were recorded. Also, semen glucose, motile spermatozoa, sluggish spermatozoa, alive spermatozoa, dead spermatozoa and total spermatozoa count were determined, following the guide of Bakst and Long (2010). Data were subjected to analysis of variance at $\alpha_{0.05}$ using SPSS (2010).

RESULTS AND DISCUSSION

Table 1 shows the influence of teaser hens on Sasso cocks' semen collection, quality and spermatozoa characteristics. There were no statistical variations (P<0.05) in all the parameters measured, except in response time to semen collection and semen volume.

Table 1: Influence of teaser hens on Sasso cocks' semen collection, quality and spermatozoa characteristics

	Semen collection techniques (±STD)		
	Control	Teaser	
Parameters	T1	T2	T3
Number of cocks	4	4	4
Body weight (kg)	4.19±0.17	3.77±0.56	3.82±0.33
NCRSC	4 (100%)	4 (100%)	1 (25%)
Response time (minutes)	5.25±1.26^{c}	9.75±3.86^{b}	30.0±0.00^{a}
Semen volume (mL)	0.22±0.03^{a}	0.17±0.03^{b}	0.12±0.00^{c}
Semen pH	7.50±1.0	7.25±0.96	7.80±0.00
Semen glucose (mol/L)	5.28±0.26	5.20±0.22	5.0±0.00
Motile spermatozoa (%)	68.75±12.48	64.25±13.68	62.00±14.88
Sluggish spermatozoa (%)	31.25±13.20	35.75±13.68	38.00±14.06
Alive spermatozoa (%)	50.00±33.66	63.75±29.26	40.00±0.00
Dead spermatozoa (%)	50.00±33.66	36.25±29.26	60.00±0.00
Total spermatozoa count ($\times 10^6$/mL)	459.10±231.5	455.50±.266.08	405.48±235.8

a,b,c: Mean values on the same row with different superscript differ statistically at 5% probability test; NCRSC: Number of cocks that responded to semen collection technique; STD: Standard deviation; T1 (Control): Massage technique; T2: Use of Sasso hen as a teaser; T3: Use of local hen as a teaser.

This observation probably indicated that irrespective of collection technique, semen quality and spermatozoa characteristics may not be compromised. It was observed that only a cock (25%) responded to semen collection when local hen was used as a teaser. This probably suggested that Sasso cocks were reluctant to mate with the local hens, resulting in delay response time of 30 minutes compared to massage technique and use of Sasso hen as a teaser, where all the cocks (100%) responded between 5 and 10 minutes. This could be largely due to the size of the local hen that was relatively very small compared to that of a Sasso hen. The observed Sasso cocks' responses to teaser hens perhaps, suggested that a teaser could be used in poultry breeder semen collection as established in cattle (Barszcz *et al.*, 2012), pigs (Dominiek *et al.*, 2011) and rabbits (Naughton *et al.*, 2003).

The superiority (P<0.05) of semen volume recorded in T1 over T2 and T3, may be a mere coincidence and probably due to only a cock that gave 0.12ml in T3, unlike in T1 and T2 where the values were obtained from 4 hens. However, it possibly indicated that massage technique may be better than the use of teasers. Generally, it has been reported that semen volume of poultry species are low but very high in spermatozoa concentration (Hafez and Hafez, 2000). Meanwhile, the semen volume, pH and glucose values were similar to what was reported in poultry species (García-Herreros, 2016; AL Mahdi *et al.,* 2014). Therefore, collecting semen from Sasso cocks using teasers without massaging, may not down grade semen quality.

There were more dead spermatozoa (60%) in semen collected with a local hen as a teaser, slightly followed by massage technique (50%) compared to 36% recorded when Sasso hen was used as a teaser. This observation could be a mere coincidence and not possibly due to the treatment. The quantum of motile spermatozoa recorded was similar to a range reported in birds by Froman (2007).

The spermatozoa concentration was within the values given as normal in poultry breeder cocks (Latif *et al.,* 2005; Nwagu *et al.,* 1996). Therefore, use of teasers in Sasso cocks' semen collection may not influence semen quality and spermatozoa characteristics.

CONCLUSION AND RECOMMENDATION

Sasso cocks apparently responded to teaser hens in semen collection yet, the semen quality and spermatozoa characteristics were seemingly not affected. Thus, use of teasers in collecting semen in poultry species could be adopted, as already being practiced in some mammals. However, in depth research investigations, on the use of different teasers in order to develop avian research and improve poultry production may be required.

ACKNOWLEDGEMENT

The Author sincerely appreciates the Representatives of African Chicken Genetic Gains, Nigeria and the Department of Animal Science, Faculty of Agriculture, Nasarawa State University, Keffi, Shabu-Lafia Campus, for providing the cocks and the facilities used in this study.

ABSTRACT

The study aimed at assessing the influence of milking hygiene on prevalence of mastitis in dromedary camel (*Camelus dromedarius*) in Azare, Bauchi State, Nigeria.A cross-sectional survey was carried out on 189 lactating dromedary camels in pastoral herds in Azare. Questionnaire and oral interview were used to generate data on pre milking udder preparation and hygiene, vaccination/medication, tick control, parity and stage of lactation. California Mastitis Test was carried out to evaluate the prevalence of mastitis in the pastoral herds.The results obtained showed only 10% of the herders wash their hands before milking and none washed hands between milking lactating camel. Only 10% of the herders practice tick control, while all herders cover/tie the udder/teat as anti-suckling device. Mastitis prevalence rate of 17.17% was recorded. Significant ($p<0.05$) association was observed between parity and mastitis prevalence. General herd management and hygiene during milking should be improved to avoid transfer of pathogen from among animals.

Key word: Udder,Hygiene, Management, Mastitis, Camel

INTRODUCTION

Camel milk is one of the main components of diet of the nomads in semi-arid and arid zones and is an essential food for livelihood of people and it may be the only milk available in places where other milking animals cannot be maintained (Abdurahman 2006). Despite the environmental constraints, camel is known to meets the demands of the pastoralist in terms of milk. Wernery (2003) reported that a good milker produce 20-30 litres of milk daily. Average daily milk yield of the Somali breed camels was reported to range from 5-8 litres (Bekele *et al.,* 2002). Estimates of lactation periods vary from 9-18 months (Ramet 2001; Bekele *et al* 2002).

Mastitis, an inflammation of the mammary gland caused by bacterial infection, trauma, or injury to the udder, remains the most common and most expensive disease affecting the dairy industries throughout the world. Micro-organisms invading the mammary gland via the teat cause 90-95% of mastitis problems in cows, while 5-10% of mastitis problems were due to injury (NebGuide 2003). Factors that predispose animals to mastitis include poor hygiene, poor animal husbandry, the malfunction of milking machines, and poor milking techniques.

Management plays a major role in the level of mastitis, which is evident on many dairy farms. Higher levels of mastitis usually occur on farms with a low level of sanitation, suboptimal teat dip application, inadequate dry cow antibiotic procedures, poor milking techniques, or inadequate machine maintenance (Costello 1998).

Improper milking practices may cause production of diseases of mastitis pathogen. Mastitis bacteria are spread from cow-to-cow at milking time by whatever touches the udder and teats, be it hands, udder cloths and teat cups (Billet 1995). Therefore, the aim of the study were to determine the influence of milking hygiene on prevalence of mastitis in dromedary camel in Azare

MATERIALS AND METHODS

Study area

This study was carried out in Azare, Katagum Local Government area of Bauchi State. Katagum lies between latitude 9.3^0 and 12.3^0N and longitude 8.5^0 and 11.0^0E (BASGD 2006). The research area lies within the Sahelian region, characterized by low rainfall (700mm in the extreme north). The rainfall in the area begins around June/July and lasted for 4-5 months. The vegetation of the area

consist of mainly short grasses, with shrubs and scanty trees. Ambient temperature fluctuates throughout the year and it reaches its peak around April/May.

Study animals

Lactating camels in pastoral herd of Arab under traditional management in Katagum Local Government area were used for the study. A total of 189 lactating camels were selected for this study accordingly.

Study design, Sampling and sample size

A cross-sectional epidemiological survey was conducted on 189 lactating camels, in which case study animals were visited once for data collection. Purposive sampling was adopted.

The desired sample size for the study was calculated using the formula given by Dahoo *et al.* (2003) for veterinary epidemiological research with 95% confidence interval and 5% desired absolute precision.

California Mastitis Test (CMT)

Sub-clinical mastitis was diagnosed based on California Mastitis Test (CMT) results and the nature of coagulation (milk and CMT) showed the presence of the infection. A squirt of milk sample was placed in each well on CMT paddle and an equal amount of 3% CMT reagent was added to each well and mixed (Quinn *et al* 1999).

Data analysis

Data were recorded in Microsoft excel spread sheet for statistical analysis using Statistical Package for Social Sciences (SPSS) Version 21. Descriptive statistic using a simple percentage was used to evaluate the prevalence of mastitis and management technique while Chi-square test was carried to evaluate the strength of association between the potential risk factors with occurrence of mastitis in camel.

RESULTS

Characterization of camel management practices

Table (1) revealed the herd management practices. Based on observation while interacting with the herdsmen in their herds early morning before milking, the results showed that, only (10%) of the herds visited washed/prepare the udder before milking the camels. They believed that the calf would clean the udder by suckling. So also none (0%) among the milkers washed their hands between milking the lactating camel. All (100%) the herders practiced the habit of covering/tying the teat while on grazing in order to prevent the calf from suckling the dam while on grazing. Only 40% of the herd visited vaccinate their camels annually. 40% of the herds visited during the study gave medication to their camels whenever their camels are sick and these happened to be the owners who give annual vaccination to their camel, while the remaining 60% do not care to treat camel with conventional drugs rather traditional or none at all. On tick control, the outcome of the research indicated that (90%) the herds visited do not practice any form of tick control. All (100%) herders around Azare gave mineral supplement (potash) to their camel, while none (0%) among the herders gives feed supplement to the camels.

Table 1: Camel Herd Management Practice**s** Azare, Katagum Local Government Area, Bauchi State

	Camel Herders Responses (%)	
Household Practices	**Yes**	**No**
Washing udder before milking	10	90
Washing hand between milking	0	100
Cover/tie udder while on grazing	100	0
Vaccination	40	60
Medication	40	60
Tick control	10	90
Mineral supplementation	100	0
Feed supplementation	0	100

Prevalence of mastitis and its risk factors

Table (2) showed the distribution of CMT results in various locations in the study area. Of the 198 camels examine for sub-clinical mastitis through CMT, 34 (17.17%) showed positive reactions.

Among many mastitis potential risk explanatory variables, two were considered as potential risk factors for the occurrence of sub clinical mastitis in the study area. These were stage of lactation and parity of the lactating camels. Tables 3 showed that there was $p<0.05$ association between parity and sub-clinical mastitis. While non significant $p>0.05$ relationship were observed between occurrence of mastitis and stage of lactation.

Table 2: Overall Prevalence of Mastitis in Dromedary Herds in Azare, Katagum Local Government Area, Bauchi State

	California Mastitis Test			
Location	**Negative**	**Positive**	**Total**	**Prevalence rate (%)**

≤2 month	88	15	73	44.12	0.933
>2 month	110	19	91	55.88	
Total	**198**	**34**	**164**		

P>0.05

DISCUSSION

It was observed that majority of the herders do not wash hands before and between milking time of the lactating camels, the results indicated poor hygiene practices during milking of lactating camel. This practice may have spread of mastitis pathogen between camels in the camel herds. Agab and Abas (1999) reported that lesions due to ticks infestation and poor udder hygiene were serious problem to udder health, and recommended that milk hygiene should be improved. Hygiene during milking process, and presence of lesion on udder or teats were reported to be significant with the prevalence of mastitis in lactating camel (Husein *et al*., 2013).

Furthermore, herders do not practice any form of tick control in their herds The ticks colonized mostly areas around the udder, particularly the teats, and this created lesions which may have probably given mastitis pathogen access to infect the udder. Amena *et al.* (2011) attributed the high prevalence of mastitis in camel to heavy tick infestation in Ethiopia. Megersa (2010) and Husein *et al.* (2013) reported that one of the factors that predisposed camels to mastitis was the lesions caused by ticks, which facilitate bacterial entry and cause permanent tissue damage, exerxabated by poor udder hygiene.

In this study, all herds visited practiced the tradition of covering the udder to protect the calves from suckling the dam. Similar outcome was reported by Abeer *et al.* (2016) which found out that all udders under his investigation showed marks of faulty anti-suckling devices. A studies carried out in Sudan by Abdurahman (2006) also explained that the use of device to prevent the calves from sucking their dams, together with heavy tick infestation of the udder was considered as the predisposing factor for camel mastitis.

In the present study the overall prevalence of mastitis in dromedary camel was 17.17%, which was significant to affect economic and public health in the study area. The overall prevalence rate reported in the present study was slightly above the values reported by Kalla *et al.* (2008) that the incidence of lactating camels having mastitis was 14.4% in Komodugu-Yobe River Basin, Nigeria. The prevalence rate observed in the present study was consistent with the findings of Al-Jaboori *et al.* (2013) which reported a prevalence rate of 18.5% in Abu-Dhabi, UAE. However, the findings was lower when compared with the findings of other authors in other countries like: Husein *et al.* (2013) 30.2% Ethiopia, Obeid *et al.* (1996) 66.8% Sudan and 29% by Osman *et al.* (1991) in Somali.

The differences in prevalence rate of mastitis in the present study and other reports could be attributed to unhygienic milking procedures and generally poor traditional management practices observed. Earlier work (Mungube *et al* 2004) showed that animals were much more infected by mastitis causing pathogens, mainly in areas where hygienic conditions were poor and treatment of mastitis cases was not well pursued. So also differences in the methods and material employed by the investigators might have been contributed in the wide variation of the prevalence rate reported by different authors.

There were high occurrence of mastitis in dromedary camel with >4 calves than those with 1-3 calves. This is in accordance with the findings of Abera *et al.* (2010) who reported that the risk of clinical and sub clinical mastitis increases with advancing age or parity of the camel. Husein *et al.* (2013) also reported that incidence of mastitis is influenced by age and parity number of the camel. While prevalence of mastitis found to be non significantly ($p>0.05$) associated with the lactation stage of dromedary camel.

CONCLUSION

It could be concluded that mastitis was prevalent in camel pastoral herds in Azare and it environs, and there was poor general herd management and hygiene during milking in the herds. General herd management should be improved to checkmate the prevalence of mastitis in camel pastoral herds in Azare.

ABSTRACT
Compilation and review of some candidate genes that can be employed in characterization of indigenous livestock in Nigeria for resistance to common diseases were undertaken in this study. The diseases that affected livestock (cattle, sheep and goats) in 2018 and 2019 were presented.
Keywords: Candidate gene, resistance to disease, cattle, sheep and goats

INTRODUCTION
Genetic variation of resistance to internal parasites has been demonstrated in numerous species, including humans and several livestock species (Kloosterman *et al.*, 1992 and Quinnell, 2003). However, the genetic architecture underlying such traits is poorly understood (Kemper *et al*., 2011). Livestock diseases adversely affect animal production throughout the world. Livestock keepers and other stakeholders involved in promoting animal health can draw on a number of approaches to reducing these negative effects (http://www.fao.org/3/a1250e/a1250e05.pdf). Some of the strategies being used to reduce the negative effects of diseases on productivity of farm animals include vaccination, elimination of disease vectors and appropriate management methods. These approaches are sometimes constrained and become less sustainable. Identification of animal genetic resources (AnGR) for resistance to some major diseases of livestock (cattle, sheep and goats) is one of the high end solutions that can provide sustainable reduction to economic losses due to diseases. For many livestock diseases, evidence has been found for genetic variation in the extent to which host animals are susceptible. This paper was aimed at reviewing some candidate genes that can be employed in characterization of indigenous livestock in Nigeria for resistance to common diseases.

Major livestock diseases reported in Nigeria by 2018 and 2019
Reported cases of livestock diseases were shown in Table 1. These reports were documented through the Agricultural Performance Survey (APS) of NAERLS (NAERLS, 2018 and 2019). Contagious bovine pleuropneumonia (CBPP) was reported in six (6) States in 2018 and 2019. Foot and mouth disease was reported among cattle populations in many States of Nigeria. Foot and mouth disease (FMD) is a severe, highly contagious viral disease of cattle. It also affects sheep and goats. Other diseases and pests that affect cattle in Nigeria in 2018 and 2019 were babeiosis, fasciolasis, foot rot, helmithiasis, rinderpest., tick infestation and tuberculosis.
Peste des petits ruminants (PPR) affected sheep and goats in all the agro-ecological zones in Nigeria. The disease was reported to have affected sheep and goats in 16 States in 2018. Plate I showed the estimated loss of sheep and goats to PPR disease in 2018. Other pests and disease that affected sheep and goats in 2018 and 2019 were fleas, foot rot, helminth worms and mange.

Candidate gene for resistance to foot and mouth Disease
Integrin subunit Beta 6 (ITB6) gene was reported to be associated with resistant to foot and mouth disease in cattle (Gowane *et al*., 2013). This gene encodes a protein that is a member of the integrin superfamily. Members of this family are adhesion receptors that function in signaling from the extracellular matrix to the cell. Integrins are heterodimeric integral membrane proteins composed of an alpha chain and a beta chain. Integrin alpha-V: beta-6 (ITGAV: ITB6) is a receptor for fibronectin and cytotactin. It recognizes the sequence R-G-D in its ligands. Internalization of integrin Alpha-V/ beta-6 via clathrin-mediated endocytosis promotes carcinoma cell invasion. It acts as a receptor for fibrillin-I (FBNI) and mediates R-G-D-dependent cell adhesion to FBNI.
The Major Histocompatibility Complex (MHC) gene is a candidate gene considered important for the immune system and disease resistance traits. MHC is a cell surface molecule involved in antigen presentation by glycoprotein receptors (Dukkipati *et al*., 2006). The MHC involves a series of highly

polymorphic genes which are responsible for the initiation of the immune response when an animal is challenged by pathogens or parasite (Santucci *et al*., 2007). The major histocompatibility complex (MHC) is a cluster of tightly linked genes that play an important role in the immune system (Klein, 1986). The products of these genes are involved in the induction and regulation of immune response. The MHC spans approximately 4Mb of human genome, 1.5Mb in mice and approximately 2.5Mb of cattle genome (Lewin, 1996). In cattle, it is located on chromosome 23. The structure and organization of MHC genes of cattle, known as the bovine leukocyte antigen (BoLA) complex, are very similar to those of the human MHC.

Table 1: Reported cases of major diseases affecting cattle, sheep and goats in Nigeria

		Reported cases by States	
Species	**Diseases**	**2018**	**2019**
Cattle	CBPP	Adamawa, Anambra, Gombe, Lagos, Nasarawa, Plateau, Taraba	Bauchi, Borno, Kogi, Kwara, Taraba, Zamfara
	Helminthiasis	Adamawa, Benue, Kano, Niger, Rivers	Benue, Edo, Kwara, Rivers
	FMD	Adamawa, Bayelsa, Gombe, Kano, Katsina, Taraba, Osun, Oyo, Rivers, Sokoto	Borno, Kano, Kogi, Oyo, Rivers, Taraba, Zamfara
	Babeiosis	Niger	Kwara
	Foot rot	Edo	Edo
	Mastitis	Nil	Osun

Candidate gene for resistance to peste des petits ruminants

Toll-like receptor (TLR) gene are vital for the detection of invading pathogens and are commonly expressed in antigen presenting cells and other immune cells (O'Neill, 2006). Toll-like receptorsare type 1 transmembrane protein expressed in almost all cell types and activate the innate immune system upon sensing pathogen associated molecular patterns ($PAMP_S$). Intracellular TLR that sense viral nucleic acids include TLR3 (double stranded RNA), TLR7 and TLR8 (single stranded RNA and TLR9 (CPG motifs in DNA) (Prajapati *et al*., 2017). The cell specific location and basal expression levels of TLR mRNA could indicate the natural pathogen-associated molecular patterns (PAMPs) load of that tissue as well as the innate host resistance to pathogens. In addition to the differential expression profiles of Tousled-like kinase (TLK), ligand induced downstream cytokine profiles and/or levels could also play a role in the innate disease resistance (Manaswini *et al*., 2018).

Candidate gene for resistance to mastitis

Toll-like receptor gene 4 (TLR4) plays an important role in bovine mastitis resistance (Wang *et al*., 2015). The protein encoded by TLR4 gene is a member of the toll-like (TLR) family which plays a fundamental role in pathogen recognition and activation of innate immunity (TLR immunity). TLR_S are highly conserved from drosophila to humans and share structural and functional similarities. They recognize pathogen-associated molecular patterns that are expressed on infectious agents, and mediate the production of cytokines necessary for the development of effective immunity.

Candidate gene for resistance to tuberculosis

Caspase recruitment domin 15 (CARD15) gene in cattle plays an important role in tuberculosis (TB) resistance (Prajapati *et al*., 2017). CARD15 gene encodes for a cytosolic protein implicated in bacterial recognition during innate immunity. Para tuberculosis represents a major problem in farmed ruminants and at the present is considered a potential zoonosis. The disease is caused by *Mycobacterium avium* subspecies (Pinedo *et al*., 2009).

Candidate gene for resistance to other types of livestock diseases

The Natural Resistance Associated Macrophage Protein 1 (NRAMP1) gene, also known as Solute Carrier family11 member A1 (SLC11A1) gene is a member of large family of metal ion-transport proteins and it was the first positional cloned gene related to infectious disease susceptibility in mouse (Vidal *et al*., 1993). Since SLC11A1 is associated with pH dependant transport of divalent cations (like Fe^{2+}, Mg^{2+}, etc.) through the phagosome membranes, are essential for many cellular functions.

Under normal physiological conditions, SLC11A1 gene delivers bivalent metal cations from the cytosol into acidic endosomal and lysosomal compartments where the Fenton and Haber-Weiss reaction generate toxic antimicrobial radicals for direct antimicrobial activity against phagocytosed microorganisms (Goswami *et al.*, 2001). SLC11A1 gene have pleiotropic effects on macrophage function, that include increased chemokine KC, tumour necrosis factor-α, interleukin-1β, inducible nitric oxide synthase and major histocompatibility complex class II expression; all are important in resistance to intracellular pathogens (Awomoyi, 2007).

There are so many experimental evidences regarding the association of SLC11A1 gene polymorphisms with resistance to infectious diseases in human beings as well as animals. In mouse SLC11A1 gene confers resistance to intracellular pathogens like *Mycobacterium spp*., *Salmonella spp*. and *Leishmania spp.* (Vidal *et al*., 1995)

Toll-like receptors (TRL-2 gene)initiate inflammatory responses following the recognition of a wide repertoire of pathogens including bacteria, fungi, protozoa and viruses. They are composed of an extracellular leucine-rich repeat domain responsible for detecting pathogen-associated molecular patterns, a membrane spanning region and an intracellular Toll/Interleukin 1 receptor domain which invokes signal transduction. Toll-like receptor 2 is the most diverse of these receptors as it recognizes infectious agents from a range of pathogenic groups.

Bovine leukocyte antigen (BoLA-DRB3) complex are very similar to those of human MHC. BoLA complex is found in two separate regions of the chromosome rather than a single cluster of genes seen in most mammals. The larger gene cluster is located at BTA23 band 22 and apparently contains all of the bovine class I and class III sequences and gene encoding both subunits of the classical class II proteins DQ and DR. The remaining BoLA class III loci (DIB, DNA, DOB, DYA, DYA, TCPI, LMP2, LMP7 and TAP2) are located in a cluster near the centromere at BTA23 band 12-13 (Rothschild *et al*., 2000). The DRB3 locus and its gene products are among the best defined in cattle. The associations between BoLA alleles and disease class I association include resistant to mastitis (Mejdell *et al*., 1994).

ABSTRACT
Blood samples were collected in heparinized test tubes from 100 smallholder goats in four local government areas (Jema'a, Kaura, Jaba, and Kachia) of Southern Kaduna. The blood samples were collected and analysed by electrophoresis to study the haemoglobin polymorphism and its frequency in indigenous smallholder goats found in Southern Kaduna. The electrophoretic test showed the presence of two co-dominant alleles HbA and HbB which produced two haemoglobin phenotypes: A homozygote HbAA and heterozygote HbAB; HbBB was not detected in this study. HbAA (61%) had the highest frequency over HbAB (39%). The gene frequency of HbA (0.805) exceeded HbB (0.195) significantly. The high preponderance of HbA allele is seen as an adaptation due to several environmental factors such as height above sea level (altitude) for oxygen utilization, temperature extremes, and presence of parasitic helminthes. The chi-square test showed high significant differences between observed and expected genotype frequencies ($P<0.01$). Thus, indicating that the flock was not in Hardy-Weinberg's equilibrium.
Key words: Goat, haemoglobin, haemoglobin polymorphism, electrophoresis, and adaptation.

INTRODUCTION
The domestic goat or simply goat (Capraaegagrushircus) is a subspecies of Capraaegagrus domesticated from the wild goat of South Asia and Eastern Europe. They are a valuable source of animal protein for humans when their meat or milk is consumed. Indigenous goats in Nigeria belong to three distinct breeds: the long-legged Sahel/desert goat found in the arid and Sahel regions; the relatively small body-sized red Sokoto goat found in the savannah zone; and the hardy, short-legged West African Dwarf (WAD) found mostly in the South. Although goat breeding is a very old tradition among indigenous farmers, no purposeful breeding programme has ever been organized for the species in Nigeria. Goat breeds have been previously evaluated for genetic variation based on morphological, physiological, pathological, productive, reproductive and behavioural features (Pourlis and Christodoulous 2008; Salako *et al*., 2007). However, these characters underestimate the true level of genetic variation. The amount of genetic variation detectable in an animal population is related to the magnitude of genetic improvement achievable within the species (Salako *et al*., 2007; Akpa *et al*., 2011). Therefore, the polymorphic variants of different proteins, enzymes, and mineral element or blood group factors represent more accurate procedure for better measurement of genetic variation in goat species. One of the important blood proteins is haemoglobin because of its biochemical, biophysical and physiological properties, having relevance to selection phenomenon of animals (Menrad *et al*., 2002). Haemoglobin have been previously reported to have variants (polymorphism) and these variants have been reported to be associated with environmental adaptability as well as being clinically important as causes of a variety of genetic disorders of blood (Peter *et al*,. 2004).
The objectives of this study were: to assess haemoglobin polymorphism which exists in goats found in Southern Kaduna; to assess the frequencies of the haemoglobin variants of goats found in Southern Kaduna; and to relate the predominant haemoglobin polymorphic form to the type of environment the goats thrive in.

MATERIALS AND METHODS
Study area
The study was carried out in four local government areas in the Southern part of Kaduna state: Kachia, Jaba, Jema'a, and Kaura local government area.
Data collection
Blood samples (5ml) were collected from 100 goats (25 goats from each local government) in four local governments of Kaduna state: Kachia, Jaba, Jema'a, and Kaura local government area. 5ml of blood was collected from each of the sampled animals by jugular venipuncture using needle and syringe and into sample bottles containing Ethylene Diamine Tetra Acetic acid (EDTA) as

anticoagulant, properly labelled with respect to the different breeds and local governments and preserved in a fridge from whence it is transported to the laboratory for analysis.

Electrophoresis

The red cell lysate was impregnated on a cellulose acetate paper with a control, placed on the electrophoresis tank and subjected to electrophoresis according to the standard procedure described by Smithies (1955) that was later modified using the procedure of Boyer and Hiner (1963). By electrophoresis, the haemoglobin fractions were separated. The identification of the haemoglobin types in the samples was achieved in accordance with the migration speed of the light spots on the electrophoretical substratum, detected from the start line towards the cathodal zone. The haemoglobin polymorphism was pointed out by detection of three migration zones coded as follows: A single faster band designated as AA homozygote, a single slower band designated as BB homozygote, and the presence of both bands designated as AB heterozygote.

RESULTS AND DISCUSSION

Table 1: Genotypic frequencies of the indigenous goats in the sampled local governments

Local govt	N	AA%	AB%	BB%	Total
Jema'a	25	68.00	32.00	0.00	100.00
Kaura	25	60.00	40.00	0.00	100.00
Jaba	25	84.00	16.00	0.00	100.00
Kachia	25	32.00	68.00	0.00	100.00
Polled	100	61.00	39.00	0.00	100.00

Result on genotypic frequencies of the indigenous goats in the sampled local governments is presented in Table 1. The results obtained revealed that AA genotype had the highest frequency across all sampled local governments areas (Jema'a: 68%, Kaura: 60% and Jaba: 84% respectively) except for Kachia local government where AB has the highest genotypic frequency of 68%. The AB genotype had the second highest frequency across the local government areas (32%, 40%, and 16% for Jema'a, Kaura, and Jaba, local government area respectively) except in Kachia local government where it had the highest frequency of 68%.The BB genotype had the lowest genotypic frequency of 0%.

Table 2: Gene frequencies of the indigenous goats in the sampled local government

Local govt	N	A (P)	B (Q)	Total (P+Q)
Jema'a	25	0.84	0.16	1.00
Kaura	25	0.80	0.20	1.00
Jaba	25	0.92	0.08	1.00
Kachia	25	0.66	0.34	1.00
Polled	100	0.805	0.195	1.00

Result on gene frequencies of the indigenous goats in the sampled local governments is presented in Table 2. The result showed that the HbA gene had the highest gene frequency across the four local governments (Jema'a: 0.84, Kaura: 0.8, Jaba: 0.92, and Kachia: 0.66 while the B gene had the lowest gene frequency in all four local government areas (Jema'a: 0.16, Kaura: 0.2, Jaba: 0.08, and Kachia: 0.34).

Result from chi-square analysis showed that there was high significant difference between observed data and expected data.

Relationship between genotype and environment

In this study, two haemoglobin genotypes were detected: homozygote (AA) and heterozygote (AB). No homozygote BB was detected in this study. The genotypic frequency of AA (61%) genotype was significantly higher than AB (39%) when polled together, from table 1. The results of this study is similar to the works of Agaviezor *et al* 2013 in which they recorded significantly higher frequency of AA genotype (75%) over AB genotype (21.67%) and BB genotype (3.33%) of indigenous goat breeds living in areas of dense vegetation. Buvanendran *et al* 1981 did not find the BB phenotype in red

sokoto breeds. Johnson *et al* 2002 reported that the BB genotype is not widely distributed. Agaviezor *et al* 2013 suggested that the AA genotype may have selective advantages against helminthic infections.

Hrinca (2010) explains that extreme temperature (acute cold or sultry heats), the extreme forms of relief (dessert or mountain) and precarious nutrition conditions favour the fixing of the allele HbA, and the temperature situated in the biological comfort zone, the moderate forms of relief (forest steppe, hill, etc) or the optimal breeding technologies are correlated with a more emphasized fixing of the allele HbB. The present study was done in the northwest of Nigeria where the temperature could be as high as 38^0C. This high temperature could probably favour the fixing of HbA over HbB. Salako *et al*. (2007) reported that Red Sokoto goats sampled in the South West of Nigeria (Rain forest zone) had a higher frequency of HbB to HbA, suggesting that they best fit in zones of moderate temperature. Evans and Warren (1958), explained that HbA genes are favoured in environment of high altitudes, while HbB are favoured by lower altitudes. The population sampled in this study came from high altitude areas of 2021ft (616m) above sea level. This may explain the higher frequency of HbA than HbB. Salako *et al.* (2007) reported higher frequency of HbB than HbA in their study; they sampled animals from a lower altitude (Ibadan is 780ft above sea level; Falling Rain Genomics Inc. 1996-2006). Das *et al.* (2004) also reported a higher frequency of HbB in Kolkata, West Bengal India (altitude 42ft). Alphonsus *et al.* 2012 also reported a high preponderance of HbA alleles (0.60) over the HbB alleles (0.335) of indigenous goats found in the in the Northern region of Nigeria. Likewise, Akpa *et al*. (2011) reported a high preponderance of HbA alleles in the indigenous goats of Northern Nigeria. These findings suggest that the natural habitat of Northern Nigeria favour goats with HbA alleles than HbB alleles. However, some studies by Das *et al.* (2004) and Salako *et al*. (2007) in goats of southern Nigeria revealed high preponderance of HbB alleles than HbA. This variation is probably due to differences in the geographical locations especially with regard to their altitudes. The southern part where Salako *et al.* 2007 and Das *et al.* 2004 conducted their study was in a relatively lower altitude (750ft and 42ft respectively); while the study of Alphonsus *et al.* (2012) and Akpa *et al.* (2011) were conducted in a relatively high altitude (2552ft) of the Northern part.

CONCLUSION

Haemoglobin polymorphism is defined by the expression of different variant (polymorphic) forms of haemoglobin. Two types of haemoglobin genotypes were found in this study, HbAA and HbAB; generally 61% of the goats had HbAA genotype while 39% had HbAB genotype. The allelic (gene) frequency for HbA was 0.805 while the allelic frequency for HbB was 0.195. This suggests that goats possessing the HbA allele had a higher chance of survival and reproduction as they might be better at utilizing oxygen, more tolerant to extreme weather conditions, and have higher resistance to helminths.

The chi-square test revealed high significant differences between observed data and expected data which show that the goat population were not in Hardy Weinberg's equilibrium suggesting differential mortality and preferential selection for particular genotypes which are more suited to the environment.

RECOMMENDATION

1. Haemoglobin variants should be put into consideration in goat's selection and breeding programs.
2. Environmental factors should always be assessed before goats are being introduced so that the goats with the most suitable genotype can be chosen.
3. Larger scale studies needs to be done to give a better understanding of how environmental factors interact with Haemoglobin forms and how these polymorphic forms interact with other biochemical factors in the animal.

ABSTRACT
Proper knowledge of variations and diversities between, among and within the populations of animals helps in classifying animals into their various genetic groups, which helps in identification and conservation of important alleles. A total of seven hundred (700) donkeys consisting of (280) adult, (210) young and (210) weaner donkeys were sampled from Jigawa, Kaduna, Kano, Katsina, Kebbi, Sokoto and Zamfara States of Nigeria using a random sampling techniques. Biometric traits measured among sampled donkeys were body weight, head length, head width, ear length, neck length, neck circumference, shoulder width, height at withers, heart girth, body length and tail length. Data obtained were subjected to statistical analysis to determine the genetic distance estimate across the strains. The classification of Black (Duni), White (Fari), Brown (Idabari), Red (Auraki) and Brown-white (Idabari-fari) donkeys (by using Euclidean as the distance measurement, Single Linkage, Average Linkage, and Complete Linkage were applied, and the obtained results were compared. The simple discriminant analysis procedure was used to classify the strains using the R 2.13.0 (R Development Core Team) package. Homogeneous genetic distance was observed for head width (16, 16) and shoulder width (21, 21) in male red donkeys. Female donkeys showed similar and closed genetic distances for ear length in red (26, 21), black (21, 26) and brown (26, 21) and male Red (26,22), Black (22, 25), White (26, 22) and Brown (22, 25) across the strains. Heart girth, body length and height at wither showed high level of genetic variability among the strains. Heaviest body weight was recorded in male red (141.90kg) donkey strain with a distance of 6.75cm compared to other strains of donkeys. Further classification of donkeys into various genetic groups should employ heart girth, body length and height at wither.
Keywords: Donkey, genetic distance, classification, strain, Nigeria.

INTRODUCTION
Knowledge of morphometric characteristics marks the first step in classification of Farm animal genetic resources (FAnGR) (Delgado *et al*., 2001). Genetic distance is a measure of the genetic divergence between species or between populations within a species, whether the distance measures time from common ancestor or degree of differentiation (Nei, 1987). Populations with many similar alleles have small genetic distances. This indicates that they are closely related and have a recent common ancestor. Genetic distance is useful for reconstructing the history of populations. For example, evidence from genetic distance suggests that Sub-Saharan Africa and Eurasian people diverged about 100,000 years ago (Nei, 1974). Genetic distance is also used for understanding the origin of biodiversity. For example, the genetic distances between different breeds of domesticated animals are often investigated in order to determine which breeds should be protected to maintain genetic diversity (Ruane, 1999). Since donkey population has suffered substantial decline in its size, it is expected that the levels of inbreeding and risk of extinction may be high which necessitates a genetic study to assess variability among donkey populations for their conservation along with their breed assignment, better utilization, production and management practices. This study aimed at determining the genetic clustering, extent of genetic diversity and classification of donkeys into various genetic groups using biometric traits.

MATERIALS AND METHODS
Seven hundred donkeys (700) donkeys comprising 280 adults, 210 young and 210 weaner donkeys were used. The study was carried out in the North West of Nigeria. The States where donkeys were sampled were Jigawa, Kaduna, Kano, Katsina, Kebbi, Sokoto and Zamfara States of Nigeria using random sampling techniques. These States in North West Nigeria were selected for this study because of existence of high population of donkeys. The age of the donkeys was determine using teeth count in combination with the information provided by donkey owners. Biometric traits measured were

body weight, head length, head width, ear length, neck length, neck circumference, shoulder width, height at withers, heart girth, body length and tail length using a flexible tailor's tape. The classification of Black (Duni), White (Fari), Brown (Idabari), Red (Auraki) and Brown-White (Idabari-fari) donkeys (by using Euclidean as the distance measurement; Single Linkage, Average Linkage, and Complete Linkage were applied, and the obtained results were compared. The cluster analysis procedure was used to classify the strains using the R 2.13.0 (R Development Core Team, 2015) package. DISCRIM procedure was used to calculate the probabilities of including an animal in determining the strain, taking into account the error made in classification of the strain. Stepwise discriminant procedure (STEPDISC) was applied to determine, which performance traits were used in the final clustering analysis.

RESULTS AND DISCUSSION

The classification by the application of Euclidean to measure distance among biometric traits of male and female donkeys are shown in Table 1. In male black donkey, homogeneous genetic relationships were observed for head width (16, 16), between cluster 1 and 2, and shoulder width (21, 21) in male red donkey. Similar genetic relationships were observed between cluster 1 and 2 for ear length in male red (26, 22), Black (22, 25), White (26, 22), and Brown (22, 25). In female donkeys, the genetic distance between cluster 1 and 2 for ear length in Red (26, 21), Black (21, 26), Brown (26, 21) and Brown-white were similar for neck length (38, 36) and head length (38, 35). Closer and similar genetic distances were also observed for head width in female Black (11, 14) and White (11, 14). Heart girth, body length and height at wither showed high level of genetic variability across the strains. Similar report was observed in the findings of Nei, 1987 who reported genetic divergence among animal populations with many similar alleles having small genetic distances. This indicates that they are closely related and have a common ancestor.

The classification by the application of single, average and complete linkage are shown in Table 2. The heaviest body weight was recorded in male red (141.90kg) donkey strain with a distance of 6.75cm compared to other strains of donkeys. Male donkey with the smallest body weight was recorded in white (123.55kg) with a distance of 12.01cm.

Female donkey with the heaviest body weight was recorded in brown donkey strains (123.07kg) with a distance of 16.78cm while the female donkey with the smallest body weight was recorded in brown-white (52.25kg). The high level of genetic variability observed among strains of donkeys signifies that the higher the genetic distance estimates among the strains, the further the genetic distances and the more or better the chances for selection in the population. The result of this study is similar with the findings of John *et al*. (2017) who reported similar and closed genetic distance estimates in the qualitative traits of donkeys.

HL: Head length; HWD: Head width; EL: Ear length; NL: Neck length; NC: Neck circumference; SW: Shoulder width; HW: Height at withers; HG: Heart girth; BL: Body length; TL: Tail length. The values for each of the five groups were ranked; the first level of ranking was cluster 1 while the second level was cluster 2.

Table 2. Classification by the application of single, average and complete linkage

Sex	Strain	Body weight (kg)	Distance
Male	Brown	130.29	16.64
	Red	141.90	6.75
	Black	137.87	9.32
	White	123.55	12.01
Female	Brown	123.07	16.78
	Red	115.90	10.91
	Black	109.60	11.40
	White	113.45	12.09
	Brown-white	52.25	0.00

CONCLUSION AND RECOMMENDATION

High level of genetic distance estimates were recorded for heart girth, body length and height at wither among donkey strains in the studied populations. Further classification of donkeys into various genetic groups should employ heart girth, body length and height at wither.

ABSTRACT

The study was carried out to determine the effects of sodium bicarbonate salt and turmeric powder on performance and haematological parameters of Isa brown hens. The experiment was conducted at the poultry unit of the Department of Animal Production Abubukar Tafawa Balewa University located in Gubi, Bauchi. A total of one hundred and eighty four (184) Isa Brown layers at 51 weeks of age were used for the study, which was conducted during the rainy season (July-October). The hens were kept in deep litter system during the experiment. The control birds were administered feed without sodium bicarbonate salt and turmeric powder while the other treatments received diet supplemented with bicarbonate salt supplemented at the level of 0.30 g and 0.70 g, turmeric powder at the level of 0.30g and 0.70g, and the combinations S30T30, S30T70, S70T30 and S70T70. During lay, the birds were fed once daily with compounded ration containing 16% crude protein, other constituents of the feed includes vitamins, minerals and amino acid. Water was ad libitum. The result revealed that the supplementation of sodium bicarbonate salt and turmeric powder did not affect the feed conversion ratio (FCR). However, significant ($P< 0.001$) differences were in feed per egg and the hen day production (%HDP). It was observed that birds on inclusion level of 0.70g sodium bicarbonate salt (116.74±0.05) increased feed per egg while the least values was obtained on birds fed with 0.30g sodium bicarbonate salt inclusion which decreased feed per egg. It was also observed that sodium bicarbonate salt and turmeric powder did not affect haematological parameters thereby making it safe for the birds. From the finding of this research it is concluded that sodium bicarbonate salt and turmeric powder significantly improved performance and is therefore recommended for Isa brown hens.

Keywords: Isa Brown, Turmeric, Sodium Bicarbonate

INTRODUCTION

Domestic poultry is an important sector of livestock keeping worldwide, the production of meat and egg being the major contribution to human nutrition. Taking into account the economic, social and cultural aspect of poultry keeping underlines the huge significance of this sector. There are about 17 billion domestic chickens worldwide (Defra, 2010). Poultry production is one of the best available sources for the production of high biological value animal protein in terms of egg and meat. Commercial hybrids both broilers and layers are being propagated for egg and meat production throughout the world (Ahmad *et al.,* 2010). However there is need to improve the output of the poultry industry through improved performance of the birds. Supplementation of sodium bicarbonate may help to maintain proper pH balance, eliminate acidosis and facilitate metabolic process, ensuring maximum growth and productivity (Abbas *et al*., 2017; Naseem *et al.*, 2005). Moreover, its use as dietary supplement may help rise in blood bicarbonate ion concentration, which can favour better performance of birds (Kaya *et al.,* 2004; Naseem *et al.,* 2005).Turmeric (*Curcuma longa*) is found to be one of such perennial herbs that are used as alternatives to antibiotics and is also found to have anti-oxidative value and certain beneficial pharmacological activities like hypolipidaemic effects. This study was designed to investigate the effects of sodium bicarbonate and turmeric powder on performance and haematological parameters of Isa brown hens.

MATERIALS AND METHODS

The experiment was conducted at the poultry house of Department of Animal Production Abubukar Tafawa Balewa University located in Gubi Village, Bauchi. A total of one hundred and eighty four (184) Isa Brown layers at 51 weeks of age were used for the study, which was conducted during the rainy season (July-October). The hens were kept in deep litter system during the experiment. The control birds were administered feed without sodium hydrogen carbonate salt ($NaHCO_3$) and turmeric powder while the other treatments received diet supplemented with $NaHCO_3$ salt at the level of 0.30 g and 0.70 g, turmeric powder at the level of 0.30g and 0.70g, and the combinations S3OT30, S30T70,

S70T30 and S70T70. During lay, the birds were fed once daily with compounded ration containing 16% crude protein with other constituents of the feed ehich includes vitamins, minerals and amino acid. Water was ad libitum.

Haematological Parameters

At the end of the experiment, six hens were randomly selected from each group and bleed using 2ml syringe at the wing. The blood is collected into collection bottle containing EDTA (ethylene diamine tetra acetic acid) as anticoagulant. Samples were taken thereafter to National Veterinary Research Institute, Vom to determine the packed cell volume (PCV), hemoglobin count (Hb), the red blood (RBC) and white blood counts (WBC).

Data Analysis

Data collected were subjected to analysis of variance using statistical package for social science (SPSS) version 26. Significant means were separated using Ryan Einot Gebriel Welsh (REGW) procedure.

N= overall 60

Table 1 shows the results for effects of sodium bicarbonate salt and turmeric powder on performance. The results revealed that the supplementation of sodium bicarbonate salt and turmeric powder could not affect the feed conversion ratio (FCR). However, significant (P< 0.001) differences were in feed per egg and the hen day production (%HDP). It was observed that birds on inclusion level of 0.70g sodium bicarbonate salt (116.74±0.05) increased feed per egg and decreased hen day production while the least values was obtained on birds fed with 0.30g sodium bicarbonate salt inclusion which decreased feed per egg and increased hen day production. This result disagrees with the findings (Yoruk *et al*., 2004) who reported that feed consumption increased with increasing level of dietary sodium bicarbonate salt supplementation. Hen's diet supplemented with 1.5% $NaHCO_3$ consumed greatest amount of feed. Supplementation of turmeric at inclusion level of 0.70g had a significant (P<0.001) effect on feed per egg which was higher (109.74±2.29) than 0.30g turmeric powder inclusion. More so, birds with 0.70g turmeric supplementation tended to have higher (87.79±1.83) percentage of HDP and the lowest value was recorded on birds fed 0.30g turmeric powder. Yoruk *et al.*, (2004) also reported that hens on supplemented sodium bicarbonate diet produced more eggs than hens that are not on sodium bicarbonate supplemented diet. Monthly feed consumption and %HDP significantly (P<0.01) differ in the month of July (115.35± 0.46 and 92.14±0.37) has the highest

values for feed consumption and %HDP respectively. The lowest were recorded in the month of September (101.38±0.73 and 80.99±0.58) for feed consumption and HDP, respectively.

Table 2 shows the results for effects of sodium bicarbonate salt and turmeric powder on haematological parameters. The results slowed that packed cell volume (PCV), white blood cell (WBC), RBC blood cell (RBC) and Haemoglobin (HB) were not significantly (P>0.05) affected by various levels of sodium bicarbonate salt and turmeric powder.

CONCLUSION AND RECOMMENDATION

From the finding of this research it is concluded that sodium bicarbonate salt and turmeric powder significantly improved performance. It was also concluded that sodium bicarbonate salt and turmeric powder did not affect haematological parameters thereby making it safe for the birds and is therefore recommended for Isa brown hens.

ABSTRACT

This study was conducted to evaluate the effects of sodium bicarbonate salt and turmeric powder on internal egg quality and body parameter measurements of Isa brown hens. The birds were sourced from CHI Nigeria limited farm and raised under similar management techniques. Isa brown is a hybrid brown egg layer being a cross between Rhode Island Whites and Rhode Island Red. The experiment was conducted at the poultry unit of the Department of Animal Production Abubukar Tafawa Balewa University located in Gubi, Bauchi. A total of one hundred and eighty four (184) Isa Brown hens were used for the research which lasted a period of 16 weeks. The results recovered showed that, supplementation of sodium bicarbonate salt and turmeric powder on the internal egg quality of the hens did not affect albumen height (1.03± 0.2) mm, yolk height (1.73±0.2) mm, yolk index (0.51±0.00), and haugh unit (84.47±0.06) mm of the eggs. However, significant (P<0.01) difference was noticed on Yolk diameter where 0.30g sole supplemented sodium bicarbonate salt and interaction between sodium bicarbonate salts and turmeric powder (0.30g $NaHCO_3$ and 0.70g turmeric) recorded the highest values (3.51±0.08 and 3.48±0.08). Body weight and comb length were not significantly (P >0.05) influenced by supplementation level of sodium bicarbonate salt and turmeric powder. However, shank length was affected (P<0.001) by addition of sodium bicarbonate salt and turmeric powder, it was observed that 0.70g sodium bicarbonate salt inclusion had the longest shank length. It was concluded that supplementation of sodium bicarbonate salt and turmeric powder significantly improved Yolk diameter. This singular improvement will influence the overall quality of the egg and also its ability to produce better quality chicks if used for hatching purposes. Shank length was also improved significantly. Sodium bicarbonate salt and turmeric powder is therefore recommended in Isa brown hens.

Keywords: Turmeric, Sodium Bicarbonate, Egg Quality, Body Parameter, Isa Brown

INTRODUCTION

Over the past few decades the production of eggs has grown faster than that of any other major food in developing countries (Shim *et al.,* 2013). This is as a result of increasing demand for animal product due to increase in population, urbanization and westernization of diet. The popularity of poultry has many advantages over other livestock. Poultry birds are good converters of feed into useable protein in eggs. These product has increased much faster than beef and veal or pig meat (Dutta, 2013). Poultry egg is found to be one of the most complete food known to man, and it provides means by which rapid transformation of animal protein intake can be achieved (Shim *et al.,* 2013). The return on investment is high, due to this there is hardly any household in the rural or semi-urban areas that does not keep one form of poultry or the other. Also, genetic improvement could be attained at a faster rate than most farm animals since they have a shorter generation interval. Eggs are also the means by which reproduction takes place in poultry, hence the internal egg quality play a major role in production of good quality chicks. Therefore this study seeks to determine the effects of sodium bicarbonate and turmeric powder on internal egg quality and body parameter measurements of laying hens.

MATERIALS AND METHODS

The eggs used in this study were laid by Isa brown chicken which were sourced from CHI farm and raised under similar management techniques. Isa brown is a hybrid brown egg layer being a cross between Rhode Island Whites and Rhode Island Red. Isa brown are hardy, they adapt themselves to all climates and environment. It has an egg production rate of approximately 300 eggs per hen in the first laying year (Bukunmi and Yusuf, 2015). The experiment was conducted at the poultry house of Department of Animal Production Abubukar Tafawa Balewa University located in Gubi Village, Bauchi. A total of one hundred and eighty four (184) Isa Brown hens were used for the research which was conducted from July to October.

***Albumen Height**:* To obtain the albumen height, each egg was gently broken into two halves not to break the vitelline membrane that enclose the yolk by using a shape knife and its contents poured into a flat tray placed on a flat surface table. The height was obtained by the use of vernier calliper, the calliper stem was pierced into the albumen at its widest part at a position half way between the yolk and the outer margin and adjusted until it touched the albumen from the top and the corresponding reading was recorded as the albumen height.
Albumen Length: The albumen length was measured with the vernier calliper it was taken as a longitudinal section of thick albumen.
Albumen Diameter: The albumen diameter was measured across the wider part of the albumen using the vernier calliper.
Yolk Height: The yolk height was measured using the vernier calliper it was taken at the highest point of egg yolk. It was done the same way albumen height was obtained
Yolk Colour: The Yolk colour has been standardized by the "Roche" colour fan, which is a set of yellow coloured blades varying from a very light yellow (number 1 on the fan) to a dark or almost reddish yellow (no 14).
Yolk Lenght: This was measured as the widest horizontal circumference with a vernier calliper
***Yolk Diameter*:**Yolk diameter determined along the chalazae line was with the calliper.
After collecting egg samples, the birds were weighed individually while the shank length and comb length were measured using a rule.

Means for groups with the same superscript(s) are statistically similar S30 =0.30g, S70=0.70g $NaHCO_3$ salt, T30 =0.30g, T70=0.70g turmeric powder inclusion in the diet; N= overall 1043

Table 1 shows the results for effects of sodium bicarbonate and turmeric powder on internal egg quality. The results recovered showed that, supplementation of sodium bicarbonate salt and turmeric powder on the internal egg quality of layers did not affect albumen height (1.03± 0.2) mm, yolk height (1.73±0.2) mm, yolk index (0.51±0.00), and haugh unit (84.47±0.06) mm of the eggs.

However, significant (P<0.01) difference was noticed on Yolk diameter where 0.30g sole supplemented sodium bicarbonate salt and interaction between sodium bicarbonate salts and turmeric powder (0.30g $NaHCO_3$ and 0.70g turmeric) recorded the highest values (3.51±0.08 and 3.48±0.08), the lowest values were observed on interaction between sodium bicarbonate salt and turmeric powder 0.30g $NaHCO_3$ and 0.70g turmeric. The improvement on the yolk diameter could be as a result of the incorporation of turmeric powder as reported by Balnave and Muhereeza (1997) who incorporated NaCl with $NaHCO_3$ and sowed that the results improved internal egg quality (Yolk diameter) in different breed of pullets. The authors concluded that 1 %. Supplemental $NaHCO_3$ improved egg shell and internal qualities (Yolk diameter) in Rhode Island Red. Internal egg qualities parameters shows that Albumen height, diameter, length, index and Yolk height, diameter, index and haugh unit were significantly (P<0.01) affected the months of production. It was observed that Albumen height, index, Yolk height and haugh unit were better in August, September and October and the least values were observed in July on the various parameters. On the other hand July, September and October were the best months with the highest value in albumen diameter, while the lowest was on August. Similarly July was the best month with the highest values for albumen length and yolk diameter. More so, August had the highest value of Yolk index and the lowest value was noticed in July.

Table 2: Effects of Sodium Bicarbonate and Turmeric Powder on Body parameters measurements.

Variable (%)	N	Body weight	Shank length	Comb length
Overall		1.78±0.03	6.81±0.05	6.45±0.12
Treatment		NS	***	NS
Control	6	1.76±0.09	$6.67±0.15^{cd}$	6.53±0.37

S70T30	6	1.72±0.09	$7.37±0.15^{ab}$	6.53±0.37
S70T70	6	1.55±0.09	$6.57±0.15^{cd}$	6.22±0.37

***=P<0.001, NS=Not Significant Means for groups with the same superscript(s) are statistically similar

S30 =0.30g, S70=0.70g $NaHCO_3$ salt, T30 =0.30g, T70=0.70g turmeric powder inclusion in the diet; N= overall 60

Table 2 shows the results for effects of Sodium Bicarbonate and Turmeric Powder on Body parameters measurements. Body weight and comb length were not significantly (P>0.05) influenced by supplementation level of sodium bicarbonate salt and turmeric powder. However, shank length was affected (P<0.001) by addition of sodium bicarbonate salt and turmeric powder. It was observed that 0.70g sodium bicarbonate salt inclusion had the best longest shank length and the least was observed on 0.30g sodium bicarbonate salt and 0.30g turmeric powder combination. The inconsistency observed in the result could be as a result of turmeric powder and sodium bicarbonate combination, though best shank length noticed on 0.70g sodium bicarbonate salt could be attributed to the fact that $NaHCO_3$ plays vital role in bone formation.

CONCLUSION AND RECOMMENDATIONS

Supplementation of sodium bicarbonate salt and turmeric powder significantly improved Yolk diameter. This singular improvement will influence the overall quality of the egg and also its ability to produce better quality chicks if used for hatching purposes. Shank length was also improved significantly. Sodium bicarbonate salt and turmeric powder is therefore recommended in Isa brown hens. Further research is also recommended.

ABSTRACT

A 112-day (16 weeks) study was carried out to investigate the effects of sodium bicarbonate salt and turmeric powder on external egg quality of Isa brown hens. The experiment was conducted at the poultry unit of Department of Animal Production Abubukar Tafawa Balewa University located in Gubi, Bauchi during the rainy season from July to October. A total of one hundred and eighty four (184) Isa Brown hens were used for the research. The result showed that increasing levels of sodium bicarbonate salt and turmeric powder had no significant effect on external egg quality. Egg weight (63.76± 0.19), egg circumference (14.30± 0.12) mm, egg diameter (4.53± 0.06) mm, shell thickness (0.46± 0.4) mm and shell egg proportion (8.46± 0.10) g. July and September recorded the highest value for egg weights which shows that there were significant variations among the months of the rainy season. From the observations of this study it was concluded that increasing levels of sodium bicarbonate salt and turmeric powder had no significant effect on external egg quality of Isa brown hens, however external egg quality was significantly ($P<0.001$) different among the months of the rainy season. It was also concluded that there exist a negative correlation between egg weight and shell thickness.

Keywords: Turmeric, Sodium Bicarbonate, Egg Quality, Isa Brown

INTRODUCTION

Currently poultry are domesticated birds used for both egg and meat production. This includes birds such as chicken, turkey, duck, goose, ostrich, quail, pheasant guinea fowl and peafowl .Chickens are the most popular worldwide irrespective of culture and religion (Al-nasser *et al.,* 2007). In a natural environment, the strength of the eggshell should be able to prevent cracking in order to preserve the embryo until hatching and also for better marketability of the eggs. The size, shape and weight of the eggs also influence the quality of chicks hatched and also consumer decision to buy or not to buy. While on the farm, eggshell is important to prevent breakage from handling and to preserve egg during transport from farm to the market (Mazzuco and Bertechini, 2014). Eggshell quality is a common problem in layer stock. The eggshell consists of 98% calcium carbonate. The necessary calcium for shell formation is derived from the feed and bone. During $CaCo_3$ synthesis in the shell gland, acidosis occurs until the twenty second hour after ovulation. Considering the adverse effect of acidogenic compounds on egg shell calcification, the utilization of alkaline salt as dietary supplements can be used to improve eggshell quality. Nirat and Ratana(2005) reported that the alterations of the dietary sodium/chlorine ratio could produce metabolic acidosis or alkalosis, regardless of the total quantities of these two ions in the diet. The requirement of sodium in laying hens for optimum performance has been a subject of investigation for a number of years. Sodium bicarbonate ($NaHC0_3$) is the sodium- containing mineral compound which is currently being used in poultry feeds. Greater shell thickness or shell strength has been reported if part of the dietary sodium was provided as $NaHCO_3$ salt rather than sodium chloride (Nirat and Ratana, 2005). Mancha *et al* (2004) reported that replacement of sodium chloride (NaCL) salt with sodium bicarbonate ($NaHCO_3$) salt resulted in a definite improvement in egg shell quality. This is because sodium bicarbonate provides sodium which favourably affects blood PH and supplies beneficial bicarbonate. Turmeric on the other hand is believed to posses antioxidant activities which might reduce oxidative stress. Therefore the objective of this research was to determine the effects of sodium bicarbonate and turmeric powder on external egg quality.

MATERIALS AND METHODS

The eggs used in this study were laid by Isa brown strain of chicken which were sourced from CHI farm and raised under similar management techniques. Isa brown is a hybrid brown egg layer being a cross between Rhode Island Whites and Rhode Island Red. Isa browns are hardy and they adapt themselves to all climates and environment. It has an egg production rate of approximately 300 eggs per hen in the first laying year (Bukunmi and Yusuf, 2015). The experiment was conducted at the

poultry house of Department of Animal Production Abubukar Tafawa Balewa University located in Gubi, Bauchi. A total of one hundred and eighty four (184) Isa Brown hens were used for the research which was conducted from July to October.

Determination of external egg quality

Egg Weight: The egg weight was measured with an electronic balance to the nearest 0.01 g. Each egg was placed on the sensitive flat surface of the electronic balance, and then the reading was taken

Egg Circumference: The egg circumference of each egg was obtained by placing a rope round the egg, and then stretching the rope on a rule to take the measurement.

Egg Diameter: The egg diameter was measured with the aid of pair of Vernier calliper (mm). The egg was placed horizontally between the outer dimension jaws of the Vernier calliper, which were moved together until they secured the egg. The screw clamp was tightened to ensure that the reading did not change while the scale was being read and recorded.

Egg shell Thickness: The eggshell thickness was measured after removing the internal content of the egg, using a micrometer screw gauge which has the precision of 0.01 mm. Measurement was taken at middle of the part of shell used.

Shell Weight/Proportion: To measure shell weight/proportion, the shell with membrane was placed on the electronic scale and the reading was obtained.

RESULTS AND DISCUSSION

Table: 1 Effects of Sodium Bicarbonate salt and Turmeric Powder on External Egg Quality

*Correlation significant at P<0.05 the level (2-tailed)

**Correlation significant at P<0.01 the level (2-tailed)

Table 2 shows the correlations among external egg quality parameters. There were positive and negative correlation between external egg qualities, shank and comb length by adding sodium bicarbonate salt and turmeric powder supplementation on the parameter. However, a strong positive correlation (r =1.000; P<0.001) was observed between %HDP and feed per egg. Similarly, very low negative correlation (r= -0.067 P<0.05) was observed between egg weight and shell thickness.

CONCLUSION

From the observations of this study it was concluded that increasing levels of sodium bicarbonate salt and turmeric powder had no significant effect on external egg quality of Isa brown hens, although external egg quality was significantly different among the months of the rainy season. It was also concluded that there exist a negative correlation between egg weight and shell thickness.

HERITABILITY ESTIMATE OF BIRTH WEIGHT IN GUINEA PIG (*Cavia porcellus*)

Maigado, A. I., Ma'aruf, B. S., Shuaibu, A. & Ahmadi, B.
Department of Animal Science, Faculty of Agriculture, Federal University of Kashere, Gombe P.M.B 0182 Gombe State
Corresponding author: alinmaigado@gmail.com

ABSTRACT
The study was conducted to estimate the heritability of birth weight in guinea pigs using using half-sibs and full-sibs methods. A total of 40 piglets generated from 24 matured guinea pigs (4 males and 20 females) nested in the ratio of 1male to 5males were used for the study. After farrowing, birth weight of individual piglet was recorded using a digital weighing scale. Data generated were analyzed using analysis of variance and restricted maximum likelihood, correlation coefficients among parent and offspring birth weights were estimated. Sire had no effect on birth weight and heritability estimates of this trait using different components of variance (sire, dam and sire/dam) were low. Correlation coefficients between the parent weight and birth weight were low, negative and non-significant. This study indicated that birth weight has low transmissibility. Further research involving larger data sets should be conducted to ascertain these findings.

Key words: Guinea pig, heritability, birth weight, phenotypic correlations

INTRODUCTION
Guinea pigs are valuable species that can improve the livelihoods of smallholders (Lammers *et al.*, 2009). Food security in most parts of Africa remains a real challenge especially when quantity and quality is concerned (IFAD, 2011). As such, global poverty and food insecurity continue to remain critical (Lammers *et al*., 2009). Conventional animal species (cattle, sheep and goat) cannot meet the protein deficiency gap because their multiplication rate is not commensurate with rapid increase in human populations (Dikko *et al*., 2009). Cavies (guinea pigs) are promising mini livestock species as they require little capital or labour for keeping and management (NRC, 1991; Ngoupayou *et al*., 1995). Therefore, food from micro-livestock such as guinea pigs, snail and grass cutter could play an important role in alleviation of protein deficiency (USDA, 2007; UA, 2008). The usefulness of guinea pigs as meat producers and source of income in peri-urban (Ngoupayou *et al.*, 1995) and rural areas (Nuwanyakpa, 1993; Lukefahr, 2004) is well documented. Published research information on cavies under different ecological and socio-economic conditions is needed to clearly show that raising of such species of livestock is one way for farmers to raise income, inexpensively produce meat for home consumption and organic manure for backyard crop production (Nuwanyapka, 1997). Therefore, to increase the output obtained from this species of livestock, genetic parameter of growth traits specifically the heritability need to be estimated on which the selection response relies. Therefore, the current studies was designed to estimate the heritability of birth weight using both half and full sib methods.

MATERIALS AND METHODS
Study Area
The study was conducted at teaching and research farm of Federal University of Kashere, Gombe State. The State falls within the northern guinea savannah zone of Nigeria and is 431m above sea level. It is located between longitudes $11^0 10'$ and 11.16^0 7'east and latitudes $10^0 15'$ and 10.25^0 0' North (NPC, 2006). Gombe State has two distinct climates, the dry season (November - March) and the rainy season (April - October) with an average rainfall of 850mm/annum. Relative Humidity of 15 - 60 % in the north zone, 25 - 50 % in the central zone, and up to 80 % in the southern zones was noticed. The ambient temperature could be as low as 16.6^0 C during the dry cold season and as high as 39.4^0 C during the dry hot season (C-GIDD, 2008).

Management of the Experimental Animals and Data Collection
Twenty four guinea pigs consisting of 4 males and 20 females sourced from Jos, Plateau state Nigeria were used for this experiment. On arrival, body weight of each was recorded using electronics scale and this is repeated after two weeks prior to the commencement of the experiment. They were fed mostly forages (grass and legume mixture) and supplemented with broiler finisher diet and Vitamin C. Scanty health management was practiced and animals are kept under good environmental condition.

In each breeding group, 5 females were nested to a male and immediately after farrowing, birth weight of piglets was recorded according to sire and dam ID.

Data Analysis

Sire effect on birth weight and variance components for both sire and dam were generated using one-way analysis of variance (ANOVA) and restricted maximum likelihood (REML), respectively in general linear model (GLM) procedure of SPSS, version 25 (2017). Significantly different means were compared using the least significant difference (LSD). Model utilized to determine the sire effect was as follows:

$\mathbf{Y_i = U + S_i + e_i}$

$\mathbf{Y_i}$ = Observation on dependent variables (birth weight)
$\mathbf{U}$ = Common Mean
$\mathbf{S_i}$ = effect of ith sire
$\mathbf{e_i}$ = random error term

After estimating the components of variance, heritability was calculated according to Becker (1984) using the following formulas:

Sire Variance Component:

$$\boldsymbol{h^2(S) = \frac{4\sigma^2 S}{\sigma^2 S + \sigma^2 D + \sigma^2 W}}$$

Dam Variance Component:

$$\boldsymbol{h^2(D) = \frac{4\sigma^2 D}{\sigma^2 S + \sigma^2 D + \sigma^2 W}}$$

Sire + Dam Variance Component:

$$\boldsymbol{h^2(S+D) = \frac{2(\sigma^2 S + \sigma^2 D)}{\sigma^2 S + \sigma^2 D + \sigma^2 W}}$$

Where

h^2 = heritability
σ^2_S = Sire Variance Component
σ^2_D = Dam Variance Components
σ^2_W = Error Variance Components

The relationships between the parents (sire and dam) live weight and offspring birth weight was determined using the Pearson's product moment correlation.

RESULTS AND DISCUSSION

Average birth weight of piglets according to sire is presented in Table 1 which indicates that sire had no effect on this trait (birth weight). Heritability estimate (h^2) of birth weight from different variance components (sire, dam and combination both sire and dam) are presented in Table 2. The heritability obtained using dam component of variance (0.125) was higher compared to those of sire and sire-dam components (0.068 and 0.012, respectively). The lower heritability estimate obtained for birth weight is consistent with those reported by Canario *et al*. (2010) and Garreau *et al.* (2008) in rabbits (0.14 and 0.06, respectively). Odubote and Somade (1992) reported estimate of 0.33±0.08 for average litter birth weight which is high compared to values of 0.068 obtained in the present study. The variation from other report might have resulted from differences in genotypes, location, environmental factors and different sample sizes. Further report by Ajayi *et al*. (2014) showed that heritability estimate of birth weight is higher and more reliable than that of weaning weight (0.19±0.15 and 0.09±0.12, respectively). Similarly, Wolf *et al.* (2008) estimated a heritability of 0.10 for birth weight in light piglets. However, Randi and Scossiroli (1980) reported higher estimate of 0.455±0.348 and 0.212 from maternal half-sibs and full-sibs methods, respectively among New Zealand white rabbits. The higher value observed when dam component was used in the estimation of heritability agrees with the earlier report of Mostageer *et al*. (1970) who reported value of 0.931 from maternal half-sibs method

and attributed this fact to maternal genetic effect. Blasco *et al*. (1982) reported values of 0.73±0.26 from maternal half-sibs for individual weight at 21 days and related it to maternal genetic effect which is believed to have originated from mitochondrial DNA of ovum (Sato and Sato, 2013). The correlation coefficients between parent weight and off-springs birth weight is shown in Table 3 and were negatively low and not significant, this indicated that off-spring birth weight cannot be predicted from parents' live weight. It also implies that genetic correlation between the two traits is low. This is in agreement with the work of Odubote and Somade (1992) that live weight of parent had no significant relationship with birth of off-spring in rabbits.

Table 1: Effect of sire on birth weight

Sire ID	Birth weight (g)
1	75.00±5.00
2	82.50±6.61
3	79.17±2.39
4	78.00±2.00
LOS	NS

NS = Non-significant

Table 2: Heritability estimates of birth weight from different components

Components	h^2
Sire	0.012
Dam	0.125
Sire + Dam	0.068

h^2 = heritability

Table 3: Correlation coefficients between parents' weight and off-spring birth weight

Parent weight	Birth weight
Sire	-0.322^{NS}
Dam	-0.132^{NS}

NS = Non-significant

CONCLUSION

From the findings of this study, it can be concluded that sire had no effect on birth weight; heritability estimate of this trait was low and parent and offspring birth weights cannot indicate each other

ABSTRACT
The experiment was conducted using three strains of layers; Isa brown, nera black and noiler (60 each) to compare their egg quality traits of the three strains. The birds were fed with commercial feed and the study lasted 6 weeks. Each strain was randomly allocated into four replicates consisting of 15 birds per replicate in Completely Randomized Design (CRD). Two eggs were collected daily from each replicate per week to determine egg quality. The internal egg quality parameter were accessed after breaking and separating each of the components, the parameter considered for internal egg quality were yolk colour, yolk length and weight. Egg weight, length and width, shell weight and thickness were considered for external egg quality. A non significant influence of strain was detected in all parameters recorded except egg production, egg weight, yolk weight and yolk colour that were significant ($p<0.05$) among the strains. Isa brown had the significantly higher ($p<0.05$) egg production (80.57%) while noiler strain had the lowest value of 57.47%.Noiler recorded the highest values for egg weight (63.80g) and yolk weight (32.17g) while Isa brown had the lowest (58.00g and 28.11g, respectively)Values recorded for egg length, egg breadth, shell weight, yolk length and shell thickness were not significantly affected by the strain of layers and the ranges were 5.17 - 5.35mm, 3.80 - 4.10mm. 7.36 - 7.54g, 1.89 – 2.09mm and 0.34 – 0.36, respectively. Conclusively, egg production of noiler was poor, but other egg qualities were better.
Keywords: Poultry, Isa brown, Nera black, Noiler, Egg Quality.

INTRODUCTION
The internal and external egg quality traits are of major importance to the egg industry worldwide (Ahmadi and Rahimi, 2011). Some researchers have studied the chicken egg quality from different perspectives. It has been reported that the quality of the chicken egg is influenced by genetic and non-genetic factors such as season, environment and feed intake (Ahmadi and Rahimi, 2011). Egg quality traits had been reported to influence embryo development, hatchability, and growth performance of chicks (Khan, 2002). There are reports on the relationship between egg size and egg quality characteristics (Sarica *et al.,* 2012; Abanikanda, 2007). Egg quality characteristics are affected by genotype and age (Zita *et al.,* 2009). According to Pradeepta *et al.* (2015), egg shell thickness of at least 0.33 mm was necessary for the eggs to have at least a 50% chance to stand without breakage under normal handling condition. The shell thickness and porosity help to regulate the exchange of carbon dioxide and oxygen between the developing embryo and the air during incubation (Roque and Soares, 1994). However, yolk colour is a function of feed not breeds Garba *et al*. (2016).Pradeepta *et al.* (2015) reported that white Leghorn had optimum egg weight (57.78g) with albumen height (8.41mm} and H.U. (92.00) and Roberts and Leary (1999) reported that albumen quality was influenced by many factors such as storage time, temperature, environmental conditions , hen age, strain of bird and nutrition. This study evaluated egg quality traits of three different strains of layers.

MATERIALS AND METHODS
The experiment was carried out at Oyo State College of Agriculture and Technology poultry unit of Teaching and Research Farm. A total number of 180, thirty week old birds consisting of 60 each of Noiler, Isa Brown and Nera black strains were obtained from poultry unit of the college farms and used for the study. The layers were allotted to three treatments with four replicates each and fifteen birds per replicate. The birds were fed commercial layer feed for the six weeks. Two eggs were collected daily from each replicate for six weeks to determine egg quality. The parameters considered were egg production, egg weight, egg length, egg breadth, shell weight, and shell thickness. The internal egg quality parameters were assessed after breaking and separating each of the components, the parameters considered were yolk colour, yolk length, and yolk weight.

Results and discussion

Results of the egg quality of the three strains were represented in table 1 and showed the egg weight, egg length, egg breadth, shell weight, yolk weight, yolk length, yolk colour, and shell thickness. Significant ($p<0.05$) effect of strain on egg production, egg weight, yolk weight and yolk colour among the strains was observed. Isa brown had the significantly highest egg production (80.57%) while noiler strain recorded the lowest value of 57.47%. Egg and yolk weight of noiler were the highest (63.80g and 32.17g, respectively) and significant to values recorded for isa brown (58.03g and 28.50g, respectively) and nera black (59.72g and 30.59g, respectively). Yolk weight as a percentage of egg weight was not significant. Yolk colour scores of isa brown (4.86) and nera black (4.35) were similar but higher than value recorded for noiler (2.23). Values recorded for egg length, egg breadth, shell weight, yolk length and shell thickness were not significantly affect by the strain of layers and the ranges were 5.17 - 5.35mm, 3.80 - 4.10mm. 7.36 - 7.54g, 1.89 – 2.09mm and 0.34 – 0.36, respectively.

DISCUSSION

The non significant effect of strain on most egg quality traits contradicted the report of Zita *et al*., (2009) who reported that egg quality characteristics are affected by genotype and age. Pradeepta *et al.* (2015) found eggs collected from 40 weeks aged white Leghorn hens have optimum egg weight (57.78g), and shell characteristics (6 g, 0.32 mm). The quality of eggs depends on physical make up and chemical composition of its constituent parts (Chukwuka, 72011). According to Tadesse *et al*. (2013) the difference in egg shell thickness was due to layer strain difference and Zita *et al*. (2009) reported that difference in egg shell thickness was the effect of layer type difference, environmental conditions and feed quality.

The egg length of isa brown was the highest value and the lowest was recorded in noiler which showed no significant difference. The egg breadth had no significant effect and was similar to that reported value by Roberts and Leary (1999). The shell weight showed no significant difference ($p>0.05$), the shell thickness was also not significantly affected ($p< 0.05$) by the strains

Yolk colour was significantly affected by strain with noiler recorded the lower value than isa brown and nera black strains. This contradicted Garba *et al*. (2016) who stated that yolk colour is a function of feed and not breeds.

Table 1: Egg quality characteristics of the three strains experimental layers

Parameters	Isa brown	Black near	Noiler	SEM
Hen day production (%)	80.57[a]	72.45[b]	57.47[c]	2.51
Egg weight (g)	58.03[b]	59.72[b]	63.80[a]	1.92
Egg length (mm)	5.35	5.36	5.17	0.08
Egg breadth (mm)	4.10	4.20	3.80	0.28
Shell surface area mm^2	14.96	15.56	16.96	0.27
Albumen weight (g)	34.16	36.94	37.59	0.85
Albumen percentage (%)	57.52	54.78	55.25	1.07
Shell weight (g)	7.54	7.40	7.36	0.45

Shell percentage (%)	14.11	14.73	12.59	1.03
Yolk weight (g)	28.50[c]	30.59[b]	32.17[a]	0.44
Yolk percentage (%)	20.69	20.68	20.60	0.79
Yolk length (mm)	2.09	2.08	1.89	0.09
Yolk colour	4.86[a]	4.35[a]	2.23[b]	0.29
Shell thickness (mm)	0.34	0.36	0.35	2.25

[ab] means on the same row with the different superscripts were significantly different ($p<0.05$)

There were no significant differences in all the strains as regards the egg shell thickness and ranged between 0.34 and 0.36, this confirmed the report of Khan *et al*. (2002) who stated that eggshell thickness between 0.33 and 0.35 mm will support hatchability. Egg production was affected by strain, isa brown had the highest value and the lowest was from noiler strain. Genetic variation in egg production between breeds, strains and lines had been reported (Hocking *et al.,* 2003). Egg weight was significantly different, the highest value was recorded in noiler and the lowest value was isa brown. Egg size as an external trait is affected by factors such as maturity, weight, age of flock, breed / genotype, diseases, nutrition and level of feeding. The increase in egg size with age is a result of increase in the yolk size, albumen and shell weight, although these increases are not proportional (Roberts and Leary, 1999). Egg size can also be affected by nutrition, the intake of protein, specific amino acids such as methionine and lysine, energy, total fat and the essential fatty acids, linoleic acid.

ABSTRACT
A study was conducted to investigate the ages and body weights at puberty of four strains of turkeys reared in Nigeria. The four strains comprised 1 exotic strain (White Nicholas, WN) and 3 local strains (White, black and silver plumage colours). A total of eighty (80) turkeys were used comprising 10 toms and 10 hens each of White Nicholas turkeys, White Local turkeys, Silver Local turkeys and Black Local turkeys. All the animals were fed 5% of their live body weights and water was given *ad libitum*. The age at puberty for the toms was determined as when first ejaculate containing viable sperm cells while that for hens was the age at first lay of egg. The trial was done in a completely randomized design (CRD). Data collected were subjected to analysis of variance. The results of the study showed that there were significant ($P<0.05$) strain effect on average daily weight gain, feed intake, feed conversion ratio and ages at puberty in both toms and hens. It was concluded that strain differences with respect to growth performance and age at puberty exist. It was concluded that strain differences affected age and body weights of toms and hens at puberty.
Keywords: Age, body weight, strain, puberty, turkeys

INTRODUCTION
Puberty in animals is sex dependent. Most definitions of puberty capture the female animal more than the male animal. However, it can be defined, in the male, as the time when fertile spermatozoa are in the ejaculate (Bearden and Fuquay, 1997) and in the female as the age at the first oviposition.The age at puberty is influenced *inter alia* by breed, genetic selection, nutrition, season of birth, as well as body size (Jafari and Hashemi, 2014). Thus, determining the age at puberty of male and female turkey genotypes commonly reared in Nigeria will facilitate adequate planning of breeding/multiplication of the various types for meat production.
Turkeys commonly reared in developing countries can be classified by their genotype or plumage colours (Thears, 2007). Several plumage colours of turkey genotype exists which include black, bronze, brown, red and white (Schoger, 1964) with black, bronze and white predominantly existing in the tropical environment (Okoro, *et al.*, 2012). Commercial turkey production in Nigeria is still rudimentary. The reason for this apparent low production seems to be lack of appreciation of its potential role in animal protein generation (Abeke and Ubani, 2008). Nevertheless, the full potentials in turkey cannot be harnessed until we come to terms with their reproductive capacities which include age at puberty.
The assessment of the semen quality characteristics of the poultry species gives an excellent indicator of their reproductive potentials and it is a *sine qua non* to effective artificial insemination programme (Zahraddeen *et al.*, 2005).
The study aimed at evaluating the ages and body weights at puberty of four strains of turkeys reared in Nigeria.

MATERIALS AND METHODS
The study was conducted at the Poultry Unit of the Department of Animal Science Teaching and Research Farm, University of Nigeria, Nsukka.A total of eighty (80) turkeys were used comprising 20 White Nicholas turkeys (10 toms and 10 hens), 20 White Local turkeys (10 toms and 10 hens), 20 Silver Local turkeys (10 toms and 10 hens), and 20 Black Local turkeys (10 toms and 10 hens). Initial body weight values were taken and subsequent weights were taken with a weighing scale and recorded every four weeks till the age at puberty. The age at puberty for the toms was determined as when first ejaculate containing viable sperm cells were collected while that for hens was the age at first lay of egg. The training of toms for semen collection started at twenty weeks of age and their responses were monitored. Semen quality evaluation to determine semen volume and progressive motility were carried out immediately the toms reached puberty. Semen samples were collected from the 10 toms in each of the strains and pooled for analysis. Semen was collected by using the

abdominal massage technique as described by Burrows and Quinn (1937) which was slightly modified in this experiment by tying the two legs with a rope and pegging the rope to the wall to enable one collector in the process as opposed to two persons in the method described by Burrows and Quinn (1937). In Burrows and Quinn's method, two collectors are involved. One is the massager who places the tom on his laps and the other is the collector who grabs the legs of the tom and scoops the semen with the centrifuge tube when it flows. The modification here uses one man for collection as opposed to two-man method by excluding the holder and collector. With this, the massaging, holding and collection can be done by a single person and it saves the cost of paying the second person. Semen quality traits with respect to volume and motility evaluated. This experiment was carried out using a completely randomized design (CRD) with the model below;

$Y_{ij} = \mu + T_i + e_{ij}$

Where;

Y_{ij} = Individual observation;

μ = Population mean;

T_i = Treatment effect, and;

e_{ij} = Experimental error associated with observation.

The data collected on body weights, ages at puberty and semen quality traits were subjected to Analysis of Variance (ANOVA) using the Statistical Package for Social Sciences (SPSS, 2010). Significantly different means were separated using Duncan's New Multiple Range Test (DNMRT) (Duncan, 1955).

RESULTS AND DISCUSSION

The results on ages and body weights of toms and hens and semen volume and sperm motility of toms in four strains of turkeys are presented in Tables 1, 2 and 3.

Table 1: Ages and body weights at puberty of the toms

Parameters/Strains	WN	Black	White	Silver	SEM
Age (days)	189.00±1.41[a]	183.00±1.41[c]	161.00±1.41[d]	175.00±1.41[b]	3.98
Body weight at puberty (k	15.00±0.00[a]	6.81±0.00[c]	6.19±0.00[b]	6.15±0.00[d]	1.42

a, b, c, d means with different superscripts in rows for different traits are significant (P<0.05). WN=White Nicholas.

Age at puberty of toms

The mean age at puberty for the four strains of toms ranged from 161.00±1.41 days – 189.00±1.41 days. White local toms were the first to attain puberty while the WN toms were the last to attain puberty. The results of this study disagree with the findings of Eaton (1992) that toms breed at 10 months of age (280 days). The White local toms with least mean age at puberty is advantageous as it breeds earlier. The reason for this may be because in both animals and humans, the age at puberty appears to be related more to body weight at maturity than to chronological age (Baker, 1985).

Body weight of toms at puberty

The mean body weights of toms at puberty showed significant (P<0.05) differences among all the strains and ranged from 6.15±0.00 kg – 15.04±0.00 kg. The highest mean weight of 15.04±0.00 kg was recorded in WN toms and the least mean value of 6.15±0.00 kg was recorded in Silver local toms. This may imply that body weight at puberty is influenced by the genetic background of the animal with more genetically endowed individuals reaching puberty at higher body weight (Bearden *et al.*, 2004).

Table 2: Ages and body weights at puberty of the hens

Parameters/Strains	WN	Black	White	Silver	SEM
Age (days)	195.00±1.41[a]	192.00±1.41[a]	188.00±1.41[b]	176.00±1.41[c]	2.76
Body weight at puberty (k	9.52±0.00[a]	4.15±0.00[b]	3.41±0.00[d]	3.57±0.00[c]	0.96

a, b, c, d means with different superscripts in rows for different traits are significant (P<0.05). WN=White Nicholas.

Age of hens at puberty

The mean ages of hens at puberty showed significant (P<0.05) differences with the range being 176.00±1.41 – 195.00±1.41 days. The highest mean value of 195.00±1.41 days was recorded in WN hens with the least mean value of 176.00±1.41 days recorded in Silver local hens. The results of this study agrees with the findings of Siopes (2010) who reported the age at lay for hens to be within the range of 24-30 weeks (168-210 days). However, the results disagree with the findings of Eaton (1992) that hens lay eggs at 10 months of age (280 days or 40 weeks). The Silver local hens that commenced laying earlier than others may imply that whether for breeding or for table egg production, they may give more profitable returns to the farmer than other strains. This trait is of considerable economic advantage and should be selected for in a planned genetic improvement of the local turkey.

Body weight of hens at puberty

The mean body weight values for hens ranged from 3.41±0.01kg – 9.52±0.00kg with significant (P<0.05) differences occurring among the strains. The highest mean value of 9.52±0.00 kg was recorded in WN hens and the least mean value of 3.41±0.01kg was recorded in White local hens. This may imply that for meat production, WN hens are more efficient than other strains. It is important to note that the highest body weight attained by the indigenous strains was obtained in Black local hens (4.5 kg). The range of body of body weights at puberty in local strains (3.41 – 4.15 kg) are generally lower and suggest that they are in the light ecotype category of turkeys.

Table 3: Semen volume and progressive motility of the toms at puberty

Parameters/Strains	WN	Black	White	Silver	SEM
Semen Volume (ml)	0.43±0.04[a]	0.28±0.04[b]	0.23±0.04[b]	0.43±0.04[a]	0.04
Progressive Motility (%)	85.00±7.07	85.00±7.07	95.00±7.07	85.00±7.07	0.50

a, b means with different superscripts in rows for different traits are significant (P<0.05). WN=White Nicholas.

Semen volume

The mean semen volumes in the local strains and WN strain studied ranged from 0.23±0.04 – 0.43±0.04 ml. The highest mean volume of 0.43±0.04 ml was recorded in WN toms and Silver local toms and the least mean volume of 0.23±0.04 ml was recorded in White local toms. The results recorded in Black and Silver local toms were in tandem with the results of Zahraddeen *et al.* (2005) and Ogbu *et al.* (2016) who found the ranges of 0.17-0.32 ml in local and exotic strains of turkeys and 0.21-0.38 ml in local toms fed zinc and selenium supplemented diets. However, the 0.43 ml recorded in WN and Silver local toms disagrees with the findings of the above researchers. Ogbu *et al.* (2016) did not consider WN toms in their work and both researchers considered local strains collectively as local breed.

CONCLUSION AND RECOMMENDATIONS

It was concluded that strain differences affected age and body weights of toms and hens at puberty. For meat production in Nigeria, WN turkeys are recommended while for breeding, white local toms and silver local hens are recommended.

ABSTRACT
A total of two hundred and twelve (212) days trial was conducted to evaluate the effect of Moringa olerifera leaf and seed extracts on egg qualities of female local turkeys. A total of 36 female local turkeys of about 8 - 9 weeks old were used for the study. There were nine turkeys per treatment group, grouped as; T1 (control no extract), T2 (1% seed w/v), T3 (0.5% leaf and 0.5% w/v) and T4 (1% leaf w/v). Each group was replicated three times with three turkeys per replicate. Data collection was done on the external and internal qualities of the egg as well number of eggs laid during the trial period. On the external egg qualities, only the shell weight and the shape index differed significantly (P < 0.05). The weight of the shell was improved by the administration of Moringa extract. All the internal egg qualities (percent shell, yolk weight (g), yolk diameter (mm), yolk depth) did not differ significantly (P>0.05). Egg lying was highest in T3 while T2 (122) had the least number of egg. Therefore, from the results of the experiment, it could be safe to say that the egg quality were not affected by the Moringa per se, but the egg lying ability was improve most by combination of the leaf and seed extracts.
Key words: Turkey, Egg, *Moringa olerifera.*

INTRODUCTION
Moringa oleifera belongs to the order Brassicalis and family,*Moringceae* (Mgbemena and Obodo, 2016). It is a called "Zogale" in Hausa "Ewe ile" among the Fulanis and "Okwe oyibo" in Igbo (Olagbemide and Philips, 2014). It is also called Horseradish (Alemede *et al.,* 2014) and miracle plant. *Moringa oleifera* is a multipurpose plant that is widely cultivated species among *Moringa* plants throughout the tropics (Junick and Robert, 2008). The leaves and seeds of *Moringa* have been used to cure many diseases due to their anti-ulcerative (Pal *et al.,* 1995) anti-hypertensive (Dahot, 1988) anti-oxidant (Nickon *et al*., 2003) and anti-diabetic (Sahoo, *et al.,* 2014) properties. According to Nickon *et al.,* (2003) it also possesses antibacterial cum anti-fungi properties. Even folk medicine practioners use the plant in curing tumors (Gupta *et al.,* 2005). Nutritionally, the fresh *Moringa* leaves contain more than twice the amount of protein (2.8g/100g) found in spinach (Olugbemi *et al*. 2010). The leaves contain magnesium, potassium and all the essential amino acids like cysteine, histidine, arginine, methionine, lysine, phenylalanine, leucine, isoleucine and valine (Alemede *et al.,* 2014). It also has anti-oxidants like $\beta - carotinoids$, lutein and xanthine (Fuglie, 1999). Hence using it to improve the fertility of local female turkeys wouldn't be a bad idea.

MATERIALS AND METHODS
The experiment lasted for 212 days. It was approved and supervised by the Michael Okpara University of Agriculture Umudike College of Animal Science Research and Experiment committee and was carried out at the Poultry unit of Chirex Agro Services Limited in Abakuru, Ohaji-Egbema Local Government Area of Imo State Nigeria.

Collection and Preparation of Experimental material

The freshly harvested leaves and seeds were sorted to remove contaminants sand particles and dead matter. They were shade dried in an open well ventilated room for about one week at room temperature. The seeds and the foliage were ground separately into powder and stored in separate clean dry containers. Treatment one (T_1) was the control group with no *Moringa* powder. One gram of the seed powder was diluted in 1000mls of clean water, sieved with cheese cloth and served as drinking water for treatment two (T_2). Treatment three (T_3) had 0.5g of leaf powder and 0.5g seed powder diluted with 1000mls of clean water sieved with cheese cloth and served as drinking water. One gram of the leaf powder was diluted in 1000mls of clean water, sieved with cheese cloth and served as drinking water for treatment four (T_4).

Experimental Animals and management.

Thirty six (36) local female strains of turkeys of white, black and lavender plumage averagely eight (8) weeks old were used for the study.

The local turkeys were procured from a reputable farm, in Anambra State. Before commencement of the experiment, the local turkeys were quarantined and allowed to acclimatize for 14 days in the Poultry unit. During the acclimatization period, the turkeys were given routine management practices which included deworming with Ivermectin solution (1%w/v) against endo and ecto parasites. Suitable vaccinations for their age were also given prior to the commencement of the experiment.
The treatment groups were administered 0 gram of *Moringa* (T_1), 1 gram of *Moringa* seed alone (T_2) combination of 0.5g of *Moringa* seed and 0.5gram of *Moringa* leaf (T_3) and lastly 1 gram of *Moringa* leaf alone (T_4) . Experimental material was given to the female turkeys at 10 weeks of age. The treatment was administered to the turkeys via drinking water between hours of 7am to 10am after which they were given clean drinking water throughout the rest of the day. The turkeys were given commercial feed during the first 14weeks of the experiment. From 24 weeks of age formulated ration in Table 1 was used. The feed sample was determined to ensure quality assessment in Table 1 by livestock feeds Plc with the aid of the apparatus; DA1650 near infra-red Spectrophotometer.

Vitamin A (Iμ) 12,500.00, Vitamin D_3 (iμ) 2,500,000.00, vitamin E (mcg) 40,000.00, Vitamin K_3 (mg) 2,000.00, vitamin B (mg) 3,000.00, vitamin B_2 (mg) 5,500, vitamin B6 (mg) 5,000, Nicocin (mg) 55,000.00, calcium pantothenate (mg) 11,500.00, Vitamin B_{12} (mg) 25,000, Chlorine Chloride (mg) 500,000.00, Folic acid (mg) 1,000.00, Biotin (mg) 80.00, Manganese (mg) 120,000.00, Iran (g) 100,000.00, Zinc (mg) 80,000.00. Copper (mg) 8,500.00, Iodine (mg) 1,500.00, Cobalt (mg) 300.00, Selenium (mg) 120.00, Antioxidant (mg) 120,000.00.

Experimental Design
The experiment was completely randomized design (CRD). It consisted of four treatments; T_1, T_2, T_3 and T_4 containing 0g, 1g of seed, combination of 0.5g of seed and 0.5g of leaf and 1gram of leaf, respectively. There were nine male turkeys in each treatment with 3 replicates of 3 turkeys per replicate.
Data Collection
As from 196 days of age (126 days into the study) that egg laying started. Egg collection was done three times per day and each of the collected eggs was labeled. The eggs were stored in a clean crate at room temperature and were analyzed within 48 hours of collection.
a. External egg parameters
Egg weight and shell weight were determined with the aid of Ohaus electronic weighing scale. The egg length and width were measured with venier calipers. Shell thickness was measured with micrometer screw gauge. Egg volume was ascertained using the Archimedes principles of water displacement.

b. The Internal egg parameters

The yolk diameter, albumen depth were measured with the Venier calipers.

The yolk weight, albumen weight were weighed with Ohaus electronic scale. The yolk; albumen ratio was obtained by; $\frac{\text{Yolk weight}}{\text{Albumen Weight}}$.

$$\text{Percent Yolk} = \frac{\text{Weight of Yolk}}{\text{Weight of whole Egg}} \times 100$$

$$\text{Percent Albumen} = \frac{\text{Weight of albumen}}{\text{Weight of whole egg}} \times 100$$

Specified gravity of the egg was obtained by dividing the weight of the egg by the weight of equal volume of water displaced by the egg.

$$\text{Specific Gravity (Sg)} = \frac{\text{Weight of Egg}}{\text{Volume of Egg}}$$

$$\text{Egg Shape Index (EI)} = \frac{\text{Weight of Egg}}{\text{Length of Egg}}$$

$$\text{Percent Shell} = \frac{\text{Shell Weight}}{\text{Egg Weigth}} \times 100$$

Results and Discussion

Table 2: Mean Values of external Egg parameters of female Turkeys administered *Moringa* leaf and seed extracts.

Parameters	**T_1**	**T_2**	**T_3**	**T_4**
Egg Weight (g)	63.18±0.48	62.18±1.32	64.27±1.37	65.93±1.92
Egg Length (g)	59.26±0.39	60.43±0.67	59.55±0.32	60.69±0.79
Egg width (g)	44.34±0.67	42.943±0.32	44.21±0.93	44.20±0.58
Shell weight (g)	7.69 ± 0.40^{ab}	7.033 ± 0.32^{b}	7.63 ± 0.35^{ab}	8.12 ± 0.096^{a}
Shell Thickness (mm)	0.65±0.08	0.6800±0.04	0.68±0.09	0.79±0.11
Shape Index	0.75 ± 0.02^{a}	0.7103 ± 0.00^{b}	0.74 ± 0.01^{ab}	0.73 ± 0.00^{ab}
Egg Volume	60.58±1.15	59.447±1.75	61.62±1.36	62.98±2.22

Means with different superscripts [a, b, c] or [d] on the same row are significantly different (P<0.05).

The result of the mean values of external egg parameters of female local turkeys administered *Moringa* leaf and seed extracts were shown in Table 2. The egg weight, egg length, egg width, shell thickness as well as egg volume were not significantly (P > 0.05) affected by the administration of *Moringa* leaf and seed extracts. Egg shape index was negatively influenced by *Moringa* extracts significantly (P<0.05) when compared with the control. The shell weight, shape index and length increased better in the *Moringa* leaf extracts than on the seed extracts as well as combination of both leaves and seeds effect. The egg weights were within the range of 62.3-79.5 reported by Adeyeye (2009) on turkeys. This was also consistent with the report of Kakengi *et al.* (2007) and the work of Teteh *et al*. (2016) report on ISA Layers with *Moringa* leaves. These improvements may be due to rich amino acid profile found in the leaves of *Moringa*. Gupta *et al*. (2005) and Foidl *et al.* (2001) observed that anti-nutrients like and oxalates have less chelating effect on feed calcium, hence improves calcification of egg shells.

Table 3: Mean Values of Internal Egg parameters of female Turkeys administered Moringa leaf and seed extracts.

Parameters	**T_1**	**T_2**	**T_3**	**T_4**
Percent Shell	12.17±0.60	11.33±0.65	11.85±0.40	12.41±0.23
Yolk Weight (g)	20.33±0.84	19.67±0.17	19.67±1.16	21.11±0.49
Yolk Diameter (mm)	40.49±0.28	40.92±0.63	40.51±1.03	42.50±0.90
Yolk Depth (mm)	14.89±0.59	14.88±0.63	15.03±0.36	15.41±0.56
Percentage Yolk	32.19±1.37	31.65±0.42	30.61±1.69	32.19±1.10
Albumen Weight (g)	34.56±0.80	34.33±0.83	36.89±1.17	40.82±4.22
Albumen Depth (mm)	9.10±0.93	9.45±0.23	9.58±0.46	10.22±0.73
Percent albumen	54.67±1.24	55.17±0.43	57.33±1.13	56.77±1.73
Albumen : Yolk Ratio	0.59±0.04	0.57±0.01	0.54±0.04	0.57±0.021
Specific Gravity	1.07±0.05	1.05±0.02	1.04±0.02	1.05±0.01

Means with different superscripts [a, b, c] or [d] on the same row are significantly different (P<0.05).

The results of mean internal egg qualities of local female turkeys administered *Moringa* leaf and seed extracts are shown in Table 3. The percent shell, yolk weight, yolk diameter, yolk depth, percentage yolk, albumen weight, albumen depth, percentage albumen, albumen to yolk ratio specific gravity did not differ significantly (P>0.05) among the treatments. This confirms the report of Teteh *et al.*, (2016) on ISA layers who observes that 1% *Moringa* leaves level of inclusion improved the egg qualities of the birds. According to the reports of Gupta *et al*. (2005) and Foidl *et al.* (2001) the level of the leaves extracts should be low so as not to attract the effect of anti- nutrients like phylates and oxalates which usually leads to chelating effect on feed calcium hence reducing shell quality, this incidence was not witnessed in our study.

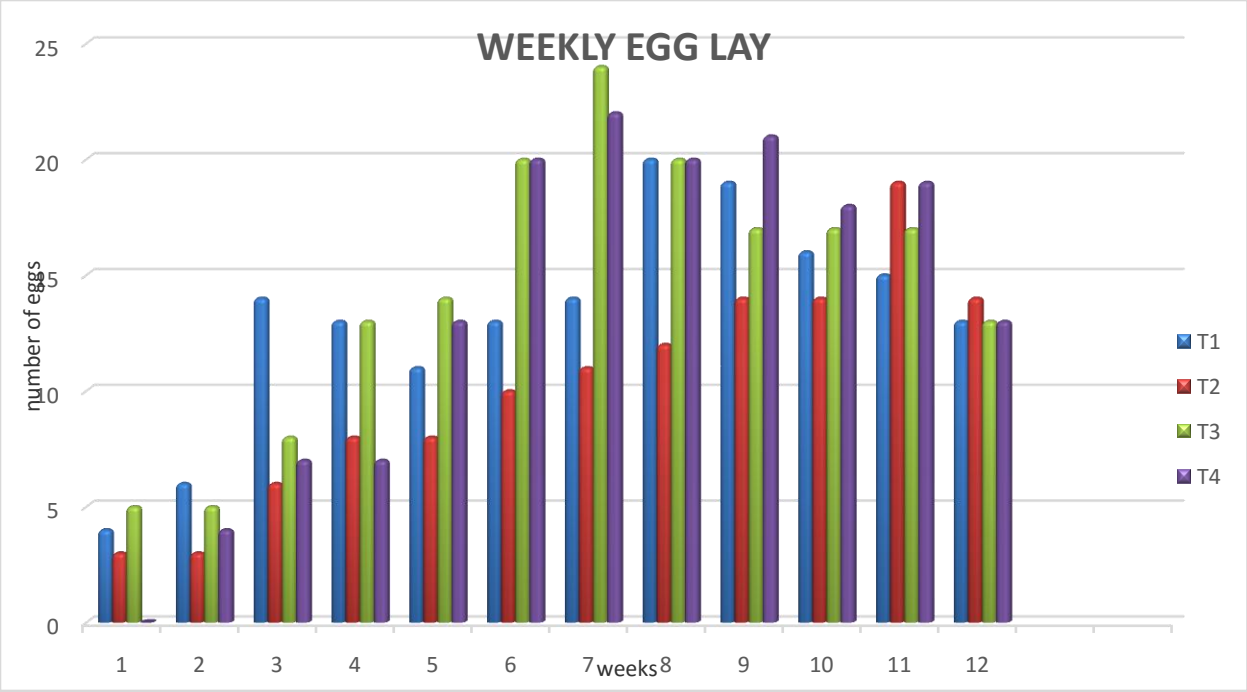

Figure 1: Weekly egg lay of female turkeys administered *Moringa* leaf and seed extracts

Egg production was increased by the combination effect of *Moringa* leaf and seed extracts with 173 eggs laid in 12weeks (figure 1).Turkeys administered leaf extracts alone laid 164 eggs, followed by the control groups which laid 154 eggs and the seed extracts alone laid 122 eggs. These results show that combination of leaf and seed extracts treatment mostly improved the turkey hen egg laying ability. This may be due to the rich steroid content of the leaves and seeds of *Moringa*, which supported egg lying. These results confirms the reports of Yakubu *et al.* (2014) who claimed that the

intake of some amount of estrogenic substances in *Moringa oleifera* inhibits the secretion of LH (Luteinizing hormone) and FSH (follicle stimulating hormone) and reduces, subsequently, endogenous oestrogen and progesterone levels. Hence these lower levels of sexual hormone may have played a serious role in the lower number of follicles and low weight of ovarian grape and oviduct seen in T_4 group. Therefore combination of the two extracts brought better results in terms of egg laying ability of the female turkeys. Although lower egg laying ability of T_2 might be due to anti-nutrients which is nutritional problem that have been observed by Nys and Guyot (2011) to be responsible for reduced rate of egg production synthesis that is very sensitive to these nutritional abnormalities.

CONCLUSION

The study on effect of *Moringa olerifera* seed and leaf extract on the egg quality of local female turkeys show that *Moringa* leaf (T4) improved egg shell weight most. Combination of leaf and seed extracts improved the egg lying ability most. Therefore to improve number of eggs laid among female turkeys there is need to use *Moringa olerifera* seed and leaf extracts at 0.5%leaf and 0.5% seed w/v.

ABSTRACT

The study was carried out to evaluate genetic diversity of selected chicken breeds in Nigeria focussing on the chicken growth hormone gene locus. The chickens studied were: Fulani ecotype, FUNAAB Alpha, frizzled feathered, Noiler and Cobb 500 broilers chicken. Genomic DNA was extracted from blood samples collected from 50 chickens (10/chicken breed). The extracted DNA was amplified using PCR and the gene sequenced. The sequenced data was used to evaluate genetic diversity and to carry out phylogenetic analysis. Results showed that the mean number of alleles (Na), mean number of effective alleles (Ne), mean Shannon information index (I), mean observed heterozygosity (Ho), mean expected heterozygosity (He), mean unbiased expected heterozygosity (uHe), mean fixation index (F) and % polymorphic locus were 2.000±0.000, 1.956±0.014, 0.682±0.004, 0.449±0.067, 0.489±0.004, 0.516±0.004, 0.083±0.138 and 100%, respectively. The gene flow (Nm) for all the population was 13.141. Results of Analysis of Molecular Variance (AMOVA) showed that the percentage of molecular variance among and within individuals was 13 and 87%, respectively. Phylogenetic analysis divided the five chickens into two broad claves; Noiler and the frizzled feathered occupied one while, the Fulani ecotype, FUNAAB Alpha and Cobb 500 occupied the other. It was concluded that great genetic diversity exists in the chicken breeds which could be exploited for further improvement especially in the more native breeds.

Key words: Genetic diversity, chickens, growth, hormone, gene locus.

INTRODUCTION

Growth performance and associated traits such as carcass traits are very important economic characters in broiler chickens production, and they are controlled by sets of multifarious genes. Growth is a very complicated procedure which is synchronized by an extensive network of neuroendocrine pathways. It is therefore very difficult to make rapid progress using more conventional methods of genetic selection within breeds (Zhang *et al.,* 2008). Recent advances in molecular technology have however provided new lee ways to evaluating genetic variability existing at the DNA level of animals (Kaya and Yildiz, 2008). The candidate gene approach has become a very powerful technique for genetic improvement in chicken breeding programmes. Applying this approach (the candidate gene approach), will likely result in higher efficiency in the detection of desired traits necessary to improve productive performances. The chicken growth hormone (*cGH*) gene located on chromosome 27, is one of the most promising candidate genes for improving growth performance and carcass quality traits in chickens (Anh *et al.,* 2015). Growth hormone and the transforming growth factor-β subfamily are the most important groups of hormones that play key roles in many physiological functions such as growth and reproduction. The *cGH* is a 22-kDa protein, consisting of 191 amino acid residues (Hrabia *et al.,* 2008). The *cGH* gene contains four exons and five introns with an overall length of 4.1kb (Kansaku *et al.,* 2008). A cursory look at the growth performance of the various chickens reared in Nigeria will show that they do not grow at the same rate. Could it be that differences exist in the *cGH* of the chickens manifesting in differential performances of the birds especially between the exotic and the more indigenous ones? It is with this in hindsight that the current study was conceived to evaluate genetic diversity at the *cGH* gene locus focussing on selected chicken breeds.

MATERIALS AND METHODS

Blood samples were collected from 50 chickens, 10 each of Fulani ecotype, FUNAAB Alpha, frizzled feathered, Noiler and Cobb 500 broilers chicken. The blood samples kept on ice packs were transported to the laboratory (African Biosciences, Ibadan, Oyo State, Nigeria) where genomic DNA was extracted using the protocols of gSYNC™ DNA extraction kit (Geneaid). The extracted DNA was checked for quality and then PCRed. The PCR products were sequenced and then aligned against the chicken genome using the BLAST programme to verify their identity. Prior to sequencing, the DNA were cleaned to ensure that the gene is not contaminated with impurities. This was done using DNA clean and concentrator kit according to the manufacturers protocol (ZYMO Research). The measurement of genetic diversity including Na, Ne, Ho, He, uHe, I, % polymorphic locus, F and AMOVA were estimated using GenAlEx 6.2 software (Peakall and Smouse, 2012). Dendrogram based on Nei's unbiased genetic distances, using the unweighted pair group method with arithmetic mean (UPGMA), was generated to show the genetic distances of the populations or subpopulations was generated using MEGA X.

RESULTS AND DISCUSSION

The genetic differentiation at the *cGH* gene locus of the chicken breeds is presented in Table 1. The FUNAAB Alpha and Cobb 500 had lower Ne (1.923), I (0.673), He (0.480) and uHe (0.505). The lowest Ho (0.200) was observed in the Cobb 500 while the highest F (0.583) was observed in the Cobb 500 broilers chicken. The entire gene locus was found to be polymorphic (100%) and the Nm over all populations for each locus was 13.141. The mean Na over the loci for each population (2.000) is much lower than the 5.10-6.28 and 3.52-6.62 reported by Lyimo *et al.* (2013) and Mtileni *et al.* (2010) in Tanzanian and South African chickens, respectively. The lower Na in the current study as compared to these other populations is indicative of the presence of a relatively limited sample of gene pool. The mean expected heterozygosity (0.464) concurs with the 0.351-0.434 reported by Marle-Koster and Nel (2000). Mtileni *et al.* (2010) reported expected heterozygosity of 0.67-0.69 among South African free range chickens while Lyimo *et al.*(2013) reported expected heterozygosity values of 0.58-0.67 in Tanzanian chicken populations. The difference observed in heterozygosity values may be due to variation in geography, chicken types, sample sizes, laboratory and sources of microsatellites used. Expected heterozygosity value of <0.5 may be due to inbreeding and admixture associated with population constraints and bottlenecks (Fariba, 2008).

Table 1. Genetic differentiation at the *cGH* gene locus of five chicken breeds

Population	N	Na	Ne	I	Ho	He	uHe	F	%P	Nm
Noiler	10	2.000	1.980	0.688	0.500	0.495	0.521	-0.010	100

SE=standard error, Na=number of alleles, Ne=number of effective alleles, I=Shannon's information index, Ho=observed heterozygosity, He=expected heterozygosity, uHe=unbiased expected heterozygosity, F=fixation index, %P=percentage of polymorphic locus, Nm=gene flow.

The negative fixation index (F, an index of inbreeding) suggests out-breeding is still occurring in the Noiler, FUNAAB Alpha and frizzled feathered chickens. The reverse is the case in the Fulani ecotype and Cobb 500. The high values could be due to high level of selection involved in the creation of Cobb 500; the close population, in which Fulani ecotype chickens are reared probably, explains the positive nature of the fixation index. Negative fixation index in a population indicates that homozygous deficiencies may have arisen from population sub divisions owing to null alleles, genetic drift and selection against inbreeding (Pemberton *et al.,* 1995). The % polymorphic loci observed (100%) showed that markers used in this study were highly informative in showing genetic diversity. Halima *et al.* (2007) used polymorphic information content to assess how informative markers were and got an average value of 0.71. The main effect of gene flow (Nm) is the homogenization of allele frequencies between populations. The more flow of a particular gene between populations, the more their similarity (El Hentati *et al.*, 2012). The estimated Nm in the studied chicken's populations (13.141) is high; this is evidence of the popular use of commercial chicken lines to improve indigenous ones. The impact of such introgressions is rather limited, possibly due to poor adaptation of exotic birds to village conditions/consumers' preference for local chickens. Diffusive gene flow prevents substantial genetic differentiation due to genetic drift, if gene flow is greater than unity (Slatkin, 1985 cited by Udeh, 2015).

Variation within and between populations of chicken breeds estimated using AMOVA (Table 2) revealed that a large proportion (87%) of the observed variance occurred within the breeds and 13% of the variance was contributed due to differences among individuals within populations. Variation among populations was 0%.

Table 2:.AMOVA table showing variation within and between chicken populations

Source of variation	df	SS	MS	Estimate of variance component	% variation
Among population	4	0.464	0.116	0.000	0
Among individual	44	12.944	0.294	0.035	13
Within animal	49	11.000	0.224	0.224	87
Total	97	24.408		0.259	100

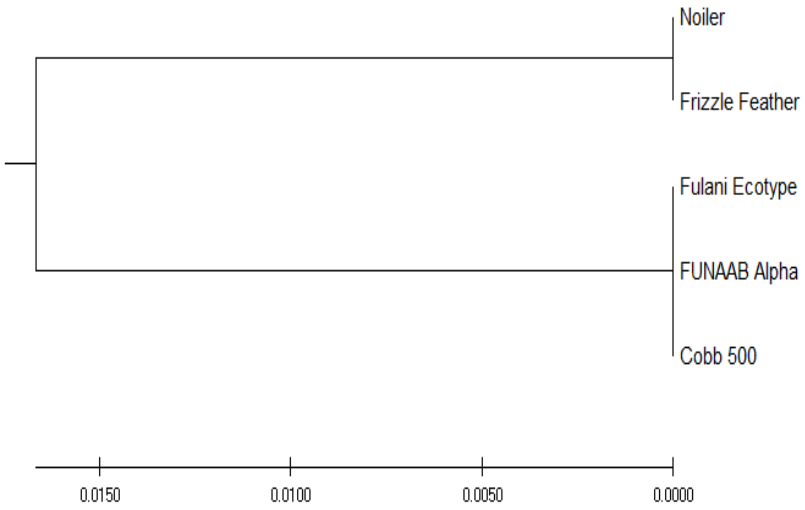

Figure 1: Phylogeny showing genetic relationships between chicken breeds at the *cGH* gene locus

A cluster analysis generated based on Nei's standard distance matrix (Figure 1) showed that Noiler and frizzled feathered chickens were in the first cluster, while Fulani ecotype, FUNAAB Alpha and Cobb 500 were in the second cluster. The closeness of the Fulani ecotype chicken to FUNAAB Alpha and Cobb 500 might not be too surprising because it has some exotic bloodline. The Fulani ecotype chicken could have been developed from crosses between exotic cockerels and indigenous hens. Halima *et al.* (2007) clustered Ethiopian indigenous chickens into two (similar to this result), showing the presence of two major breeds. A cluster shows the level of inbreeding and populations in it could be having coancestry (Halima *et al.,* 2007).

CONCLUSION

Results of the study showed the existence of great genetic diversity in the chicken breeds which could be exploited for the genetic improvement especially of the more native breeds.

ABSTRACT
This review paper discusses the use of biotechnology in livestock production. It takes into consideration the application of biotechnology in solving problems of livestock production, current uses and ethical issues. Application of biotechnology in livestock production include: production of good and high yielding animals, nutrition and feed utilization, reproduction, animal breeding and genetics as well as animal health. Application of biotechnology in animal husbandry has the potential to rapidly increase livestock production, help address some challenges of un-favourable environmental and climatic conditions and food insecurity in Nigeria.

INTRODUCTION
Biotechnology refers to any technique that utilizes living organisms or substances from such organisms to produce or modify a product, to improve animals or to develop micro-organisms for specific purposes (Armstrong and Gilbert, 1991). This sphere of science is becoming a frontier in ensuring a sustainable means of improving livestock production by influencing nutrition, reproduction, breeding and genetics as well as animal health. In recent years, biotechnological achievements have emerged as powerful tools to improve various livestock products including milk and meat products. Other applications of biotechnological tools include: production of high yielding animals, improved animal products, production of hormones, efficient by-product utilization and quality control (Fereja, 2016). Application of biotechnology will lead to a shift in the economic returns from livestock. Livestock production currently accounts for about 6% of the overall gross domestic product and 10% of the agricultural GDP in Nigeria (Rege, 1994). Globally, livestock production is growing faster than any other sector and by 2020 livestock is predicted to become the most important agricultural sector in terms of added value (Fereja, 2016). The demand for livestock products has significantly increased, hence the need to improve livestock and its derivatives through genetic manipulation and related technologies (Onteru *et al.*, 2010). Therefore, the purpose of this paper is to review available biotechnologies which have potential application in livestock production.

Production of good and high yielding animals
Livestock production in Nigeria is expected to grow rapidly with the projected demand for animal products as well as increase in human population (Rege, 1994). This has necessitated that methods of livestock production have to be changed to allow for efficiency and improvement in productivity. Biotechnological research will serve as tools to respond to the pressure of producing feed for animals which in turn will cater for the animal protein requirement of the ever-teeming human population in Nigeria. Transgenic animals such as Cattle, sheep, pigs and rabbits have been developed with the aid of biotechnology (Gupta and Savalia 2012). Transgenesis is a technique that involves the manipulation of genes of one organism and subsequent introduction into the genome of another organism of the same or other species such that the genes are not only expressed but also get transmitted into its progeny (Srinivasa and Goswami 2007). Transgenesis enhances growth rate and improved quality of meat and milk of livestock. For example, transgenic cows were developed to produce milk containing high amount of beta and kappa casein in milk fat and increased level of human lactoferrin (Brophy *et al*., 2003). Similarly, transgenic pigs with IGF 1 had 30 % more loin mass, 10% more carcass lean tissue and 20% less total carcass fat (Pursel *et al*., 1999).

Nutrition and Feed Utilization
The application of Gene-based technologies to improve animal nutrition by modifying feeds to make them more digestible is on the increase (Bedford, 2000). Such applications will go a long way in combating the shortage of feed in most developing countries such as Nigeria as well as reducing the cost of feed ingredients implying reduced production costs. Application of biotechnology in animal nutrition such as the use of enzymes, probiotics, single-cell proteins and prebiotics in feed (Fereja,

2016). In Nigeria some of these technologies are currently being used to improve nutrient availability of feeds and productivity of livestock and poultry.

Reproduction

Artificial insemination (AI) and Embryo Transfer (ET) are popular methods adopted in most developed and developing countries (Cunnigham, E.P. (1990). Artificial insemination is the most widely used biotech in animal reproduction in Nigeria and has resulted in rapid genetic progress that is four times better than natural mating (Van Vleck, 1981). Also, the use of reproductive hormones such as progesterone and pregnant mare's serum gonadotropin (PMSG) treatments as well as immunization against androstenedione have been reported to increase ovulation in both large and small ruminant animals (Kahi and Rewe 2008). However, modern biotechnological techniques which have the potential for increased reproductive efficiency are marred with complexity in process and implementation such as production of transgenic animals and cloning and will probably have low rates of adoption in both large scale and small-scale farms in future. This low adoption rates may be as a result of ethical considerations and not necessarily cost implications (Bonneau and Laarveld 1999).

Animal Breeding and Genetics

Biotech tools have been useful in influencing the rate of genetic gains in different livestock species. Such tools include: marker assisted selection (MAS), Genome mapping through the use of restriction fragment length polymorphism (RFLP) which makes use of amplifiers, short DNA Primers in polymerase chain reaction (PCR) have been essential in developing DNA fingerprinting technique and genetic characterization of a wide range of organisms (Williams *etal.,* 1990, Kahi and Rewe 2008). The application of transgenic techniques in gene manipulation of different livestock is beneficial, such that genes are not only expressed but transmitted to offspring (Gupta and Savalia 2012). These techniques are already in use in Nigeria and have great potential for adoption in livestock breeding schemes.

Animal Health

Biotech in animal health have been developed in a number of areas which includes: disease prevention, diagnosis, treatment and control (Bonneau and Laarveld, 1999). Disease prevention is key to livestock survival as well as production of healthy animals. Vaccine development and vaccination is a biotechnique that is now well rooted in most African countries including Nigeria. Vaccines are widely used either as attenuated or inactivated and have proved very efficient in establishing resistance (Bourne and Bostock,1992). The application of biotech in disease discovery has helped to identify diseases at early stages to facilitate treatment. It has also enabled the application of enzyme-linked immunosorbent assay (ELISA) which now uses recombinant antigens developed via gene cloning and sequencing for detection of antibodies and provide information to antibody recognition sites (Kahi and Rewe 2008).

Biotechnologies and their potential impact on livestock production

Area of Application	Biotechnologies	Scale of Impact	Potential of Adoption	
			Developed Countries	Developing Countries
Animal health	SAD	Large	High	High
	ELISA	Large	High	Moderate
	DNA detection	Large	High	Low
	Vaccination	Large	High	High
	PCR	Large	High	Moderate
Animal nutrition				
	Enzyme degradation of fibrous feeds	Large	High	Low
	Rumen (GIT) manipulation	Large	High	Moderate
Animal reproduction	AI	Large	High	High
	MOET	Large	High	Moderate
	Embryo sexing	Large	High	Low
	Cloning	Large	Low	Low
Animal breeding	Nucleus breeding	Large	High	Moderate
	Developing of composite breeds	Large	High	Moderate
	MAS	Large	Moderate	Low

SAD=specific antibody detection; ELISA=enzyme linked immuno-sorbent assay; DNA=di-neuclic acid; PCR=Polymerase chain reaction; GIT=gastro-intestinal tract; AI = artificial insemination; MOET= multiple ovulation embryo transfer; MAS= marker assisted selection. Modified from Cunnigham (1990) and Doyle and Spradbow (1990)

Constraints in applying Biotechnology

A number of factors act as deterrents against the use of biotechnology for livestock production in developing countries. Developing countries such as Nigeria are plagued withpoor hygiene, poverty, malnutrition and disease incidences. In recent years, the green revolution has brought comparative prosperity to farmers who are land owners, whereas those who keep livestock were neglected. Some of the major constraints in the use of biotechnology are: lack of trained personnel (scientists, technicians and extension agents) to develop and apply the technologies, absence of accurate database on livestock and their herders, high cost of technological inputs (materials, biological and equipment), failure to address issues of biosafety and conduct of risk analysis, as well as the negligible investment in animal biotechnology (Fereja, 2016).

CONCLUSION AND RECOMMENDATION

The application of biotechnology to animal husbandry is of great significance in ensuring increased productivity in the livestock sector of Nigeria. It is therefore necessary to create awareness to encourage its usage amongst livestock producers in Nigeria.

PREVALENT BACTERIA ISOLATED FROM BOAR SEMEN EXTENDED WITH THE INCLUSION OF MORINGA LEAF EXTRACT (MLE) IN BELTSVILLE THAWING SOLUTION.

***Omodewu, I. A., Olorungbohunmi, T., & Boladuro B. A.**
**Institute of Agricultural Research and Training, Moor Plantation, Ibadan*
***Corresponding Author**: Omodewu Ifeoluwa. A. **E mail**: ifeayo24@yahoo.com**Tel:** 08167330502*

ABSTRACT:
Antimicrobial agents are added to semen extenders to control the growth of microbes contaminating semen. However, non-therapeutic use of antibiotics comes with its challenges as it may contribute to antibiotic resistance. This study compared the efficacy of Natural antibiotic source: MLE as an alternative to Penicillin and streptomycin. Forty ejaculate each of four exotic boar breeds (Large White, Landrace, Duroc and Gene Converter 750 boars) were collected using gloved hand technique and extended with MLE incorporated at 0, 0.25, 0.50, 0.75 and 1.00g/250ml of BTS although 0g inclusion had penicillin and streptomycin as control. Semen samples were analysed for microbiological contamination and isolate identity was deduced from the Bergey's manual of Systematic Bacteriology, results revealed absence of bacteria in 0g MLE for all breeds except Gene Converter 750 where *Alcaligenes spp* was found. Gram –ve bacteria were isolated in all the ejaculates with MLE (0.25-1.00g). *Pseudomonas spp, Aeromonas spp, Enterococcus spp, Alcaligenes spp, Serratia marcescens, Escheria coli* were isolated in all breeds. *Acinetobacter baumanii, Buchholdera mallei, citrobacter spp and Pseudomonas fluorescens* were also isolated. We inferred that the inhibitory activity of the MLE as an antimicrobial agent for swine extender may be limited or inadequate because of the high presence of gram –ve bacteria in MLE inclusions. The presence of bacteria would in turn lead to reduction in the quality of stored semen, the utilization of a higher dosage of MLE is recommended and procedures with high standards of hygiene and microbiological control.
Key words: Ejaculate, antimicrobial, antibiotic, extenders and bacterial contamination.

INTRODUCTION
Bacteriospermia remains a challenge in processing boar semen; it leads to decreased shelf life, motility, sperm agglutination as well as reproductive problems in inseminated females (Althouse *et al*., 2000). The boar itself is a source of bacterial contamination in the ejaculate, likely due to the preputial diverticulum (Althouse and Evans, 1994). Appropriate hygiene during semen collection can decrease contamination (Althouse *et al*., 2005). Sources of contamination could also include human handlers, water used for semen extension, collection and laboratory equipment (Althouse *et al*., 2005). To determine the source of contamination, raw and corresponding extended ejaculates should be cultured, as well as the water source and laboratory equipment. Even if there is no known bacterial problem on site, semen should be cultured regularly to monitor for contamination (Reicks, 2003). Most boar semen extender contains at least one antibiotic with the aim of inhibiting the growth of bacteria; however, there are disadvantages to this practise both for sperm quality and for the environment. The antimicrobials may have detrimental effect on sperm survival, thus limiting the choice of agents that can be added to semen extenders. In a bid to reduce the toxicity caused by bacteria various highly potent broad spectrum antibacterial agents are used. However, use of antibiotics can contribute to the development of antibiotic resistance and this can in turn be transferred to other bacteria in other host species (Johansson *et al*., 2004) one of such extender with the inclusion of broad spectrum antimicrobials is the Beltsville Thawing Solution (BTS). The BTS was initially developed for frozen semen and later adapted to condition fresh swine semen at 15-18°C. Due to challenges of antibiotics resistance, unavailability, expensive price and the ban on some antibiotics the use of natural plant sources to boost and preserve semen is on the increase. *Moringa oleifera* as a plant has an impressive range of medicinal uses with high nutritional value throughout the world. *Moringa* contains pterygospermin which has powerful antibacterial effects (Rao *et al*., 1946). The leaves of *Moringa oleifera* have been reported to be a valuable source of macro and micronutrients, rich source of β-carotene, protein, vitamin C, calcium, potassium and act as a good source of natural antioxidants (Siddhuraju and Becker, 2003). A number of medicinal properties attributed to different parts of Moringa have been recognized by both Ayurvedic and Unani systems of medicines (Mughal

et al., 1999). Components of *Moringa* preparations have been reported to have antibacterial activity which includes 4–(4'-O–acetyl-α-L rhamnopyranosyloxy) benzyl isiothiocyanate, niazimicin, pterygospermin, and 4– (α-L-rhamnopyranosyloxy) benzyl glucosinolate (Fahey *et al.*, 2005). The benefit for the treatment or prevention of disease or infection that may accrue from either dietary or topical administration of *Moringa* preparations (e.g. extracts, deconcoctions, poultices, creams, oils, emollient, powders) are not quite well known (Palada, 1996) hence, culturing semen extended in BTS with MLE replacing antibiotics and identifying prevalent bacteria isolated in semen of four exotic breeds of boar is encouraging**.**

MATERIALS AND METHODS

Experimental site

The experiment was carried out at the Artificial Insemination Centre of the Trypano-tolerant Livestock Improvement Program of the Institute of Agricultural Research and Training, Ibadan (I.A.R & T) in Ikenne, Ogun state, West Africa (Latitude $6^0$55' N, longitude $30^0$35' E).

Experimental animals and management

A total of 16 exotic boars of different breeds and of similar age (2year) and weight (150-200kg) namely 4 Large White, 4 Landrace, 4 Duroc and 4 Gene Converter 750 (GC 750) were used for the experiment. The boars were housed intensively and fed balanced ration according to NRC (2005) maintenance requirement for breeding boars.

Methanolic extraction of *Moringa oleifera* leaf

Fresh *Moringa Oleifera* leaves were obtained from Bora Farm of the Institute of Agricultural Research and Training (I. A. R & T.) Ibadan. The leaves were air dried for two weeks and 2000 g of the powdered leaves was extracted with 500 ml of 70% methanol for 72 hours. The mixture was filtered and extracted on a water bath for evaporation and solidification of the extract (Afolabi *et al*., 2013).

Preparation of the BTS extender

The Beltsville thawing solution (BTS) was constituted from: Glucose 39.1g, Sodium bicarbonate 1.32g, Tri-sodium citrate 1.32g, EDTA 1.32g, Potassium chloride 0.79g, Streptomycin 1.1g, Penicillin (IU/ml) 1.1g and 1000 ml Distilled water. The Moringa leaf extract were included at T1 (BTS+ antibiotics), T2 (BTS+0.25gMLE), T3 (BTS+0.50gMLE), T4 (BTS+0.75gMLE) and T5 (BTS+1.00gMLE)

Semen Collection

Semen was collected from boars weekly using gloved-hand technique as described (King and Macpherson, 1973). Forty (40) ejaculates were collected from each breed between 8.00 and 10.00am over a 10 week period. The semen was extended with the constituted Beltsville thawing solution at a ratio 1:10. The extended semen were transferred into labelled tubes with the inclusion levels and then transferred in a climate box to the laboratory.

Bacteriological Evaluation of Extended Semen

All semen samples were analysed for the presence of microbiological contamination by plating on the following media: Nutrient Agar, MacConkey agar (Oxoid), Blood agar, Sabouraud agar (Oxoid, UK), Manittol Salt Agar and nitrate reduction medium. The media were prepared according to the manufacturer's instructions and the plates were incubated in aerobic conditions at 37^oC. The phenotypic properties of isolated bacteria were investigated using different methods, depending on type; the identification process was based on the use of the Gram staining and Analytical Profile Index systems (API 10S, API Staph and API 20NE; bioMe´rieux, France). Motility test, Catalase test, Oxidase test, Indole test, Starch hydrolysis, Methyl red test, Voges-Proskauer test, Citrate utilization test, Nitrate reduction test and Sugar Fermentation were all carried out as described (Bergeys manual of Systematic Bacteriology, 2000).

Biochemical characterization of isolates

Pure cultures of bacteria isolates were subjected to various biochemical tests to determine the probable identity of the bacteria isolates. The result of each test was recorded and the probable identity of the isolates was deduced with reference to the Bergeys manual of Systematic Bacteriology (2000). Bacteriological characteristics were determined as described (Bezuidenhout *et al*., 2002).

RESULTS AND DISCUSSION

The results of bacteria isolation obtained in this study showed that T1(0g MLE + antibiotics) inhibited the growth of bacteria in all boar semen except the Gene Converter 750, which had *Alcaligenes spp*. Inhibition of bacteria growth observed in T1 attest to the potency of synthetic antibiotics as reported by Vyt *et al*. (2007). The presence of gram –ve bacteria *Alcaligenes spp* in Gene Converter (GC) 750 could be breed dependent as reported by Kommisrud *et al.* (2002). Duroc semen with varying inclusions of MLE had *Alcaligenes spp and Acinetobacter iwoffi* at 0.25g, *Serratia marcescen* and *Alcaligenes spp* at 0.50g, *Citrobacter spp and E coli* at 0.75g inclusion while 1.00g MLE had *Pseudomonas auregenosa and Enterococcus spp*.

The semen samples of Large White had *Aeromonas spp* at T2, T3 and T4 while *Serrattia marcescens and E coli* were isolated at T5. The Landrace boar semen had no growth at T1, while T2 had *Buckholdera mallei;* T3 had *Shewanella putrifaciens and Pseudomonas flourescens,* T4 *had Shewanella spp and Shawanella putrifaciens* while T5 had *Pseudomonas Flourescens and Escherichia coli*. GC 750at T1 had *Alcaligenes spp,* T2 and T3 had *Acinetobacter baumanii* while *Alcaligenes spp* was isolated from T4. In T5, *Alcaligenes spp* and *Enterococcus spp* were the most prevalent. Enterococcus *spp, Pseudomonas flourescens, Serrattia marcescens, Citrobacter spp* were similar to bacteria reported by Althouse *et al*. (2000). Althouse *et al*. (2000) reported that potential sources of contamination include Laboratory equipment, disposable and non-disposable supplies, powdered/reconstituted extenders, boars and the boar stud environment. *Alcaligenes spp, Acinetobacter iwoffi, Aeromonas spp*, *Buckholdera mallei*,*Shawanella putrifaciens*, *Acinetobacter baumanii* and *Alcaligenes spp* were different from bacteria reported byAlthouse *et al.* (2000) and this could be as a result of ecological differences. The results from this study are in line with the works of Althouse and Lu 2005, Okazaki *et al*. 2010, U´ beda *et al*. 2013 and Kuster and Althouse (2016) that largely confirms the general view that Gram-negative bacteria, especially from the *Enterobacteriaceae* family are most prevalent in boar semen. These results are consistent with those of other authors, compiled by Maroto Martı´n *et al*. (2010), who concluded that, of at least 25 different bacteria genera identified in boar semen, the species *Pseudomonas*, *Staphylococcus*, *Proteus*, and *E. coli*, occur most frequently. The isolates in these results suggest the low efficacy of the MLE inclusions. Results are nevertheless consistent with the reports of Althouse *et al*. (2000) and Baracaldo and Ward (2008).

CONCLUSION

The synthetic antibiotic (penicillin and streptomycin) remains more effective against bacteria in semen when compared to natural antibiotic source (MLE). This study discourages the utilization of all inclusion of MLE (0.25-1.00g) in semen extender BTS as this could result in reproductive challenges in inseminated gilt/sows. A higher dose of MLE is recommended for further research to examine if a higher dose could reduce or further inhibit bacteria population.

Table 1: The prevalent bacteria isolated from semen samples extended with varying inclusions of MLE in BTS.

Breeds	MLE	Prevalent Isolates from sample with MLE

ABSTRACT
This study was conducted with New Zealand White (NZW) and Dutch Black (DTB) breeds of rabbits' crosses to estimate heterosis and heritability. Forty-eight (48) rabbits, comprising twelve (12) bucks (6 per breed) and thirty-six (36) does (18 per breed) were used in the mating ratio of 1:3. Parameters taken on both the parents and their progenies according to the different breeding groups include Body Weight (BW) and Body Length (BL). The measurements were taken at 4, 8, 12 and 16 weeks of age. The results revealed negative heterosis of -1.90% and -4.34% at 4th and 12th week for NZW x NZW, -2.58% at 8 weeks for DTB x DTB, while NZW x DTB and DTB x NZW yielded positive heterosis of 2.22%, 20.96%, 15.96% and 5.30% at week 4, 8, 12 and 16 respectively. Heritability estimates from the body weight were generally low to moderate at 4th to 8th weeks for all the crosses. Conversely, at 12th week heritability estimates were high, 0.68±0.15, 0.44±0.15, 0.50±0.39 and 0.56±0.53 for NZW x NZW, DTB x DTB, NZW x DTB and DTB x NZW respectively. It could be concluded from this study that using the DTB to sire DTB x NZW crossbred progeny in rabbit breeding programme can yield considerable hybrid vigour.
Key words: Rabbits, crossbreds, heterosis, heritability and hybrid vigour.

INTRODUCTION
Rabbit is in the class of micro livestock that provides alternative to meat production instead of the traditional use of cattle, sheep and goat. It has gained much prominence in recent times due to its prolificacy, comparatively low production cost, and no religious restriction (Ansah *et al.,* 2014). Rabbit has been used as an experimental animal in genetics and reproductive physiology since the beginning of the century. It was not until 1950 that first findings on quantitative genetics were published, about the maternal influence on birth weight in rabbits, and research on the genetic improvement of the rabbit for meat production (FAO, 1997). Rabbits are characterized by high reproductive ability with a short generation interval and so can produce a high quantity of meat in a short period (Zerrouk *et al*., 2005). Rajendra (2000) opined that rabbits are highly prolific and are 2.5 and 4 times more efficient in extracting protein from forages than sheep and beef cattle, respectively. This study seeks to exploit all the hybrid vigour thereby improving genetically the production traits of rabbit for mankind.

Crossbreeding is one of the tools with which the breeder improves his animals. That is why Apori *et al.,* 2014) observed that crossbreeding has offered a much better alternative for improving on the growth rate and litter size of some chosen rabbits. One major challenge in crossbreeding exercise is the choice of the breed to serve as sire or dam line, hence we rely on reciprocal crossing (Hagon and Opoku-Mensah, 2019). Reciprocal effect is the deviation between crosses of two parental lines in which their roles were reversed.

In Nigeria today, there is need to diversify our animal production from the natural cattle, sheep, goat, swine and poultry to micro livestock animals like rabbit so as to fulfill the ever-growing demand for animal proteins. A person with one pair of rabbits can produce 60 to 80 rabbits each year to eat or sell (Elmer, 1990). It is no longer secret that most Nigerians struggle for meat in any gathering which exposes their scarcity of meat. Besides, the minimum animal protein requirement according to World Health Organization is 35g per head per day, but an average Nigeria animal protein intake is as low as 6.5g per head per day (FAO, 2005). In addition, genetic improvement of rabbit is important in order to increase their contribution to the much-needed animal protein. One of the pre-requisites for genetic improvement is knowledge of genetic parameters for important economic traits (Akanno and Ibe, 2005). It is very unfortunate that the information on these parameters is scanty in available literature for rabbits raised in the tropics. Buchanan and Northcutt (2011) observed that heterosis or hybrid vigour is a difference between the hybrid and the mean of the two parents and it is often called midparent heterosis. It is therefore a measure of the superior performance of the crosssbred relative to

average of the pure breed parents involved in the cross. The probable cause of most heterosis is due to combining genes from different breeds, concealing the effects of the inferior genes. This is very important to a farmer in exploiting parents to achieve a better offspring.

MATERIALS AND METHODS

The study area

The study was carried out at the Rabbitry unit of the Teaching and Research farm, Department of Animal Science, University of Nigeria, Nsukka

Experimental animals and management

A total of forty eight (48) rabbits, comprising twelve (12) bucks (6 per breed i.e. 6 New Zealand White Bucks and 6 Dutch Black Bucks) and thirty six (36) does (18 per breed i.e. 18 New Zealand White does and 18 Dutch Black does) were used and assigned into the experimental hutch cages at mating ratio of 1:3.

Routine hygiene was maintained especially during kindling. The nest box was checked regularly to remove any dead animals during parturition. The newly born rabbits were weighed and weaning age was 28 days or a month. Commercial feed (vital growers feed, CP= 15% min, fat 7% max, CF=10% min, available phosphorus = 0.35% min and metabolizable energy = 2550Kcal/kg minimum) was used throughout the experiment as the concentrates. Forages-grasses and legumes like *Panicum maximum*, *Centrosema pubescens*, *Ageratum conizoides*, *Aspilia africana* and *Andropogon gayanus* were used throughout the experiment as supplementary ration.

Percentage heterosis = (crossbreed average- pure breed average/ Pure breed average) x 100.

Heritability (h^2) (narrow sense) is the measure of additive genetical variation in proportion to the phenotic variation for a trait expressed in a rabbit population (Mahmoud, 2008).

Experimental design and statistical analysis

The statistical package used was Statistical Product and Service Solutions (SPSS) in which variance components from the procedures of analysis of variance (ANOVA) were used to estimate heritability.

The statistical design was the nested (hierarchical) design in which each sire was mated to 3 dams and each mating resulting in number of progenies. The model **was as shown below:**

$Z_{ij} - \alpha_i = \mu + \beta (X_{ij} - \bar{x}) + E_{ij}$ (Beker, 1992).

Where:

Z_{ij} = is the mean of the records of the offspring from a mating ofi-th sire to the j-th dam;

μ = common mean;

α_i = the effect of the i-th sire;

β = the regression co-efficient of Z on X;

X_{ij} = the record on the j-th dam mated to the i-th sire;

$\bar{x}$ = the phenotypic mean of the dams; Eij = the deviation of the means of the progeny.

The regressions from the sire families are pooled to obtain the common regression co-efficient, β.

Sire effect was removed by obtaining the regression of offspring on dam within the sire.

RESULTS AND DISCUSSION

Table 1: Estimation of heterosis for the different breeding groups at different weeks.

Weeks	Pure crosses		Main crosses	Reciprocal
	NZW x NZW	DTB x DTB	NZW x DTB	DTB x NZW
4	-1.90%	2.58%	12.12%	2.22%
8	5%	-2.58%	4.28%	20.96%
12	-4.34%	2.58%	5.55%	15.46%
16	5.56%	9.09%	1.92%	5.30%

Key: NZW = Newzeland white, DTB = Dutch black

Table 1 above shows the estimate of heterosis from the mid-parent method. There were negative heterosis for body weight of -1.90% at 4th week and -4.34% at 12th week for the pure crosses (NZW). There was also a negative heterosis of -2.58% at 8th week for the pure crosses of (DTB). The main crosses and reciprocal crosses of NZW and DTB yielded positive heterosis for body weight especially the reciprocal crosses of DTB x NZW which yielded 2.22%, 20.96%, 15.96% and 5.30% at week 4, 8, 12 and 16 respectively. This result was similar to Ibe *et al*. (2005) who reported 5% and 5.81% heterosis for body weight for a crossbreed of New Zealand White rabbit and Dutch black, Chinchilla and Dutch rabbit crosses respectively. This supports the fact that non-additive effects of genes could be exploited by crossbreeding for body weight. This shows that, apart from selection for economic improvement for traits highly heritable, crossbreeding method is an asset to achieve the same goal. This result also is similar with that of Fayeye (2013) who reported that the percentage heterosis for litter size in local white x local brown crossbred rabbits were positive at the 7th, 14th and 21st day postpartum (+24.20%, +31.63% and + 22.94% respectively). Similarly, Yousset *et al*. (2008) showed a direct heterosis of 24 and 28 percent for litter size at birth and at weaning age in crossing v-line and Baladi Red rabbits.

Table 2: Heritability estimates of body weight (BW(g)) of the breeding groups. Breeding groups and their h^2± S.E (h^2).

Weeks	NZW x NZW	DTB x DTB	NZW x DTB	DTB x NZW
4	0.17±0.48	0.17±0.46	0.10±0.25	0.27 ±0.32
8	0.01± 0.37	0.01±0.37	0.32±0.44	0.23±0.36
12	0.68±0.15	0.44±0.15	0.50±0.39	0.56±0.53
16	NE	NE	NE	NE
Mean ($\bar{x}$)	0.29±0.33	0.21±0.33	0.31±0.36	0.35±0.40

Key**:** BW (g) = Body weight in (g), h^2 = Heritability, NE =negative variance, S.E (h^2) = Standard error of heritability

Table 2 shows the heritability estimates of the body weight of the breeding groups at various weeks. At 4th week (the weaning age), all the groups recorded low heritability for body weight except the reciprocal crosses (DTB x NZW) which recorded a moderate heritability of 0.27. The implication of low heritability is that variation due to additive gene action is probably small or that the non-additive gene action (dominance, over dominance and epistasis) may be more important than additive and environmental factors. Low heritability here could be that at this age (4th week), all the genes have not fully expressed themselves. However, Rojan (2009) obtained a moderate heritability 0.38±24 at 4th week. However, at 12th week, all the breeding groups yielded high heritability of 0.68, 0.44, 0.50, and 0.56 respectively. The implication of high heritability is that additive gene effect was stronger than the non- additive gene effect, epistasis or even environmental factors and that at this age crossbreeding aim was very much achieved.

At 16th week however, heritability could not be estimated. This was as a result of negative offspring variance components in the analysis of covariance. That is, pooled offspring weight was less than that of parent (dam). Negative variance components are regarded as an indication of the negligible contribution of additive genes to variation of the traits concerned. This could be that there was a negligible contribution of additive gene effect or that environmental factors seem to take the lead in the interplay between the genes and the environment

CONCLUSION

In this study, there was a positive heterosis for body weight especially among the crossbred.
Therefore, the potentials of crossbreeding to tap the non-additive genes for improvement of economic traits were seen in this study. The high heritability estimates at week 12 for all the breeding groups had been implicated on the age of the animals.

ABSTRACT
The study was conducted to determine the characteristic and economic value of exotic breeds of pigeon in Bauchi Metropolis. Purposive sampling was employed to select farmers of exotic breeds of pigeon in Bauchi metropolis and a total of 60 respondents were used. The study revealed that 100% of the respondents were males and 50% aged between 26-35 years, followed by 16-25 years (25%) while the least (10%) aged between 5-15 years. Majority (51.67%) of the respondents had secondary school certificate while 48.33% attained tertiary education level. Majority (58.33%) of the farmers practiced inbreeding only. However, 41.67% of the respondents practiced both inbreeding and out-breeding. Furthermore this study revealed that 28 different exotic breeds of pigeon with unique features were available in Bauchi metropolis. Majority (66.7%) of the exotic breeds of pigeon with good flying ability were small size while the least (11.1%) was recorded among large ones. However, the large breed recorded highest poor flying ability (60%) followed by (40%) among average size, none of small size breed had poor flying ability. Most (75%) of them had average resistance to prevalence diseases when compared with the local breed. Female farmers should be encouraged to rear exotic breeds of pigeon. Cross breeding of exotic and local breeds of pigeon should be employed to complement each other.
Keywords: Exotic, Breed, Pigeon

INTRODUCTION
The domestic pigeon (*Columba livia domestica*) belongs to class: Aves, order: Columbiformes and family: Columbidae. Pigeons have made contributions of considerable importance to humanity especially in times of war (Levi, 1997). In war the homing ability of pigeons has been put to use by making them messengers. The homing pigeon is a variety of domestic pigeon derived from the rock pigeon, selectively bred to find its way home over extremely long distance (Levi, 1997). Members of this breed of pigeon are still being used in the sport of pigeon racing and the white release-dove ceremony at weddings, anniversaries and funerals. The wild rock pigeons have an innate homing ability (Blechman, 2007) meaning that they will generally return to their nest and mate.

Pigeon can also be reared as a meat. Young pigeons bred for meat are known as squabs. Rearing pigeons for meat is an accepted industry in overseas countries, particularly Europe and the United States (Bolla, 2007). In Kano state, the domestic pigeon (*Columba livia domestica*) is reared for meat production by some household, thereby contributing significantly to the protein need of the local populace (Rabiu and Arzai, 2012). However this aspect is yet to be optimally exploited in Nigeria as a whole. Breeding for fancy pigeon is an overwhelming aspect in pigeon production with a lot of economic and tourist potentials. There has been an insignificant development in the Nigerian fancy pigeon industry since its introduction from overseas some years ago. Most of exotic breeds of fancy pigeon have been proven to be adaptive to our local environment. Those who love bird life can find unlimited pleasure in the breeding of pigeons and besides, as they become more proficient in the art of breeding can earn a nice little income from their birds (Hazard, 1922). Pigeon can be bred for purposes which include: breeding for utility, breeding for fancy, breeding for homing and breeding for racing and show. All these provide wider areas of specialization for breeders and researchers in pigeon production. However, there is limited information today on the characteristic and availability of exotic breeds of pigeon in Nigeria. Their potentials and production are yet to be efficiently exploited in Nigeria. Therefore, this study aimed to determine the phenotypic characteristic and breeding method exotic breed of pigeon in Bauchi metropolis.

MATERIALS AND METHOD

Description of Study Location

The study was carried out from January to August 2019 in Bauchi metropolis. Bauchi state is located in the northern guinea savannah agro-ecological zone of Nigeria. The state is located geographically at approximately 10°17'N, 9°49'E and 690.3m above sea level (Kowal and Knabe, 1972).

Sampling Procedure

The Research-sampling design that was used to select the sample was non-probability purposive sampling. A total of 60 exotic breeds of pigeon farmers were used.

Methods of Data Collection

Data for this study were collected using both primary and secondary sources. The primary data (Type, size, flying ability, and relative disease resistance,) were collected through farm visitation and physical examination of the pigeons. Secondary data (breeding methods) were collected by using a questionnaire.

Statistical Analysis

The data collected were subjected to simple descriptive statistic and χ^2 test for association using SPSS version 17

RESULTS

The socio-Economic characteristic of the exotic breeds of pigeon farmers in Bauchi metropolis were presented in Table 1. The results revealed that 100% of the respondents were male and (50%) were within the age bracket of 26-35 years, followed by 16-25 years (25%) and 36-45 years (25%) while the least (10%) were within 5-15 years old, non-of the farmers was above 45 years.Majority (51.67%) of the respondents had secondary school certificate, 48.33 % were able to attained tertiary education while none of the respondent had non-formal or primary education as highest level of education. The results also showed that (50%) of the respondents were new in the pigeon farming with 0-5 years of experience followed, by 31.7% with 6-10 years of experience while the least (18.3%) had above 10 years of experience.

Table 2 presented the distribution of some phenotypic characteristics of exotic breeds of pigeon in Bauchi metropolis. The results showed that most (78.6%) of the exotic breeds of pigeon in Bauchi metropolis were fancy type while the least 21.4% were utility.With respect to size 39.3% of the breeds were medium, followed by large (35.7%) while 25% were small in size. Majority (53.6%) of the breeds had poor flying ability, 32.1% were good, while 10.7% had average flying ability. Most (75%) of the breeds had average resistance to diseases while 25% were susceptible to prevalence diseases.

Table 3 presented the association between the body size and flying ability of exotic breeds of pigeon in Bauchi metropolis. Significant (P > 0.01) association between body size and flying ability of exotic breeds of pigeon in Bauchi metropolis was detected. Majority (66.7%) of the exotic breeds of pigeon with good flying ability were small size while the least (11.1%) was recorded among large ones. However, the large breed recorded highest poor flying ability (60%) followed by (40%) among average size, none of small size breed had poor flying ability.

Table 4 presented breeding methods employed by exotic breed of pigeon farmers in Bauchi metropolis. The results revealed that (55%) of the respondents practice only inbreeding, followed by 45% practice both inbreeding and out-breeding, while none practice only out-breeding. Out of 45% of the respondents that practice out-breeding, only few (3.33%) performed a planned cross-breeding while majority (41.67%) performed unplanned cross-breeding without targeting any trait.

Table 3. Association between Body Size and Flying Ability of Exotic Breeds of Pigeon

Body Size	**Flying Ability**			χ^2	**LOS**
	Good	Average	Poor	17.4	**
Small	6 (66.7%)	1 (25%)	0 (0.0%)

DISCUSSION

The result obtained from this study that only males embarked on exotic breeds of pigeon farming in Bauchi metropolis is in line with the findings of Bakoji *et al.* (2012) and Suleiman *et al.* (2017) they reported more males participation than females in poultry farming in Bauchi and Kaduna states respectively. The (50%) of exotic breeds of pigeon farmers in Bauchi metropolis were within the age bracket of 26-35 years is similar to findings of Bakoji *et al.* (2012), who reported (48.89%) of quail birds' farmers in Bauchi Local Government were within the age bracket of 31-40 years. . The age distribution might have been influenced by the nature of the business which required highly energetic and independent youths for effective farming and marketing. The high literacy level of the respondents in this study is in line with the findings of Nurudeen (2012) that the majority of the poultry farmers had tertiary education. Bukunmi and Yusuf (2015) reported that level of education had a positive coefficient which could be because education helps the farmers to understand better the innovation introduced to them. Experience in poultry production usually determines the effectiveness of farmers' decision with respect to inputs combinations or resource allocation (Umar, 2012). The (50%) of respondents were still new in the business with 0-5 years of experience. This implied that the business was still at young stage and therefore, more studies were still needed to be done in the exotic pigeon farming for better improvement.

The majority (78.6%) of the exotic breeds of pigeon in Bauchi metropolis were fancy type. Fancy pigeon breeds are kept for their gorgeous colour, form and texture. The higher availability of fancy breeds could be an indication that exotic breed of pigeon production in Nigeria was mostly targeted for pet. Most of these exotic breeds of pigeon had average resistance to diseases when compared with the local breeds is in accordance with the findings Bunza *et al.* (2008) reported zero infestation of tick on local breed of pigeon at Sokoto central market.

The significant association observed between body size and the flying ability of exotic breeds of pigeon. Sudik (2007) reported high and positive correlations between live weight and body size in chickens. Pigeons with larger body size will likely have higher body weight which will make them have poor flying ability. Pigeon with small body size has the tendency of lower body weight and good flying ability. This might serve as vital guide line to future breeders. While selecting for racing pigeon breeding, the size of the pigeon should be considered.

Majority (58.33%) of the respondent practice only inbreeding was to maintain the breed purity and to prevent any limitation on the required features.

CONCLUSION AND RECOMMENDATION

It can be concluded that most of the farmers practice inbreeding. Therefore, Cross breeding of exotic and local breeds of pigeon should be employed to complement each other.

ABSTRACT
Boar semen preservation is associated with the production of reactive oxygen species which leads to reduction of sperm quality and decrease in fertilizing ability. The aim of this study was to replace conventional semen extender with watermelon juice (WMJ) and to determine the most effective dilution rate that will maintain the viability of the spermatozoa over a 48-hours extension period. Semen was collected from a boar at the piggery unit of the teaching and research farm University of Ibadan, Ibadan using the glove hand method. The experiment was divided into five treatments with Beltsville Thawing Solution being replaced by WMJ at the following rate; 0, 12.5, 25, 37.5 and 50% and designated as T1, T2, T3, T4 and T5 respectively. Diluted semen samples were stored at 17^0C and were evaluated at 0, 24 and 48 hours for morphology. The experimental design was a completely randomised Design; data obtained were analysed using descriptive statistics and ANOVA.
The results showed that 50 % of BTS can be replaced by watermelon juice. However the effect of watermelon juice was only ascertained not more than 48 hours of storage. This evaluation shows that extender developed with WMJ could be an extender of choice for a reliable short term preservation in swine artificial insemination programme.
Keywords: Boar, Watermelon Juice extension, Semen quality, Spermatozoa.

INTRODUCTION
Successful swine fertility programs can be achieved using extended cooled semen when compared to those using natural service. Although the former is a routine procedure, its use is limited because sperm cells remain viable for about 3 to 5 days (Gadea *et al.*, 2005). Many studies have been carried out on carotenoids, considered an important group of natural antioxidants (Bast *et al*., 1998, Møller *et al*., 2000, Schabath *et al*., 2004 and Rao and Rao, 2007). For over a decade, lycopene, a carotenoid present in tomatoes (*Lycopersicon esculentum*) and several ripe fruits and vegetables, such as watermelon, pink grapefruit and carrots (Nguyen and Schwartz, 1999, Perkins-Veazie *et al*., 2003 and Tadmor *et al*., 2005), has been considered in some studies related with human and animal health (Bhuvaneswari and Nagini, 2005, Rao *et al*., 2006, Avci and Durak, 2007 and Bhom, 2007) and reproductive physiology (Martino *et al*., 2006, Goyal *et al*., 2007, Mangiagalli *et al*., 2007, Turk *et al*., 2007 and Mendiola *et al*., 2010). In roosters, in particular, Mangiagalli *et al*. (2010) found positive effects of lycopene addition on fertility and qualitative characteristics of semen.
With AI expanding rapidly, the demands for semen increased. The simplest way to meet this demand was to "stretch" each ejaculate further by using fewer spermatozoa per insemination, provided that this could be accomplished without sacrificing fertility.
The main objective of semen preservation is to extend the usefulness of genetically superior males for purposes of expanding the genetic base of breed, repopulating/recreating breeds or lines and discovering new gene (Waberski *et al.*, 1994; Purdy *et al.*, 2008). It is important to evaluate the effectiveness of natural antioxidants that are readily available, such as watermelon juice in reducing the oxidative stress in post ejaculated boar semen, to evaluate the effectiveness of antioxidant in watermelon juice on the boar semen quality and determine the proportions of *watermelon juice* that is suitable for preserving boar semen quality.

RESULTS

TABLE 1: Characteristics of semen collected from Boar.

Parameters	Value
Volume (ml)	50
Progressive Motility (%)	95
Mass activity	++++
Morphology (%)	95

Characteristics of semen collected

Table 1 shows the results from the initial evaluation of boar semen before extension was done. The result reveals that the sample was suitable for extension as the values fall within acceptable ranges for high quality semen.

Table 2: Effect of water melon juice fortification on extended boar semen quality at 0 hour (Mean ±SD)

Parameters (%)	T1	T2	T3	T4	T5
Morphology	94.33±0.57^{a}	90.00±0.00^{a}	85.00±5.00^{b}	91.67±5.77^{a}	86.67±2.88^{a}

abc = mean values in the same row with different superscripts are significantly different (P<0.05); SD = Standard deviation

Effect of water melon juice fortification of boar semen quality at 0 hours

Table 2 shows the mean of morphology and of extended boar semen supplemented with graded levels of watermelon juice refrigerated at 17 ^{0}c.

There was a significant reduction (P<0.05) in morphology in treatment 3 (25 % WMJ) which gave the least mean value.

Table 3: Effect of water melon juice fortification on extended boar semen quality at 24 hours (Mean ± SD)

Parameter	T1	T2	T3	T4	T5
Morphology	87.66±2.51^{a}	87.66±0.57^{ab}	85.30±0.57^{ab}	85.30±0.00^{ab}	81.66±0.88^{b}

abc = mean values in the same row with different superscripts are significantly different (P<0.05); SD = Standard deviation.

Semen quality of extended (17 ^{0}c) boar semen fortified with water melon juice, (24 hours)

Table 3 shows the mean values of morphology of extended boar semen supplemented with graded level of watermelon juice refrigerated at 17^{0}C. There was a significant difference (P<0.05) in mean value at 24 hours. Significant reduction (P<0.05) in morphology was observed with the increase in concentration of watermelon juice extract.

Table 4: Effect of water melon juice fortification on extended boar semen quality at 48 hour (Mean ± SD)

Parameters	T1	T2	T3	T4	T5
Morphology	83.66±1.15^{a}	82.00±0.00^{ab}	80.00±0.57^{b}	80.33±0.57^{b}	79.33±1.15^{b}

abc = mean values in the same row with different superscripts are significantly different (P<0.05); SD = Standard deviation

Effect of water melon juice fortification on extended boar semen quality at 48 hours
Table 4 shows the mean values of morphology of extended boar semen supplemented with graded level of watermelon juice refrigerated at 17^0C. Significant differences in mean values was observed. It was significantly lower ($P<0.05$) in T5 (50 % WMJ).

DISCUSSION

Morphology

For sperm morphology, it was observed that significant amount of spermatozoa were normal according to Shipley *et al.* (1999) that the percentage spermatozoa should be at least 70 %. Also, Cerolini *et al*. (2000) reported that inclusion of antioxidant into storage diluents prevented deterioration of boar spermatozoa quality and provided protection to the cells up to 5 days of storage through its prevention of oxidative reduction in the levels of major polyunsaturated fatty acid.
The highest mean value recorded for spermatozoa morphology in treatment 2 can be accrued to inclusion of antioxidant as a supplement in the extender. This is in agreement with the report of Cerolini *et al*. (2000) that the inclusion of antioxidant into storage diluents prevented deterioration of boar semen quality and provided protection to cells up to 5 days of storage through its prevention of oxidative reduction in levels of major polyunsaturated fatty acid.

CONCLUSION

This study was carried out to investigate the effect of watermelon juice fortification of extended boar semen. Semen was collected from a mature landrace boar and extended with BTS (Beltsville thawing solution). The control treatment contained only BTS with a semen- extender ratio of 1 to 4, while the other treatments contain BTS with different concentrations of watermelon juice. The semen was stored using liquid storage (17^0C). After collection and assessment for odour, colour, volume, morphology and satisfactory results were obtained, the semen was added to the extender and placed in a regulated refrigerator. Semen evaluation was carried out at every 24 hours for three days. Semen characteristics evaluated include morphology. Mean value for morphology was reduced but falls within the normal range that can support fertilisation. The results obtained in the study suggest that 50 % of BTS can be replaced by watermelon juice; however the effect of WMJ anti-oxidative properties is inconclusive up to 48 hours of storage. Watermelon juice extract has proven to have potentials to supply exogenous antioxidant thus inhibiting oxidative stress condition in boar semen. Even at a high level of inclusion in extended semen, it was able to give a percentage motility that was capable of fertilising the oocyte. From this study, extended semen (17^0C) at 12.5% inclusion level of watermelon juice extract gave the best percentage in morphology throughout the experimental period because all mean values are within acceptable range of normal values indicative of good semen quality.

SEMEN CHARACTERISTICS AND FERTILITY OF THREE STRAINS OF NOILER COCKS

***S Amur.,D.J.U Kalla & Y.P Mancha**

Department of Animal Production Abubakar Tafawa Balewa University Bauchi, Bauchi State Nigeria

**Corresponding author: amursamaila@gmail.com mobile No: 07063937365*

ABSTRACT

A study was carried out to determine the semen characteristics and fertility of three strains of noiler cocks. A total 180 normal feathered Noiler birds were procured at nine weeks of age from Bauchi state Agricultural Development Program (BSADP) farm comprising of 45 Noiler cocks (15 brown, 15 black and 15 spotted) and 135 Noiler hens (45 brown, 45 black and 45 spotted). The experiment lasted a period of eight months and they were fed commercial diet throughout the period of the experiment. Two types of incubator were used, namely automatic incubator (A) and locally built water bed (B). The study was conducted at the poultry unit of the BSADP. The result showed that in parameters such as semen colour, pH, total motility, dead sperm, abnormal sperm cells and sperm concentration ($x10^9$) there were no significant difference ($p<0.05$) between the strains however volume, mass activity and sperm concentration were significantly different ($P<0.05$). Statistical difference ($P<0.05$) were observed from incubator A, where brown strain showed high fertility, followed by spotted and least in black with 83.7%, 80.8% and 75.3% respectively. From incubator B, it shows significant difference ($P<0.05$) with black strain showing highest fertility percentage (86.3%) followed by spotted (78.1%) and least were observed in brown with 72.6%. Chick quality with regards to weight is statistically not different ($P<0.05$) among strains. The data obtained from this study indicate that there were variations among the stains in parameters such as semen volume, mass activity and semen concentration. However these variations did not influence the quality of day old chicks as no statistical difference was observed. This study there for recommends that any of the three strains of Noiler cocks can be used for breeding purposes.

Keywords: Noiler, Semen, Strain, Cocks, Characteristics

INTRODUCTION

The demand for animal protein has globally increased, in the last five years meat consumption has gone up satisfactorily. The recent ban on the importation of poultry and their products has constituted a major challenge to the indigenous poultry industry to meet up the immediate and future protein needs of the country. This challenge calls for improvement and/or change in the traditional production system and optimization of poultry reproductive traits such as fertility, hatchability and chick quality. With Noiler chicken breed, the production of animal protein is cheaper and sustainable. The Noiler chicken is a dual purpose breed of chicken developed in Nigeria, Noiler s are suitable for rural communities and small holder farmers (justagric.com, 2019). Reproductive performance is usually expressed in terms of egg production in the hen and seamen yield and quality in cocks. Assisted reproduction technologies (ART's), such as artificial insemination (AI) contribute to increased poultry production, as it allows a wider use of genetically superior cockerels. In a breeder flock, fertility rates are often related to the male performance Surai and Fisin (2012) stated that chick viability is important in the profitability of the poultry industry. In contrast to mammals, chicken embryonic development takes place in a semi-closed environment, the egg, with only exchange of gas and water with the outside. However, information about Noiler chicken's fertility, hatchability and chick quality is not fully understood. This research was designed to determine the semen characteristics and fertility of three strains of Noiler cocks.

MATERIALS AND METHODS

The study was conducted at the poultry unit of the Bauchi State Agricultural Development Project (BSADP) Bauchi State, Nigeria. It lies between latitude 9.30° and 12.3° north of the equator, and Latitude 8.48° and 11° East of the Greenwich meridian. A total 180 normal feathered Noiler birds were procured at nine weeks of age from Bauchi state Agricultural Development Program (BSADP) farm comprising of 45 Noiler cocks (15 brown, 15 black and 15 spotted) and 135 Noiler hens (45 brown, 45 black and 45 spotted). The experiment lasted a period of eight months and they were fed commercial diet throughout the period of the experiment. Two type of incubator were used, namely automatic incubator (A) and locally built water bed (B).

Semen collection

Semen samples were collected weekly by abdominal massage technique (Donoghue and Wishart, 2000). After restraint, the back of the cock was gently stroked from behind the wings but firm and rapidly toward the tail. The cock responded with tumescence erection of the phallus, and the handler then gently squeezed the cloaca expressing semen through the external papillae of the ducti deferentis and collected semen into clean 1 ml Eppendorf tubes. The tubes were then held at a suitable temperature for analysis.

Semen analysis

Semen volume-this was obtained as the difference between weight of tube and sample. Semen colour-this was visually assessed immediately after collection and scored as; 1=creamy, 2=creamy-white and 3=opaque (Peters et al., 2008).

Semen $_{P}$H- a drop of semen was evenly placed onto a $_{P}$H paper, after the colour of the impregnated zone became uniform (<30 seconds) it was compared with the calibrated strip to read the $_{P}$H. Mass activity (gross motility) - was determined by placing a drop of raw undiluted semen on a pre-warmed slide and covered with a slip to spread it into a uniform thickness and to prevent drying up, it was viewed under a microscope at 100x and motility estimated by subjectively assessing the wave patterns and ranked as follows, 4 – rapid swirling, 3- slower swirling, 2 – generalized oscillation and 1 – sporadic oscillation.

Individual sperm motility-examined at 400x magnification several fields were examined and estimated to the nearest 10% subjective assessment was carried out and expressed as percentage of motile sperm with moderate to rapid progressive movement.

Percentage live dead and normal/abnormal spermatozoa were evaluated using the eosin nigrosine staining procedure. One drop of the stain was taken using a pipette and placed at the end of a warm slide and mixed with one drop of semen. After making the smear the slide was allowed to dry, and then examined using a light microscope at a magnification power of 400x, the live spermatozoa were identified as bright and not stained. Their outlines were clearly defined and their heads were bright and retractile against the backgrounds. The dead spermatozoa stained pink and outlines were not clearly defined. The percentage of live and dead spermatozoa was calculated from 200 spermatozoa which were counted in each slide from different microscope fields. The morphologically abnormal spermatozoa were also estimated on the same smears by counting 200 spermatozoa in different microscope fields.

Semen concentration was determined using the improved neubauer hemocytometer and applying the direct cell count method. Counting was carried out at 400x magnification. The spermatozoa's head that falls within the sub-divided smaller squares at the four edges and Centre of the hemocytometer were counted. The concentration was expressed (Peters et al., 2008) as: C = 50,000 xNxD, Where

C=concentration of semen per volume (ml),

N=number of sperm cells counted,

D=dilution rate.

Chick quality

Chick quality was assessed based on chick weight. Weight was taken using an electronic balance to the nearest 0.01g.

RESULTS AND DISCUSSION

The semen analysis for three strains of Noiler cocks are presented in table 1. It shows that, in parameters such as colour, pH, total motility, dead sperm, abnormal sperm cells and sperm concentration ($x10^9$) there were no significant difference ($p<0.05$) between the strains however, volume, mass activity and sperm concentration were significantly different ($P<0.05$). The pH observed in the three strains in this study are similar to those reported by Peters et al. (2008) for Nigeria indigenous cocks. Siudzinska and Lukas Zewicz (2008) indicated that chicken sperm can tolerate a pH range of 6.0 to 8.0. Low pH reduces motility, lactic acid production and oxygen whereas high ph increases metabolic rates in vitro (Donoghue and Wishart, 2000). The sperm concentration observed in this study are similar to those reported by Bah et al. (2001). It is however lower than the reported by peters et al (2008) for Nigerian cocks. The influence of strain on fertility percentage for incubator A and B are presented in table 2. Statistical difference ($P<0.05$) were observed from incubator A, where brown strain showed high fertility, followed by spotted and least in black with

83.7%, 80.8% and 75.3% respectively. From incubator B, it shows significant difference (P<0.05) with black strain showing highest fertility percentage (86.3%) followed by spotted (78.1%) and least were observed in brown with 72.6%. Table 3 shows the influence of strain on chick quality, from both incubators, it shows that chick quality with regards to weight is statistically not different (P<0.05) between strains.

A = automatic incubator
B = water bed incubator

CONCLUSION AND RECOMMENDATION

The data obtained from this study indicate that there were variations among the stains in parameters such as semen volume, mass activity and semen concentration. However these variations did not influence the quality of day old chicks as no statistical difference was observed. This study there for recommends that any of the three strains of Noiler cocks can be used for breeding purposes.

ABSTRACT

A study was conducted to determine the effects of strain on gross testes morphology of three strains of noiler cocks (brown, black and spotted). The study was conducted at the poultry unit of the Bauchi State Agricultural Development Project (BSADP). The study lasted a period of eight months. A total of 45 normal feathered Noiler cocks were used for this experiment which were procured at nine weeks of age from the BSADP farm and fed commercial diet throughout the duration of the experiment. They comprised of three strains (15 brown, 15 black and 15 spotted). Testes were collected from all cocks. Testes were trimmed of all adhering fat and tissue, and weighed to the nearest 0.01mm using an electronic scale. Testis length and width were measured using a Vanier calliper to the nearest 0.01mm. Using a measuring cylinder containing known quantity of water, the testis was dropped in the cylinder and the volume of water displaced was recorded as value. The result showed that live weight, paired testes weight, paired testes volume, left testes volume and right testes volume were statistically different ($P<0.05$) among the strains. There were no significant differences observed from the other parameters across the strains which comprises of the right and left testes weight, length, width. The results showed that brown strain was superior to black and spotted. Testis weight of all the three strains fell within the range of 9-30g. From the finding of this study it is concluded that strain had significant effect on the gross testes morphology of Noiler Cocks.

Keywords: Strain, Testes, Noiler, Cocks, Morphology

INTRODUCTION

The most commonly reared poultry in Nigeria are chickens, turkeys, ducks, guinea fowls, pigeons and more recently ostriches. Those that are of commercial importance are chickens, guinea fowl's quails and turkeys. Local chickens are reared through extensive or semi-intensive system, thus reducing cost of production. They are more tolerant to endemic diseases and environmental conditions, as compared to the exotic breeds (Okpe etal, 2010). The recent ban on the importation of poultry and their products has constituted a major challenge to the indigenous poultry industry to meet up the immediate and future protein needs of the country. This challenge calls for improvement and/or change in the traditional production system and optimization of poultry reproductive traits such as fertility, hatchability and chick quality. Despite the advantages of the local chickens, most poultry improvement programmes in Nigeria have been directed towards introduction of specialized or exotic breeds, (Ikanni and Annatte, 2000). Efforts have been geared towards the development of indigenous chicken breed with improved meat and egg production and these efforts has led to the development of the Noiler breed by Amo farm sieberer hatchery limited. Therefore this research was designed to investigate the gross testes morphology of three strains of Noiler cocks.

MATERIALS AND METHODS

The study was conducted at the poultry unit of the Bauchi State Agricultural Development Project (BSADP) Bauchi State, Nigeria. It lies between latitude 9.30° and 12.3° north of the equator, and Latitude 8.48° and 11° East of the Greenwich meridian. The study lasted a period of eight months. A total of 45 normal feathered Noiler cocks were used for this experiment, they were procured at nine weeks of age from the Bauchi state Agricultural Development Program (BSADP) farm and fed commercial diet throughout the duration of the experiment, they comprised of three strains (15 brown, 15 black and 15 spotted).

Gross Morphology of Testes

Testes were collected from all cocks. Testes were trimmed of all adhering fat and tissue, and weighed to the nearest 0.01mm using an electronic scale (SF – 400). Testis length and width were measured using a Vanier calliper to the nearest 0.01mm (Bath and chaudhari, 2002). Volume was obtained using Archimedes principle. Using a measuring cylinder containing known quantity of water, the testis was dropped in the cylinder and the volume of water displaced was recorded as the volume.

Statistical Analysis

The data collected was subjected to analysis of variance procedure as contained in statistical package for social sciences (SPSS) 2011 version. Significant means were separated using Duncan Multiple Range Test (DMRT) procedure.

RESULTS AND DISCUSSION

Table 1 Gross Testes Morphology of Three Strains of Noiler Cocks.

Parameter	BLACK	SPOTTED	BROWN	SEM	LS
Live weight (kg)	3.53b	3.43b	3.83a	0.942	*
Paired Testes weight (g)	33.00b	32.66b	37.00a	0.846	*
Left Testis weight(g)	15.00	15.66	18.00	0.503	NS
Right Testis weigh (g)	17.00	17.00	18.33	0.412	NS
Left Testis length (mm)	39.84	40.07	44.46	1.049	NS
Right Testis length(mm)	40.50	39.81	42.70	0.866	NS
Left Testis width(mm)	20.56	21.39	22.94	0.554	NS
Right Testis width(mm)	21.47	31.53	21.63	0.497	NS
Paired Testis volume(ml)	34.02b	29.95b	41.07a	1.88	*
Left Testis volume(ml)	16.85b	15.17b	19.97a	0.715	*
Right Testis volume(ml)	17.17b	15.14b	21.10a	1.02	*

NS = Not Significant ($p>0.05$), LS = level of significant, * = significant ($p<0.05$), a b = means within the same row bearing different superscript varies significant.

Table 1 shows the influence of strain on gross testes morphology. Live weight, paired testes weight, paired testes volume, left testes volume and right testes volume were statistically different ($P<0.05$) between the strains. There were no significant difference ($P<0.05$) observed from the other parameters across the strains which comprises of the right and left testes weight, length, width. The results showed that the brown strain was superior to black and spotted. Testis weight of all the three strains fell within the range of 9-30g which has been widely reported for chickens at sexual maturity. Testicular length and width were slightly lower than values reported by Chidozie et al. (2010). The width diameter for the different strains recorded in this study are lower than the average reported by Chidozie et al. (2010) for the Nigerian local chicken.

CONCLUSION

From the finding of this study it is concluded that strain had significant effect on the gross testes morphology of Noiler Cocks.

ABSTRACT
The study was conducted to determine the effects of season on reproductive and growth performance of non-descript rabbits. A total of 24 non descript late grower rabbit comprising a males and 20 females were purchased from Dagwom farm of the National Veterinary Research Institute (NVRI) Jos and used as parent stock. 59 kits (34 in dry season and 25 in raining season) were used for the experiment. The kits were housed according to season. Data on litter size, birth weight, weekly body weight, weekly body weight gain and growth rate were obtained and subjected to one way analysis of variance. The results obtained from this study indicated that season had significant ($P \leq 0.05$) effect on birth weight, weekly body weight, weekly body weight gain and growth rate. Rabbits raised in raining season had significantly ($P<0.05$) higher body weight except at week 7 and 8 which were not significant. Also, season had significant ($P<0.05$) effects on body linear measurements. Rabbits raised in raining season had significantly ($P<0.05$) better body length and hind leg length while rabbits raised in dry season had significantly ($P<0.05$) longer tail length and ear length than those of raining season. From the findings of this research, it was recommended that rabbits should be bred and raised in the raining season than the dry season to maximise better growth performance.
Key word: body linear measurements, body weight, Growth rate, litter size.

INTRODUCTION
In tropical countries, the high temperature or heat stress affects the success of rabbit farming (Carneiro*et al.,* 2009), as it leads to a significant reduction in the daily weight gain, daily feed intake and feed efficiency. Above 25-28°C of ambient temperature, rabbits decreased their feed consumption and required more digestible energy (Lebas *et al.*, 1983). At 30°C, the average feed consumption was reported to be decreased by 30% and affected growth as well (Carneiro *et al.*, 2009). The effect of experimental hot environment conditions in rabbits have been extensively discussed in the last two decades mainly on growth performances and feed intake (Lebas *et al.*, 1983). But, the information based on experimental conditions, which are often quite different from each other, provide incomplete picture (Carneiro *et al.*, 2009) and cannot be implemented universally at least under farmer's conditions in developing countries. The objective of this study was therefore to determine the effect of season on reproductive performance of non descript weaner rabbit.

MATERIALS AND METHODS
The experiment was carried out at the Livestock Teaching and Research Farm of the Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University, Nasarawa State. The total of twenty four non-descript late growers rabbit were purchased from Dagwom farm of the National Veterinary Research Institute (NVRI) Jos and used as parent stock for generating offspring to be used as the foundation stock.

This was comprised of 4 males and 20 females. They were bred at ratio of 1 male to five females. Extra 2 males were bought and kept as reserve in case of mortality. 59 kits (34 in dry season and 25 in raining season) were used for the experiment. The kits were housed according to season. Hutches were cleaned, scrubbed and disinfected using vinkokil disinfectant and allowed to fallow for two weeks before arrival of the rabbits. The males were kept separately from the females for a period of four weeks for quarantining and determination of pregnant rabbit doe. During quarantining, the rabbits were given anti stress, antibiotics and all other necessary medications as appropriate. After quarantining, female rabbit on heat was taken to the male rabbit hutch for mating. This was to ensure successful mating. Each rabbit doe were mated twice to ensure conception. However, palpation was carried out ten days after successful mating to determine pregnancy. Any rabbit doe detected not to be pregnant after palpation was re-mated. The rabbit were fed formulated diet at the rate of 3kg of their body weight and forages *adlibitum*. The offspring were housed according to the season in which they

were kindled. Two major seasons such as dry (October to April) and rainy (May to September) season were considered. The rabbits were assessed to determine the effect of seasons on their reproductive and growth performance up till weaning. During this period, the rabbits were fed both concentrate and forages.

Parameters that were measured: Data collected include litter size, birth weight, weekly body weight, weekly body weight gain, growth rate and body linear measurements at weaning

Experimental Design and Analytical Procedure

The design of the experiment was Completely Randomized Design (CRD). Data collected on phenotypic traits of body weight and body linear measurements were analyzed using Analysis of Variance (ANOVA) of the Statistical Package for Social Science (SPSS) 2011 version. Duncan Multiple Range Test were used to separate the means were significant difference was observed.

RESULT

The effect of season on litter size, birth weight and weekly body weight of non discript rabbits is presented in table 1. Season had significant (P<0.05) effect on birth weight, body weight at weeks 1, 2, 3, 4, 5 and 6. Rabbits raised during raining season had significantly (P<0.05) higher birth weight and weekly body weight. However, no significant influence of season on litter size and body weight at weeks 7 and 8 was detected.

Table 1: Effect of season on litter size, birth weight and weekly body weight of non-discript rabbits

Body weight	Dry season	Raining season	LOS
Litter size	4.00±0.58	4.75±0.69	NS
Birth	35.74±0.95^{b}	39.16±1.18^{a}	*
Week 1	69.08±2.17^{b}	94.53±4.99^{a}	*
Week 2	100.65±3.82^{b}	150.58±9.50^{a}	*
Week 3	130.57±5.24^{b}	191.81±13.00^{a}	*
Week 4	188.62±7.66^{b}	251.90±15.24^{a}	*
Week 5	243.53±10.33^{b}	317.55±18.10^{a}	*
Week 6	318.97±11.99^{b}	387.74±23.97^{a}	*
Week 7	406.08±13.90	456.23±29.45	NS
Week 8	508.74±16.23	540.57±34.44	NS

NS = not significant, * = significant at 5 percent probability, ^{ab} = values with different superscript in the same row are significant (P<0.05)

Table 2 present the effect of season on weekly body weight gain of non discript rabbits. Season had significant (P<0.05) effect on weekly body weight gain at weeks 0-1, 1-2, 5-6 and 7-8. Rabbits raised during raining season had significantly (P<0.05) higher body weight gain at weeks 0-1 and 1-2 while rabbits raised during dry season had significantly (P<0.05) higher body weight gain at weeks 5-6 and 6-7. Season effect was not significant on body weight gain at weeks 2-3, 3-4, 4-5 and 7-8.

Table 2: Effect of season on weekly body weight gain of non discript rabbits

Body weight	Dry season	Raining season	LOS
Week 0-1	33.34±1.79[b]	54.39±3.97[a]	*
Week 1-2	33.03±3.01[b]	57.00±5.25[a]	*
Week 2-3	29.92±2.65	41.23±4.82	NS
Week 3-4	58.05±3.20	60.10±5.57	NS
Week 4-5	61.57±6.72	65.65±4.14	NS
Week 5-6	98.19±9.54[a]	70.19±7.14[b]	*
Week 6-7	100.63±11.90[a]	71.97±6.60[b]	*
Week 7-8	102.65±4.36	87.71±8.31	NS

NS = not significant, * = significant at 5 percent probability, [ab] = values with different superscript in the same row are significant (P<0.05)

Season effect on weekly growth rate (Table 3) was significant (P<0.05) at weeks 0-1, 3-4, 5-6, 6-7 and 7-8. Rabbits raised in raining season had significantly (P<0.05) higher growth rate at week 0-1. However, at weeks 3-4, 5-6, 6-7 and 7-8, rabbits raised in the dry season had significantly (P<0.05) higher growth rate compared to those of raining season.

Table 3: Effect of season on weekly growth rate of non-discript rabbits

Body weight	Dry season (1)	Raining season (2)	LOS
Week 0-1	47.37±1.32[b]	56.79±1.33[a]	*
Week 1-2	31.68±1.57	36.43±1.69	NS
Week 2-3	22.25±1.48	20.56±1.40	NS
Week 3-4	30.43±0.97[a]	24.36±1.86[b]	*
Week 4-5	23.74±1.65	20.93±0.87	NS
Week 5-6	28.94±2.30[a]	17.43±1.07[b]	*
Week 6-7	23.48±2.35[a]	15.29±0.81[b]	*
Week 7-8	20.23±0.69[a]	16.15±1.30[b]	*

NS = not significant, * = significant at 5 percent probability, [ab] = values with different superscript in the same row are significant (P<0.05)

Body linear measurements (Table 4) were significantly (P<0.05) affected by season except fore-leg length, and chest circumference which were not significant. Rabbits raised in raining season had significantly (P<0.05) better body length and hind leg length while rabbits raised in dry season had significantly (P<0.05) longer tail length and ear length.

Table 4: effect of season on weaning weight and body linear measurements at weaning of non-discript rabbits

Parameters	Dry season (1)	Raining season (2)	LOS
Number of observation	34	25	
Body length	28.91±0.27[b]	31.40±0.39[a]	*
Tail length	7.13±0.11[a]	6.39±0.25[b]	*
Hind leg length	14.06±0.12[b]	14.94±0.19[a]	*
Fore leg length	7.91±0.11	7.59±0.26	NS
Ear length	8.45±0.16[a]	7.32±0.32[b]	*
Chest circumference	5.93±0.09	6.23±0.18	NS

NS = not significant, * = significant at 5 percent probability, [ab] = values with different superscript in the same row are significant (P<0.05)

DISCUSSION

The significant effect of season on birth weight and weekly body weights of non discript rabbits with respect to mean birth weight of 35.74±0.93 and 39.16±1.18 g for dry and raining season observed in this study is lower than 51.0 g reported by Zerrouki (2004). Differences in litter size at birth may be due to differences in ovulation rate, pre-implantation viability, high uterine capacity, maternal effects, body size and age of the rabbit doe (Rashwan *et al.*, 1995; Argente *et al.*, 2003). The body weight increased progressively till week 8 as similarly reported by Zerrouki (2004). The results of weekly body weights at birth and from week 1 to 8 obtained in this study were similar to those of Khader *et al.* (2001) at birth and by De Paula *et al.* (1996) and El-Maghawry *et al.* (1999) at weaning and those of Darwish *et al*. (1995) and Saleh *et al.* (2005). The mean body weight obtained in this study across season at week 3 (130.75±5.24 and 191.81±13.00 g, respectively for dry and raining season) were lesser than the value of 205g and 222g for Egyptian and Bouscat rabbits reported by Brun and Ouhayoun (1989).

The effects of season on the body weight gain and growth rate of non discript rabbits indicates that season had significant effects on body weight gain and growth rate. With advancing age, body weight gain increased while growth rate decreases. The present result agrees with the report of El-Bayomi *et al.* (2012) who observed a decline in growth rate with advancing age in their work on the New Zealand White, Californian and Gray Giant Flander breeds. The significant better birth weight and weekly body weight for rabbits raised in raining season in current study is in agreement with those obtained by Seleem (2005) who reported that superiority of litters weight may be due to hybrid vigour which appeared in different ages of kits up till weaning.

CONCLUSION AND RECOMMENDATION

The result of this study indicates season had significant effects on birth weight, weekly body weight and body linear measurements. Rabbits raised in raining season had better birth weight and weekly body weight. Body weight and body weight gain increases progressively with age until 8 weaning. However, growth rate decreases with advancing age. Generally, rabbits raised in raining season performed better than their counterpart raised in the raining season. From the findings of this research work it was recommended that: Rabbits should be bred in the raining season than the dry season to maximized better litter size and higher birth weight which will translate to higher body weight at various ages.

ABSTRACT

A study was carried out to determine live weight, serum biochemical indices and hormonal profiles of Muscovy drakes in Maiduguri, Borno state. Fifteen (15) one year old drakes were dewormed and quarantined for a period of two weeks during which they were fed a commercial layer diet (16%CP) and water *ad libitum*. The live weight of each drake was taken before blood collection. Blood samples for serum biochemical analysis and hormonal assay was collected from the wing-vein by means of a sterile disposable (21-guage) syringe and needle and placed in anticoagulant free samples bottles to obtain serum. Total protein, albumin, globulin, sodium, potassium, chlorine, testosterone, luteinizing hormone (LH) and follicle stimulating hormone (FSH) levels were recorded. Live weight of the drakes ranged from 1800-3900g with an average of 2766.67±139.71g. The mean levels of total protein, albumin and globulin were 48.67g/l, 17.00g/l and 31.53g/l respectively. Testosterone level of 3.79±0.45ng/mol, Follicle stimulating hormone (FSH) range of 0.10-1.40mmol/ml with a mean of 0.51mmol/l and mean Luteinizing hormone (LH) of 2.93±0.44 mmol/ml were recorded. A positive relationship was noted between body weight and luteinizing hormone levels while serum protein was negatively related to body weight. It was concluded that the sex hormones levels (testosterone, FSH and LH), testicular morphology and serum biochemical profiles of Muscovy ducks in the semi-arid zones of Nigeria are similar to those reported in literature.

Key Words: Ducks, Serum biochemistry, Testosterone, Follicle stimulating hormone

INTRODUCTION

Ducks have the potential to play an important role with respect to food production and security in Nigeria. With an estimated population of about 9,553,911, ducks are the third most populous poultry in Nigeria (National Bureau of Statistics, 2012). Ducks lay many and large eggs and have rapid growth rate and high dressed weight (Duru *et al.*, 2006). Yakubu (2013) opined that increased duck rearing would be a great addition to total poultry output since they do not interfere with chicken production due to different rearing and scavenging venues. Yakubu (2013) further noted that the morphological, meat and egg attributes of the Muscovy duck readily make it the waterfowl of choice for Nigerian poultry farmers. He concluded that Nigeria needs to take advantage of the economic and nutritional benefits from duck rearing to improve the shortage in the animal protein supply in the family diet. Pym *et al.* (2002) also noted that keeping ducks is one of the possible means of breaking out of the poverty trap for resource poor small holder families in low income countries. Small scale duck farming has not only been proved to be beneficial occupation for small, marginal and landless farmers, but also a potential source of self-employment (Jabber, 2004).

The domestic duck in Borno and elsewhere in Nigeria is the Muscovy duck, of South American origin. It was probably introduced on the sea-coast by the Portuguese and spread inland. Ducks are kept sporadically throughout northeast Nigeria, especially in riverine areas (Blench, 1995). Duck farming is still carried out under extensive management in the form of small family flocks. Low fertility is a major problem in such flocks and the role of drakes in this problem has not been sufficiently studied. Information on blood parameters and reproductive hormone levels of the Muscovy drakes can be used to serve as baseline data to be used in clinical evaluation and improvement in fertility of local stock. This study was therefore designed to determine the relationship among reproductive hormonal profile and serum biochemical parameters of Muscovy drakes in Maiduguri, Borno state.

MATERIALS AND METHODS

The study was conducted at the poultry unit of the Teaching and Research Farm of the Department of Animal Science, Faculty of Agriculture, University of Maiduguri, Borno state – Nigeria. Maiduguri is located between latitude 11º 15 and 12 º north, longitude 30º 05 and 14º east and at an altitude of 345m above sea level (Raji *et al.,* 2014).

A total of fifteen (15) one year old drakes were purchased from households in Maiduguri and used for the experiment. The drakes were dewormed and quarantined for a period of two weeks during which they were fed a commercial diet (16%CP) and water *ad libitum.*

The live weight of each drake was taken before blood collection using a manual weighing balance to the nearest 50g. To obtain blood samples for sera analyses, the drakes were fasted overnight and 5ml of blood was collected from the wing-vein by means of a sterile disposable (21-guage) syringe and needle and placed in anticoagulant free samples bottles to obtain serum for serum biochemical analysis and hormonal assay measurements. Total protein, albumin, globulin, sodium, potassium and chlorine levels were estimated through calorimetric method using Digital Vas Ultraviolet Spectrophotometer while testosterone, luteinizing hormone (LH) and follicle stimulating hormone (FSH) were estimated using ELISA kits by a solid phase enzyme immuno-assay. The blood biochemical analysis and hormonal assay were done at the haematology laboratory of the University of Maiduguri Teaching Hospital.

RESULTS AND DISCUSSION

Table 1 shows the descriptive statistics for live weight, serum biochemical indices and hormonal profiles of Muscovy drakes in Maiduguri, a semi-arid environment. The live weight of the drakes ranged from 1800-3900g with an average of 2766.67±139.71g which is similar to the 2.73 kg and 2.2 kg reported for Muscovy drakes in Nigeria by Yakubu (2013) and Ikani (2003) respectively.

The mean levels of total protein, albumin and globulin were 48.67g/l, 17.00g/l and 31.53g/l respectively which were similar to those reported by Olayemi *et al*. (2006) in adult Nigerian ducks. The means for serum sodium and potassium observed in this study was similar to the means (140.00±1.00 mmol/l and 3.77±0.15) observed by Okeudo *et al.* (2008) for Muscovy drakes in southeastern Nigeria.

The testosterone level of 3.79±0.45ng/mol was similar to values reported by Snapir *et al.* (1998) for healthy Muscovy drakes. FSH range of 0.10-1.40mmol/ml with a mean of 0.51mmol/l and LH level of 2.93±0.44 mmol/ml were obtained in this study.

Table 2 shows the correlation between live weight, reproductive hormone levels and serum biochemical profiles of Muscovy drakes. Live weight of the drakes was highly correlated (r = 0.59) with LH levels but negatively correlated with total protein (r = -0.56) and globulin (r = -0.57). A moderate but negative relationship existed between albumin and the total protein. There was a high and positive relationship between globulin and total protein, whereas it was strong but negative between globulin and albumin. This is an expected trend since albumin and globulin are components of total protein. A moderate but negative correlation between sodium and total protein, sodium and albumin were observed. There was a low but positive relationship between potassium and sodium and a moderate but negative relationship between potassium and chlorine.

Table 1: Live weight, Serum Biochemical Indices and Hormonal Profiles of Yearling Muscovy Drakes in Maiduguri

Parameter	Minimum	Maximum	Mean	±SEM
Live weight (g)	1800.00	3900.00	2766.67	139.61
Total protein (g/l**)**	39.00	69.00	48.67	1.98
Albumin (g/l)	10.00	22.00	17.00	0.84
Globulin (g/l)	17.00	56.00	31.53	2.54
Sodium (mmol/l)	129.00	152.00	141.47	1.88
Chlorine (mmol/l)	89.00	106.00	97.33	1.58
Potassium (mmol/l)	3.20	6.20	4.42	0.25
Testosterone (ng/mol)	1.00	6.60	3.79	0.45
FSH (mmol/ml)	0.10	1.40	0.51	0.09
LH (mmol/ml)	0.10	6.90	2.93	0.44

FSH – Follicle stimulating hormone; LH – Luteinizing hormone

Table 2: Correlation of Some Serum Biochemical Indices and Hormonal Profile of yearling Muscovy Drakes in Maiduguri

Parameter	1	2	3	4	5	6	7	8	9	10

*- Correlation is significant at 0.05 level (2 tailed); **- Correlation is significant at 0.01 level (2 tailed)

CONCLUSION AND RECOMMENDATION

It was concluded that the sex hormones levels (testosterone, FSH and LH), testicular morphology and serum biochemical profiles of Muscovy ducks in the semi-arid zones of Nigeria are similar to those reported in literature. A positive relationship was noted between body weight and luteinizing hormone levels while serum protein was negatively related to body weight.

ABSRACT

The experiment was conducted at the Teaching and Research Farm of the Department of Animal Science, Bayero University, Kano to determine the effect of crystalline progesterone on ovarian changes of eighteen Lohmann Brown hens between March to July, 2017. A single factor completely randomized design was used with each treatment replicated three times. Six different doses (0, 5, 10, 15, 20 and 25 mg/bird) of crystalline progesterone were administered intramuscularly via the keel muscle twice a week for a total period of six weeks. Data obtained were analyzed using GraphPad InStat® statistical package. Results revealed that median ovulation rate (33.3%) in the 5 mg crystalline progesterone group decreased significantly by a magnitude of 66.7% when compared to its corresponding value (100%) in control birds.No significant changes were observed in median weights of ovarian stroma and oviduct across crystalline progesterone treatment groups.Significant decrease was recorded in median count of large yellow follicles across crystalline progesterone treatment groups.There were no significant differences in median counts of small yellow, large white and medium white follicles. In conclusion, crystalline progesterone has effect on the birds ovulation rate, large yellow follicle count, laying pause days, egg sequence length, egg shell weight and egg yolk and albumen volumes in Lohmann Brown hens. It is therefore commended that crysteline progesterone could administerd on laying birds up to 20 mg.

Key word: Crystalline Progesterone, Ovarian, Lohmann Brown Hens

INTRODUCTION

The term poultry is used on birds domestically raised primarily for the economic purpose of producing eggs and meat. Poultry production involves egg and meat production from egg type and broiler chickens (Kumaravel, Hema & Kamaleshwari, 2012). Poultry meat and eggs offer considerable potential for meeting human needs for dietary supply of animal protein (Folorunsho & Onibi, 2005). Egg production in laying hens is a process that takes around 24 to 27 hours (Akbas, Unver, Oguza & Altan, 2002). The Lohmann Brown strain of chicken is an early maturing hybrid bird which is among the best egg producers with good quality eggs and excellent feed conversion rate (Lohmann Tierzucht, 2015). The Lohmann Brown strains are easy to manage and are adaptable to all types of production systems with laying commencing at about 18 weeks of age, producing about 300 to 320 eggs in a year (Lohmann Tierzucht, 2015). Eggs are the major business output in commercial egg production and the higher the egg production the better will be the profit (Farooq, Mian, Ali, Durrani Asghar, & Mugarrab, 2001). Hormones are very essential for poultry reproductive functioning (Johnson & Tilly, 1990). Progesterone is a hormone secreted by granulosa cells of large mature hierarchical follicles (F1) in birds (Bahr, Wang, Huang & Calvo, 1983). It acts at the level of the ovary to stimulate the luteinizing hormone surge for ovulation. Its production by F1 follicle peaks 6 to 8 hours prior to ovulation (Johnson & van Tienhoven, 1984). Progesterone triggers release of gonadotropin-releasing hormone (GnRH) by the hypothalamus. This in turn is followed by an increase in luteinizing hormone and follicle stimulating hormone release from the anterior pituitary (Bahr *et al*., 1983). The luteinizing hormone stimulates an even greater output of progesterone by the granulosa cells of the F1 follicle, completing the positive feedback loop and producing the LH peak 4 to 6 hours prior to ovulation (Tanabe, Nakamura, Tanase & Dior, 1981). The present study aimed at determining the effect administration of exogenous progesterone on ovarian changes of loman Brown hen.

Experimental Location and Duration of Study

The study was conducted at the Poultry Unit of the Teaching and Research Farm of the Faculty of Agriculture, Bayero University Kano (GPS coordinates: N11.97643°, E008.42995°) for a duration of six weeks.

Experimental Design and Treatment

The experiment was laid in a Single Factor Completely Randomized Design, comprising six treatments replicated three times. The six treatments were 0, 5, 10, 15, 20 and 25 mg crystalline progesterone/bird. These doses were administered via the breast muscle between 10 and 11 am on Mondays and Thursdays throughout the experimental period.

Oviposition Pattern

Oviposition pattern comprising number of egg sequences, egg sequence length, pause days and intersequence pause length were determined according to the procedure described by Blake, Balander, Flegal and Ringer (1987).

Statistical Analysis

To determine the effect of crystalline progesterone on ovarian changes, oviposition pattern, laying performance and egg quality parameters, Kruskal-Wallis Test was used. Where significant effects exist, mean rank differences were compared using Dunn's Multiple Comparisons Test. Graphpad Instat package (Graphpad InStat®, version 3.05, 32 bit for Win 95/NT, Graphpad Software Inc., 2000) was used for the statistical analysis.

RESULTS AND DISCUSSION

Ovarian Changes

The effect of crystalline progesterone levels on oviduct weight in Lohmann Brown hens is presented in Table 2. There was no statistically significant ($P>0.05$, Kruskal-Wallis Statistic = 9.075) difference in median oviduct weights (74.5, 46.0, 26.0, 38.5, 30.0 and 47.0) across progesterone treatments. The minimum oviduct weights recorded were 74.5, 32.0, 20.0, 30.0, 20.0 and 46.0 g across 0, 5, 10, 15, 20 and 25 mg crystalline progesterone treatment groups, respectively. Crystalline progesterone treatments levels (0, 5, 10, 15, 20 and 25 mg) recorded respective maximum oviduct weights of 76.8, 60.0, 31.0, 47.0, 52.0 and 51.0 g.

Chronic injection of progesterone has been shown to increase baseline concentrations of progesterone and result in arrested laying and disrupted distribution of hierarchical follicles in turkeys (Liu *et al*., 2001; Bacon & Liu, 2004). High baseline concentrations of progesterone in arrested hens might negatively feedback on the ability of the hypothalamus to secrete surges of GnRH and subsequently surges of LH, or on the ability of the pituitary to respond to surges of GnRH secretion if they occur (Liu *et al*., 2001; Bacon & Liu, 2004; Liu & Bacon, 2005). This could explain the dose-dependent decrease in ovulation rate, count of large yellow follicles, number of eggs laid and egg sequence length in the current work due to low GnRH and LH which subsequently translates into low endogenously produced progesterone. Also, no egg was produced at crystalline progesterone dose beyond 5 mg probably due to strong negative effect on egg production rate and hierarchical follicular maintenance and development (Zaghari, Taherkhani & Honarbakhsh, 2009). It is also evident that, though the decrease in egg production started as early as when 5 mg crystalline progesterone was administered, reduction in egg production to the level of zero production manifested as the dose of crystalline progesterone was increased to 10, 15, 20, and 25 mg. The arrested laying and disruption in hierarchical follicles observed in the present study agrees with results of Liu *et al*., (2001) and Bacon and Liu (2004).

In conclusion, intramuscular administration of crystalline progesterone to actively laying Lohmann Brown hens affected ovulation rate, large yellow follicle counts, laying pause days, number of egg sequence, egg sequence length, egg yolk and albumen volumes, and egg shell weight.

ABSTRACT
A study was conducted to evaluate the influence of genotype on reproductive performance of two breeds of rabbit and their reciprocal crosses as well as body weight performance of their first filial generation. A total of 126 kittens were generated from cross of Newzealand white (NZWXNZW), Chinchilla (CHXCH) and their reciprocal crosses Newzealand male and Chinchilla female (NZWXCH) and Chinchilla male and Newzealand female (CHXNZW). The parameter measured were Gestation length (GL), Litter size at birth (LSB), Litter size at weaning (LSW), Birth weight (ABWT), Body weight at weaning (AWWT) and weekly body weight. The data obtained were subjected to analysis of variance and significance means were separated using Duncan multiple range test. The results indicated that genotype significantly ($p<0.05$) influenced weekly body weight during the preweaning stages. The NZWXCH had significantly higher body weight than the other three genotypes. It was also observed that NZWXCH had significantly ($p<0.05$) better LSW (4.95±0.03), ABWT (37.00±0.03), GL (28.33±0.67), AWWT (594.55 ±12.18), and percentage mortality (5.71±8.69) than other genotypes. It was concluded that NZW X CH be used for breeding purposes to increase rabbit production, as this genotype indicated better suitability in the tropics, thus increasing and improving protein intake in the study area.
Key words: Rabbit, Body weight, Reproductive, Performance, Genotype

INTRODUCTION
The population growth in developing countries like Nigeria is rapidly increasing, thus the need for alternative source of protein to meet up the protein requirement of the population. Rabbit production is a veritable way of alleviating animal protein deficiency in Nigeria (Ajala and Balogun, 2004), because rabbit has immense potentials and good attributes which include high growth rate, high efficiency in converting forage to meat, short gestation period, and high prolificacy, relatively low cost of production, high nutritional quality of rabbit meat which includes low fat, sodium and cholesterol levels. It also has a high protein level of about 20.8% and its consumption is bereft of cultural and religious biases (Biobaku and Oguntona, 1997).

The production of rabbit meat is based on pure breed selected for meat traits and on their crosses (Maj *et al.*, 2009). As production of livestock directly depends on reproduction, reproductive performance of rabbits becomes an important aspect in determining profitability and economic success of commercial rabbits breeding. Litter size (the number of kits born) is the most important economic character in rabbit production (Nofal *et al*., 2005).. Litter size is mainly controlled by heredity and can be improved by crossbreeding between breeds (Nofal *et al*., 2005). Pre-weaning survival percentage of kit rabbits is of vital importance in commercial rabbit farming, where it plays a major role in determining the net financial income of the farms (Rashwan and Marai 2000)..

Factors such as breed, season, age and weight of females influence the reproductive performance of animals (Lazzaroni *et al.*, 2012). Cross breeding is one of the fast tools offered to a breeder to improve many traits in farm animals including rabbits (Nofal *et al.*, 2005). The major essence of deliberate selection for breeding is to improve the quantitative traits.

Genetic improvements of animal require a good understanding of basic concepts of animal breeding (Ibe, 1998). Previous works by Fayeye (2013) revealed significant heterosis for growth rate and body weight though at variable values of parental means. Chineke,(2006) reported superiority of the crossbreds over pure breeds for mean body weight and linear body parameters. Rochambeau (1988) in a study conducted to compare pure breed rabbits and the terminal crosses involving these breeds, observed heteroic effect on litter growth rate. In similar experiment, (Oseni *et al.*, 1999) reported that crossbred rabbits showed superior performance over pure breeds in all pre-wearing litter traits studies. These findings suggested that cross breeding under tropical condition hold some promises in improving performance traits in

rabbits. Therefore, this study was conducted to evaluate reproductive and pre-weaning characteristics of two strains of rabbits and their reciprocal crosses in Obio Akpa, in Nigeria.

Experimental Site

This experiment was carried out at the Rabbitary Unit, Teaching and Research Farm, Akwa Ibom State University Obio Akpa Campus. Obio Akpa is located between latitudes $5^0 17^1$N and $5^0 27^1$N and between longitudes $7^0 27^1$N and $7^0 58^1$E with an annual rainfall ranging from 3500mm – 5000mm and average monthly temperature of 25^0C, and relative humidity between 60-90%. (Wikipedia, 2016).

Experimental Animals and Management

A total of forty (40) adult rabbits (New Zealand White and Chinchilla) comprising 18 New Zealand White does and 18 Chinchilla does, 2 New Zealand White bucks and 2 Chinchilla bucks were used. One New Zealand White buck was selected to mate with 9 New Zealand White does and the second new Zealand buck was selected to mate with 9 Chinchilla does. While one Chinchilla buck was selected to mate with 9 Chinchilla does and the second chinchilla buck selected to mate with 9 New Zealand White does. At the end of breeding period one hundred and twenty six (126) kittens produced from crosses comprising of NZW x NZW, CHA x CHA, NZW x CHA and CHA x NZW (Table 1) were used for this study. The rabbits were kept in 4 hutches each measuring 170cm by 32cm and consisting of 10 cells, each of which was measuring 34cm x 30cm x 28cm such that one rabbit was accommodated in one cell. Identification marks such as tags were placed on the cell in which each rabbit was accommodated.

All the rabbits in their respective cells were fed with forages such as *Ipomea batata*, *Centrosema spp*, *Peuraria phaseoloides* and commercial concentrates feed was also given with drinking water ad-libitum. The diet fed to the animals consisted of 18% CP, 2600 Kcal/kgME, and 8% CF as analyzed. Routine management operations were carried out on a daily basis. Pregnancy was detected by careful abdominal palpation on 14th and 21st days after mating, if confirmed pregnant, nest boxes were provided on 28th day of pregnancy.

Table 1: Mating scheme and number of progeny produced

Genotype	Number of sire	Number of Dam	Number of Progeny
CH X CH	1	9	35
NZW X NZW	1	9	27
CH X NZW	1	9	31
NZW X CH	1	9	33

Note: CH = Chinchilla; NZW = New Zealand White

DATA COLLECTION

Measurement/Data Collection

The following parameters were measured

Gestation Length: This was measured by finding the interval between the date of last mating and date of kindling.

Litter Size at Birth: This was measured by direct counting of the kittens immediately after kindling with still birth inclusive.

Litter Size at Weaning: This was the number of weaner's (young rabbits) in each litter at weaning time (6 weeks).

Birth Weight: This was measured by transferring all the kittens in a litter with gloved hands well rubbed on the body of the doe in question to the weighing scale and the weight of the litter read off and divided by the total number of kittens in the litter.

Body Weight at Weaning: This was measured by taking the weight of each kitten in a litter at weaning time (6 weeks).

Weekly Body Weight: This was measured by weighing each kitten in a litter on weekly basis.

Statistical Analysis / Experimental Design

The effect of sire breed and dam breed on performance traits (gestation length, litter size at birth, birth weight, litter size at weaning, body weight at weaning and weekly body weight) were subjected to analysis of variance (ANOVA) using the General Linear Model (GLM) procedure of SPSS. Significant means were separated using New Duncan Multiple Range Test. The Model incorporated Genetic Groups as fixed factors while performance traits (gestation length, litter size at birth, birth weight, litter size at weaning, body weight at weaning and weekly body weight) were dependent variables.

The linear model was as follows;

$Y_{ij} = \mu + Bi + E_{ij}$

Where:

Y_{ij} = measurement on traits

μ = Population mean

B_i = Effect of ith genetic groups (CH x CH, NZW x NZW, NZW x CH, and CH x NZW)

E_{ij} = Random error effect

RESULTS AND DISCUSSION

The means of weekly body weight of kittens from the four genetic groups are presented in Table 2, the result showed that NZW X CH genotype had significantly ($P<0.05$) highest weight (145.23g) followed by NZW X CH (133.30g) and CH X NZW (111.75g) which were statistically similar; while CH X CH had the least weight (84.62g) at end of week one. At week two NZW X CH still showed significant ($P<0.05$) higher body weight (201.08 ± 3.85) than other genetic groups which were statistically similar, 127.83 ± 7.09, 182.61 ± 4.18 and 146.160 ± 2.96 for CH X CH, NZW X N2W and CH X NZW respectively. This trend was observed throughout the pre weaning period of 6 weeks. The result obtained from this studies are similar to those reported by Ajayi *et al*., (2018), Oke *et al*., (2010) who all observed significant differences on body weight of different breeds of rabbits. But this study is contrary to the reports of Ozimba and Lukefahr (1991) who observed no significant differences for growth traits of different breeds of rabbit in a comparative study. The animals increased in body size and other body dimensions as they grow in age indicating that, the animals were in normal good physiological and health conditions, Ajayi *et al.*, 2018 had earlier indicated that the genotype and environmental factors such as nutrition, disease, hormone and general management could lead to variation in growth rate or weight gain of rabbit within the same breed or among different breed. However variation in body weight in this study could be as a result of genetic variations in the various genotypes used. Body weight is said (Ajayi *et al*., 2018) to be highly heritable and hence the selection of heavier individuals in a population should result in genetic improvement of the trait.

Table 2: Mean (± s.e) Body weight (g) performance of 2 breeds of rabbit and their crosses

Age (weeks)	CH × CH (g)	NZW × NZW (g)	CH × NZW (g)	NZW × CH (g)
1	84.62 ± 5.33[c]	133.30 ± 3.39 [b]	111.75 ± 1.285[b]	145.23 ± 4.39[a]
2	127.83 ±7.09[b]	182.61 ± 4.18[b]	146.160 ± 2.96[c]	201.08 ± 3.85[a]
3	190.12 ±10.77 [c]	267.77 ± 11.16[b]	188.20 ± 2.94[c]	315.48 ±15.11[a]
4	326.59 ±14.91[b]	397.53 ± 9.09[b]	266.60 ± 6.08[c]	468.09±13.87[a]
5	364.57 ± 16.77 [c]	474.88 ± 8.57[b]	335.76 ± 6.06[c]	522.26 ±12.82[a]
6	418.78 ± 16.57 [c]	532.88 ± 7.554[b]	394.04 ± 8.07[c]	594.55±12.18[a]

a,b,c = Mean with different superscripts in the same row are significantly different (P<0.05).

The means of the reproductive traits of the four genotypes are presented in Table 3. The result indicated that there were no significant differences among the genetic groups in litter size at birth (LSB). The result of this study is contrary to reports of Fadara and Fatoba (2018) who observed significant differences between genetic groups in litter size. But agrees with the work of MaryKitty and Nandakumar (2000) who reported non-significant effect of breed on litter size and litter weight at births.

However, significant (P<0.05) differences were observed among genetic groups in litter size at weaning (LSW) ,NZW X CH crosses had significantly (p<0.05) higher litter size at weaning (4.95 ± 0.54) than other genotypes which were similar statistically. The average birth weight (ABWT) also followed the same trend as litter size at weaning. The NZW X CH crosses had significantly (P<0.05) heavier body weight at birth, while other genotypes were similar. Litter size at weaning is considered to be the best trait to us as selection criteria for improving reproductive performance (Moustafa *et al*., 2014; Fadara and Fatoba (2018). This is because the productivity of rabbit depends primarily on the number of young kits surviving the pre-weaning stage. The ability of the doe to produce thrifty young at birth and to raise this young to weaning determines her productivity (Sorensen *et al*., 2001). Thus, to maintain efficiency in rabbit production, high litter size at weaning is necessary. The report from this study is in line with the reports of Fadara and Fatoba (2018) who observed that litter size and litter weight at weaning were affected by breed.

The best gestation length (shortest) of 28.33 ± 0.67 days was recorded for NZW X CH crosses which was significantly (P<0.05) different from other genotypes which were statistically similar 31.67 ± 1.14, 31.37 ± 0.67 and 30.50 ± 0.56 for CH X CH, NZW X NZW and CH X NZW respectively. Variations in gestation length of rabbit due to differences in breed had earlier been reported by Apori *et al*., 2015.

The result (Table 3) indicated that there were significant (p<0.05) differences between the genetic groups in percentage mortality. It was observed that NZW X NZW genetic group had the highest percentage of mortality (50.28 ± 5.78) followed by CH XCH genetic group (25.10 ± 3.87) the crosses CH X NZW and NZW X CH genetic groups had similar percentage mortality, 8.87 ± 4.05 and 5.71 ± 8.69 respectively. The high percentage mortality observed in NZW X NZW genetic group could be attributed to poor mothering ability, which may have resulted from inability of the does to produce sufficient fur in the nesting boxes for the naked kits at birth. It may also be attributed to tropical environmental condition which may not favour the genotype. Earlier report by Topezewka (2013) and Fadara and Fatoba (2019) indicated variation between rabbit breeds in percentage mortality.

Table 3: Mean (± s.e) of reproductive traits of 2 breeds of rabbit and their crosses

Age	CH × CH	NZW × NZW	CH × NZW	NZW × CH
LSB	5.83 ± 0.98	5.50 ± 0.34	4.50 ± 0.67	5.17 ± 0.67
LSW	4.30 ± 0. 89[b]	2.67 ± 0.21 [b]	4.00 ± 0.52[b]	4.95 ± 0.54[a]
ABWT	32 .55 ± 0.02[b]	35 50 ± 0.01[b]	33. 05 ± 0.01[b]	37.00 ± 0.03[a]
GL	31.67 ± 1.14[a]	31.37 ± 0.67[a]	30.50 ± 0.56[b]	28.33 ± 0.67[a]
AWWT	418.78 ± 16.56[b]	532.88 ± 7.56[b]	394.04 ± 8.07[b]	594.55 ±12.18[a]
% MORT	25.10 ± 3.87[b]	50.28 ± 5.78[a]	8.87 ± 4.05[c]	5.71 ± 8.69[c]

Mean with different superscripts in the same row are significantly different (P<0.05), LSB = Litter size at birth,

CONCLUSION

NZW X CH had a significant higher performance in body weight during the pre-weaning stage and other reproductive parameter measures (LSB, LSW, ABW, GL, AWWT and %mortality). Therefore, the NZW X CH genotype is suitable in the humid tropics in serving as protein source for the populace in Obio Akpa.

EFFECT OF FLOCK AGE ON FERTILITY AND HATCHABILITY TRAITS OF SHIKABROWN® CHICKENS

Suleiman S., W.A. Hassan & A.A. Kwaido
Department of Animal Science, Kebbi State University of Science and Technology Aliero, Nigeria
Corresponding author: Suleiman S.; Email: sstune98@yahoo.com Mobile:+2348060792941

ABSTRACT
The research was conducted to determine the effect of flock age on fertility and hatchability traits of ShikaBrown® chickens in Aliero. A total of 1177 hatchable eggs were collected from birds of African Chicken Genetic Gains (ACGG) project in Kebbi State and incubated at different flock age (48, 49, 50 and 51 weeks). The experimental design used was the Nested type (Henderson, 1963). The Parameters considered include mean egg weight, fertility, hatchability, hatch weight and embryonic mortality. The data was analyzed using GLM of SPSS (2013). Significant interaction (P≤0.05) was observed between flock age and egg weight, fertility, hatchability, embryonic mortality and hatched weight. Highest egg weight (58.40±0.32g) and hatchability (68.57±1.91%) were recorded at age 51, fertility was highest (94.65±1.75%) at age 50 weeks and lowest (89.52±2.21) at 48 weeks. Egg weight, hatchability and hatched chicks' weight were amplified (P≤0.05) with increase in age (48-51 weeks). Embryonic mortality improves with advancing age (P≤0.05) and was highest at the early stage and lowest at mid-stage of incubation.
Key words: Flock age; fertility; hatchability traits; chick weight; ShikaBrown®

INTRODUCTION
Fertility and hatchability are interrelated heritable traits that vary among breeds, and individuals in a breed (King'or, 2011). According to Brillard (2003), fertility of individual egg is a function of the genotype of the embryo to which both parent (sire and dam) contribute. Thus if the fertility in a flock is low many infertile eggs will be incubated. Hatchability on the other hand is the rate at which incubated or fertile eggs are turned into viable chick after 21 days of incubation. Hatchability is determined based on the number of eggs set or fertile eggs set after candling on the seven and eighteen days of incubation (Orunmuyi *et al.*, 2011). Failure of an egg to hatch is caused by infertility or by death of embryo after fertilization.

Several genetic and non-genetic factors have been reported to influence fertility and hatchability of chicken eggs. These factors include: breed, egg age, storage condition, nutrition, system of husbandry and rearing technology, mating system, mating ratio, incubation relative humidity, temperature and eggs turning angle (Wilson, 1997; King óri, 2011; Bobbo *et al.*, 2013).

The ShikaBrown® chicken breed is the preferred layer breed in Nigeria having remarkable characteristics that include excellent shell quality, high production rate, persistency, egg weight, livability, and feed conversion and is well adapted to the harsh tropical environment with resistance to many diseases of economic importance (Ayorinde *et al.*, 2016). However, there is paucity of information on fertility and hatchability traits of the breed. The present work was carried out to determine effect of flock age on the fertility and hatchability traits of ShikaBrown® chickens.

MATERIALS AND METHOD
Location of experiment

The research was conducted at the Animal Science Laboratory, University campus at Aliero (Lat. 12° 18'18" N, Long. 4° 29'52"E and Alt. 266.2m above sea level) in the dry sub-humid zone of Nigeria.

Management of breeding stock

During the onset of lay, the birds were fed diet containing 2,600 ME Kcal/kg and 16-18% crude protein. Egg production of the parent stock was observed before selection and setting up of mating pens. A total of 96 ShikaBrown® chickens of age 48 weeks were used as parents for the study. The birds which consisted of 84 pullets and 12 cocks were selected and allowed to mate in separate pens labelled according to the cocks (sire).

Mating and incubation of fertilized eggs

The pullets with brown plumage were mated to white- brown cocks at a ratio of 1:7. Fertile eggs were collected three times daily (7:00am, 2:00pm, and 5:00pm). The eggs were sorted to remove cracked eggs, soiled eggs, small sized or oversized eggs.

Selected eggs were labeled, fumigated and stored in cool room at a temperature of 19°C for a period of 24 hours before setting them in an automated incubator. The incubation process was conducted according to flock age, taken into account the number of fertile eggs and number of eggs hatched in each breeding pen. Candling was done at the 7th and 14th day to remove infertile eggs and eggs with dead embryos. At the 20th -23rd day of each batch of incubation hatched chicks were removed and eggs that failed to hatch were removed, examined and counted as late stage of embryonic mortality.

Experimental design

The experimental design used was the Nested type (Henderson, 1963), in which a sire is mated to several dams with each mating producing several offspring. The model is given below:

$Y_{ijk} = \mu + A_i + B_j + W_k + \varepsilon_{ijk}$

Where Y_{ijk}= any observation; μ = overall mean; A_i = effect of sire; B_j = effect of flock age;

W_k = effect of interaction between sire and flock age and ε_{ijk} = random error

RESULTS AND DISCUSSION

Effect of age on egg weight of ShikaBrown® pullets

Expectedly, age has significant effect on egg weight (P≤0.05). Eggs of age 51 weeks were heaviest (58.40±0.32g) and were statistically similar in weight with those of 48 and 50 weeks (57.82±0.29 and 57.90±0.28). However, eggs of 49th week (57.41±0.24) were the lightest (P≤0.05). The mean egg weight in this study concurred with the findings of Abudabos *et al.* (2010) who reported that egg weightwas affected by collection week or hen's age (p≤0.05), heavier eggs were produced in weeks 3 and 4 (45.42 and 45.48 g, respectively) compared with weeks 1, 2, 6, 7, 8, and 11 (44.72, 44.54, 44.59, 44.65 and 44.28 g respectively).

Effect of age on fertility of ShikaBrown® chickens

The fertility of 94.65±1.75 and 93.69±1.87 percent observed at the age 50 and 49 weeks, were similar and higher (P≤0.05) than 92.07±1.96 and 89.52±2.21 of age 51 and 48 weeks respectively. Percent fertility at week 51 and 48 were similar (P≤0.05). The flock fertility observed increases with age reached maximum and tends to decline at 51 weeks of age. The results agreed with the findings of Abudabos *et al.* (2017) who reported that fertility (F) was influenced by collection week or hens' age (p≤0.05), with eggs collected in week 3 presenting the lowest fertility percentage (60.45%), which, however, was similar to those collected in weeks 2, 6, 8, and 9 (73.68, 71.53, 71.79, and 71.14%, respectively). Similarly, Elibol and Brake (2006) reported 97.1% and 81.1 % fertility for young (34 and 37 weeks) and old (59 and 61 weeks) broiler breeder flocks respectively and suggested that fertility of total eggs differed with flock age (P ≤ 0.01) and was more for young than for old flocks.

Effect of age on hatchability of ShikaBrown® eggs

Hatchability of eggs was influenced significantly by the flock age (P≤0.05). The highest hatchability recorded at 51st week (68.57±1.91%) and the lowest was at 48th week (47.00±1.66%). Hatchability at 49th week (61.66±1.78) was similar (P≤0.05) with that of 50th week (59.51±3.02). Expectedly, the results showed a trend of relatively increasing hatchability rates with the flock age since the flocks studied were within their first year in lay and under normal conditions, hatchability is expected to drop during second year in lay (Oluyemi and Roberts, 2000).

Effect of age on hatch weight of ShikaBrown® chicks

Hatch weight was significantly influenced by flock age (P ≤ 0.05). The hatch weight at age 50 (43.12±0.25g) and age 51 weeks (43.08±0.22g) were not different statistically, but were higher (P ≤ 0.05) than the hatch weight of 42.42±0.20g and 42.69±0.19g for age 48 and 49 weeks respectively. Expectedly, the results show a linear relationship between age and hatch weight which proves that as the pullets ages hatch weight increases. The hatch weights obtained in this report agreed with the findings of Abudabos *et al.* (2017) who studied hatch weights of free-range Hassawi indigenous chickens and

reported that lightest hatchlings were obtained from eggs collected in week 1 (28.96 g), while eggs collected in week 2 produced intermediate weight hatchlings (29.77 g) ($P \leq 0.01$) and the heaviest chicks hatched were from eggs collected in weeks 3, 4, 6,7, and 8 (30.65, 30.99, 30.70 and 30.56, respectively).

Effect of age on embryonic mortality

Age had significant effect on early, mid and late stage embryonic mortality ($P \leq 0.05$). Early embryonic mortality was higher at age 48 weeks (27.24%±2.23) than 17.96%±1.84, 20.34%±1.78 and 16.17%±1.58 (at age 49, 50 and 51 weeks respectively). Similarly, midterm embryonic mortality was highest (9.56%±1.58) at 50 weeks of age and the lowest (4.56%±1.04) was at 49 weeks. Late embryonic mortality was higher ($P \leq 0.05$) at age 48 (18.54±1.61%) and 49 weeks (15.81±2.12%) than at 50 (10.59±1.20%) and 51 weeks (8.98±1.68%). Late embryonic mortality decreases with flock age (48-51 weeks). Generally, highest embryonic mortality was observed at the early stage of incubation followed by the late stage while the least was observed at mid-stage of incubation. The results partially disagree with the findings of Iqbal *et al*. (2016) who reported that age of hen had no influence ($P \geq 0.05$) on embryonic mortality during incubation but observed highest embryonic mortality at early stage of incubation and the least at mid-stage of incubation. The results however, partially agreed with the findings of Elibol and Brake (2006) who observed highest embryonic mortality in the early phase followed by the late phase and mid phase had the least embryonic mortality in both young and old broiler breeder flocks. They however reported higher early and late embryonic mortality in old than in young flocks ($P \leq 0.01$).

Similarly, total embryonic mortality varied significantly ($P \leq 0.05$) with flock age. The highest (52.9±1.66%) was at 48 weeks of age and the lowest (31.4±1.83%) was at 51 weeks.

Table 1: Age effects on hatchability traits of ShikaBrown® eggs

Parameter	Age of birds (week)			
	48	49	50	51
Egg weight (g)	57.82±0.29^{ab}	57.41±0.24^{b}	57.90±0.28^{ab}	58.40±0.32^{a}
Egg fertility (%)	89.52±2.21^{b}	93.69±1.87^{a}	94.65±1.75^{a}	92.07±1.96^{ab}
Hatchability (%)	47.00±1.66^{c}	61.66±1.78^{b}	59.51±3.02^{b}	68.57±1.91^{a}
Chick weight (g)	42.42±0.20^{b}	42.69±0.19^{ab}	43.12±0.25^{a}	43.08±0.22^{a}
Early E.M (%)	27.24±2.23^{a}	17.96±1.84^{b}	20.34±1.78^{b}	16.17±1.58^{b}
Mid E.M (%)	7.22±1.19^{ab}	4.56±1.04^{b}	9.56±1.58^{a}	6.27±1.11^{ab}

Total E.M (%)	53.00±1.66^{a}	38.34±1.78^{b}	40.49±3.01^{b}	31.43±1.91^{c}

Means along the same row bearing different superscripts are significantly different ($P \leq 0.05$).
E.M = Embryonic mortality

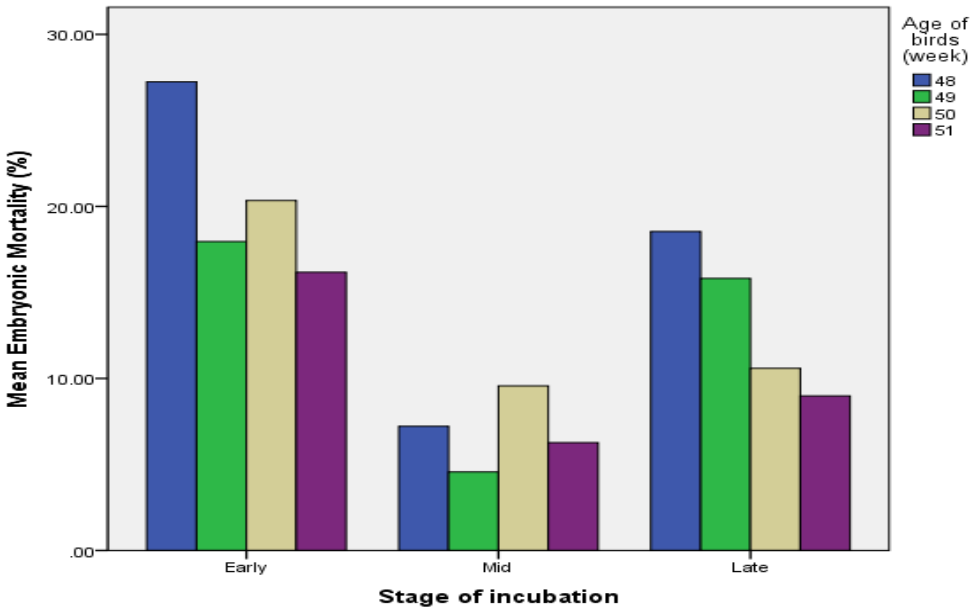

Figure 1: Stages of embryonic mortality based on flock age

CONCLUSION AND RECOMMENDATION

From the results of this work, it can be deduced that age has great influence on egg weight, fertility, hatchability, embryonic mortality and hatched chicks' weight of ShikaBrown® chickens. At the age (48-51 weeks) investigated, the birds proved to have high fertility, increasing hatchability rates and hatched chicks' weight. Further research should be conducted beyond the period covered in this study to determine the period of maximum reproductive efficiency of the breed.

ABSTRACT

The objective of this study was to estimate genetic diversity at TLR7 locus in the Nigerian indigenous chicken populations and ISA Brown commercial layer chicken. Eight (8) chicken populations (naked neck, normal and frizzled-feathered Nigerian indigenous chickens in rain forest and Guinea Savannah regions respectively, Fulani ecotype chicken and ISA Brown commercial layer chicken) were used for this study. Blood samples were collected from each of the eight chicken populations. Genomic DNA was isolated from each blood sample using the Zymo Quick-gDNA^{TM} Miniprep kit. Sequencing of chTLR7 gene was done using the Sanger Sequencing Chemistry. Genetic distance estimates ranged from 0.007 to 0.054 and were close to zero, which suggests that the chickens have a close ancestor. The estimates of nearest-neighbour statistic ranged from 0.227 to 0.714, which showed that the chicken populations were part of the same panmictic population, hence were not genetically differentiated (P>0.05) at the TLR7 locus.

Keywords: Chicken, diversity, genetic distance, nucleotide, Toll-like receptor.

INTRODUCTION

Toll-like receptor 7 (TLR7) gene is one among the genes implicated in the immune system of vertebrates, especially in recognition of viral Pathogens. TLR genes are proven associated with resistance to infectious diseases. Chicken toll-like receptor (chTLR) genes have been reported to be polymorphic among different avian breeds, suggesting a varied resistance across numerous chicken breeds (Ruan *et al*., 2012a; 2012b). Although TLR domains are highly conserved among species and among different members of the multi-gene family because of their crucial participation in signaling transduction (Barreiro *et al*., 2009), recent reports have revealed that mutation on their sequences can bring about single nucleotide polymorphisms (SNPs), hence creating genetic variants among populations of the same species. For example, four new single nucleotide polymorphisms (SNPs) of TLR7 gene were discovered in Chinese ducks (Zhu *et al*., 2011). Recent reports suggest that the ability of certain individuals to respond properly to TLR ligands may be impaired by single nucleotide polymorphisms (SNPs) within TLR genes, resulting in an altered susceptibility to, and development of infectious or inflammatory disease (Schroder and Schumann, 2005).

However, TLR7 gene has not been investigated in the Nigerian indigenous chicken populations. The Nigerian indigenous chickens found in different ecological locations in Nigeria may have evolved adaptive characteristics in response to changes in natural environmental conditions, which could potentially affect individual's ability to sense invading viral pathogen-associated molecular patterns.

We hypothesize that indigenous chicken ecotypes in different regions of Nigeria may have developed varied ability to respond to viral pathogens.

This study, therefore, was designed to access the genetic diversity at the TLR7 locus in the Nigerian indigenous chickens and ISA Brown commercial layer chicken.

MATERIALS AND METHODS

Blood sample collection

About 1 ml of blood sample was aseptically collected from the brachial vein of each bird, separately into vacutainer tubes (SARSTEDT Monovette®) containing Ethylene-diamine-tetra-acetic acid (EDTA), using sterile needles. Blood samples were collected from naked neck, normal-feathered, frizzle-feathered

indigenous chickens from rainforest zone, Guinea Savannah zone, Fulani ecotype chicken, and ISA Brown commercial layers chickens.

DNA extraction, Polymerase Chain Reaction and Sequencing

Genomic DNA was isolated from each blood sample using the Zymo Quick-gDNA™ Miniprep kit (D3024, Zymo Research Corporation, Irvine, CA, USA) following the manufacturer's instructions. The concentration and purity of each DNA sample was ascertained using Nanodrop Spectrophotometer.

Three (3) DNA samples from each genetic group were taken for polymerase chain reaction (PCR) amplification of TLR7 gene. The primers used were designed using the Primer3 and BLAST option at the NCBI database (www.ncbi.nlm.nih.gov). The following primers were used: Forward-AGGCTTGCTGTTGTGGCATGGA and Reverse- ACTGGAAGCCCTTCCTCCACTGT. PCR were performed in a 50 µl reaction volume containing 10 µl of 5X FIREPol® Master Mix (Solis BioDyne, Tartu, Estonia), 2.5 µl each of forward and reverse primers, 31 µl of nuclease-free water and 4 µl sample DNA template. PCR conditions consist of 1 cycle of 95°C for 4 minutes initial denaturation, 35 cycles each of 95°C for 30 seconds denaturation, 62°C for 30 seconds annealing, 72°C for 1 minute elongation, followed by 72°C for 10 minutes final elongation. DNA sequencing of chTLR7 gene was done using the Sanger Sequencing Chemistry. Laboratory analysis was performed at African Bioscience Laboratory in Ibadan, Nigeria.

RESULTS AND DISCUSSION

Estimates of Nearest-neighbour statistic (Snn) between the Nigerian indigenous chickens in rain forest region, Guinea savannah region, Fulani ecotype and ISA Brown layer chickens ranged from 0.292 to 0.714, with a value of 0.227 for the sequences pulled together (Table 1). Permutation test on estimates of Snn with 1000 replications and excluding sites with alignment gaps gave *P*-values ranging from 0.186 to 0.687 and were not significant ($P>0.05$). This implies that the Nigerian indigenous chickens from rain forest and Guinea savannah, Fulani ecotype and ISA Brown layer chickens were not genetically differentiated at the TLR7 locus.

The nearest-neighbour statistic (Snn) is a measure of how often the nearest neighbours (in sequence space) of sequences are from the same locality in geographic space (Hudson, 2000). The Snn estimates are expected to be near one when the populations at the two localities are highly differentiated and near one-half when the populations at the two localities are part of the same panmictic population (Hudson, 2000). The nearest–neighbour statistic is very useful when genomic data are collected on individuals from two or more geographic locations. In this study, analysis of TLR7 gene sequences from the Nigerian indigenous chicken populations and ISA Brown commercial layer chicken revealed that the nearest-neighbour statistic (Snn) were close to one-half, which implies that the Nigerian indigenous chickens from rain forest, Guinea savannah, Fulani ecotype chicken and ISA Brown commercial layer chicken were part of the same panmictic population.

Table 1: Nearest-neighbour statistic, Snn between populations of Nigerian indigenous chickens and ISA Brown commercial layer chicken

Populations	S_{nn}	P-value of S_{nn}
Fulani ecotype VS. Guinea savannah	0.525	0.517^{NS}
Fulani ecotype VS. ISA Brown	0.467	0.382^{NS}
Fulani ecotype VS. Rain forest	0.714	0.186^{NS}
Guinea savannah VS. ISA Brown	0.292	0.854^{NS}
Guinea savannah VS. Rain forest	0.388	0.687^{NS}
ISA Brown VS. Rain forest	0.438	0.635^{NS}
Entire population	0.227	0.459^{NS}

NS= not significant (P>0.05)

The estimates of mean genetic distance among Nigerian indigenous chicken populations from different locations and ISA Brown commercial layer chicken are presented in Table 2, while Table 3 shows the estimates of mean genetic distance among the Nigerian indigenous chicken genotypes and ISA Brown

commercial layer chicken. The estimates of mean genetic distance (Table 2) ranged from 0.007 to 0.014, and were also close to zero. The least between group mean genetic distance (0.007) was observed between the Fulani ecotype chicken and the rain forest chicken, while the highest mean distance (0.014) was between ISA Brown layer chicken and Guinea savannah chicken. Analysis of TLR7 gene sequences from the different chicken genotypes (naked neck, frizzle-feathered and normal feathered chickens) from different regions, Fulani ecotype chicken of Nigeria and ISA Brown commercial layer chicken revealed that genetic distance estimates ranged from 0.006 to 0.054 and were also close to zero (Table 3). The observed close-to-zero estimates of genetic distance is an indication that the Nigerian indigenous chickens genotypes found in different regions of the country and ISA Brown commercial layer chicken were closely related at the TLR7 locus. This report seems to be the first investigation of TLR7 locus in the Nigerian indigenous chickens and ISA Brown commercial layer chicken. The level of genetic relatedness observed in this study showed that although the indigenous chickens are found in different region in Nigeria, the locus was not under ecological or geographical divergence; consequently, the TLR7 locus is highly conserved among the Nigerian indigenous chicken populations. This finding corroborates the report of Bulumulla *et al*. (2011) that the TLR7 locus is a conserved region among Sri Lankan indigenous chicken population and Ceylon jungle fowl (*Gallus lafayetti*).

Table 2: Estimates of mean genetic distance among Nigerian indigenous chicken populations and ISA Brown commercial chicken

*Populations	FEC	GSC	ISA	RFC
FEC	-	0.002	0.003	0.002
GSC	0.011	-	0.003	0.003
ISA	0.010	0.014	-	0.003
RFC	0.007	0.013	0.010	-

Estimates of genetic distance are shown below the diagonal; Standard error of estimates are shown above the diagonal; FEC= Fulani ecotype chickens; GSC= Guinea Savannah chickens; ISA= ISA Brown layer chickens; RFC= Rain forest chickens

Table 3: Estimates of mean genetic distance among the Nigerian indigenous chicken genetic groups and ISA Brown commercial layer chicken

Groups	FE	GF	Gn	GN	ISA	RF	Rn	RN
FE	-	0.004	0.006	0.003	0.004	0.004	0.0040	0.003
GF	0.014	-	0.007	0.004	0.005	0.003	0.004	0.004
Gn	0.042	0.054	-	0.007	0.006	0.007	0.006	0.007
GN	0.007	0.012	0.048	-	0.004	0.003	0.004	0.005
ISA	0.026	0.034	0.045	0.028	-	0.005	0.004	0.005
RF	0.010	0.009	0.051	0.006	0.030	-	0.004	0.005
Rn	0.020	0.022	0.045	0.019	0.030	0.016	-	0.005
RN	0.007	0.014	0.047	0.012	0.031	0.013	0.024	-

Estimates of genetic distance are shown below the diagonal; Standard error of estimates are shown above the diagonal; FE= Fulani ecotype chicken, GN= Guinea savanna naked neck chicken, Gn= Guinea savannah normal chicken, GF= Guinea savannah frizzle-feathered chicken, RF= Rain forest frizzle-feathered chicken, RN= Rain forest naked neck chicken, Rn= Rain forest normal chicken, ISA= ISA Brown commercial layer chicken

The percent identity of TLR7 gene sequence from the Red jungle fowl (*Gallus gallus*) retrieved from the National Centre for Biotechnology information (NCBI) database (Accession No.NC_006088.5), with the consensus sequence of TLR7 gene of Nigerian indigenous chickens and ISA brown was 99%. The estimates of genetic distance between the Red jungle fowl and the Nigerian indigenous chickens and ISA

brown commercial layer chicken at the TLR7 locus were very low and ranged from 0.007±0.002 to 0.012±0.003 (Table 4). This implies a very close relationship and low level of divergence at the TLR7 locus in the Nigerian indigenous chicken populations, ISA Brown commercial layer chicken and the Red jungle fowl. This also suggests that the Nigerian indigenous chickens and ISA Brown commercial layer chicken are not genetically distanced from the Red jungle fowl at the TLR7 locus. This is in line with the report of Bulumulla *et al*. (2011) that TLR7 locus is a conserved region among the indigenous chicken population.

Table 4: Genetic distance between the Nigerian indigenous chickens, ISA Brown commercial layer chicken and the Red jungle fowl (reference sequence)

Chickens	Red jungle fowl
Fulani ecotype	0.008±0.004
Guinea savannah	0.012±0.003
Rain forest	0.007±0.002
ISA Brown layers	0.008±0.003

CONCLUSION

The results of this study revealed that genetic distance estimates among the Nigerian indigenous chickens, ISA Brown commercial layer chickens and the Red jungle fowl were close to zero, which suggests that the chickens were not under ecological divergence. The estimates of nearest-neighbour statistic obtained in this study showed that the Nigerian indigenous chickens from the rainforest, Guinea savannah, Fulani ecotype and ISA Brown commercial layer chickens were not genetically differentiated at the TLR7 locus, thus were part of the same panmictic population.

ABSTRACT

This study was carried to produce hybrids between crosses of *Clariid* catfish species of *Clariasgariepinus* and *Heterobranchusbidorsalis* for stock improvement. Fertility data revealed significant difference ($p<0.05$) between the hybrid cross ♀*C. gariepinus*× ♂*H. bidorsalis* (88.00±1.00%) compared to its reciprocal ♀*H. bidorsalis*× ♂*C. gariepinus* (71.67±10.41%). The reciprocal ♀*H. bidorsalis*× ♂*C. gariepinus* recorded the highest deformity (11.67±3.06%) that was significantly different ($p<0.05$) from the rest of the crosses. Equal sex ratio in the hybrids compared with the two parent species was recorded. Specific growth rate (SGR) of the fish species revealed highest significant difference ($p<0.05$) in the hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* (2.64±0.09%), followed by the cross of ♀*C. gariepinus*× ♂ *C. gariepinus* (1.91±0.02%) while there were no significant differences ($p>0.05$) between the reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* (2.20±0.57%)and♀*H. bidorsalis*× ♂*H. bidorsalis* (2.19±0.19%). The SGR analysis proved that the crosses ♀*C. gariepinus*× ♂*C. gariepinus* had slow growth performance compared to its hybrid ♀*C. gariepinus*× ♂*H. bidorsalis*. Critical evaluation based on survival and specific growth performance showed superiority of the hybrid ♀*C. gariepinus*× ♂*H. bidorsalis*. The least survival in reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* (27.33%) can be explained from significant deformity (11.67%) recorded due to maternal effects. Hence, the hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* performed better in the SGR and survival.

Keywords: catfish, hybrid, specific growth rate, survival, deformity

INTRODUCTION

Hybridization has been of importance in both research and commercial aquaculture due to its benefits such as increased growth rate, sex ratio manipulation, production of sterile species and enhancement of many other desirable economic traits (Colombo *et al.,* 1996; Beaumont and Hoare, 2003; Dunham, 2004). Hybrid species possibly present higher growth and survival than either one or both of their parents species, and/or one or more characteristic(s) sought-after in the either parent species e.g. robustness, salinity/ thermal tolerance, morphology, flesh quality among others (Lenormand, 1988). Hybridization may also result to other traits that cannot be predicted from the knowledge about their parents' species and may be absent altogether, particularly in certain teleost families (Colombo *et al.,* 1996). Therefore, hybridization can be a source of evolution and speciation (Dunham, 2004). This study was aimed at producing hybrid progenies between the of *C. gariepinus* and *H. bidorsalis* for enhanced stock improvement.

MATERIALS AND METHODS

Location: The research was carried out at Biotechnology Laboratory, Department of Animal science, Obafemi Awolowo University, Ile-Ife.

Research Design: Milt and eggs of both *C. gariepinus* and *H. bidorsalis* were collected for same parent species and inter-specific crosses. The data on fertility, hatchability, deformity and survival were obtained following Olaniyi and Omitogun (2013). The hatchlings were left for 2 weeks in the hatchery before they were transferred to bigger breeding plastic tank (2M × 1M ×

0.5M). Thirty-five fingerlings of each of the crosses were allotted into breeding plastic tank, whereby more parameters such as survival, weight, and specific growth rate were recorded up to 12th week. The data were subjected to statistical analysis using the General Linear Models (GLM) procedure of software SAS, 2002 (SAS Institute, 2002).

RESULTS AND DISCUSSION

Effects of hybridization on fertility, hatchability and survival on the hybrids of C*larias gariepinus* and *Heterobranchus bidorsalis*: Table 1 showed the effects of hybridization on fertility, hatchability and survival with respect to crosses between *C. gariepinus* and *H. bidorsalis*. The fertility data revealed significant difference between the hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* (88.00±1.00%) compared to its reciprocal cross ♀*H. bidorsalis*× ♂*C. gariepinus* (71.67±10.41%). While all the other crosses hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* (88.00±1.00%), reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* (71.67±10.41%), were not significantly different from other crosses - same parent crosses (♀*C. gariepinus*× ♂*C. gariepinus*, 83.00±7.21%; ♀*H. bidorsalis*× ♂*H. bidorsalis*, 80.67±6.03%), ($p>0.05$). Hatchability revealed no significant differences between the all same parent species crosses (♀*C. gariepinus*× ♂*C. gariepinus*, 74.67±7.23%; ♀*H. bidorsalis*× ♂*H. bidorsalis*, 68.33±3.06%) ($p>0.05$), and hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* (79.33±4.04%), except with reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* (48.67±5.13%) that these were significantly different from all other crosses ($p<0.05$). The reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* recorded the highest deformity (11.67±3.06%) that was significantly different ($p<0.05$) from the rest of the crosses.The percent deformity of other crosses were not significantly different from one another ($p>0.05$). A week survival (%) revealed no significant difference ($p>0.05$) between the ♀*C. gariepinus*× ♂*C. gariepinus* (70.33±4.16%) and hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* (71.00±5.29%), but both showed significant difference ($p<0.05$) compared to the crosses of the reciprocal hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* (27.33±6.81%) that had the least at a week survival. Survival at both 4th through 12th weeks for hybrid ♀*H. bidorsalis*× ♂*C. gariepinus* was lowest and revealed significant difference among the rest of the crosses ($p<0.05$).

Sex ratio* (Male:Female)	1:1^{ns}	1:1^{ns}	1:1^{ns}	1:1^{ns}

^{abc}Means within a row with different superscripts are significantly different (P<0.05). General Linear Model procedure (SAS®, 2002). C= *Clarias gariepinus*, H=*Heterobranchus bidorsalis*

Body weights at 4th and 12th weeks of the different crosses revealed no significance (P<0.05). The specific growth rate analysis proved that the progenies of ♀*C. gariepinus*× ♂*C. gariepinus* recorded slow growth performance compared to its hybrid ♀*C. gariepinus*× ♂*H. bidorsalis*. However, critical evaluation on the survival and specific growth performance showed the superiority of hybrid ♀*C. gariepinus*× ♂*H. bidorsalis*. In a related study, but with *C. gariepinus* with *H. longifilis*, Legendre *et al.* (1992) reported the hybrids to have similar growth rates performance with *H. longifilis* and at the same time in one of their experiments hybrid ♀*H. longifilis*× ♂*C. gariepinus* displayed faster growth than the *H. longifilis.* In another related study, the performance of hybrid ♀*C. gariepinus*× ♂*H. bidorsalis* was significant than its reciprocal

♀*H. bidorsalis*× ♂*C. gariepinus* (Ndimele *et al.*, 2011). Colombo *et al.* (1996) explained that five possible beneficial outcomes may result from hybridization, viz: intermediacy, combinability, luxuriance, monosexuality and novelty. In the light of this study, the outcome of hybridization with respect to parameters like SGR, average daily weight gain, sex ratio etc of the different crosses confirmed the varying or mixed outcome of hybridization. Colombo *et al.* (1996) further explained that hybridization can give traits that cannot be predicted from the knowledge about the hybrids' parent species and also, it may be absent altogether particularly in some teleost families. The sex ratio (male: female) showed no significant deviation from 1:1 chi-square testing ($p>0.05$) across all the progenies (Table 2). This study showed an outcome of equal sex ratio in the hybrids compared to their parents. This result corroborated the study of Legendre *et al.* (1992) that also found out equilibrated sex ratio in the hybridization study between *H. longifilis* and *C. gariepinus*. The outcome of equal sex ratio between the hybrids and the parents confirmed the hypothesis of same sex determining mechanism as also reported in hybridization study between *H. longifilis* and *C. gariepinus* (Legendre *et al.*, 1992).

CONCLUSION AND RECOMMENDATION

♀*C. gariepinus*× ♂*H. bidorsalis* revealed better survival and growth based on the data, and is therefore recommended to commercial fish farmers.

ABSTRACT
Genetic variability of grasscutter (*Thyronymus swinderianus L*) was investigated using random amplified polymorphic DNA markers in Imo state. A total of four primers of arbitrary sequence were used and all of them generated reproducible, scorable and polymorphic bands. The highest percentage polymorphic band was recognized for primer OPA19 (100%) while the lowest percentage of polymorphic band was recognized for the primers OPA14 (50%). The observed number of alleles (Ne) had values ranging between 1.50±0.52 – 2.00±0.00 for OPA14 and OPA19 respectively. Similar trend was observed for Ne, H, and I with values ranging between 1.39±0.42 for OPA14 to 1.81±0.14 for OPA19; 0.22±0.23 for OPA14 to 0.44±0.05 for OPA19 and 0.31±0.33 for OPA14 to 0.64±0.05for OPA19 respectively considering the genetic diversity indices for combined loci. Similarly, considering the genetic diversity indices between the grasscutter population/strain, the light strain had the higher value for all the diversity indices; Na (1.71), Ne (1.56), H (0.25) and I (0.44) than the dark strain; Na (1.61), Ne (1.39), H (0.25) and I (0.34). The study therefore suggested that RAPD can be successfully utilized for detecting genetic variability among the studied grasscutter population and there could be selection within and between the studied populations for genetic improvement.
Keywords: Grasscutter, RAPD markers, genetic variability, strain, heterosis.

INTRODUCTION
Asibey and Adel (2000) reported that grasscutter is the most preferred and most expensive bush meat in West Africa (Nigeria, Togo, Benin, Ghana and Cote d'ivoire) and contributes to both local and export earning of most of these countries. The meat is a delicacy (Adu and Yeboah, 2000; Addo, 2002) eaten by all classes of people with no religious prohibition (Opara, 2010b), and is also exported to continental Europe and the United states, where it is sold mainly to West Africans living in these regions (Adu, 1999).

According to Akinloye (2005), Grasscutters show slight phenotypic variations especially in the colour of their fur so it is important to analyze their genetic variability in order to identify populations and individuals of particular merit.

Nowadays, due to advancement in molecular genetics and affordability of DNA analysis, genetic diversity can be measured directly on the DNA itself and it accurately presents the genetic variations between breeds, within breeds, and within half and full-sib groups. Hence the study intends to identify the genetic variability of grasscutter in Owerri, Imo State, using RAPD markers; determine allelic diversity of the populations and the genetic distance between the two studied strains of grasscutter (*thryonymus swinderianus),* to help understand the evolutionary process that affect it.

MATERIALS AND METHODS
The research was conducted in Owerri and Okigwe, Imo State Nigeria. Owerri is one of the largest and the populous cities in Southern Nigeria. It is the capital city of Imo State with coordinates; 5°28'34.7160" N and 7°1'33.0708" E. and Okigwe has the coordinates; 5°49'0" N and 7°21'0" E. Annual rainfall in Imo State usually varies from 1990mm to 2200mm. The mean annual temperature is above 20° c with an average annual relative humidity of 75%. Five to ten hair samples were taken from a total of 30 grasscutters (15 grasscutter from each colour variants) selected from two different locations; the wild (by hunters from bush meat market, Okigwe) and from Imo State Zoo, Owerri, both in Imo State between November - December, 2018 during the survey stage of the study. The hair samples were preserved and transported to African Bioscienecs Laboratory, Ibadan, Oyo State, for molecular analysis. Out of the 30

hair samples collected, only 24 samples lysed while 6 samples were unable to lyse. Therefore, DNA extraction was carried out with 24 samples that were able to lyse. The quantity and quality of DNA was measured using NanoDrop spectrophotometer (Thermo Scientific, USA). The DNA was then stored at -30°C until ready for use. The extracted DNA was amplified by Polymerase Chain Reaction (PCR), and the amplified products were size-fractionated in a 1.2% agarose gel containing ethidium bromide in Tris-borate EDTA buffer and visualized under UV transillumination. The PCR amplified bands were scored visually on the basis of their presence (1) or absence (0). The scores obtained were then pooled for constructing a single data matrix, which was used for estimating the genetic diversity indices using GenAlex software.

RESULTS AND DISCUSSIONS

The result on table1 reveals the genetic diversity indices for all loci combined. The displayed diversity indices were; observed number of allele (Na), effective number of alleles (Ne), Nei's heterozygosity (H) and Shannon's index (I). The observed number of alleles (Na) had values ranging between 1.50±0.52 – 2.00±0.00 for OPA14 and OPA19 respectively. Similar trend was observed for Ne, H and I with values ranging between 1.39±0.42 for OPA14 to 1.81±0.14 for OPA19; 0.22±0.23 for OPA14 to 0.44±0.05 for OPA19 and 0.31±0.33 for OPA14 to 0.64±0.05 for OPA19 respectively. There is no previous information about using RAPD marker to investigate genetic diversity of grasscutter. However, the range values obtained for the diversity indices are compared with other rodents such as rabbits and laboratory rats, guinea pig and mice. Shannon index value obtained in the study was lower than that reported by Kumar *et al*., (2014). The Shannon Index of Nigerian grasscutter breed in the study revealed low species richness and evenness since all the indices were below 3.5, the mark set for high species evenness and richness (Krebs, 1989). The low average Shannon's Index (I) obtained in the study could be attributed to close descent. The value of effective number (Ne) of alleles obtained in the study was lower than the findings of El- Sayed *et al*., (2018) and Mohammed and Abdelfattal (2018). The lower value of (Ne)could be attributed to effective sample size. This agrees with the findings of de Vicente, (2004) who opined that effective number of allele (Ne) can be used with codominant marker data and its calculation may be affected by sample size. Heterozygosis deficiency (low genetic variability) recorded in the study may have also resulted from one or more of these following factors; presence of null alleles, small sample size, Wahlund effect and/or the decrease in heterozygosity due to increased consanquinity (inbreeding) (Kumar *et al.,* 2006).

Table 1: **Genetic diversity indices for all the loci combined**

Markers	Na	Ne	H	I
OPA08	1.92 (0.29)	1.72 (0.33)	0.32 (0.16)	0.56 (0.21)
OPA11	1.92 (0.29)	1.58 (0.31)	0.34 (0.14)	0.51 (0.19)
OPA14	1.50 (0.52)	1.39 (0.42)	0.22 (0.23)	0.31 (0.33)
OPA19	2.00 (0.00)	1.81 (0.14)	0.44 (0.05)	0.64 (0.05)

Na – Observed number of allele, Ne – Effective number of allele, H – Nei's heterozygosity or gene diversity, I – Shannon's Information Index, OPA08 – primer 1, OPA11 – primer 2, OPA14 – primer 3, OPA19 – primer 4.

The result of the genetic diversity indices within the grasscutter population is shown in table 2. Diversity indices values for the light strain population were; Na (1.71), Ne (1.56), H (0.31) and I (0.44). While indices for the dark strain were; Na (1.61), Ne (1.39), H (0.25) and I (0.34). the values for the light strain were generally higher than those for the dark strain/population.

Table 2: Genetic Diversity Indices between the Grasscutter Population/Strain

Population/strain	Na	Ne	H	I
Light	1.71	1.56	0.31	0.44
Dark	1.61	1.39	0.25	0.34

Na – Observed number of allele, Ne – Effective number of allele, H – Nei's heterozygosity or gene diversity, I – Shannon's Information Index.

Nei's original measure of genetic similarity and Genetic distance were used to assess the genetic similarity (above diagonal) and genetic distance (below diagonal) across the two colour variants population of grasscutter in Imo state as shown in Table 3. The genetic similarity obtained in the result was 0.7904 (79.04%), while the genetic distance was 0.2353 (23.53%). Genetic distance is a measure of the genetic divergence between species or between populations within a species, whether the distance measures time from common ancestors or degree of differentiation (Nei, 1987). However, the genetic similarity of the grasscutter populations studied in Imo state was very high while genetic distance in the grasscutter populations was very low. This is an indication that the population/strains are closely related and have common ancestors. Hence, this will give an insight on the level at which the species is endangered as suggested by Ruane (1999).

Table 3: Measures of Genetic Similarity and Genetic Distance (Nei's 1972)

Population ID	Dark	Light
Dark	…….	0.7904
Light	0.2353	……

Above diagonal, genetic similarity; below diagonal, genetic difference

CONCLUSION

As far as genetics of grasscutter is concerned, this is the first time RAPD markers have been used to study the population in Nigeria and of course the first of its kind in the species range. These results will form a baseline from which inferences can be made for comparison in future variability, and diversity studies on the grasscutter. Since variations exist within and between the studied populations, selection of superior individuals within and between the populations/strains could be done for outcrossing. The diversity indices revealed how informative the primers are in assessing heterogeneity in the population and serves as an index that reflects genetic variation of RAPD loci. Hence, the various values of the diversity indices showed that assertions should not be made only with an index. There is need to combine the various information from the indices before assertions could be made.

RECOMMENDATIONS

The study therefore recommends that the light population should be given more attention for selection and improvement, since it harbors more diversity in the gene, as this will help the population to adapt to changing environmental conditions. However, superior individuals within the different populations/strains could be selected, cross bred within the populations (inbreeding) and crossed between the populations/strain (outcrossing) for improvement and heterosis respectively. Further molecular genetic

studies should be conducted on grasscutter in Nigeria, especially one involving the use of other marker tools and sequencing of the DNA to infer accurately and precisely, if the colour variations that exist within this breed could have a genetic potential needed for breeding, other than mere phenotypic variation.

ABSTRACT
This study was conducted to evaluate the effect of temperature-humidity index on milk traits of pure Holstein-Friesian cows in Kano State. Twenty mid-lactating Holstein-Friesian cows (three years of age with a mean weight of 1200kg) were used for this experiment. The cows were raised intensively in a covered free stall barn ($3m^2$ per cow) with straw bedding. Metrological data, both inside and outside, of the barn including temperature (maximum and minimum) from both digital and analogue (dry and wet bulb) thermometers and relative humidity were collected. Three composite samples of milk from the cows were taken per month (on the 15th day of each month) and were analysed for protein, fat and somatic cells. Meteorological data were analysed to identify the most appropriate temperature-humidity index (THI) to measure heat stress in this study. Data were analysed using Analysis of Variance (ANOVA) and correlation procedures in the Statistical package SAS (2013). Comparison of the Means was done using Duncan Multiple range tests of the same statistical package. The minimum temperature for the period of the experiment had the lowest value (23.08 ± 0.62^0C) in the month of December in Early dry season while the highest value (33.64 ± 0.83^0C) was recorded in the April of the Late dry season. The differences in the THI for the two periods resulted in significant different ($P < 0.05$) in milk yield and milk composition traits. It was concluded that, heat stress affect milk production, milk composition of Holstein-Friesians cows reared in Kano State environment.
Keywords: Heat stress, Milk yield, Milk composition traits, Holstein-Friesian, and Kano State

INTRODUCTION
Nigeria population is increasing rapidly (Ibeawuchi *et al*., 2000) and domestic output of 407,000 metric tonnes of milk (Olaloku, 1999) obtaining from 14 million cattle in the country (RIM, 1992) can barely satisfy the milk demands of the growing population. For this reason, milk production in the country is being supplemented by milk from imported breed of dairy cows. Holstein Friesian is one of the commonly exotic breeds of cows being used for milk production in Nigeria. This breed however tends to perform below their potential when compared with their level of production abroad.

Thermal environment is a major factor that can negatively influence milk production of dairy cattle especially those of high genetic merit (Kadzere *et al*. 2002). Yano *et al.* (2014) indicated that individual cow genetic composition and some environmental conditions such as temperature are contributing factors that affect milk yield in dairy cow. The temperature-humidity index (THI) could be used to determine the influence of heat stress on productivity of dairy cows (Ghavi *et al*., 2013; Adedibu *et al*., 2015). Extensive efforts have been made to quantify the effect of heat on milk production, investigating such factors as humidity, wind speed, daylight length, and temperature and humidity indices (THIs) (Bouraoui *et al*., 2002; Ghavi *et al*., 2013; Yano *et al*., 2014) for different breeds of cattle in different environments in the world. Results from such works would provide useful information on heat tolerant traits and could be used as a guide in making selection decision from existing breeds and also a guide in management of dairy breeds. This kind of information however is limited for Holstein breed of cattle in Nigeria. The objective of this research is to evaluate the effect of temperature-humidity index on daily milk production of Holstein cows under climate conditions in Kano State.

MATERIALS AND METHODS
Study Area
The study was conducted at Sa'ada Farm Dawakin Kudu Local Government Area of Kano State, Nigeria.TheState covers an area extending between Latitudes 10º 3'N and 12º 4'N of Equator and

Longitude 7º 4'E and 9º 3'E of the Prime meridian. The State experiences two seasons, the rainy season, which starts in April and ends in late October, and the dry season, which starts in November and ends in April (Asimalowo, 2011). This can be subdivided into early dry (November, December and January), late dry (February, March and April), early rain (May, June and July) and late rain (August, September and October) (Josiah *et al*., 2015).

Experimental Animals and their Management

Twenty mid-lactating Holstein Friesian cows (three years of age with a mean weight of 1200kg) were used for this experiment, the cows were raised intensively in a covered free stall barn ($3m^2$ per cow) with straw bedding. They were fed according to the production level. The metal roofs used in covering the stall barn is covered with straws.

Data Collection

Daily Milk Yield and Milk Composition

The cows were milked two times daily (6:00 - 7:00, and 17:00 – 18:00 h) with Asin® electric milking machine manufactured by Popsort® of China. Three composite samples were taken per month (on the 15th day of each month) and were analyzed for protein, fat and somatic cells. Milk samples were prepared following the method proposed by Bobe *et al*. (1998) and were preserved using Bronopol, 2-Bromo-2-Nitropropane-1,3-diol that was added immediately to raw milk samples at 0.6:100 to prevent microbial growth. The samples were later stored at 4^0C (Nagy *et al.*, 2013) before it they were transported for laboratory analysis.

The milk samples were taken to the Biochemistry laboratory, Department of Biochemistry, Bayero University, Kano to analyse for, milk fat (%) and milk protein (%). Fat yield and protein yield were deduced from milk fat (%) and milk protein (%) respectively, following the methods of Bouraoui *et al.* (2002). The fat yield was estimated as milk fat (%) times milk yield ($kg.d^{-1}$) and protein yieldwas estimated as milk protein (%) times milk yield ($kg.d^{-1}$).

Somatic Cell Count

Part of the milk was also analysed for Somatic cell counts at the Clinical Microbiology Laboratory in the Department of Microbiology Bayero University, Kano. The electronic microscope was used to determine the somatic cell counts using the microscopic factor to determine the number of cells per ml of milk.

Meteorological data

Temperature and humidity both inside and outside of the barn were measured using two of Youkong® digital thermometer and hygrometer manufactured by HTC of China. Daily maximum and minimum temperatures were recorded at 7:00 hour, 13:00 hour and 17:00 hour using maximum-minimum thermometers.. This digital thermometer and hydrometer were mounted in the open, under the tree, and the other thermometer and hydrometer mounted in the shed

Data Analysis

Meteorological data was analyzed to identify the most appropriate temperature-humidity index (THI) to measure heat stress in this study. Temperature-Humidity index for the period of experiment was calculated using Angular (2008):

$$THI = (1.8 \times T + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times Ta - 26);$$ (Angular, 2008);

T = Temperature in degree Celsius (^{0}C); RH = Relative humidity in percentage (%)

Statistical analysis

To determine the effect of temperature humidity index on milk yield and milk compositions a fixed model where repeated measurements per cow was considered random. Data was analysed using Analysis of Variance (ANOVA) procedures in the Statistical package SAS (2013). Comparison of the Means was done using Duncan Multiple range tests of the same statistical package.

Statistical Models

$$Y_{ij} = \mu + P_i + \mathcal{E}_{ij}$$

Where: Y_{ij} = the ith observations (milk yield, milk fat, milk protein) at the different i^{th} period;

μ = mean effect;
Pi = effect of ith period (early dry and late dry);
$\mathcal{E}_{ijk}$ = residual effect.

RESULTS AND DISCUSSUION

The results of the average values of climatic factors for the period of experiment and the conventional comfort zone for Holstein-Friesian cows is presented in Table 1. There was variation in the average temperature (T), relative humidity (RH), the temperature-humidity index (THI) during the period of the experiment. T, RH and THI for the late dry season was higher than the early dry and also was higher than the values of the comfort zone for dairy cattle.This indicates that during these seasons Holstein cows reared in Kano state were subjected to heat stress. Gantner *et al*. (2011) gave the bovine thermal comfort zone to be between -13°C to +25°C, within this temperature range, the animal comfort is optimal, with a body temperature between 38.4°C and 39.1°C. However, in situation where temperature is above 25°C, and even as low as 20°C (Gantner *et al.*, 2011) the cow suffers from heat stress: its health status and production performance are affected. On the other hand, a mean daily THI in value of 72 is considered to be the critical point at which milk yield is reduced (Johnson, 1985; Gantner *et al*., 2011).

The results of the effect of heat stress on milk yield and milk composition is as shown in Table 2. Temperature humidity index (THI) values went from 69 in the early dry period to 74.38 in the late dry season period. The differences in the THI for the two periods resulted in significant different ($P<0.05$) in milk yield and milk composition traits. The milk production was higher in the Early dry season compared to the late dry season. Similar pattern was also observed for milk fat, milk protein, fat yield, protein yield and somatic cell counts. This results corroborate with the findings of Bouraoui *et al*. (2002) who indicated that a rise in THI from 68 in spring to 78 in the summer had effect on milk production in confined Holstein cows in the Mediterranean climate. This is because heat stress is known to result in reductions in voluntary feed intake and thus subsequent declines in milk production in lactating dairy cows (Johnson, 1985; Bouraoui *et al*., 2002). The resultant declination in milk yield lead to consequential reduction in the milk composition as researchers have found a high correlation between milk yield and other milk composition (Ghavi, *et al*., 2013). This explain the lower values recorded for milk composition traits in this study when the THI was above the comfort zone for Holstein-Friesian cows.

Table 1: Average value of climatic factors for the experimental period and the comfort zone for Holstein-Friesian cows

Factor	Early dry season	Late dry season	Comfort zone for Holstein cattle
Temperature (^{0}C)	25.88±0.36	31.22±0.31	-13 to +25 (Lefebvre and Plamondon, 2003)
RH (%)	13.10±0.31	13.19±0.49	0 to 45 (Gantner *et al*., 2011)
THI	68.99±0.44	74.38±0.47	Bellow 72 (Johnson, 1987)

THI- Temperature-Humidity index RH- Relative Humidity

Table 2: Heat stress (THI) effect on milk yield and milk composition

Traits	Periods		
	Early dry season (THI = 69.00)	Late dry season (THI = 74.38)	P-value
Milk yield ($kg \cdot d^{-1}$)	20.12±1.04[a]	12.99±1.04[b]	0.0002
Milk fat (%)	3.56±0.16[a]	2.84±0.16[b]	0.0048
Milk protein (%)	3.26±0.12[a]	2.48±0.12[b]	0.0004

Protein yield ($g \cdot d^{-1}$)	0.66±0.04[a]	0.33±0.04[b]	0.0001
Somatic cell counts × 10^5	2.86±0.45[a]	4.03±0.45[a]	0.0482

THI- Temperature-Humidity index for the period

[ab]means along the same row are significantly different

CONCLUSION AND RECOMMENDATION

Heat stress influence milk production traits, milk composition traits, body weight, body condition score and udder traits of Holstein-Friesians cows reared in Kano State environment. Breeder and dairy farmer should consider milk yield and milk composition traits in the selection and in the management of dairy cows.

ABSTRACT
A total of twelve (12) healthy Noiler cocks, with an average weight 4.3kg were randomly allotted to three experiment groups in complete randomized design. Treatment one (T1) was provided with aloe vera free water while treatments two (T2) and three (T3) were provided with 10% and 20% aloe vera gel per litre of drinking water respectively. The cocks were housed individually and were fed with commercial grower diet. Feed and water were offered *adlibitum* throughout the two months experiment period. Data collected from the study included semen colour, ejaculate volume, motility, semen concentration and live sperm cells percentage. The data obtained were subjected to statistical analysis. The result showed that semen color were similar for all groups. There was significant ($P<0.05$) impact of the aloe vera gel on ejaculate volume, motility, sperm concentration and live sperm cells percentage. Ejaculate volume was higher ($P<0.05$) for cock on 20% aloe vera gel compared to the control and 10% inclusion. It was concluded from the study that 20% aloe gel had better semen quality than 10% and control, hence based on this aloe gel can enhance semen characteristics in adults Noiler cocks at 20% inclusion level.
Key words: Aloe vera gel, Noiler, Semen production, Semen quality.

INTRODUCTION
Local chickens are important in overall food production systems in developing economies mostly because of their adaptation to the tropical environment. They may appear to produce less than highly specialized commercial breeds; however, they possess attributes that make their sustainability on available local resources more ecological and economical in the long term. Incorporation of the Nigerian local chicken as a parent breed stock in the nation's breeding programme is important to meet the increase in poultry product demand by the citizenry (Adeoye *et al*., 2017). Noiler is an improved breed of chicken that have some adaptive features of local chicken. It however, grows faster and bigger. They are dual purpose hardy breed. They require low technology inputs and are becoming popular among back yard farmers (Olurundare, 2015).
Resistance of pathogenic microorganism to drugs frequently as feed additive on poultry production has made scientist to focus on medicinal plants (aloe vera, neem, mulberry leaves etc.) to improve nutritional and health status of poultry (Babak *et al*., 2011). The consumption and demand for medicinal plants in poultry production have been adopted in many countries because of its low cost, availability, affordability for a common farmer, good antimicrobial nature, reduced diseases associated risks, lowering blood cholesterol level and diversified functions in improving performance in birds. *Aloe vera* is a wild plant, however its application in the domestic society cannot be over emphasized (Darabighane and Nahashon, 2014). The most important part of *Aloe vera* is its leaf which is composed of two main sections: latex and gel. The gel composed of about 98.5% to 99.5% water, Polysaccharides (glucomannan and acemannan) Others are carboxypeptidase, magnesium, zinc, calcium, glucose, cholesterol, salicylic acid, prostaglandin precursors (gammalinolenic acid [GLA]), vitamins A, C, E, lignins, saponins, plant sterols and amino acids (Sharrif and Sandeep, 2011).
Modaresi and Khodadadi (2014) reported that aloe vera extract in Mice affected spermatogenesis directly via stimulating activity of germinal cells and cell division and also indirectly via stimulating leydig cells and increasing testosterone. The assessment of semen quality characteristics of poultry birds gives an excellent indicator of their reproductive potential (Hani *et al*., 2016).

The aim of this study was to determine the effect of aloe vera gel on the semen characteristics of Noiler cocks.

MATERIALS AND METHOD

Location

The study was conducted at the teaching and research farm of Federal Polytechnic Bauchi, Nigeria. Bauchi is on latitude 10^{0C} 27'North, 9^{0c}49' East at an altitude of 690.2 meters above sea level (Zaharaddeen *et al*., 2005).

Experimental Birds and Management

A total of twelve apparently healthy Noilers cocks, with an average weight of 4.3kg were used for the present study. The cocks were obtained from back yard poultry farmers in Bauchi metropolis. They were individually housed single in a well-ventilated cage. They were fed a commercial grower diet. Fresh water was given, medical care such as deworming and broad spectrum anti-biotic were provided during the adjustment period. The twelve cocks were weighed and randomly divided into three treatments (i.e. four cocks per treatment).The control group (T1) were provided with plain water while treatment T2 and T3 were provided with 10 and 20ml aloe-Vera gel per litre of water respectively.

Preparation of Aloe Vera Gel Infusion

Aloe Vera gel infusion was prepared according to method of Durrani *et al*., (2008). Fresh aloe Vera was collected from garden for extraction of the gel. The extraction from the leaf was done manually by making a cut, using a small knife. Latex of the leaf was remove and gel was collected in a beaker. The 10% and 20% concentration infusion were prepared by mixing 100g and 200g of fresh gel in a glass bottle and one litre of boiled water at room temperature was shaked for 5-7 minutes to ensure through mixing and was then kept for 6-8 hours at room temperature prior to usage.

Semen Collection and Evaluation

Prior to the collection of the semen, the birds were subjected to preliminary training for two weeks to enable them produce enough semen during actual semen collection exercise. Semen was collected twice a week using abdominal massage methods (Quinn and Burrow, 1936). Semen colour was obtained by visual appraisal of the sample. Volume was determined using a calibrated pipette. Motility of cells were obtained by placing a drop of the sample on a glass slide and observed with a microscope using low power at X10 and X40 magnification respectively. The results were graded from 1 to 5 (Tarif *et al*., 2013). To determine concentration, the sample was diluted with normal saline at 1:400. Hemocytometer was filled with the diluted semen by capillary action. The hemocytometer was then mounted and the sperm cells were counted and expressed as billion per ml. Eosin was used to determine the live sperm percentage. The stain was prepared by dissolving 1.67g of eosin, and 2.9g sodium citrate with two molecules of water in 100ml distilled water. The stain was filtered before use. Briefly, a 10µl drop of fresh semen was mixed with 200µl of eosin stain on a glass slide followed by making a thin smear of it. The spermatozoa were examined at 400x magnification under a phase contrast microscope. At least 100 spermatozoa were counted to determine the percentage of live sperm spermatozoa. The spermatozoa which appeared pink (stained with eosin) were regarded as dead while those not stained (no penetration of eosin stain) were regarded as live (Tarif *et al*., 2013).

Statistical analysis

The data were were subjected to analysis of variance in a completely randomized design using SPSS software (ver.20.0 for windows, IBM SPSS) Means were compared for significance of differences by Duncan multiple range test (Duncan, 1955).

RESULTS AND DISCUSSION

Table below showed that the ejaculate volume varies ($P<0.05$) at 20% percent level of aloe gel from control and 10% inclusion. The semen volume obtained in this study was within the range (0.2 to 0.8ml) for red and white Shika brown as recorded by Rwaan *et al.* (2009). The motility of the semen was significant at 10% ($P<0.05$), followed by 20% level of aloe vera gel and the least ($P<0.05$) in control

group. The values for motility in this study were within the range of 61.22 to 83.00 recorded by Adeoye *et al*. (2017). The motility of the sperm cells suggests the number of sperms assumed to be capable of advancing from the point where semen is deposited in the course of insemination to the sperm storage tubules in the hen (Adeoye *et al*., 2017). Semen concentration was highest at 20% aloe vera gel and least at 0% (control group). The semen concentrations in the present study were similar to range 1.58 to 2.78 billion cells reported Saleh *et al*. (2018) for FUNAAB-alpha cocks but lower than values 8.6 to 9.5/ml obtained in different lines of cocks as recorded by Tariff *et al*. (2013) in Bangladesh.

The proportion of live sperm varies from 68.4 to 74.4% in the present study. Live sperm were highest ($P<0.05$) at 20% aloe gel compared to 10% and control. This is within the range of 45 to 80 as recorded by Rwaan *et al*. (2009) for White Shika brown challenged with New castle disease and those administered vaccine.

Table 1: Semen quality characteristics of Noiler Cocks fed Aloe vera Gel

Treatments	**Ejaculate Volume(ml)**	**Semen Color**	**Motility (%)**	**Semen Concentration X 10^9**	**Live Sperm (%)**
Control (0%)	0.40^{b} ±0.00	Milky	60.00 ± 0.00^{c}	2.07 ± 0.21^{c}	68.40 ± 0.51^{b}
10% Aloe Gel	0.41^{b} ±0.02	Milky	70.52 ± 0.18^{a}	2.56 ± 0.20^{b}	69.40 ± 0.93^{b}
20% Aloe Gel	0.50^{a} ±0.00	Milky	66.20 ± 0.81^{b}	4.31 ± 0.19^{a}	74.40 ± 1.03^{a}

^{a,b,c,}……means within each column with different superscript differ significantly at $P < 0.05$

CONCLUSION

It was concluded that 200g of *aloe vera* gel per litre (20%) of improves semen quality of noiler cocks drinking water can have influence on semen parameters at 20% inclusion level of adult Noiler cocks. However, further studies should examine its effect on morphology of spermatozoa as well as testicular morphology and histology.

EFFECT OF AQUEOUS ADMINISTRATION OF *MORINGA OLERIFERA* LEAF AND SEED EXTRACTS ON THE GROWTH PHYSIOLOGY OF LOCAL MALE TURKEYS.

Ogbu, O.C.
Department of Agricultural Technology, Federal Polytechnic, Oko Anambra State Nigeria.
Corresponding author: ogbuonyinyeac@gmail.com

ABSTRACT
The aim of the study was to evaluate the effect of Moringa olerifera leaf and seed extracts on the growth physiology of male turkeys. A total of 36 turkeys of about 8 – 9 weeks were used. There were nine turkeys per treatment groups, grouped as; T_1 (control) T_2 (1% leaf w/v) T2 (0.5% leaf and 0.5% seed w/v) and T_4 (1% w/v) Each group was replicated three times with three turkeys per replicate. The study latest for 154 days with all routine management practices duly observed. Data were collected from body weight gain, feed intake, feed conversion efficiency, carcass cut part weight, viseromatic index on the internal organ weights. The result of the experiment showed that, average final body weights were improved significantly ($P<0.05$) by the administration of Moringa extracts with T_4 (6.20 ± 0.02^a) having the highest weight. Feed efficiency was also better ($P<0.05$) among the Moringa administration group than the control with the T_4 (3.90 ± 0.00^c) been most efficient. The viscera-somatic index differed significantly ($P<0.05$) in the mean percentage size of the pancreas, gizzard and gall bladder only, but did not take adequate pattern that can be attributed to the Moringa. The cut parts were greater ($P<0.05$) quarter thigh weight(kg) and asymmetry half carcass cut(kg) which are prime cut parts. These differences were higher among the Moringa extract group.In conclusion, Moringa seed and leaf extracts improved the growth on male local turkeys with the leaf extract alone (T4 1% w/v) giving the best results.
Key words: Turkey, Growth, Extracts.

INTRODUCTION
The local turkeys in Nigeria are gradually becoming endemic. The poultry population in the country is estimated at 104.3 million comprising 72.4 million chickens, 11.8 million ducks, 4.7 million fowl, 15.2 million pigeon and only 0.2 million turkeys (FDLPCS 1992). Despite the quick return rate to investment, turkey production has not being as successful as successful as chicken production. Its production in Nigeria is largely on a backyard small scale level. Therefore to improve this, there is need for additives preferably natural ones that can improve maturation rate so as to generate, quicker returns to investment. *Moringaolerifera* plants are loaded with lots of chemicals like phenols substances, antioxidants, vitamins, minerals and earth rare metals found to improve general well-being. *Moringa* leaf extract has been used to check growth performance apparent digestibility of broiler chicken (Alshukri *et al*., 2018). Khan *et al.*, (2017) have studied the effect of *Moringaolerifera* leaf powder supplements on growth rate as well as intestinal morphology of broiler chickens and had a positive observation.Hence, using both the leaf and seed of *Moringaolerifera* on local male turkeys will bring to lime light a serious improvement in the turkey production industry.

MATERIALS AND METHODS
The experiment lasted for 154 days. It was approved and supervised by the Michael Okpara University of Agriculture Umudike (CASAP) Research and Experiment committee and was carried out at the Poultry unit ofChirex Agro Services Limited in Abakuru, Ohaji-Egbema Local Government Area of Imo State Nigeria.

Collection and Preparation of experimental material

The freshly harvested leaves and seeds were sorted to remove contaminants sand particles and dead matter. They were shade dried in an open well ventilated room for about one week at room temperature. The seeds and the foliage were ground separately into power and stored in separate clean dry containers. Treatment one (T_1) was the control group with no *Moringa* powder. One gram of the seed powder was diluted in 1000mls of clean water, sieved with cheese cloth and served as drinking water for treatment two (T_2). Treatment three (T_3) had 0.5g of leaf powder and 0.5g seed powder diluted with 1000mls of clean water sieved with cheese cloth and served as drinking water. One gram of the leaf powder was

diluted in 1000mls of clean water, sieved with cheese cloth and served as drinking water for treatment four (T_4).

Experimental animals and their management

Thirty six (36) local male strains of turkeys of white, black and lavender plumage averagely eight (8) weeks old were used for the study.

The local turkeys were procured from a reputable farm, in Ikenga,Aguata Local Government Area in Anambra State. Before commencement of the experiment, the local turkeys were quarantined and allowed toacclimatize for 14 days in the Poultry unit. During the acclimatization period, the turkeys were given routine management practices which included deworming with Ivermectin solution (1%w/v) against endo and ecto parasites. Suitable vaccinations for their age was also given prior to the commencement of the experiment. The 36 male turkeys were randomly allotted into treatments. There were four (4) treatments in all with nine (9) turkeys per treatment. Each treatment group was replicated three times to contain three (3) turkeys per replicate. The treatment groups were administered 0 gram of *Moringa*(T_1), 1 gram of *Moringa*seed alone (T_2) combination of 0.5g of *Moringa*seed and 0.5gram of *Moringa*leaf (T_3) and lastly 1 gram of *Moringa*leaf alone (T_4) . Experimental material was given to the male turkeys at 10 weeks of age. The treatment was administered to the turkeys via drinking water between hours of 7am to 10am after which they were given clean drinking water throughout the rest of the day. The turkeys were given commercial feed during the first 14weeks of the experiment. From 24 weeks of age formulated ration in Table 3.1 was used. The feed sample was determined to ensure quality assessment in Table 3.1 by livestock feeds Plc with the aid of the apparatus; DA1650 near infra-red Spectrophotometer.

Experimental Design

The experiment was completely randomized design (CRD). It consisted of four treatments; T_1, T_2, T_3 and T_4 containing 0g, 1g of seed, combination of 0.5g of seed and 0.5g of leaf and 1gram of leaf, respectively. There were nine male turkeys in each treatment with 3 replicates of 3 turkeys per replicate.

Data collection

Growth performance

Daily feed intake was measured by weighing the quantity of feed given to the turkeys and their left over with the Dana weighing scale**.** The initial body weight was take before the commencement of the experiment and final body weights taken at the end of the study. These data were used to calculate;

$$\text{Daily weight gain} = \frac{\text{final body weight} - \text{initial body weight}}{\text{number of turkey per treatment} \times \text{number of days}}$$

$$\text{Feed efficiency } \frac{\text{Quanity of feed consumed}}{\text{weight gained}}$$

Weight gain = final body weight – initial body weight

Carcass evaluation

Three turkeys from each treatment was scarified at the end of the experiment. The carcass was carefully sectioned into parts thigh, shank, and head, quartered and symmetrical half body measurements were weighed with the aid of Dana weighing scale. While there lengths were measured with tape rule. The internal organs (liver, heart, kidney, lungs, gizzard, bile, large, intestine and small intestine were weighed using Ohams electronic scale.

Data analysis

Data collected were subjected to analysis of variance using SAS (2008).

RESULTS AND DISCUSSION

Growth performance

The growth performance of male local turkeys administered aqueous *Moringa* extracts is shown in Table 2.

Table 2: Mean values of growth parameters of male turkeys administered aqueousextractsof*Moringa* leaves and seeds

Parameters	**T_1**	**T_2**	**T_3**	**T_4**
Average Initial Body weight (kg)	0.70 ± 0.04	0.70 ± 0.01	0.70 ± 0.03	0.70 ± 0.00
Average Final body weight (kg)	5.80 ± 0.03^{c}	6.07 ± 0.36^{b}	6.02±0.04^{b}	6.20± 0.02^{a}
Weight gain (g)	5103 ± 0.03^{d}	5407± 0.00^{b}	5307± 0.00^{c}	5503± 0.03^{a}
Daily weight gain (g)	28.60 ± 0.03^{c}	29.70 ± 0.03^{b}	29.70 ± 0.00^{b}	30.20 ± 0.03^{a}
Daily feed intake(g)	120.41± 0.02	118.50 ± 0.001	118.21± 0.002	117.78±0.00
Dressing percentage (%)	87.93 ± 0.58^{b}	91.80 ± 0.58^{a}	91.67 ± 0.58^{a}	93.55 – 0.58^{a}
Feed efficiency	4.21 ± 0.00^{a}	3.99 ± 0.00^{b}	3.98 ± 0.00^{b}	3.90 ± 0.00^{c}

Means with different superscripts $^{a, b, c}$ or ^{d} on the same row are significantly different (P<0.05).

The mean values of growth parameters of male turkeys administered aqueous extracts of *Moringaoleifera* leaves and seeds are shown in Table 2.2. There were significant differences (P<0.05) between the

treatments for the final body weight, weight gain, feed conversion ratio and daily weight gain. The mean final body weight was highest in T_4 (leaf extracts) 6.19 ± 0.02kg followed by T_2 (seed extracts) 6.07± 0.04kg, and T_3 (seed and leaf extracts 6.02 ± 0.04kg, compared with T_1 (control) 5.84± 0.03kg. The mean weight gain was highest among the *Moringa* treated turkeys (T_4 5.50 ± 0.03; $T_2$5.41± 0.00 and T_3 5.31± 0.00kg) than the control treatment (T_1 5.10± 0.03) kg.

The mean daily weight gain was also significantly higher (P< 0.05) in T4 30.20±0.00g, T_3 29.70± 0.03g and T_2 29.70± 0.33g than T_1 28.60g± 0.03g. The feed conversion ratio was significantly (P<0.05) lower among the treatment groups administered aqueous *Moringa* leaf and seed extract ($T_4$3.91± 0.00; T_3 3.98±0.00 and T_2 3.99±0.03) when compared with the control (T_1 4.21±0.00).

The results suggest that *Moringaoleifera* improved the growth rate of male turkeys in this study. This could be due to high protein content of *Moringaoleifera* which is advantageous in poultry (Dong *et al*., 2007; Krauze and Grela, 2016). This finding collaborates with the resultsof Nkukwana*et al*. (2014); Khan *et al*. (2017) and Sun *et al*.(2017) on the benefits of *Moringaoleifera*.

This improvement in weight gain could also be attributed to the nutrients and contents of the administered extracts which according to Sowande*et al.* (2008) is the basis for improved productivity. The increase in daily weight gain was significantly higher (P<0.05) in the leaf extract treatment group than in the combined seed and leaf as well as seed extracts alone. This advantage may be due to the anti- nutrients like saponines found in*Moringa* which Francis *et al.* (2002) reported to have inhibitory properties. The leaves of *Moringa* according to Fereira*et al.* (2008) are good sources of highly digestible protein. This could be the reason for their higher weight gain and better dressing percentage on T_4.

The mean values of feed efficiency (FE) were significantly lower in the *Moringa* extract administered treatments. Ogbonna*et al*. (2002) noted that low feed efficiency (FE) value is a measure of superiority of the treatment. There was higher weight gain and lower FE values among the local male turkeys administered aqueous *Moringa* leaf extracts. These facts therefore make T_4 the preferred treatment of choice among the groups.

Viscero-somatic index of male turkeys administered aqueous*Moringa* leaf and seed extracts

Viscero-somatic index of male turkeys administered aqueous*Moringa* leaf and seed extracts is shown in Table 3.

Table 3:The mean values of viscero-somatic index of male turkeys administered aqueous*Moringa* leaf and seed extracts

Parameter (%)	**T_1**	**T_2**	**T_3**	**T_4**
Live Weight	5.10 ±0.35	5.50±0.23	5.40±0.06	5.60±0.23
Spleen	0.06±0.04	0.06±0.01	0.05±0.01	0.06±0.01
Pancreas	0.14±0.01^{a}	0.12±0.00^{ab}	0.15±0.00^{a}	0.10±0.00^{b}
Heart	0.48±0.05	0.41±0.01	0.46±1.00	0.34±0.04
Kidney	0.32±0.02	0.39±0.04	0.38±0.03	0.31±0.04
Liver	1.41±0.02	1.51±0.16	1.57±0.18	1.22±0.08
Lungs	0.52±0.05	0.55±0.05	0.61±0.08	0.52±0.04
Gizzard	2.96±0.02^{a}	2.55±0.01^{ab}	2.56±0.12^{b}	2.36±0.01^{c}
Small Intestine	2.26±0.16	2.24±0.03	2.22±0.14	1.93±0.09
Large Intestine	0.87±0.03	0.82±0.10	0.78±0.12	1.00±0.19
Gall bladder	0.10±0.04^{a}	0.03±0.01^{b}	0.04±0.00^{ab}	0.06±0.00^{ab}

Means with different superscripts $^{a, b, c}$ or ^{d} on the same row are significantly different (P<0.05).

The mean values of viscero-somatic index of male turkeys administered aqueous*Moringa* leaf and seed extracts are shown in Table 3.

There were significant differences (P<0.05) in the mean percentage sizes of the pancreas, gizzard and gall bladder while the heart, kidney, liver, lungs, small intestine and large intestine did not differ significantly among the treatments.

The pancreas which performs dual function; digestion as well as to regulate blood sugar (Widmaier*et al.*, 2004), differed significantly (P<0.05) with T_1 (control 0.14 ± 0.01%) and T_3 (0.15 ± 0.00%) been higher than T_2 (0.12 ± 0.00%) then T_4 (0.10±0.00) as the least. The abnormal increase in size of the pancreas in the treatment T_1 may be attributed to the high level of glucose seen in this study on T_1.Small sized of pancreas may mean that the pancreas was not over stressed trying to metabolise and digest micronutrient of digestion as was seen in T_4. The size of gizzard differed significantly (P<0.05) among the Turkeys administered *Moringa* leaf and seed extracts. The *Moringa* extract groups had the significantly small sized gizzard which may have resulted due to the degrading effect of the aqueous extract on the feed particles thereby facilitating fast digestion rate of feeds. This affirms the reports of Amerah*et al.* (2009) that coarse feed particles normally stimulate constriction of the gizzard, which affects its development and increases the size. This increase in size as a result of over work to augment the shortage or ameliorate the effect of excess supply of fiber was not witnessed among the *Moringa* groups.

There were significant differences (P<0.05) on the gall bladder size among the Turkeys administered *Moringa* leaf and seed extracts. The bile aids in emulsification of fat. Decreasing size of the bile organ could be attributed to the fact that extracts from *Moringa* aids degradation as well as emulsification of fats thereby reducing the work load of the gall bladder in secreting bile salt thus enhancing its functionality especially in the leaf extract treatment group as against the control group that had the biggest increase in gall bladder size.

Carcass parameters of male turkeys

Table 4: The mean values of cut parts of male turkeys administered *Moringa* leaf and seed extracts

Parameter	**T_1**	**T_2**	**T_3**	**T_4**
Dressed weight (kg)	5.10±0.35	5.50±0.23	5.75±0.14	5.60±0.23
Thigh Length (cm)	21.85±0.32^{a}	17.85±0.43^{b}	15.55±0.43^{c}	18.00±0.12^{b}
Thigh Width (cm)	17.60±0.92	17.40±0.52	17.80±0.75	17.25±1.13
Shank Length (cm)	11.65±0.66	12.03±0.03	11.60±0.23	11.90±0.06
Breast length (cm)	18.33±0.17	18.45±0.26	18.00±0.12	18.15±0.87
Back length (cm) (Head to rum)	18.33±0.17	18.45±0.26	18.00±0.12	18.15±0.87
Head Weight (g)	119.00±0.58^{b}	126.50±5.48^{b}	143.50±0.87^{a}	124.05±2.92^{b}
Paired shank weight (g)	106.50±15.88^{b}	136.00±5.20^{a}	126.50±0.87^{ab}	147.00±3.46^{a}
Neck weight (g)	525.00±14.43	540.50±23.38	445.00±10.39	537.50±108.83
Quarter wing weight (kg)	0.90±0.00	0.93±0.04	0.93±0.04	1.000±0.06
Quarter thigh weight (kg)	1.03±0.01^{b}	1.15±0.06^{a}	1.08±0.02^{ab}	1.10±0.29^{ab}
Half carcass symmetry (kg)	2.02±0.02^{ab}	2.02±0.09^{ab}	1.98±0.01^{b}	2.15±0.03^{a}

Means with different superscripts $^{a, b, c}$ or ^{d} on the same row are significantly different (P<0.05).

The mean values of cut parts of male turkeys administered *Moringa* leaf and seed extracts are shown in Table 4.4. The thigh length, thigh weight, head weight, paired shank weight quartered thigh weight and half carcass symmetrically differed significantly ($P<0.05$). However dressed weight, thigh width, shank length, breast length, back length, neck weight as well as quartered wing weight did not differ significantly ($P<0.05$). From these results, the quartered thigh (kg) which is a prime meat cut differed significantly among the treatment groups with things of turkeys exposed to *Moringa* extracts having bigger weights ($P<0.05$) compared with the control. This therefore implies that *Moringa* promoted muscle weight gain which may be due to the fact that it is rich in easily digestible protein found in the leaves (Ferreira *et al*., 2008),thus making the leaf extracts a better option when muscle building in male turkeys is desired.

In conclusion, *Moringa* seed and leaf extracts improved the growth on male local turkeys with the leaf extract alone (T4 1% w/v) giving the best results.

[3]Department of Animal Science and Range Management, Modibbo Adama University of Technology Yola, Adamawa State, Nigeria

ABSTRACT

The study was conducted to evaluate some parameters of external and internal egg quality of local chickens and guinea fowl in Benue and Taraba states. A total of 160 eggs (40 eggs from each breed per state) were collected to study for egg (weight, shape index), albumen (weight, percentage), yolk (weight, percentage) and shell (weight, percentage, thickness, strength) quality. The results showed that the egg weight and egg length of local chickens in Benue were significantly higher ($P < 0.05$) than that of guinea fowl in the same state, whereas difference in egg shape index between these breeds were not significant ($P > 0.05$). Differences in albumen weight, albumen percentage, yolk weight and yolk percentage of the chicken breeds were statistically non-significant ($P > 0.05$). Albumen height was significantly higher ($P < 0.05$) in local chickens in Benue compared with local chickens in Taraba state. The significantly ($P < 0.05$) higher values of yolk height and yolk index were detected in guinea fowl in Bemue state than others. The shell weight and proportion were affected by the breed of hens ($P < 0.05$) but there were no significant differences ($P > 0.05$) in egg shell thickness and strength. It was concluded that the breed of chicken and location affected some parameters of exterior and interior quality of eggs. Further were recommended on other breeds of chicken to also determine the quality of their eggs.

Key words: Egg quality, guinea fowl, local chickens.

INTRODUCTION

The livestock industry is an important subsector of the agricultural sector of Nigeria's economy. The role of this sector cannot be over- emphasized considering the importance of animal protein in the diet of people and contribution from this sector to the gross domestic product (Adekaye and Akinrade, 2006). They enumerated livestock types found in Nigeria to include cattle, sheep, goats, pigs, poultry, horses, donkeys and camel. The term poultry refers to all domesticated birds kept for meat or egg production which consist of chicken (domestic fowl), turkey, ducks and geese (Obioha, 1992). Poultry eggs yield desirable products in all parts of the country with no cultural restrictions. Poultry eggs are rank second to cow milk in terms of nutritive value and are the most economically produced animal protein (Ikeme, 1990). Eggs are considered a wholesome diet, since an egg contains adequate amounts of protein, energy, amino acid, vitamins and minerals to satisfy the body needs. Lombin (2001) emphasized that, the FAO/WHO recommended daily intake of 65g of protein out of which 35g (38.8%) should be from animal sources. She further stressed that Nigeria's consumption of protein is now 5g per head per day (14.3% requirement). The need therefore to bridge the gap of protein shortage through good quality eggs cannot be over-emphasized. Eggs have constituted an important part of human diets for centuries because of its high quality protein (Forson *et al*., 2011). They are known to supply the best proteins besides milk (Vaclavik *et al*., 2008). It is also rich in amino-acids, carbohydrates, easily digestible fats and minerals, as well as valuable vitamins (Huopalahti *et al*., 2007). The yolk and white components are all of high biological value and are readily digested (Joel *et al*., 2010). Eggs play important culinary roles and are therefore prepared into different dishes. There are many types of poultry species' eggs consumable as a protein and amino acid supplement (Trziska, 2000). Nigeria has the highest number of poultry farm in Africa. Nigeria presently produces about 300,000 tons of poultry meat per annum officially and 650,000 tons of eggs (USDA, 2014). A parallel record from Poultry Association of Nigeria (PAN), indicates that Nigeria produces presently above 1.25million tons of egg per year. South Africa is the second producer of eggs in Africa. The question arises whether there are interspecies differences in poultry eggs quality which may affect the nutritive value and quality as human food. In Nigeria, domestic fowl dominated the

poultry industry. Out of 150 million poultry population, 120 million (80%) were indigenous. Domestic fowl constituted 91% of this while guinea fowl, duck, turkey and others were 4%, 3% and 2% respectively (Adenowo *et al*., 1999). Chicken eggs are the most commonly consumed eggs; they are also an inexpensive single-food source of protein.

MATERIALS AND METHODS

The study was conducted in Benue and Taraba state. Freshly-laid egg samples from birds of two (2) different genotypes (domestic chicken and guinea fowl) were obtained between September and October 2018 from poultry keepers in Benue and Taraba States, Nigeria. The eggs were analyzed for different parameters of egg quality. At laying time the domestic fowl were approximately 28 weeks and guinea fowl were approximately 32 weeks old. The birds' genotype was Pearl (guinea fowl) and normal feathered (domestic chicken). Both the domestic chicken and guinea fowl had outdoor access all the year round Fed with cereal, hay, clover, vegetables, green crops and cereal-based mixed fodder with several additives daily. The egg samples were thoroughly washed with distilled water in the laboratory. The yolk and albumin were separated by breaking a small part of the egg shell at one end and separating the egg albumin from the yolk. Forty (40) eggs each from both local chickens and guinea fowl were used for the study.Freshly laid eggs were collected at 26, 34, 42, and 50 wk. For each examination, 40 eggs were randomly selected from each group to measure the internal and external characteristics. Time interval between the eggs being laid and measured was less than 24 hours. The eggs were stored at room temperature before measurement.

RESULTS AND DISCUSSION

The result of thecomparative analysis of egg quality of guinea fowl and local chickens in Benue and Taraba states is presented in table 1, 2, 3 and 4.

Table 1: Effect of Breed on Egg Parameters

	Benue State		Taraba State	
Parameters/ Breed	**Local chicken**	**Guinea fowl**	**Local chicken**	**Guinea fowl**
Egg weight (g)	58.69±3.64^{a}	56.74±3.58^{c}	57.96±3.59^{b}	57.78±3.67^{b}
Egg length (cm)	5.83±1.14^{a}	5.71±1.13^{bc}	5.79±1.14^{b}	5.78±1.13^{b}
Egg width (cm)	4.34±1.08	4.27±1.07	4.31±1.10	4.32±1.09
Egg shape index (%)	74.44±0.44	74.78±0.35	74.43±0.31	74.74±0.36

Table 2: Effect of Breed on Egg Albumen Parameters

	Benue State		Taraba State	
Parameters/ Breed	**Local chicken**	**Guinea fowl**	**Local chicken**	**Guinea fowl**
Albumen weight (g)	34.87±3.85	33.07±3.68	34.23±3.88	34.12±3.79
Albumen percentage (%)	59.41±3.96	58.29±3.88	59.05±3.95	58.75±3.94
Albumen height (mm)	55.86±2.42^{a}	55.07±2.46^{b}	54.72±2.39^{b}	55.11±2.44^{ab}
Albumen width (mm)	78.25±0.78	78.63±0.65	78.06±0.68	78.48±0.72
Albumen index (%)	71.39±2.14^{a}	70.04±2.08^{b}	70.09±2.13^{b}	70.22±2.09^{ab}

Table 3: Effect of Breed on Egg Yolk Parameters

	Benue State		Taraba State	
Parameters/ Breed	**Local chicken**	**Guinea fowl**	**Local chicken**	**Guinea fowl**
Yolk weight (g)	17.83±1.08	17.93±1.66	18.07±1.64	18.23±1.68
Yolk percentage (%)	30.38±0.85	31.60±0,87	31.17±0.89	31.39±0.82
Yolk height (mm)	17.25±1.17	17.97±1.09[a]	17.12±1.14	16.73±1.07
Yolk width (mm)	41.26±0.68	40.98±0.59	41.22±0.64	41.14±0.67
Yolk index (%)	41.81±0.69	43.85±0.79[a]	41.53±0.75	40.67±0.61
Yolk colour (^{0}LR)	9.65±0.95		9.49±0.99	9.57±0.88

Table 4: Effect of Breed on Egg Shell Parameters

	Bauchi State		Gombe State	
Parameters/ Breed	**Local chicken**	**Guinea fowl**	**Local chicken**	**Guinea fowl**
Shell weight (g)	5.99±0.33[a]	5.74±0.33[b]	5.67±0.32[b]	5.43±0.33[b]
Shell percentage (%)	10.21±0.65[a]	10.11±0.61[a]	9.98±0.62[ab]	9.40±0.60[b]
Shell thickness(μm)	371.45±24.29	368.82±24.42	364.39±24.27	361.58±24.22
Shell strength (N cm^{-2})	30.44±5.62	29.81±5.39	29.27±5.48	30.18±5.53

The result of the egg parameters is presented in Table 1. The result showed that there were significances difference in egg weight and egg length while there were no significance differences in some of the parameters such as egg width and egg shape index. The study showed significantly (P<0.05) lower egg weight of guinea fowl in Benuein comparison with local chicken, followed by guinea fowl in Taraba. Eggs from local chickens in both states gave higher values compare to guinea fowl.

The values obtained in this study were similar to those recorded by Zanon *et al*. (2006), who published egg weight for local light Italian breeds Modenese and Romagnolo (53.7g and 54.0g). For guinea fowl, hen egg weightwas balanced from 57.0 to 58.0g (Anderle *et al*., 2014).For example, Turkish breeds Benizli and Gerze lay eggs with weight 53.94 and 54.30g (Sarica *et al*., 2006).

The study also recorded a similar average egg shape index from 74.43% for local chickens in Taraba state to 74.78 % forguinea fowl in Benue state. The values in this study were lower than those reported bySingh (2000) who recorded higheregg shape index (75.46%). Egg shape is influenced by genetic factors and individual traits, and is determined in the oviduct. The egg shape index ranges between 57 % and 92 %, but it is believed that values under and below 74 % are a cause for higher incidence of cracked and broken eggs (Narushin, 2005; Popova-Ralcheva *et al*., 2009).

Albumen Parameters

The result of the albumen parameters is presented in Table 2. There were significant differences in albumen height and albumen index while there were no significant differences in albumen weight, albumen percentage and albumen width. The values obtained in this study were lower than those reported by Anderle *et al*. (2014) reported albumen proportion for local chicken from 58.4 to 60.1 %. In the present study it has been observed that local chickens in Benue state have significantly (P<0.05) higher albumen height than local chickens in Taraba. Albumen percentage was significantly higher (P<0.05) in local chickens in Benue compared with guinea fowl in Benue, local chicken in Taraba and guinea fowl in Taraba. The difference in albumen height observed is in agreement with the results of Monira *et al*. (2003) who reported different albumen heights for different breeds, but Haunshi *et al*. (2011) observed non-significant differences in albumen height among Vanaraja and White Leghorn breeds of chickens.

Yolk Parameters

The results of the yolk parameters are presented in Table 3. The results showed that there was no significant difference in yolk weight and yolk percentage among chicken breeds. Guinea fowl in Benue showed significantly (P<0.05) higher yolk heightand yolk index than local chicken in Benue, local chickens in Taraba and guinea fowl in Taraba. The yolk weightof chickens breed was from 17.83 g (local chickens in Benue) to 18.23 g (guinea fowl in Taraba). Stahishevskaya and Toritisna (2007) published similar weight of yolk in local breeds, 18.2g, in Rhode Island 18.3g and in Leghorns 17.4g.In this study, the yolk percentage range from 30.38% for local chickens in Benue to 31.60% for guinea fowl in Benue state. Anderle *et al*. (2014) reported yolk proportion for Czech Golden Spotted hens from 31.2 to 32.9 % and Zanon *et al*. (2006)found yolk proportion 34.69% in Modenese and 32.35% in Romagnolo. Haunshi *et al*. (2011) observed significant differences in the yolk index of different breeds of chickens.The colour of yolkwas almost uniform in all the breeds of chickens, this could be due to the fact that the birds received thesame compound poultry feed.

Egg Shell Parameters

The weight, percentage, thickness and strength of egg shell are presented in Table 4. In shell weight and percentage, there was significantly (P<0.05) lower value for guinea fowl in Taraba compared with local chickens in Benue and guinea fowl in Benue. There were no significant differences (P>0.05) in egg shell thickness and strength among local chickens in Benue, guinea fowl in Benue, local chickens in Taraba and guinea fowl in Taraba state.Zanon *et al*. (2006) reported higher eggshell proportion for both Italian breeds Modenese and Romagnolo (12.88 and 13.29%)compared with the result in this experiment. The proportion of eggshell from the egg weight in Czech Golden Spotted hens ranged from 9.0 to 9.5 % (Anderle *et al*., 2014). Shell percentage can be used to estimate the eggshell quality (Mertens *et al*. 2006).

CONCLUSION

Based on the results obtained in this study, it can be concluded thatthe breed of chicken and location affected some parameters of exterior and interior quality of eggs considered. This effect is most pronounced in egg weight, egg length, quality of albumen, yolk (height, index), egg shell weightand percentage.

RECOMMENDATIONS

From the study conducted, it can be concluded that, layers should be fed with high quality diets to improve the quality of their external and internal egg parameters. Proper management practices should be carried out in a layers house to ensure the laying of eggs with high quality parameters. Further research should be carried out on other breeds of chicken to also determine the quality of their eggs.

ABSTRACT
Preservation of boar semen is associated with the production of reactive oxygen species which leads to a reduction of spermatozoa quality and decrease in fertilizing ability. The outcome of Artificial Insemination (AI) largely depends on the ability of the acrosome to penetrate the zona pellucida, for the deposition of DNA materials into the oocyte, for a successful fertilization and embryonic development. The objective of this study was to investigate the potential of Ethanolic Allium sativum Extracts (EASE) on acrosome integrity and pH of extended boar semen. Semen was collected using the gloved hand technique. Aliquot portions of semen were divided into sixty sample bottles comprising of five treatments with three replicates. T1 served as the control (Beltsville Thawing Solution (BTS) + semen) in ratio 1:3 semen-extender, while other treatments T2 to T5 contained semen-extender at the same ratio, but supplemented with EASE at varying concentrations of 50, 75, 100 and 125 µg/L respectively in a completely randomized design. Extended semen samples were stored at 17 °C . Data obtained were subjected to assess relationship between acrosome integrity and pH and one way ANOVA to evaluate extract effects.
Results suggest a strong and negative relationship between pH and acrosome integrity. Also, supplementation of BTS with EASE at 125 µg/L maintained the acrosome integrity of the spermatozoa compared to control.
Keywords: Acrosome Integrity, Boar semen, Ethanolic *Allium sativum* Extracts (EASE), semen quality, spermatozoa fertilizing potential.

INTRODUCTION
The outcome of Artificial Insemination (AI) largely depends on the semen quality and the insemination procedure. The fertilizing potential of a semen dose is inherently linked to the quality of the spermatozoa itself (Tsakmakidis *et al.*, 2010). But during preservation after collection, due to fluctuation and changes in temperature and other metabolic activities, the fertilizing potential, acrosome integrity inclusively of the spermatozoa is altered or impaired. The quality of boar semen stored in a liquid state is influenced by the type of extender and storage time (Johnson *et al.*, 2000). Currently, many different diluents are used for the storage of semen, which help maintain the viability of the spermatozoa for several days (Gadea, 2003). Research has shown that short and medium-term extenders (up to 5 days), as early as on the second day of storage, spermatozoa motility and the percentage of normal spermatozoa morphology decrease and DNA disintegration increases, which makes them unsuitable for insemination (Klimont *et al.*, 2015). It is well-known that for *in vitro* semen preservation, a good extender should also provide an environment that inhibits the formation of harmful reactive oxygen species (ROS) or lipid peroxide (Orok *et al*., 2010) and cold shock. Boar spermatozoa are very sensitive to cold-shocked temperature resulting in reduced survivability during preservation (Gączarzewicz *et al.*, 2015). The fertility enhancing capacity of plant extract has been reported in numerous studies. Plant derived antioxidants have been getting major focus due to their lower cytotoxicity and are considered to be better than synthetic antioxidants (Gupta and Sharma, 2006 and Sen *et al*., 2010).
Garlic (*Allium sativum*) has been shown to have varied biological properties, including anti-carcinogenic, anti-thrombotic, anti-microbial, anti-inflammatory, anti-atherosclerotic, anti-oxidative, and various other biological actions. Potential antioxidant properties of garlic are as a result of presence of phenolic and flavonoids fractions (Miller *et al*., 2000).
Hence, the study to investigate the effect of garlic (*Allium sativum*) on the acrosome integrity of extended boar semen.

MATERIALS AND METHODS

Experimental Location

Semen collection was carried out at the Piggery Unit of the Teaching and Research Farm, University of Ibadan (7º20'N, 3º50'E; 200 - 300 above sea level), while the analyses of semen were carried out at the Animal Physiology and Bioclimatology Laboratories of the Department of Animal Science of the same institution.

Management of the Boar and Semen collection

Semen was collected from a mature boar with a proven semen quality and fertility for this study. The boar was kept in an intensively managed, clean and well ventilated pen. Feed and clean water were supplied *ad libitum.* Semen was collected into a boar semen collection cup; lined with a disposable plastic bag and covered with a disposable milk filter. The gel-fraction was separated from the sperm-rich fraction by the milk filter covering the semen collection cup. The gloved-hand technique/method was used to collect semen from the boar. Before the ejaculate collection, the boar was thoroughly washed to eliminate urine and other materials that could lead to semen contamination during collection. As the boar initiates extension of the penis on a standing heat sow, the end of the penis, which is cork screw shaped was held strongly by gloved hand. Collection procedure started with strong force to the coiled part of the penis by hand. Collection continued until the boar dismounted.

Preparation of Extracts from Garlic *(Allium sativum L.)*Bulb

Fresh garlic bulbs were purchased from a location, about 2 km from the study site. The fresh garlic bulbs were peeled and 150g was weighed out and fully chopped to increase its surface area, then oven dried at 45 ºC, for seven days and later ground into a powdery form using a ceramic mortar. Ethanol (absolute) was used for the extraction using a Sohxlet extractor. Rotary evaporator was further used to obtain a concentrated garlic extracts. Afterwards, the garlic extracts was dried up in an incubator at 45 ºC for 24 hours. The garlic extracts was recovered and reconstituted using dimethyl sulfoxide (DMSO) and stored (4 ºC) for subsequent use.

Semen Processing

Semen samples collected were immediately evaluated for mass activity, progressive motility, liveability, percentage normal spermatozoa, pH and the temperature was checked 15 minutes after collection. The volume of collected ejaculate was estimated by weighing on a top loader balance. Semen aliquots were diluted in each of experimental extenders (treatments). Diluted semen was preserved in a thermo regulated fridge at 17 ºC and evaluated for acrosome integrity.

Acrosome integrity assessment:

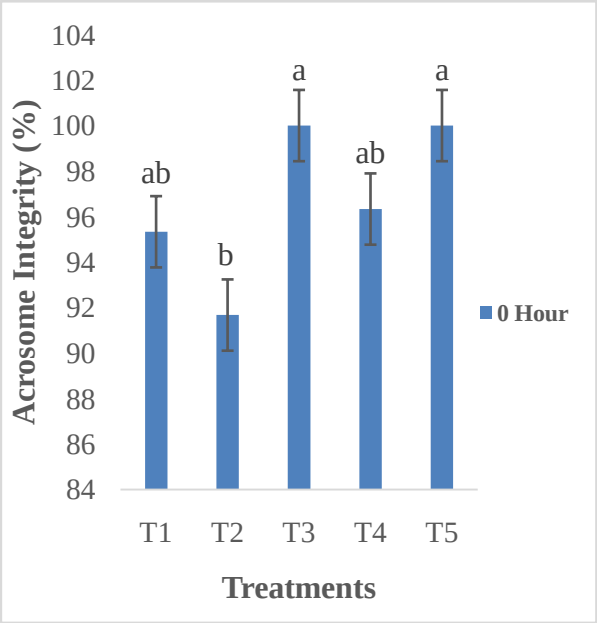
Ejaculate smears of all samples were prepared for confirmation of acrosome integrity condition utilizing eosin-nigrosin stain. All the slides were assessed under oil immersion at X1000 magnification using a bright field microscope. A total of one hundred spermatozoa per slide were assessed, and normal acrosomes (spermatozoa without apical shifts) were expressed as percentages.

Experimental Treatment and Design

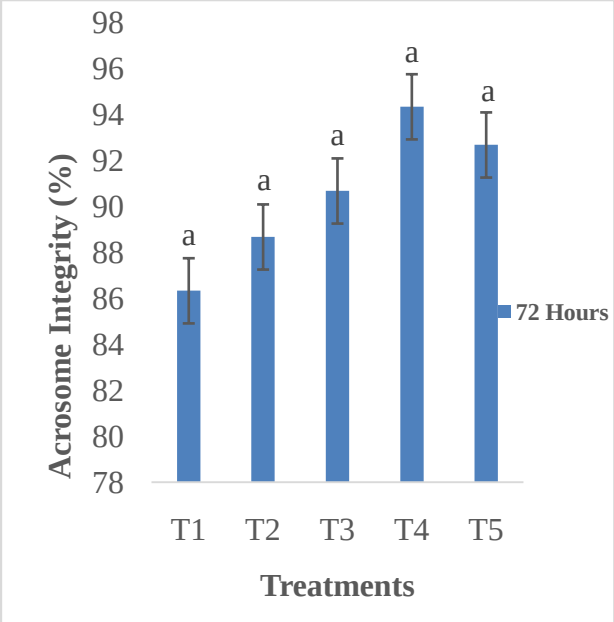
Aliquot portions of diluted semen were allotted to five treatments with three replicates per treatment in a completely randomized design (CRD) and spermatozoa of acrosome integrity was evaluated .

Treatment description:

Treatment 1: Semen+ Beltsville Thawing Solution (BTS®)
Treatment 2: Semen+ BTS + 50 µg/L Ethanolic *Allium sativum* Extract (EASE)
Treatment 3: Semen+ BTS + 75 µg/L EASE
Treatment 4: Semen+ BTS + 100 µg/L EASE
Treatment 5: Semen+ BTS + 125 µg/L EASE



Statistical Analyses



Data obtained were analyzed using one-way analysis of variance (ANOVA) procedure of SAS (2010) and means were compared using Duncan's multiple range test of the same software.

RESULTS

Table 1: Correlations between pH and Acrosome integrity

Parameter	Acrosome integrity
pH	-0.585

T1: Control; T2: 50µg EASE; T3: 75µg EASE; T4: 100µg EASE; T5: 125µg EASE; EASE: Ethanolic *Allium sativum* Extract

a,b: bars with different superscripts are significantly different (P<0.05)

Figure 1&2: Effect of EASE on acrosome integrity of extended boar semen at 0 and 72 hours respectively

DISCUSSION

Effect of EASE on Acrosome Integrity of Extended Boar Semen

Acrosome integrity of spermatozoa in extended boar semen, supplemented with EASE at 17 °C is presented in Figures 1 and 2. Significant difference (P<0.05) occurred at 0 hour. Acrosome integrity is an important parameter useful in predicting the fertilizing capacity of

spermatozoa *in vitro*. From this study, it was observed that acrosome integrity was intact across the treatments from 0 to 72 hours of observation, except for a little fluctuation in T4 at 48 hours observation. This is an indication that EASE has the capacity to maintain the integrity of the acrosome. However, acrosome integrity decline with storage time at 17 °C. This finding supports Gadea *et al.* (2005) report that reduced gluthathione could reduce acrosome integrity, improving the function and fertilizing capacity of frozen boar spermatozoa. This aligns with Orok *et al*. (2010) storage of semen for longer period causes ultra-structural, biochemical and function damage to the spermatozoa, resulting in a decline in motility, viability, fertility and impaired acrosome integrity and transport. Also, reduction in acrosome integrity will result in induced acrosome reaction of greater portion of spermatozoa before reaching the site of fertilization. This scenario is suggested in the negative relationship in pH and acrosome integrity. Reduced pH indicates more metabolic activity in the system and possibility of acrosome reaction before spermatozoa arrival at fertilization site. This finding indicates that EASE inclusion at 125µg competes favourably in preservation of the acrosome integrity better than a conventional extender (T1).

CONCLUSION

From this study, it was observed that BTS supplemented with 125 µg/L EASE, has the potential of maintaining the acrosome integrity of extended boar semen for 72 hours of preservation.

ABSTRACT
288-six weeks old Japanese quails at the point of lay were used to determine the effect of age and egg size on the fertility and hatchability of quail eggs after adjusting for three weeks. Eggs were taken daily from the birds with a mating ratio of one cock to four hens for a period of five days when the quails attained 9, 13, 17 weeks old respectively and sorted on the basis of small (<9g), medium (9-10g) and large eggs (>10g) using a sensitive electronic scale. The eggs were stored in a temperature of 15°C before setting in the incubator to inhibit embryonic development in an experiment that lasted for 12 weeks. The small, medium and large eggs collected at the corresponding ages of 9, 13 and 17 weeks were assigned into a 3 x 3 factorial arrangement in a completely randomized design having six replicates each. Results obtained revealed that percent fertility was highly significantly (P<0.01) affected by age with a fertility of 92.90% at 13 weeks followed by 89.92%, 82.91% at 9 and 17 weeks. The percent hatchability was significantly (P<0.05) affected by egg size and the best recorded in the medium eggs with 69.58% in relation to the large and small eggs having 64.95% and 63.62%, respectively. The fertility and hatchability were neither affected (p>0.05) by the interaction effects of age and egg size. In conclusion, the age of quails had significant effect on fertility of quail eggs whereas the hatchability was affected by egg size.
Keywords: Japanese quails, age, egg size, fertility, hatchability.

INTRODUCTION
Fertility and hatchability of chicken eggs is determined by an array of factors such as physiological, social, environmental and genetic makeup of the birds (Islam *et al.,* 2002). The reproductive performance of livestock particularly avian is severely affected by the age of the bird (Brillard, 2003). The author reported that the decline in fertility of the hens may be related to the inability of the hens to retain spermatozoa in the oviduct while the fertility of the cocks is a function of its ability to successfully mate and deposit adequate quality and quantity of semen in the hen's reproductive tract. A reoccurring setback observed with the commercial broiler breeders is the sharp decline recorded in its fertility at the declining phase of its laying period which occurs as the hens attain 50 weeks of age (Walsh and Brake, 1997). Munir and Mohammed (2010) reported that there was an increased percent fertility and hatchability in Arbor acre and Lohman brown hybrid layers between the ages of 24-45 weeks which was followed by a decrease in the fertility and hatchability when the birds increased in age from 50-65 weeks. The factors which affects both sexes has its peculiarity with the age of the bird. The influence of age relating it with other factors as they affect fertility and hatchability of eggs is not clearly understood (Bramwell, 2009).
In the findings of Abiola*et al.* (2008), the author opined that from the three categories of small, medium and large sized eggs of broiler chickens, the best hatchability of 96.67% was obtained in the average eggs compared with the large and small eggs. There is paucity of information regarding the factors affecting the fertility and hatchability of quail eggs. The precise causes are yet to beascertained. The predisposing factors in commercial poultry birds may also apply to quail eggs (Gonzalez *et al.,* 1999). This work was designed to substantiate the effect of age and egg size of Japanese quails on its fertility and hatchability.

MATERIALS AND METHODS
The experiment were conducted in the poultry unit, Teaching and Research Farm of Ahmadu Bello University, Samaru, Zaria and the hatchery unit, College of Agriculture, Mando, Kaduna respectively. According to Akpa*et al.* (2002), Zaria is within Latitude 11° 12^{1}N and longitude 7° 12^{1}E. The altitude is 610m above the sea level and located in the Northern Guinea Savannah zone of Nigeria. The National Veterinary Research Institute (NVRI) Vom, Plateau state, Nigeria supplied the quails used for

this study.The number of Japanese quails used for the study was 288-six week's old unsexed Japanese quails with a mating ratio of one cock to four hens which were raised in cages partitioned into $0.5m^2$ to house each group of four quails (a cock and four hens). The quails were fed a formulated diet of 23% crude protein from six to eighteen weeks of age. The management practices involved in raising the birds with regard to the feeding, lighting and watering were the same in the course of the twelve week experimental period. Eggs were taken daily from the birds for a period of five days when the quails were nine, thirteen and seventeen weeks old respectively and stored in a room with a temperature of 15^oC prior to setting in the incubator to inhibit embryonic development. The egg classification were as follows; eggs weighing below nine, nine to ten and above ten grams were classified as small, medium and large eggs using an electronic scale at the corresponding age taken. Each batch of eggs from the corresponding ages together with the different egg sizes were individually set on marked trays with six replicates and each having a minimum of 80 eggs. The eggs were further set in the incubator for 15 days and hatched on the 18th day. Candling of the eggs was carried out on the 15th day as follows; the infertile eggs were removed before onward transfer to the hatcher and the chicks were hatched on the 18th day. The fertility and hatchability were determined as follows:

Percent fertility = Total fertile eggs/Total eggs set in the incubator x 100

Percent hatchability = Total chicks hatched/ Total fertile eggs from the incubator x 100

The small, medium and large eggs collected at the corresponding ages of nine, thirteen and seventeen weeks were assigned into a 3 x 3 factorial arrangement in a completely randomized design.

Statistical Analysis

The generated data from the experiment was analyzed using the General Linear Model Procedure of SAS (1993). The least significant difference was used to separate the means in the treatment groups where significant differences were observed.

The model used for the analysis of data generated in this study is shown below:

$Y_{ijkl} = \mu + A_i + S_j + (AS)_k + E_{ijkl}$

Where: Y_{ijkl} = Response variable (fertility or hatchability) as the case were:

μ = Overall mean

A_i = Effect of i_{th} age of quail hens

S_j = Effect of j_{th} egg size

AS_k = Interaction effect of age of quail hens and egg sizes on fertility or hatchability

E_{ijkl} = Random error

RESULTS

The effect of age and egg size on the percent fertility and percent hatchability is presented on Table 1. Percent fertility was highly significantly ($P<0.01$) affected by age, whereas egg size and the interaction effect of age and egg size had no significant ($P>0.05$) effect on the percent fertility of the quail eggs. The pattern revealed that as the birds increased in age from 9 to 13 weeks, there was an increase in the percent fertility and subsequently declined at 17 weeks as the birds advanced in age suggesting that the best fertility is obtained in quails at 13 weeks of age after which there is a gradual decline. The percent hatchability was significantly ($P<0.05$) affected by egg size and was neither affected by the age or the interaction effects of age and egg size. The best hatchability was obtained in the medium sized eggs followed by the large and small sized eggs respectively.

DISCUSSION

The increase in the percent fertility as the quails increased in age could be as a result of higher sexual activity at the 9th and 13th week while the decrease at the 17th week could be as a result of decreased sexual activity as birds advanced in age. This is in agreement with the report of Bramwell (2009), that the decrease in fertility and hatchability with increasing hen age may be due to a decline in the ability of the older hens to retain sperm in the special sperm host glands of the oviduct and the ability of the cock to successfully mate and deposit adequate quality and quantity of semen in the hen's reproductive tract. The author noted that, in all avian species, as well as in other animals, increasing age has an adverse effect on reproductive performance.Abiola*et al*. (2008) reported that younger flocks in broiler parents (aged between 29 and 41 weeks) compared with older flocks (aged between 52 and 68 weeks) achieved considerably higher intensity of laying and produced more fertilized eggs. The higher percent hatchability recorded in the medium sized eggs in relation to the large and small eggs in Japanese

quails implies that hatchability of quail eggs is a function of the egg size. This is in line with the findings of Gonzalez *et al*. (1999) in a related study who suggested the setting of eggs of average weight in other to achieve good hatchability. These assertions also corroborates the findings of Abiola*et al.* (2008) who reported the highest hatchability of 96.67% in medium eggs and the lowest of 82.88% for large eggs in broilers. The range in the percent hatchability of 61.84%-72.45% obtained for Japanese quails in this study conformed to the range of 62.63 to 71.19% reported by Musa *et al*.(2007) and Bawa*et al*. (2011), respectively.

CONCLUSION AND RECOMMENDATION

It can be concluded that in Japanese quails, the peak in fertility is 9 to13 weeks with the value of 89.92-92.90% followed by a gradual decline of 82.91% after 17 weeks of age. The best hatchability is obtained in the medium sized eggs followed by the large and small eggs. In Japanese quails, age plays a critical role in the fertility of the eggs whereas hatchability is a function of the egg size. The fertility and hatchability were neither affected by the interaction effects of age and egg size respectively.

ACKNOWLEDGEMENTS

We thank the Management of Landmark University OmuAran, Ahmadu Bello University, Zaria and College of Agriculture, Mando, Kaduna for providing sponsorship to this conference and the facilities used for this study respectively.

ABSTRACTS
This study was conducted to evaluate the biochemistry, differential count and liver function profiles of broiler chickens served dietary inclusion of probiotics (*Saccharomyces cereviasae*) and enzyme (Bio-enzyme). One hundred and twenty day-old broiler chicks of Agrited strain were used for the study. The birds were randomly allotted to four dietary treatments. Each treatment contained 30 birds replicated three times to contain 10 birds per replicate in a completely randomized design experiment. The four dietary treatments were T1 Control (no probiotics and enzyme), T2 (had both probiotics and enzyme), T3 (probiotics only) and T4 (Enzyme only). The probiotics and enzyme was included at 0.8% and 0.02%, respectively. The birds were given feed and water *ad-libitum*. The experiment lasted eight weeks. At the end of the experimental period, three birds were randomly chosen from each replicate for biochemistry, differential count and liver function profiling. The results showed that inclusion of Saccharomyces cerevisiae and bio-enzyme had significant effect ($p<0.05$) on the biochemistry, differential count and liver function profile. The dietary inclusion of probiotics and enzyme reduced total cholesterol and low density lipoprotein, gut and intestinal microoganisms and favoured the functionality of the liver of the broiler chickens. It was therefore concluded that probiotics and bioenzyme should be included in broiler diets for immunity improvement and reduction of cholesterol levels.
Key words: Broilers, probiotics, enzyme, biochemistry, differential count and liver function

INTRODUCTION
Antibiotics as a growth promoter have been widely used extensively in poultry feed for more than 50 years (Haque*et al.*, 2017), playing a crucial role in promoting chicken growth and lowering enteric diseases. However, the deleterious effect of this product on the health of the consumers cannot be overemphasized. In Europe and South Korea, growth promoting antibiotics have been banned since 2006 and 2012 respectively, and these bans are expected to affect the rest of the world (Aude*et al*., 2015). Hence, tremendous research has been geared towards finding alternatives to antibiotics that would maintain low mortality rate, good level of animal yield while preserving environment and consumer health. Several alternative strategies have been proposed with some success that mimics the function of antibiotics as growth promoters and these include the use of probiotics, prebiotics, organic acids, and exogenous enzyme, among others (Yadav and Jha, 2019).
Probiotics are living microorganisms that confer health benefits to the host when administered in adequate amounts. The most important advantage of probiotics is that they neither have any residues in animal products nor exerts any antibiotic resistance on consumption while having good impact on the poultry performance. The use of probiotics in poultry production is a recent practice which has progressed from the transplantation of feces from healthy adult hens into neonatal chicks to a more mature technology focused on developing probiotics formulation to address specific, wide-ranging issues relevant to today's modern poultry industry (Wolfenden and Hargis, 2020). In broiler nutrition, probiotic species belonging to Lactobacillus, Streptococcus, Bacillus, Bifidobacterium, Enterococcus, Aspergillus, Candida and Saccharomyces have a beneficial effect on broiler performance, modulation of intestinal flora, intestinal histological changes, immunomodulation, in addition, have an impact on specific haemato-biochemical parameters and improving microbiological meat quality of broilers Ashayerizadeh*et al*., 2009).
The role of exogenous enzymes is to fulfill the absence of endogenous enzymes, to counter the anti-nutritional factors present in conventional and unconventional poultry diet. Probiotics and exogenous enzymes can also enhance broiler productivity and likely immunity too, that may represent an alternative to the use of sub-therapeutic doses of antibiotics, meeting the growing public concerns on the contribution of this practice to the increasing antibiotic resistance (Yadav and Jha, 2019). As information on the effect of a mixture of probiotic microorganisms and enzymes on the immunity of broilers are very limited, this study intended to determine the effect of different dietary levels of a

probiotic (*Saccharomyces cereviasae*) and enzyme (bio-enzyme) inclusion to broiler chickens on their immune response, lipid profile and liver function profile.

MATERIALS AND METHODS

Study location

The experiment was conducted at the Poultry Unit, Department of Animal Science Teaching and Research Farm, University of Nigeria, Nsukka, Enugu State, Nigeria. Nsukka is in Enugu state, Nigeria

Experimental design, animals and management

The study was conducted to evaluate the biochemistry, differential count and liver function profiles of broiler birds served dietary inclusion of probiotics (*Saccharomyces cereviasae*) and enzyme (Bio-enzyme). One hundred and twenty day-old broiler chicks of Agrited strain were used for the study. The birds were randomly divided into four groups and assigned to the four dietary treatments. Each treatment contained 30 birds replicated three times to contain 10 birds per replicate in a completely randomized design. The four dietary treatments were T1 Control (no probiotics and enzyme), T2 (both probiotics and enzyme), T3 (probiotics only) and T4 (Enzyme only).The probiotics and enzyme was included at 0.8% and 0.02%, respectively. The birds were given feed and water *ad-libitum* and the quantity of feed consumed each day were determined through weigh back techniques. The birds were weighed weekly throughout the experimental period and the experiment lasted for eight weeks. Vaccination and medications were provided as when due and other routine management practices were provided accordingly. At the end of the experimental period, three birds were randomly chosen from each replicate for biochemistry, differential count and liver function profiling. Blood samples were collected into EDTA containers with the aid of sterile syringes and needles and taken to the laboratory for analysis.Proximate analysis of feeds was done according to AOAC (1990). Data collected were subjected to analysis of variance (ANOVA) using Statistical Package for Social Sciences (SPSS, 2013) version 19.00. Significant different means were separated using Duncan's new multiple range test (Duncan, 1955).

RESULTS AND DISCUSSION

The effect of probiotics (*Saccharomyces cereviasae*) and enzyme (bio-enzyme) inclusion on the lipid profile of broiler birds is presented in Table 2. The serum total cholesterol, LDL, HDL and triglyceride concentrations were significantly ($P<0.05$) reduced in broiler chickens fed treatments that were supplemented with *Saccharomyces cereviasae*and bio-enzymes when compared to the control treatment. The value of Total.Chol (3.99g/l), TG (1.61g/l) and HDL (0.79g/l) were lowest in the treatment group with only probiotics while LDL value (2.18g/l) was lowest in the treatment group with mixture of *Saccharomyces cereviasae*and bio-enzymes dietary inclusion. The value of total cholesterol and TG obtained in this work was in line with that of Haque*et al*. (2017) who reported highest serum total cholesterol, and TG level in the control group compared to all other groups supplemented with either antibiotics or probiotics. Similarly, the result concurred with the result of Shokryazdan*et al*. (2017) who observed that the supplementation of the three L. salivarius strains to broilers significantly reduced their serum LDL, but did not affect HDL levels at 21 and 42 days of age. This result is also in agreement with Saleh*et al*.(2012) who reported that the inclusion of Aspergillusawamori and Saccharomyces cerevisiae in chickens feed reduced blood saturated fatty acids and increased the polyunsaturated.

The effect of probiotics (*Saccharomyces cereviasae*) and enzyme (bio-enzyme) inclusion on the differential count of broiler birds is presented in Table 3.Neutrophil and lymphocyte were lower in treatment groups with dietary inclusion of probiotics. However, the neutrophil and lymphocyte counts were significantly ($p<0.05$) different in the control treatment groups. Monocyte and eosinophil count were significantly ($p<0.05$) different in the treatment group with a mixture of probiotics and enzyme with the value 2.33% and 3.67% for monocyte and eosinophil respectively. There were no significant differences in the basophil count across the treatment groups. This result perfectly agrees with the work of Mohamed *et al*. (2019) who reported a significant reduction in lymphocyte percentage by treatment groups with dietary inclusion of probiotics. This implies that probioticsimproves the

immune system of broiler chicken. This improvement is achieved by reducing intestinal pH, intestinal bacteria composition and digestive activity. Probiotic bacteria produce molecules with antimicrobial activities such as bacteriocins which inhibits toxins' production and pathogens' adhesion. On the other hand, probiotics stimulate the immune response and increase resistance to colonization of bacteria (Hassanein and Soliman, 2010).

The effect of probiotics (*Saccharomyces cereviasae*)and enzyme (bio-enzyme) inclusion on the liver function profile of broiler birds is presented in Table 4.AST, ALT and ALP activities were significantly ($p<0.05$) different in treatment groups with bio-enzyme compared to the control groups and the treatment group with only probiotics. The activities of Tot.Bili and D.Bili were lower in treatment groups with probiotics or enzyme. The decrease in AST, ALT and ALP value in the probiotics treated groups perfectly aligns with the work of Haque et al., 2017 who measured highest value in the control treatmentsand least value in probiotic supplemented group. These findings concur with the finding that the supplementation of probiotics lowers AST and ALT level. Mechanisms of action of probiotics include stimulation of endogenous enzymes, reduction of metabolic reactions that produce toxic substances, and production of vitamins or antimicrobial substances (Hassanein and Soliman, 2010).

CONCLUSION

Dietary inclusion of *Saccharomyces cerevisiae*significantly lowered blood cholesterol and glucose levels in broiler which are beneficial parameters to enhance broiler production. Immune response, lipid profile and liver function profile of broiler chicken were improved by the treatment with probiotics inclusion (*Saccharomyces cerevisiae*). In this regard *Saccharomyces cerevisiae*should be included in the diet of broiler chicken as alternative to the use of antibiotics growth promoters.

ABSTRACT
One hundred and twenty (120) freshly laid eggs by 36 weeks old Isa brown layers kept at the Poultry Unit, Teaching and Research Farm, Ondo State University of Science and Technology, Okitipupa were randomly collected and stored at room temperature for 21 days. At week 0, week1, week 2 and week 3 of storage, 30 eggs were broken for egg quality analysis. Data collected were subjected to statistical analysis. Duration of storage had significant effect ($p<0.05$) on all the internal and external parameters except shell index and shell thickness. The overall egg weight, egg length, egg width, shell index, shell weight, shell ratio and shell thickness were 56.82, 5.69, 4.43, 78.02, 7.45, 13.11 and 0.28 respectively, while yolk height, albumen height, yolk weight, albumen weight, albumen ratio, yolk ratio and Haugh unit were 13.55, 4.97, 16.32, 33.06, 58.11, 28.82 and 67.50 respectively. Most of the traits declined in values as the storage duration increased except yolk weight and ratio which increased as the egg aged. Duration of storage of egg had effect on the egg quality that determines acceptability by consumers.
Keywords: Eggs; Isa brown; storage duration; shell index; yolk ratio

INTRODUCTION
The egg is a complex structure distinguished by having four different parts; the egg shell, shell membrane, albumen and yolk. When eggs are for human consumption, it is important that they are suitable for this purpose (Kabir *et al.*, 2014). This is determined by both the internal and external quality (Smith, 1990). Egg quality is composed of characteristics that affect its acceptability to consumers such as cleanliness, freshness, weight, shell quality, yolk index, albumen index, Haugh unit and chemical composition (Song *et al.*, 2000). Unlike external quality, internal egg quality begins to decline as soon as the egg is laid. Variability in the quality and nutritional values of eggs have significant impact on consumers' health and welfare. Some factors affect egg quality. They include the breed and strain of layers (Kucukyilmaz *et al*., 2012), dietary composition (Goldberg *et al*., 2012), birds' health, environmental conditions and storage, processing and handling and age (Ryu *et al*., 2011 and Kabir *et al.*, 2014). The objective of this study is to determine the effect of duration of storage on the internal and external quality of eggs kept at room temperature.

MATERIALS AND METHODS
One hundred and twenty (120) freshly laid eggs were randomly collected in a batch from 36 weeks old exotic chickens (Isa Brown) kept at the Poultry Unit, Teaching and Research Farm, Ondo State University of Science and Technology, Okitipupa, 30 of the eggs were analysed for internal and external quality within 24 hours of laying. The remaining were stored at room temperature on the laboratory desk and at weekly interval 30 eggs were randomly selected till 21 days and similarly analysed.The external quality parameters included egg weight (EWt), egg length (EL), egg shell weight (ESWt), egg width (EWdt), shell index (SIdx), shell ratio (SRatio) and egg shell thickness (EST). The internal egg quality traits included albumen weight (AlbWt), albumen height (AlbHt), albumen ratio (AlbRatio), yolk weight (YlkWt), yolk height (YlkHt), yolk ratio (YlkRatio), Haugh unit (Hu).Data collected were subjected to one-way analysis of variance procedure of SAS (2003). Significant means were separated using Duncan Multiple Range Test, (Duncan, 1955). The following statistical model was employed:

$Yij = \mu + Di + eij$

Where: Yij= Individual observation, μ= Overall mean, Di= Effect of the ith duration (i= 1, 2, 3, 4) and eij= Random error.

RESULTS

Table 1 shows the summary statistics of egg quality traits. The external quality traits - egg weight, length, width and shell index, weight, ratio and thickness were 56.82 g, 5.69 mm, 4.43mm, 78.02 %, 7.45 g, 13.11 %, 0.28 mm respectively, for external traits. The internal quality - yolk height, albumen height, yolk weight, albumen weight, albumen ratio, yolk ratio and Haugh unit were 13.55 mm, 4.97 mm, 16.32 g, 33.06 g, 58.11 %, 28.82 % and 67.50 respectively.

Table 1. Summary Statistics for egg quality traits

Variables	Means	N	Minimum	Maximum	CV
Egg weight (g)	56.82 ± 0.40	109	47.3	67.96	7.37
Egg length (mm)	5.69 ± 0.03	109	5.06	6.62	6.39
Egg width (mm)	4.43 ± 0.02	109	4.06	5.28	6.12
Shell index	78.02 ± 0.50	109	64.23	92.63	6.70
Shell weight (g)	7.45 ± 0.07	109	5.60	9.14	9.39
Shell ratio	13.11 ± 0.10	109	10.91	15.52	7.58
Shell thickness (mm)	0.28 ± 0.02	109	0.01	0.49	59.40
Yolk height (mm)	13.55 ± 0.23	85	7.09	16.90	15.84
Albumen height (mm)	4.97 ± 0.15	107	2.36	10.23	30.76
Yolk weight (mm)	16.32 ± 0.19	89	12.50	22.90	10.92
Albumen weight (g)	33.06 ± 0.40	89	24.10	41.87	11.41
Albumen ratio	58.11 ± 0.37	89	46.35	65.20	6.02
Yolk ratio	28.82 ± 0.34	89	21.22	40.00	10.98
Haugh unit	67.50 ± 1.21	107	40.15	100.00	18.58

Table 2 shows the effect of duration of storage on the external traits. Significant difference ($P<0.05$) was observed in all the traits considered except shell index. In egg weight, no significant difference was observed from week 0 to 2. Egg weight reduced with age. Egg lengths across weeks were 5.72, 5.87, 5.63 and 5.49 mm. No significant difference was observed from week 0 to 2. Similar trends were observed in egg width and shell ratio. The values for shell weight were 7.72, 7.38, 7.19 and 7.43 for the weeks respectively. Table 3 shows the effect of storage duration on the internal quality traits. Significant difference ($P<0.05$) was observed in all the traits considered. For yolk height, significant difference was observed from week 0 to 3. Hence, yolk height reduced as the egg age. The values for albumen height were 6.80, 4.32, 4.30 and 3.86. Similar trend was observed for albumen ratio and Haugh unit. Albumen ratio reduced as the egg age, but yolk ratio increased with age.

Table 2: Effect of storage duration on external quality of egg

Variable	0-week	1-week	2-week	3-week	SEM
Egg weight (g)	58.48^{a}	57.38^{a}	56.29^{a}	53.94^{b}	0.40
Egg length (mm)	5.72^{ab}	5.87^{a}	5.63^{bc}	5.49^{c}	0.03
Egg width (mm)	4.48^{ab}	4.54^{a}	4.36^{bc}	4.27^{c}	0.03
Shell index	78.52^{a}	77.61^{a}	78.06^{a}	77.84^{a}	0.50
Shell weight (g)	7.72^{a}	7.38^{ab}	7.19^{b}	7.43^{ab}	0.07
Shell ratio	13.22^{b}	12.87^{b}	12.78^{b}	13.44^{a}	0.10
Shell thickness (mm)	0.24^{a}	0.30^{a}	0.26^{a}	0.33^{a}	0.02

Means with different superscript in a row are significantly different ($p<0.05$)

Table 3: Effect of storage duration on internal quality of egg

Variable	0-week	1-week	2-week	3-week	SEM
Yolk height	15.22[a]	14.37[b]	11.52[c]	10.33[d]	0.23
Albumen height	6.80[a]	4.32[b]	4.30[b]	3.86[b]	0.15
Yolk weight	15.54[b]	16.56[ab]	16.53[ab]	17.09[a]	0.19
Albumen weight	35.09[a]	33.36[ab]	32.61[b]	28.96[c]	0.40
Albumen ratio	60.10[a]	58.15[b]	57.89[b]	54.29[b]	0.37
Yolk ratio	26.71[c]	28.94[b]	29.38[b]	32.04[a]	0.34
Haugh unit	81.48[a]	61.68[b]	63.39[b]	58.98[b]	1.21

Means with different superscript in a row are significantly different ($p<0.05$)

DISCUSSION

The significant effect of duration of storage observed on virtually all egg quality traits observed in this study is in agreement with the works of earlier researchers (Akyurek and Okur, 2009; Silversides and Scott, 2001; Sekeroglu *et al.*, 2008; Sung and Kyung, 2014). The decrease in egg weight observed in this study as egg aged could be attributed to evaporation of water through the shell pores. This is in line with the observation of Sung and Kyung (2014). This could also be responsible for decrease in Haugh unit, albumin weight, yolk height, albumen height with age. However, yolk weight increased as the duration of egg storage increased,Khan *et al*. (2013) postulated the movement of water from albumen to the yolk as the possible explanation of the increased yolk weight with storage duration. This also accounted for decrease in albumen weight.During aging there is carbodioxide and oxygen exchange and water evaporates through the shell increasing the air chamber and reducing albumen height. The Haugh unit of 61.6 at the seventh day of storage is lower to 66.2 reported by Sung and Kyung, 2014 at room temperature. The discrepancies could be attributed to differences in age and breed of the layers used. The non-significant effect of storage duration on shell thickness and shell index is similar to the observation of Sung and Kyung, 2014 while the significant effect observed in shell weight is contrary to the report of the researchers. It could be concluded that storage reduces the acceptability of egg by consumers as quality is grossly affected.

WEIGHT GAINS OF FRIESIAN X BUNAJI CALVES AS AFFECTED BY FEED GRADE SELENIUM AND VITAMIN E SUPPLEMENTATION

***[1]Achi, N.P., [1]Barje, P.P. & [2]Achi, J.N**

[1]National Animal Production Research Institute/Ahmadu Bello University, Shika-Zaria

[2]Department of Animal Science, Ahmadu Bello University, Shika-Zaria

ABSTRACT

The experiment was carried out to determine the effect of supplementing feed grade selenium and vitamin -E on weight gains of Friesian x Bunaji calves. Twenty pregnant Bunaji cows inseminated with Friesian semen were used for the study. The animals were grouped into four treatments with each treatment consisting of five animals in a completely randomized design. Treatment I served as the control, treatment II Se (3mg), treatment III vitamin E (20mg) and treatment IV Se + Vitamin E (3mg + 20mg). At calving, the calves were weighed using a weighing scale and subsequently monthly until they were weaned. There were no significant differences ($p<0.05$) for the weights at calving, 1st and 2nd month after calving in all the treatments. Weight at weaning showed significant differences ($p<0.05$) in all the treatments with the control having the lowest (55.0 kg) while the Se + vitamin E treatment had the highest (65.8 kg) weight. It was concluded that selenium and vitamin E supplementation had no effect on calving weight, weight at 1st and 2nd month except at weaning with the combination of Se + vitamin E performing best.

INTRODUCTION

The last months of gestation for cows represents the critical period for the selenium availability. The transfer of selenium to the fetus and subsequently to the calf occurs even when cows are deficient in selenium. Cows release selenium available to them to ensure adequate intake for newborns (Hefnawy and Tortora-Perez, 2010). This situation is explained by the fact that the renal selenium levels in the fetus remain unchanged whereas that of cows, at the end of pregnancy, decline (House and Bell, 1994). The mineral selenium is not well transferred into the milk (Pehrson *et al*., 1999), and thus is not efficient in maintaining adequate selenium status in calves. Compared to mineral selenium, use of organic selenium in foods was shown to cause better selenium transfer rates in calves (Ceballos *et al*., 2009). Nearly 70% of the selenium in the membrane is found to bind to the anion exchanger 1 (AE1) protein, which suggests that the integral protein AE1 is responsible for the membrane transport of selenium.

An increase of the immunoglobulin concentration in calves has been demonstrated to be caused by a selenium supplementation of cows before calving (Rowntree *et al*., 2004; Guyot *et al*., 2007). Indeed, strengthening of their immature immune system helps them to resist inadequate environmental conditions. At temperatures below 14.6^0C, newborn calves present sensitivity to cold (Schrama *et al*., 1993). To cope with this stress, the thermogenic response is generated by the metabolism of brown adipose tissue. The metabolism of the adipose tissue is regulated by T_3 hormone which is a seleno-dependent hormone (Rowntree *et al*., 2004). In cases of severe selenium deficiency in calves, it is advisable to administer aselenium injection incombination with a dietary selenium source as such practice helps to rapidly restore an adequate selenium status for a few months (Eversole *et al*., 1988). Selenium does not play a direct role in promoting growth in calves. However, it helps to remove all constraints that may delay or inhibit growth such as oxidative damage, stress, reactive forms of oxygen etc.

MATERIALS AND METHODS

Study Location

The study was conducted at the Dairy Research Programme farm of the National Animal Production Research Institute (NAPRI), Ahmadu Bello University, Shika-Zaria, Nigeria. Shika is located in the Northern Guinea Savanna and lies on latitudes 110 06' 40" N and longitudes 70 43' 21"E at an elevation of 644m above sea level, with an annual maximum and minimum temperature of 31.0 ± 3.2 0C and 18.0 ± 3.7 0C, respectively. Shika has an average annual rainfall of 1100 mm, usually lasting

from May to October with a mean relative humidity of 72 %. The dry season lasts from November to April with the mean daily temperature, ranging from 15 – 36 ^{0}C and mean relative humidity ranging from 20 – 37 % (IAR, 2017).

Experimental Design and Management of Animals

A total of twenty pregnant Bunaji cows with an average weight of 300 kg in the third trimester of pregnancy were used for the study. The study consisted of four treatments with five animals per treatment in a Completely Randomized Design (CRD). Treatment I was the Control without Selenium or Vitamin E supplementation. Treatment II was supplemented with 3 mg/kg feed of feed grade Selenium, treatment III with 20 mg/kg feed of feed grade Vitamin E. Treatment IV received a combination of 3 mg feed grade Selenium and 20 mg of Vitamin E. the treatments were given once a week until calving.

The animals were grazed on free range pastures and supplemented with concentrate diet consisting of 48 % Cotton Seed Cake, 13.7 % wheat bran, 35.3 % maize, 2 % bone meal, 1 % common salt, 88 % dry matter, 15 % crude protein and 55 % total digestible nutrients after grazing. Water was provided *ad-libitum*. All the experimental animals were ear-tagged for ease of identification. The animals were dipped twice a week for effective control of ectoparasites.

Calves were weighed at calving, first and second month after calving then at weaning using a weighing scale. The animals were weighed using an Avery large weighing scale prior to calving and postpartum. Data generated was analyzed using the general linear model of SAS (2002).

RESULTS AND DISCUSSION

Calving weight, weight after first and second month were similar ($p>0.05$). Weight at weaning was significantly different ($p<0.05$) for Friesian x Bunaji calves with Se, vitamin E and Se + vitamin E supplementation as shown on Table 1.

In ruminants, the transfer of selenium from cow to the newborn is via the placenta and milk but transfer via the placenta is more efficient than that made through the milk (Enjalbert *et al*., 1999). The higher weight at weaning for supplemented calves could be attributed to the antioxidative potency of mineral and vitamin supplementation which invariably improved immune system of calves, thereby resulting in growth and development, this is agreement with Salles *et al*. (2014). The improved immune system of the calves helps them to resist extreme environmental conditions of cold and heat especially in the tropical region.

Although Se does not play a direct role in promoting growth in calves, however, it helps to remove all constraints that may delay or inhibit growth. A selenium-deficient diet causes a reduction of triiodothyronine (T_3) and an increase of the tetraiodothyronine (T_4) and a decrease in the ratio T_3/T_4 levels in blood (Thompson *et al*., 1995). The reduction in T_3 and an increase in T_4 can influence growth rates since T_3 is an active form of T_4 which is known to be involved in the growth mechanisms (Thompson *et al*., 1995).

CONCLUSION

It was concluded that calving weight, weight at 1st and 2nd month were not affected by selenium and vitamin E supplementation except at weaning weight with Se + vitamin E performing better.

PREDICTION OF BODY WEIGHT OF TWO STRAINS OF LAYERPULLETS USING MORPHOMETRIC TRAITS

M.N. Sabo, J. Sani & R. A. Hamzat
Department of Animal Science, Federal University Dutsin-Ma, Katsina State

ABSTRACT
A total of 200-day old layer chicks comprising of 100 chicks each of Nera Black and Lohmann Brown Classic were used to determine prediction models for body weight from morphometric parameters. Data were collected on body weight and morphometric trait; breast girth, body length, wing length, shank length and thigh length. All the morphometric traits measured in chick were significantly ($P<0.05$) correlated with body weight. The breast girth has better correlation with body weight than other morphometric trait in Nera Black (0.763) and for the two strains combined (0.788). However, body length had the highest correlation with body weight in Lohmann Brown Classic chicks. Breast girth showed the highest coefficient of determination (R^2 value) of 0582 in Nera Black while body length had the highest R value of 0.715 and 0.610 for Lohmann Brown Classic and the two strains combined respectively. This study showed that morphometric trait like body length and breast girth can be used in estimation of body weight.
Keywords: Trait, prediction, correlation, regression, body weight

INTRODUCTION
Morphometric traits also called linear body measurements or conformation traits are important parameters in predicting body weight and this has been observed by commercial breeders and producers. Breeders, therefore, breed desirable sizes of chickens which also have the desirable production traits particularly body weight (Ojedapo *et al.*, 2010). Apart from body weight, a number of conformation traits are also known to be good indicators of good growth (Ibe, 1989). Such conformation traits include shank length, breast width, knee length, wing span, chicken height, body length, and head circumference (Ojo *et al.*, 2010). Linear body measurements have been used to predict live weights in poultry (Okon *et al.*, 1997), Prediction of body weight with morphometric traits in layers is therefore important.The easiest way to assess an animal's body mass is to weigh the animal. However, under some situations scale may not be available and prediction of body weight from body measurements could be preferred practically (Latshaw and Bishop, 2001). The objective of this study therefore to determine the morphometric parameters of egg strain chicks, their correlation between with body weight and develop a prediction equation for body weight from those parameters of egg strain chicks

MATERIAL AND METHODS
The experiment was conducted in the Department of Animal Science Teaching and Research Farm, Federal University Dutsin-ma. It lies within latitude 11° 7' and 13° 22' N and longitude 6° 52' and 9° 2' E (Abaje *et al.*, 2014).
A total of 200 day-old- layer chicks purchased from a reputable hatchery in Nigeria were used in the experiment.Routine management practices were carried out on the layer chicks. The chicks were fed *ad-libitum*. The data of prediction of body weight in egg layer strain chicks using morphometric traits were collected.Birds in each replicate were weighed at the beginning of the experiment and subsequently on weekly basis. Feed intakes were recorded weekly and were determined by the weigh-back technique. Feed conversion ratio was determined. The Linear Body Measurements were taken at week 10. The body parameters were taken in centimetres with the use of tape. Morphometric parameters measured include:thigh weight, shank length, breast girth, wing length and body length. SPSS (2008) Package was used to obtain estimate of correlation and regression between body weight and each of the morphometric trait. The significance of the correlation regression coefficient was determined at P-value of less than 0.05

RESULT AND DISCUSSION

Table 1 shows the comparison of means of body weight and linear body measurements of Nera Black and Lohmann Brown Classic layer strain chicks. Body weight, breast girth, wing length and thigh length were not significantly different between the strains. However, body length was significantly different with Nera Black having longer body length (23.55cm) than Lohmann Brown Classic (22.71cm).

Table 1: Comparison of means of body weight (g) and morphometric traits (cm) of Nera Black and Lohmann brown classic layer strain chicks at 10 week of age.

Trait	Near black	Lohmann brown classic	SEM
Body weight	552.24	531.68	13.55
Body length	23.55[a]	22.71[b]	0.22
Breast girth	19.87	19.73	0.27
Wing length	15.56	15.33	0.13
Shank length	6.88	6.57	0.11
Thigh length	7.25	6.99`	0.11

[a, b] Values with different superscripts differ significantly, SEM= Standard error of mean

Table 2 shows the correlation of the body weight and Morphometric traits of combined layer strain at week 10. Body weight is highly correlated to all the morphometric traits with Breast girth having the highest correlation (0.788).

Table 2: Combined correlation of body weight and morphometric traits of Nera Black and Lohmann Brown classic layer strains chicks at 10 week of age

	BW	BL	BG	WL	SL	TL
BW	1.000					
BL	0.781	1.000				
BG	0.788	0.545	1.000			
WL	0.732	0.795	0.582	1.000		
SL	0.592	0.797	0.298	0.729	1.000

BWT-body weight; BG-Breast girth; BL-Body length; WL-Wing length; SL-Shank length; TL-Thigh Length; SEM= Standard error of mean

Table 3 shows prediction equations relating the body weight and morphometric traits in combined layer strain at week 10. The R^2 values of range from 0.351 to 0.610 with Body length have the highest R^2 value of 0.610. This implies that body length could be the best predictor of body weight of layer strains.

Table 3: Combined regression of body weight of morphometric traits of Nera Black and Lohmann brown classic layer strains chicks at 10 week of age

DISCUSSION

The high correlation between body weight and morphometric measurements in this study agrees with the earlier report of Yahaya *et al.* (2012) who obtained high correlation coefficients between body weight and morphometric traits in Hubbard and Arbor Acre broiler strains. The estimates contained in their reports were generally higher than the values obtained in the present study. The observed close relationship between body weight and breast girth in both Nera black and Lohmam brown classic agrees with the earlier findings of Adebambo *et al*. (2006) who reported that breast girth is a good indicator of predicting body weight in most poultry species.

The regression result shows that breast girth and body length could be the best predictors of the body weight of layer strain chicks. This result agreed with Udeh and Ogbu (2011) who reported that Arbor Acre strain with R^2 of 96% in breast girth and 92% in body length were the best predictors of the body weight of broiler strains. All other linear body parameters in all studied reported R^2 values above 50% which implies any of linear body parameter could also be used to predict body weight of the layer strain chicks. The result of regression coefficients of the two strains combined agrees with the observation Ubani *et al* (2011) who reported that breast girth and body length recorded the highest R^2 value among Nu-breed, Arbor, Acre and Marshall Strains between 3-5 weeks of age. The body length and breast girth are best for predicting body weight in layer chicks (Nera Black and Lohmann Brown Classic).

The result obtained from this research shows that prediction of body weight is possible from various linear body parameters. Generally breast girth and body length were found to be the best and most reliable parameter in estimates body weight. In terms of hierarchy, breast girth was significantly highest followed by body length in Nera Black and Lohmann Brown Classic at week 10. Application of linear model to all parameters at week 10 was found to be highly significant (P<0.05). All linear body parameter whose R^2 values were above 50% could be used to predict body weight of the layer strain, although the accuracy of prediction increased with an increase in the R^2 value.

CONCLUSION AND RECOMMENDATION

The present study showed that there exists strong correlation between body weight and most of the morphometric indices like body length, breast girth, wing length, shank length and thigh length of Nera Black and Lohmann brown Classic. Prediction of body weight is possible from various linear body parameters. Generally breast girth and body length were found to be the best and most reliable parameter in estimates body weight. It is therefore recommended that body length and breast girth be used in predicting body weight.

ABSTRACT
The study investigated the effects of breed, season, sex and age on body weight, packed cell volume, Haemoglobin concentration and Faecal egg count of some indigenous breeds of sheep in Gombe State between March and October, 2017. Stratified random sampling was applied to collect the 300 samples comprising of 130 Yankasa, and 73 Balami 97 Uda sheep. Faecal egg count was measured using the modified McMaster technique for faecal samples found positive forgastro intestinal parasite eggs. Packed cell volume (PCV) was determined by micro-haematocrit technique. Faecal egg count (FEC) significantly (P<0.001) differed among the breeds with highest value of 1271.65epg recorded in Uda. Balami and Uda had higher values of body weight than Yankasa. There were no breed effects on PCV and HBC recorded in this study. Seasonal effects on BWT, PCV, HbC and FEC was observed with the wet season recording higher values of 32.32kg,36.04%, 11.99g/dl and 1140.95epg.This could be attributed to the fact that wet season is the period of lush pasture which has positive influence on BWT, PCV, and HbC. Furthermore, the wet season is a suitable period for the development of the infective stages of the Gastro intestinal parasites and hence higher burden. Age of sheep affected the values of BWT, PCV, HbC and FEC significantly. The values of 45.02kg,32.43%,10.82g/dl and 725.34epg forBWT, PCV, HbC and FEC respectively were significantly higher in adult than the younger sheep. This could be attributed to the fact that these parameters normally increase with age and physiological changes.
Key note: Season, Sex, breed, Packed cell volume, Haemogolobin Concentration, Faecal egg count.

INTRODUCTION
Nigerian sheep population is estimated at 44.3 million and over 70% is found in the Savanna regions where three of the four breeds of sheep (Balami, Yankasa and Ouda) predominate. Sheep thrive in a wide variety of environments in the tropics and sub tropics and requires less capital as they can be completely maintained on pastures, browse and agricultural waste products (FAO, 2007).Gastro-intestinal infections among other variables are significant constraints to livestock production (Badran*et al*. 2012). The major factor that influences gastrointestinal parasites infection in small ruminants, especially sheep is exposure to faecal contamination of grazing land (Pathak, 2011).Greer (2008) stated that the degree of disease infection varies with the host immune response. Males are generally more susceptible than females due to the production of androgen hormone which lowers immune response (Asif*et al*., 2008). Heavy animals also show more resistance due to sufficient body fat reserves that aids immune responses (Bilbo and Nelson, 2001). During rainfall the number of infective larval stages increase and animal are also more susceptible to infection (Kantzoura*et al.*, 2012). Blood properties are indices of the physiological and pathological changes in animals (Cambell, 2007). Haemotological tests have been widely used for the diagnosis of disease and nutritional status of animals. Information gained from blood parameters substantiates physical examination and together with medical history provide the basis for judgment and decision making (Schalm *et al*., 1975). Several researches were conducted on the effects of breed, season, sex and age on PCV, HbC and FEC on sheep in Nigeria particularly the northern part however; there was scant information on that in Gombe state. This study was carried out to bridge the gap in information, provide useful information for further research and to make recommendations.

MATERIALS AND METHODS
Area of the Study
The research covered the three senatorial zones of Gombe State comprising North, Central and South. Gombe State. It is situated in North East region of Nigeria and occupies a total land area of about 20,265 Km^2. The state is located between latitude 9^0 30' and $12^0$30'N and longitude $8^0$45' and $11^0$45'E of the Greenwich Meridian (Abubakar, 1974).

Experimental Animals

Three indigenous breeds of sheep namely Yankasa, Balami and Uda commonly reared by peri urban and urban households in Gombe state were used for this study.

Study Design.

Faecal and blood samples were collected randomly from 300 sheep for laboratory analysis. Stratified random sampling was applied to collect the 300 samples comprising of 130 Yankasa, 73 Balami and 97 Uda sheep. The total sample size was calculated according to Thrusfield (2005) using 95% confidence and expected prevalence of 89.1% from previous study of James (2014) and desired precision of 5% as follows:

$n = 1.96^2 P_{exp} (1- P_{exp}) / d^2$

Where n = sample size

P_{exp}= expected prevalence (89.1% of James, 2014)

d = desired absolute precision of 5% (0.05).

$n = 1.96^2 \times 0.891 (1-0.891)/ (0.05)^2$

$n = 3.8416 \times 0.891(0.109)/ 0.0025$

$n = 0.3731/ 0.0025$

n = 150 samples approximately

The value of 150 was multiplied by 2 to avoid sampling error in accordance with (Jatau*et al*., 2011).

Faecal sample collection and analysis

Fresh faecal sample (5g) was collected using hand gloves, directly from the rectum of the sheep into clean universal containers, labeled and stored. The samples were subsequently processed for gastro-intestinal parasite presence and identification.Samples found positive were counted using the modified Mcmaster technique according to Soulsby (1986).

Blood sample collection and analysis

Blood samples (5 ml per animal) were obtained from the jugular vein using a10 ml syringeattached to 21gauge x ½ inch needle. Air was first cleared from the syringe before puncturing at 20^0 angle (Pratt, 1985) and the syringe was aspirated to confirm insertion and collection of blood. The blood sample collected was then placed in labeled tubes coated with ethylene-diamine tetra-acetic acid (EDTA) as anticoagulant. Packed cell volume (PCV) was determined at Gombe State Specialist Hospital laboratoryusing the micro-haematocrit technique (Pratt, 1985) and classified into low, normal and high.Haemoglobin concentration wasdeterminedby dividing PCV values by 3 according to (Addass, 2010) and also classified as low, normaland high whilehaemoglobin type was identified through electrophoresis (Wintrobe, 1967).

Data Analysis

Data collected were analyzed using descriptive statistics and were further subjected to analysis of variance (ANOVA) using the general linear model (GLM) procedure of SPSS, version 22 (Allen *et al.,* 2013) as in the following model. Significantly different means were separated using the Duncan multiple range test (DMRT).

$Y_{ijk} = \mu + B_i + E_j + e_{ijk}$

Where;

Y_{ijk}= Observations on dependent variables

μ = common mean

B_i = effect of ith breed

E_j= effects of all other factors, but taken individually; number and types (of factor) varied with the dependent variable.

e_{ijk}= random error term.

The relationships among PCV, HbC, Bwt and FEC were determined using the Pearson's product moment correlation coefficient.

Table 1: Effects of Breed, Season, Sex and Age on BWT, PCV, HbC and FEC

Factor	Parameter BWT		PCV		HbC		FEC

High	1126.67	1080.00	955.74[a]

LS = Level of significance, PCV = Packed cell volume (percent), HbC = Haemoglobin concentration (gramme per decilitre), Bwt= Body weight (Kilogramme), NS = Non-significant. Values in a column with different superscripts are significantly different.

RESULTS AND DISCUSSIONS

The means and standard deviations of BWT, PCV, HbC and FEC by breed, season, sex and age are presented in Table 1. The overall values of BWT, PCV, HbC and FEC were 35.67Kg, 34.25%, 11.42g/dl and 1083.45 epg.Faecal egg count (FEC) significantly (P<0.001) differed among the breeds with highest value of 1271.65epg recorded in Uda. This finding is similar to observations reported byFantu*et al*. (2012) and Hassan *et al*. (2013) but disagrees with Mbap and Chiroma (1998) who found that Yankasa breed had higher FEC values than the others. The body weights recorded in this study were similar for Balami and Uda but differed significantly from value obtained for Yankasa.Balami and Uda had higher values than Yankasa, this report corroborates with earlier findings of Mason (1997).There were no breed effects on PCV and HbC recorded in this study, similar observations was reported by Kasali*et al*. (1988). The lower FEC in Yankasa in this study could probably be due to breed difference. Significant (P<0.001) seasonal effects on BWT, PCV, HbC and FEC was observed with the wet recording higher values, and this concur with earlier reports of Kasali*et al*. (1988) and Fantu*et al*. (2012). The wet season is the period of lush pasture which has positive influence on BWT, PCV, and HbC (Pathak and Pal, 2008). Furthermore, the wet season is a suitable period for the development of the infective stages of the Gastro intestinal parasites and hence higher burden. Sex had no influence on the parameters assessed in this study, this contradicts earlier reports by (Dangnachew*et al*., 2011; Hassan *et al.*, 2013), the authors reported significant sex variation on faecal egg count. Male sheep are generally more susceptible than females due to the production of androgen which lowers immune response. Oestrogen in females increases resistance to worm burden. However, female sheep become prone to parasitism due to hormonal changes during pregnancy; especially in the later stages (Asif*et al*., 2008). Age of sheep affected the values of BWT, PCV, HbC and FEC significantly; this is in agreement with earlier report of James (2014). Body weight, packed cell volume, haemoglobinand faecal egg count are usually higher in adult than the young because these parameters normally increase with age due to physiological changes (Fantu*et al*., 2012). This is however, contrary to reports of Winkler (1982), Mbap and Chiroma (1998). The authors reported higher FEC in the younger sheep and attributed it to low innate immunity and so-called self-cure phenomenon and/or high acquired immunity which increasewith age. Table 2 shows the influence of PCV, HbC and Bwt on worm burden. There was significant influence of Bwt (P<0.01) on FEC. The value of 578.93 epg, for the medium weight category was lower than 1023.30 and 955.74 epg for the lower and higher respectively. The PCV and HbC however had no significant influence on FEC.The PCV, HbC and Bwt are all indicators of body condition and thus are related to the physical, physiological and health status of animals.

CONCLUSIONS AND RECOMMENDATIONS

In conclusion, the study revealed that three indigenous breeds of sheep studied harbors gastrointestinal parasite however, the level of infection is more in Uda. Balami and Uda had higher body weights and worm burden. However, breed had non-significant effect on PCV and HbC. Body weight differed among breeds with Balami and Uda recording higher values than Yankasa. Furthermore, Balami and Uda had higher FEC than Yankasa. Season had significant influence on Bwt, PCV, HbC and FEC with the wet season recording higher values. Sex had no influence on the parameters assessed but, there were significant age differences in BWT, FEC, PCV and HbC .Proactive measures are required to sensitize farmers on the need to ensure routine deworming exercise and adherence to good husbandry practices all year round. Further study should be conducted using molecular marker to determine the genetic distance between the sheep breeds in terms of resistance to gastrointestinal parasite infection.

ABSTRACT
The aim of this study was to validate and hence evaluate the effects of different concentrations of hydrogen peroxide on the healing of excision wounds in rats. Following wound creation, the animals in their respective groups were treated as follows; group A-0.9% normal saline (control), group B-1% hydrogen peroxide, group C-3% hydrogen peroxide and group D-5% hydrogen peroxide. Post-wounding, rate of wound contraction and re-epithelialisation time were used to assess the wound healing rate. Group C animals achieved 100% wound contraction on day 21 while 68.75%, 79.33% and 79.00% were obtained on the same day in groups A, B and D respectively. The result of this study has validated 3% hydrogen peroxide as the optimum concentration necessary for wound dressing since it provided the environment necessary for faster rate of wound contraction and healing with no visible side effect in this study.
Keywords: excision wounds, hydrogen peroxide, rat, re-epithelialisation, contraction

INTRODUCTION
A wound is a disruption in the normal continuity of tissues and metabolic function of body structures (Alam*et al*., 2011). Wound healing is the restoration of the disrupted anatomical stability and functional status of damaged tissues (Room and Ukrainsky, 2005). The process of wound healing according to Drouso*et al*. (2003) begins with wound cleansing. This has been made possible clinically by employing various methods and agents that promote healing (Drouso*et al*., 2003). The agents popularly used in wound cleansing since the nineteenth century is antiseptics. Commonly used antiseptics include povidone iodine, chlorhexidine, methylated spirit, chlorine compounds, silver compounds, hydrogen peroxide and a host of others (Zhu *et al*., 2017).
Hydrogen peroxide according to Bruno and Raynard (1994) is the most widely used among all the commercially prepared antiseptics. Zhu *et al*. (2017) proposed that hydrogen peroxide is a typical antiseptic which kills pathogens through oxidative burst and local oxygen production. In recent times, there have been arrears of controversy on the use of hydrogen peroxide as an antiseptic (Drosou*et al*., 2003). Kwakman*et al*. (2011) reported that since hydrogen peroxide is dangerous to new cells, it should not be recommended to clean every wound. Kwakman*et al*. (2011) stated that hydrogen peroxide damages cells that are needed for the wound to heal and hinder them from getting to the areas where the healing needs to take place. Hydrogen peroxide at various concentrations has been claimed by some authors to have both antibacterial and good wound healing effect. A cream containing 1% hydrogen peroxide has been reported by (Neithammer*et al*., 2009) to be effective and safe topical treatment of human *Impetigo contagiosa*caused by*staphyloccusaureus.* Thereport also said that 1% hydrogen peroxide cream showed excellent antibacterial effect and eliminated most of the bacteria from the skin. No side effect such as skin irritation or allergic reaction in human patients was noted with use of 1% hydrogen peroxide cream. A cream containing hydrogen peroxide at 1.5-3% concentration has been reported to increase circulation in ischemic ulcer and surrounding skin in a guinea pig model (Tandara and Mustoe, 2004).
Animal and human studies have also shown hydrogen peroxide to have a negative effect on wound healing at 3% concentration. Hydrogen peroxide was reported not to retard re-epithlialization in a rat model after irrigation but showed minimal bactericidal effect in-vitro (Tidhar*et al*.,2017). Kwakman*et al*. (2011) also found acceleration of re-epthlializationin wounds of rat treated with 3% hydrogen peroxide. In view of the above reports, and with the use of hydrogen peroxide as the most popular antiseptics in wound management, surprisingly few experimental studies have been conducted to examine its efficacy on wound healing process and as a wound antiseptic.
Additionally, we have observed that use of commercially available hydrogen peroxide (6 % concentration) on open wounds without dilution causing severe charring. In view of the above reports, the benefits and demerits of low and high concentrations of hydrogen peroxide on wound healing

needs to be fully investigated. The basic objective of this study was to ascertain the appropriate concentration of hydrogen peroxide which when used on open wounds will facilitate wound proliferation thereby enhance wound healing.

ANIMALS

Adult wistar rats (n=32) weighing between 170-184 g were used for this study. They were fed on commercial growers mash (Vital feeds®) and water was provided *ad libitum*. These rats were acclimatized for 2 weeks in the animal house at the Department of Veterinary Surgery, University of Nigeria, Nsukka.

WOUND HEALING STUDIES

Thirty two rats were anaesthetized by injecting intramuscularly 10 and 50 mg/kg bw of xylazine hydrochloride (Xylazine 20®, Kepro Holland) and ketamine Hydrochloride (Mark pharmaceuticals® Nigeria) respectively. Under general anaesthesia, dorsum of the rats were shaved and with mild antiseptic solution (0.5% chlorhexidine). Full thickness circular excision wound of 2cm in diameter was made on the scrubbed area of each rat and carefully dissected out. The animals were left untreated for 24 hours to allow for bacterial contamination of the wounds. Post wounding, the rats were randomly assigned into 3 groups of 8 animals per group and treated as follows: group A was treated with normal saline while groups B, C and D were treated with 1%, 3% and 5% hydrogen peroxide respectively. The animals were housed individually in clean and dust-free cages in the Department of Veterinary Surgery, University of Nigeria, Nsukka to avoid wound biting and/or licking and treated daily with their respective extract concentrations or drug until complete healing occurred.

ASSESSMENT OF WOUND HEALING

Wound healing was assessed using the percentage wound contraction rate as described by Chah*et al.* (2006) while wound re-epithelialisation was studied as described by Okoli*et al.* (2009).

RESULTS

Rate of wound contraction

Assessment of the effect of the different concentrations of H_2O_2 on the rate of wound contraction showed that increase in the percentage wound contraction was first noticed on day 4 post surgery in groups B and C rats. Day 7 post surgery, group C animals significantly ($P<0.05$) had a higher rate of wound contraction (21.50 %) than those in groups A (8.40%), B (9.33%) and D (5.00%).By day 21, 100% wound contraction was recorded in group C animals while 68.75%, 79.33%, 79.00% and were obtained in groups A, B and D animals respectively. The rate of wound contraction of group C animals remained significantly higher ($P<0.05$) when compared with those of groups A, B and D (Table 1).

Table 1: Percentage rate of wound contraction in rats post wounding.

	Groups			
Days	A(N/saline)	B (1% H_2O_2)	C (3% H_2O_2)	D (5% H_2O_2)
1	-6.86±1.32^{ab}	-5.25±1.93^{ab}	-4.13±0.79^{a}	-7.63±1.35^{b}
4	-3.00±0.79^{b}	1.75±3.22^{ab}	5.13±1.14^{a}	-2.13±0.64^{b}
7	8.40±1.81^{b}	9.33±4.85^{b}	21.50±4.19^{a}	5.00±1.21^{b}
14	48.00±6.55^{b}	57.67±0.67^{b}	71.50±3.23^{a}	55.75±2.25^{b}
21	68.75±4.59^{c}	79.33±2.6^{b}	100.00±0.00^{a}	79.00±2.35^{a}

Different superscripts$^{a, b,c}$ in a row indicate significant difference between mean at P<0.05

Wound Epithelialization

In this study, group C animals treated with 3% concentration of H_2O_2 had higher rate of wound epithelialization followed by groups A, D and B animals. Wound epithelialization occurred on days 45, 28, 19 and 32 in groups A, B. C and D animals respectively.

Table 2: Wound epithelialization time of rats post wounding.

Groups	**A (n/saline)**	**B (1%)**	**C (3%)**	**D (5%)**
Days of wound epithelialization	44.75±3.20^{b}	28.60±0.29^{ab}	19.00±0.71^{a}	32.00±2.04^{b}

Different superscripts in a ^{a,b} row indicate significant difference between mean at P<0.05.

DISCUSSION

The effects of different concentrations of hydrogen peroxide on healing of excision wound were evaluated in this study. Grossly, the effect on contraction and rate of wound epithelialization were studied. Wound contraction and epithelialization play a significant role in healing of excision wounds. According to Eichler*et al*. (2006) contraction of wound begins approximately a week after wounding when fibroblasts have differentiated into myofibroblasts. Wound contraction as documented by Sussman*et al*. (2005) peaks at 5-15 days post wounding. In this study a progressive decrease in wound size was observed on day 7 in all the groups and this finding was in agreement with the works of other researchers as documented above.

The fastest rate of wound contraction observed in 3% H_2O_2 treated group could be attributed to its content of antimicrobial properties. It kills microbes by interrupting cellular respiration of the microbes and as well prevents wound contamination by microorganisms with minimal tissue damage around the wound (Edward and Harding, 2004).

In conclusion, the result of this study validates 3% H_2O_2 as the optimum concentration of hydrogen peroxide necessary for wound dressing as it provides faster rate of wound healing with no visible side

effects while 5% concentration should not be used in wound dressing due to its damaging effects on the tissue and blood vessels thus delaying wound healing. Also, 1% hydrogen peroxide and normal saline should not be used as wound dressing agents for excision wounds probably due to their poor antimicrobial property.

EFFECT OF VITAMIN E FORTIFIED DIET ON SEMEN QUALITY AND BODY WEIGHT OF GUINEA COCKS

ELILE, C.F* UGWU, S.O.C & OGBONNA, O.C****
**Department of Training and Internship, Nigerian Institute of Animal Science (NIAS), Abuja, Nigeria*
*** Department of Animal Science, University of Nigeria Nsukka (UNN), Enugu State, Nigeria*
Correspondent: E-mail: franciselile4god@yahoo.com, 08033984059.

ABSTRACT
In spite of numerous advantages of guinea fowl over chicken, rearing of guinea fowl is believed to be uneconomical due to high information of PUFA that instigates poor semen quality. However, the study was designed to evaluate effect of vitamin E at different levels on semen quality and body weight of guinea cocks. Twenty-four guinea cocks were equally and randomly distributed into T1, T2, T3 and T4 of 0mg, 125mg, 250mg and 350mg vitamin E per kg diet respectively in a completely randomized design. Initial and final body weights were determined and semen samples were collected twice a week. Best values of semen volume, sperm concentration, sperm progressive motility, percentage live and dead sperm cells were obtained from cocks in T2. Reduction ($P<0.05$) in values of semen volume, sperm concentration, sperm progressive motility and percentage live were observed from cocks in T3 and T4 indicating that 250mg and 350mg vitamin E inclusion were in excess and had adverse effect on semen parameters of guinea cocks. Cocks in T2 had highest ($P<0.05$) gains in body weight than the control while cocks in T3 and T4 expressed significant ($P<0.05$) body weight lost. These results therefore prove that semen quality and body weight of guinea cocks were negatively influenced by 250mg and 375mg vitamin E inclusion while 125mg vitamin E inclusion had an improved semen quality at better body weight which is recommendable.
Keywords: Guinea fowl, guinea cock, vitamin E, semen characters, body weight,

INTRODUCTION
Increase in Nigerian population has not been marched by growth in agricultural productivity especially in the area of animal production. This has caused low intake of animal protein intake in Nigeria as reported by FAO(1989). To correct this shortfall, there is need to improve on indigenous farm animals like guinea fowl (*Numidameleagris*) which is predominantly reared in northern part of Nigeria. Guinea fowl has many advantages over chicken which include low production cost, premium quality meat, greater capacity to scavenge for insects and grains, better ability to protect itself against predators and better resistance to common poultry parasites and diseases (Microlivestock, 1991). Guinea fowl products also have numerous nutritive and socio-cultural values. In spite of these, rearing of guinea fowl is believed to be uneconomical due to their monogamous and seasonal reproductive behavours.
The use of Artificial Insemination (AI) has not been properly explored as better alternative to break the inbreeding and monogamous behaviours of guinea fowl(Aire*et al*., 1983). Rengaraj and Hong (2015) reported thatavians are rich in PUFA which instigate oxidative damages that causes infertility. These damages may be controlled by given certain minerals and vitamins to act as antioxidants which vitamin E is a well unknown one.Vitamin E is a fat soluble vitamin that accumulates in tissues like testes and other reproductive organs (Rengaraj and Hong, 2015). This trace element is necessary for effective functioning of hormonal regulation and the reproductive system (Herrera and Barbas, 2001). This element is to increase the value semen parameters like sperm concentration, sperm livability and semen volume (Danikowski*et al*., 2002).However, excessive inclusion of vitamin E has also been reported to decrease semen quality (Arscot *et al*., 1995) and body weight (Aburto and Britton, 1998)of guinea cocks.
Information on reproductive responses of chicken, turkey and quail given different levels of vitamin E has been investigated by many authors like Kling *et al*. (1987), Danikowiki *et al*. (2002), Lin*et al*. (2005), Hooda*et al*. (2007) and Biswas*et al*.(2009). Yet, no work has been done on effect of vitamin E inclusion on semenparameters and body weight of guinea cocks reared in humid tropics. Therefore, this work is designed to establish the level of vitamin E inclusion that will improve semen quality recommendable for natural and AI breeding management in guinea cocks with sustainable body fitness.

MATERIALS AND METHODS

Location and duration of the study: This study was conducted in the Poultry Unit of the Teaching and Research Farm of the Department of Animal Science, University of Nigeria Nsukka, Enugu State. Nsukka lies in the derived savannah region, and is located on longitude $6^{o}\,25^{1}$ N and latitude $07^{o}\,24^{1}$ E, at an altitude of 430m above sea level (Ofomata, 1975). The climate is a typical humid tropical type with a relative humidity range of 56.01% - 103% (Energy Centre UNN, 2008). Average diurnal minimum temperature ranges from 22.0°C–25.2°C while the average diurnal maximum temperature ranges between 33^{0}C-37^{0}C (Energy Centre UNN, 2008). Annual rainfall ranges from 1567.05mm to 1846.98 mm (Energy Centre UNN, 2008). The study lasted 18weeks in which two weeks were used to acclimatize the birds.

Procurement, distribution and management of experimental guinea cocks: A total of twenty-four mature guinea cocks of 35-37 weeks old were procured from dealers in Abuja and acclimatized to the farm environment. The cocks were randomly allotted into four treatments: T1, T2, T3 and T4 of six cocks per treatment at different levels of vitamin E: 0mg, 125mg, 250mg and 375mg inclusion respectively. Initial and final body weights of the cocks were also determined. Diet containing metabolizable energy and crude protein of 2650Kcal/kg and 16.5% respectively was formulated which met the dietary recommendation for guinea fowl breeders under tropical conditions as recommended by NRC (NRC 1994) and served at 110g/day/cock as prescribed by Embury (2001). Water was given *ad libitum*.Other procedures carried out in this study were complied with the provisions of theUniversity of Nigeria, Nsukka Ethical Committee on the use of animals for biomedical research (2005).

Collection of semen samples: The guinea cocks were trained on semen collection within the period used for acclimatizing the birds. Semen samples were obtained by massage technique as described by Burrows and Quinn (1935). Semen samples were collected twice per week i.e. Saturdays and Wednesdays and were evaluated considering the processes described by Ugwu and Oleforu (2008).

Experimental design and statistical analysis: The experimental design that was used is a completely randomized design (CRD): $\mathbf{X_{ij} = \mu + T_i + E_{ij}}$; where$\mathbf{X_{ij}}$= individual observations of (ith) guinea cock fed with (jth) different level of vitamin E; **μ**= overall mean of the experiment; **T**i= effect of vitamin E on (ith) individual guinea cock;$\mathbf{E_{ij}}$= experimental error associated with observations of guinea cock fed with (jth) different level of vitamin E. The data were subjected to analysis of variance based on a Completely Randomized Design (CRD) using Statistical Package for Social Sciences (SPSS) computer package (SPSS, 2001). Significant means were separated using the Duncan option of SPSS.

RESULTS AND DISCUSSION

Results in Table 1 showed that there were significant differences ($P<0.05$) among the cocks in semen volume, progressive motility, sperm concentration, percentage dead sperm cells, percentage live sperm cells and total sperm cells with best mean values obtained for cocks fed with 125mg vitamin E (T2).The mean values of semen volume, live sperm cells and total sperm cells obtained for cocks in T3andT4 were significantly lower ($P<0.05$) than number of dead sperm cells whencomparedwith the control.Semen of cocks in T3 and T4 had slightdecrease ($P<0.05$) in progressive motility and sperm concentration values when compared with control treatment. These resultstherefore indicate that inclusion of125mg vitamin E

Table 1: Physical semen characters of the guinea cocks fed with different dietary levels of vitamin E

Semen Characters	T1 (control) (0mg vit. E)	T2 (125mg vit. E)	T3 (250mg vit. E)	T4 (375mg vit. E)
Semen volume (ml)	0.038^{a}±0.01	0.044^{a}±0.02	0.022^{b}±0.03	0.020^{b}±0.02
Progressive motility (%	45.43^{b}±3.25	65.22^{a}±4.05	40.40^{b}±4.15	40.40^{b}±4.15
Sperm Concentration ($x10^{6}$/ml)	2.35^{b}±0.09	4.35^{a}±1.13	2.20^{b}±0.21	2.00^{b}±0.16
Live sperm cells (%)	90.12^{a}±3.34	92.56^{a}±3.40	82.28^{b}±2.28	81.53^{b}±2.21
Dead sperm cells (%)	10.34^{b}±0.04	8.29^{a}±0.22	18.77^{c}±1.58	19.56^{c}±1.50
Total sperm cells (10^{9}/ ejaculate)	0.83^{a}±0.018	0.91^{a}±0.025	0.51^{b}±0.017	0.41^{b}±0.010

a, b, c Means with different superscripts in a row are different (P<0.05).

perkg diet improved semen quality of guinea cocks.Further increase of vitamin E to 250mg and 375mg may progressively reduce values thesesemen parameters. These values were in accordancewith those of Arscot*et al*. (1995) and Danikowski*et al*. (2002) who reported that semen parameters of cocks may be negatively affected when they are given high level of 250mg vitamin E in diet.

Table 2: Daily live-weight gain of guinea cocks fed with different dietary levels of vitamin E

Body weight	T1 control (0mg vit. E)	T2 (125mg vit.E)	T3 (250mgvit. E)	T4 (375mgvit. E)
Initial weight(kg)	0.65±0.075	0.64±0.080	0.63±0.067	0.65±0.082
Final weight(kg)	0.78^{b}±0.063	0.82^{a}±0.403	0.56^{c}±0.055	0.56^{c}±0,057
Total weight gain (kg)	0.13^{b}±0.021	0.18^{a}±0.028	-0.07^{c}±0.019	-0.09^{c}±0.023
Daily Live-weight gain(g)	3.09^{b}±0.19	4.28^{a}±0.24	-1.67^{c}±0.15	-2.01^{c}±0.07

a, b, c Means with different superscripts in a row are different (P<0.05)

Results in Table 2 showed that cocks in T2 had highest (P<0.05) daily live-weight gains (4.28^{a}±0.24) while cocks in T3 and T4 had negative values (P<0.05) live-weight gains of -0.71g±0.15 and -0.92g±0.07 respectively indicating a reduction in body weights when compared to 3.98g±0.19 daily live-weight gain for the birds in control treatment. Also, similar trends were observed in final weight and individual weight gain of cocks given the different dietary levels of vitamin E (Table 2). These results agreed with the reports of Yates *et al*. (2009) that body, liver and heart weights of rats given dietary vitamin E were better at lower levels (42 IU and 242 IU) than (2042 IU and 20,042 IU). Similarly, Aburto and Britton (1998) observed that the body weights and bone ash of broilers were reduced significantly at high levels of vitamin E supplementation when compared with increased body weights and bone ash obtained forbroilers fed with lower levels of vitamin E. Dju*et al*. (1950) observed that fowls fed with excess vitamin E for a prolong period eliminate more than 75% of ingested feed through faeces. This may cause great loss of metabolizable nutrients including the energy required for production of quality semen and body development among others. In contrast, Pudelkiewics *et al.* (1960) reported that chicken receiving diet supplemented with 35g of vitamin E/kg diet defecate only 23% of ingested feed. This proves that more nutrients will be stored and utilized for production of semen of good quality and sustaining better body development among the chickens.

CONCLUSION AND RECOMMENDATIONS

These results suggest that guinea cocks required reduced amounts of vitamin E for body growth, gamete production and subsequent fertility. Deficiency or long-term omission of vitamin E in the diets of breeding guinea cocks may not significantly affect semen production, fertility and body weight

gains while excessive inclusion of 250mg to 375mg of vitamin E per kg impair semen quality with significant loss of body weight which may further cause emaciation. These results showed that 125mg of vitamin E per kg diets reduces the oxidative damages of PUFA and therefore improves the semen parameters recommendable for natural and AI operations with better body fitness essential for optimum guinea fowl production.

ABSTRACT

The experiment evaluated the influence of strain on haematological values, blood chemistry and carcass characteristics of three strains (black, brown and spotted) of Noiler chicken. The experiment was conducted at the poultry section of the Bauchi State Agricultural Development Programme (BSADP) in Bauchi. A total of one hundred and thirty-six (136) eight weeks old Noiler birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system. They were randomly distributed into 3 treatment groups based on strain using a Completely Randomized Design(CRD). The experiment lasted for a period of three months from the first day of lay. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum. At 34 weeks, seventy-two (72) birds were randomly selected from three different strains (24 birds per strain) for haematology and biochemical analysis while at the end of the experiment, a total of fifty-seven (57) birds were randomly selected from different strains (19 per strain) for gut and carcass analysis.The Haemoglobin (Hb) result indicated that all the treatments were within the normal range (10.2 – 15.1g/dl), the packed cell volume (PCV) were within the normal recommended values.The result for lymphocytes fell within the normal value of 40 – 70% indicating that the birds were normal. The lymphocytes, neutrophils, Basophils, Eosinophils and monocytes were all within the normal range. The result showed that strain ($p<0.05$) significantly affected albumin glucose cholesterol and calcium. Dressing percentage, liver, large intestine pancreas and abdominal fat were also influenced by strain. This study therefore concludes that strain affected the haematological values, blood chemistry and carcass characteristics of Noiler chicken.

Keywords: Strain, Noiler, Haematological, Carcass, Blood Chemistry

INTRODUCTION

Chickens are regarded as the most important and widely spread avian species among poultry birds (Dutta*et al.,* 2013).Poultry production is an important agricultural activity of almost all rural communities in Africa and provides scarce animal protein in the form of meat and eggs, and is a reliable source of petty cash, they are said to be one of the important animal genetic resources used as a weapon for fighting poverty and malnutrition, especially in rural areas of most developing countries, which results in the growing interest on the use of chicken as a tool for poverty alleviation in villages throughout the world (Dunya *et al.,* 2015). However, chicken growth and development is a complicated life process and is subject to a significant amount of control by genetic and non-genetic factors (Pourtorabi *et al.,* 2017; Zhenqiang *et al.,* 2013).Poultry production is fast growing in Nigeria as it significantly contribute to animal protein source of the Nigeria population, Most farmers keep broilers for meat and pullets are kept for egg production. With the increasing population, there is need for a low cost feed input breed with increased output of meat and egg production.To achieve this, a dual purpose chicken breed like Noiler is unavoidable. Noiler is a dual purpose breed of chicken developed in Nigeria by a noble hatchery with the sole aim of addressing the challenges of animal food insecurity and also to solve problems of financial challenges especially of rural communities and small holder farmers as Noiler production is highly profitable and can easily substitute local chicken. The haematological profile, both in human and animals is an important index of the physiological state of the individual, the ability to interpret the state of blood profile in normal and diseased conditions is among its primary tasks (khan *et al,* 1987). Hematological indices are an index and a reflection of the status and condition of the blood available for an animal to meet its physiological, biochemical, and metabolic necessities (Euola *et al*,2004). Therefore the objectives of this study was to establish the haematological and serum biochemical values of the three strains of Noiler chicken and to determine the effects of strain on carcass yield and gut characteristics of Noiler chickens.

MATERIALS AND METHODS

The experiment was conducted at the poultry section of the Bauchi State Agricultural Development Programme (BSADP) along Yelwan Makaranta Dass Road, Bauchi State. A total of one hundred and thirty-six (136) eight weeks old Noiler birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system where they were randomly distributed into 3 treatment groups based on strain using a Completely Randomized Design(CRD). The experiment lasted for three months from the first day of lay. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum.

Data Collection and Analysis

At 34 weeks, seventy-two (72) birds were randomly selected from three different strains (24 birds per strain) for haematology and biochemical analysis. 3ml of blood samples were collected from the basillic vein of the birds into a well labelled sterile bottle containing Anticoagulants. These were used to determine packed cell volume, haemoglobin (hb), white blood cell count (WBC), and the differential counts which are Neutrophils, lymphocites, monocites, Eosinophil and Basophils. Another 3ml sample of blood was collected into sterile labelled bottles without anticoagulants to determine the serum biochemical metabolites as follows: total protein, cholesterol, Glucose, Albumin, calcium, phosphorus, uric acid.

Hematological technique

Total red blood cell count and Total white blood cell count were determined by a manual method using hematocytometer (Campbell,1995). Differential counts were made on monolayer blood films, fixed and stained with leishman – stain. Packed cell volume was measured by a standard manual technique using micro hematocrit capillary tubes and hematocrit reader. Haemoglobin concentration was measured by cyanhemoglobin method (Ritche *et al*.,1994).

Biochemical technique

Total protein, glucose, calcium, phosphorus, cholesterol, and uric acid, were determined by automatic analyzer.

Gut and Carcass Analysis

At the end of the experiment, a total of fifty-seven (57) birds were randomly selected from different strains (19 per strain). They were deprived of feed for twelve hours but provided with drinking water. The chickens were weighed and slaughtered. Slaughtered birds were scalded in hot water (about 50^0c) for 1 minute and plucked manually, offal were then eviscerated for carcass yield and organ weight determination. The carcass yield and organ weight were calculated as percentage of the live weight. Dressing percentage was calculated using the relationships: -

$$\text{Dressing percentage} = \frac{\text{carcass weight}}{\text{live weight}} \times 100$$

Statistical Analysis

Analysis of variance was carried out on data collected using the general linear model of SPSS 20.0 (2011). Where means differed, Duncan multiple range test (DMRT) was used to separate them (Duncan, 1955).

RESULTS AND DISCUSSION

The result for haematological analysis of three strains of Noiler chicken is presented in Table 1. The result showed ($p<0.05$) significant difference among some of the parameters measured. Haemoglobin (Hb) values were similar among the treatments. The Hb result indicated that all the treatments were within the normal range (10.2 – 15.1g/dl) which is in agreement with the finding of Petra *et al*, (2014). The packed cell volume (PCV) were within the normal recommended values for healthy birds in all the treatments (30 – 49%) as outlined by Petra et al, (2014). The result for white blood cell count (WBC) revealed that all the treatments were within the recommended range ($3 – 11 \times 10^9$). The result for lymphocytes fell within the normal value of 40 – 70% indicating that the birds were in a normal health status. The neutrophils, Basophils, Eosinophils and monocytes are all within the normal range for healthy birds as outlined by Petra et al.

Table 1: Haematological values of three strains of Noiler Chicken

Parameters	Black strain	Sported strain	Brown strain	LS
Hemoglobin (g/dl)	11.13	10.33	11.54	0.38827 NS
Packed cell volume%	33.33	30.13	34.13	1.17851 NS
Whiteblood cell(x10)	5.41	3.65	3.75	0.53758 NS
neutrophil%	39.50	40.25	36.45	0.75785 NS
Lymph%	55.45a	51.79b	56.33a	0.86534 *
Mono%	3.92a	2.29b	3.45a	0.17382*

Eosinophils	0.42a	0.00b	0.00b	0.06034 *

Ls= level of significant,NS/=Not significant, a and b= means with different superscript on the same row varies significantly.

Table 2: Blood Chemistry of three strains of Noiler Chicken

Parameters	**Black strain**	**Sported strain**	**Brown strain**	**SEM**
Total protein (gl)	57.62	60.24	56.67	1.19269NS
Albumin (mmol/l)	21.62^{b}	22.00_{b}	26.19^{a}	0.46649*
Glucose (mmol/l)	1.35^{b}	2.95^{a}	1.65^{b}	0.23103*
Cholesterol (mmol/l)	4.91^{b}	3.45^{c}	6.05^{a}	0.22020*
Calcium (mmol/l)	2.26^{b}	3.00^{a}	2.40^{b}	0.07510*
Phosphorus (mmol/l)	2.42	2.11	2.30	0.13478NS

NS= not significant ($p<0.05$), SEM= standard error of mean, a, b and c= means with different superscripts on the same row varies significantly, *= significant.

The result for blood chemistry of the three strains of Noiler is shown in Table 2**.** The result showed that strain has effect on most of the serum biochemical parameters measured. The total protein was not significantly different among the three strains, but albumin values were similar in two of the treatments (Black and spotted) but differs significantly ($p<0.05$) with the brown. The result for glucose showed a similar value for the black and brown strain but differs significantly ($p<0.05$) with the spotted. All the treatments were within the normal glucose range for birds. Cholesterol levels were within the normal range but vary significantly ($p<0.05$) among the treatments. Brown strain records higher value for cholesterol compared to the Black and Spotted. Calcium and phosphorus levels were

within the normal range indicating proper metabolism of the calcium and phosphorus and also a proper functioning of the parathyroid gland.

Table 3: Carcass characteristics of three strains Noiler chicken

Parameters	Black strain	Sported strain	Brown strain	SEM
Live weight (g)	2738.5	2853.8	2638.5	0.10608

Caecum (%)	1.78	1.72	1.76	2.73NS
Lungs (%)	1.24	1.08	1.06	0.470NS
Hearts (%)	1.23	1.06	1.21	0.44NS
Testes (%)	0.71	0.73	0.78	2.211NS

SEM= standard error of mean, a and b= means with different superscript on the same row varies significantly. NS- not significant.

The result for carcass characteristics of three strains of Noiler chicken is shown in Table 3. The result showed that there were no significant difference on parameters like liver, plucked, eviscerated and carcass weight. The similarity may be as a result of uniformity in feed, environment and their genetic potentials for growth. The result for organ and gut expressed as percentage of body weight showed no significant difference in kidney, heart, testes, lungs, ceacum, spleen, gizzard, and small intestines. However, significant ($p<0.05$) difference was recorded for liver with the black strain recording the highest (42.62). Other parameters measured include pancreas, large intestine, abdominal fat which varied significantly ($P<0.05$) among the treatments.

CONCLUSION

In conclusion, strain affected the haematological values, blood chemistry and carcass characteristics of Noiler chicken.

ABSTRACT

The aim of this study is to seek the effect of dietary energy and protein on the egg qualities. A total of four hundred and eighty day old un-sexed Japanese quails of about the same weight (26.56±0.02) were studied over a period of 12 weeks. After hatching, chicks were raised together during one week and fed with starting diet then divided into four dietary treatments (T1, T2, T3 and T4) with 30 quails in each replicate. Each treatment was replicated four times. T1: Control (Standard diet)SD; T2: High Energy Low Protein diet (HELP) ; T3 : High Energy High Protein diet (HEHP) andT4 : Low Energy High Protein diet (LEHP) in a completely randomized design. After 12 weeks of laying, eggs were collected from each treatment for both the external and internal egg characteristics. Data obtained were analyzed using ANOVA at $\alpha_{0.05.}$

Egg weight was higher (P<0.001) in the HEHP diet, egg height was also higher (P<0.05) in HEHP diet as well. Internal egg qualities, albumin height and albumen length had a significant influence (P< 0.05) in the HEHP diet.The albumen volume and the Yolk weight had the highest level of significance (P<0.001) in the HEHP diet. The shell weight was significant (P<0.001) with the HEHP diet having the highest values. There was also significance (P< 0.001) in the shell membrane and shell percent (P< 0.01) in the LEHP diet. The haugh unit are not significant in all the diets (P>0.05) but HEHP had the highest % of haugh unit.The results indicate that high energy and high protein (HEHP) diets is suitable for optimum performance of Japanese quail in terms of weight gain and egg quality.

INTRODUCTION

Increased poultry production has been advocated as one of the fastest means of providing quality animal protein at minimum cost (Nwachuckwu, 2015). The quail production story is more recent and also has the same characteristics that occurred in the broiler and laying hen production.

The establishment of quail production assumed importance worldwide in the last decade, not only for being a laboratory animal for poultry and biomedical research, but also because it is commercially exploited for production of meat and eggs.

Japanese quails mature in about 6 weeks and are usually in full egg production by 50 days of age. With proper care, hens should lay 200 eggs in their first year of lay. Life expectancy is only 2 to 2½ years (Randall, 2008).Quails produce up to five generations per annum (Saidu, 2014).

The optimum performance of livestock depends largely on the quality and quantity of their dietary nutrients (El-katcha, 2014). Precise nutrient supply reduces feed cost, wastage of nutrients, environmental pollution, and bad aroma in poultry house, and thus improves animal welfare (Kaur, 2015). Nutrition is by far the most important single factor under the environment in which poultry birds are reared, since it accounts for 60-75% of the inputs in poultry industry.

The aim of this study is to seek the effect of dietary energy and protein on the egg qualities.

MATERIALS AND METHODS

Location:

The experiment was carried out in the Poultry Division of the National Veterinary Research Institute Vom which is located in Plateau state ,central Nigeria in Jos South Local Government .Its geographical coordinates are on Latitude 09^0 44' 0'' North ,08^0 4' East .The trial was carried out from September to November 2018 (Maplandia.com).

Animals and management:

A total of four hundred and eighty day old un-sexed Japanese quails of about the same weight (26.56±0.02) were studied over a period of 12 weeks . The birds were sourced and raised in the Poultry Division of the National Veterinary Research Institute Vom in Plateau state. After hatching, chicks were raised together during one week and fed with starting diet then divided into four groups of 30 chicks each.

Experimental diets:

Diets were composed with local available feedstuff such as corn, soya bean cake and offered as mash (Table 1) and were randomly assigned to each treatment. The experiment included 4 dietary treatments (T1 , T2 ,T3 ,and T4) with 30 quails in each replicate. Each treatment was replicated four times.

The experiment consisted of 4 treatments designated as:

T1 : Control (Standard diet)(SD)

T2 : High Energy Low Protein diet (HELP)

T3 : High Energy High Protein diet (HEHP) and

T4 : Low Energy High Protein diet (LEHP)

Egg collections

After 12 weeks of laying ,eggs were collected from each treatment for both the external and internal egg characteristics.

Data collected

External characteristics

Internal characteristics

Statistical analysis

Data collected were analyzed using General linear model of SAS (SAS 2010). Statistical variations were observed and means were separated using Duncan's multiple range test.

RESULTS

The effect of the diets on egg quality is presented on Table 1. The Egg width and Egg shape index were similar for all the groups (P>0.05). Egg weight was higher (P<0.001) in the HEHP diet, Egg height was also higher (P<0.05) in HEHP diet as well. For the internal egg qualities, the Albumin height and the Albumen length had a significant influence (P< 0.05) in the HEHP diet .The Albumen weight was significant (P<0.01) in the LEHP diet .The Albumen volume and the Yolk weight had the highest level of significance (P<0.001) in the HEHP diet. The yolk volume was significant (P<0.01) with the HELP diet having the highest value.

The shell quality showed no significant difference (P>0.05) in the shell thickness, values in all the diets ranged between 0.10mm to 0.15mm. However, the shell weight had values ranging from 1.38g to 1.74g ,and it was significant (P<0.001) with the HEHP diet having the highest values. There was also significance (P< 0.001) in the shell membrane and shell percent (P< 0.01) in the LEHP diet.The Albumen width ,Haugh unit ,Albumen index ,Yolk percent ,Yolk height ,Yolk width ,Yolk length , Yolk colour ,Yolk index ,Yolk /Albumen ratio , were all not significant in all the diets (P>0.05).

[a, b] means with different superscripts within the same row differ significantly ($p<0.05$)., SEM means standard error of mean

SD= Control (Standard diet); HELP= High Energy Low Protein diet; HEHP= High Energy High Protein diet

LEHP= Low Energy High Protein diet

This present result was in line with Muhammad (2016), who indicated that the protein levels had no significant effect on albumin weight, yolk height, yolk width, yolk weight, yolk index, yolk colour and Haugh unit ($P>0.05$). In this study all that were indicated were not significant except Albumin weight which was significant ($P<0.01$). It was concluded in his study that increasing dietary protein level of 25% will increase the egg production performance of Japanese quails. Similar results was obtained with the report of Lotfi (2018) who reported that the groups of quails that were fed more energetic feeds, significantly higher egg weights were achieved. Gunawardana (2008) reported that dietary energy had no influence on egg weight. Wu *et al.* (2005), and Sohail (2003), who reported that egg weights of hens with high protein diets were greater than of those hens with low protein diets, which is a consequence of the increase in albumen and yolk weights was in line with the results obtained in this study. This study is also in agreement with Lotfi (2018) who reported that the increase of albumen weight might be partially attributed to the improved nutrient (protein, total sulfur amino acids, or lysine) utilization with increased dietary energy. On the other hand, Novak *et al.* (2006) reported that shell quality was affected by protein and its ratio in diet, which could potentially have serious consequences for commercial egg-laying operations which is in line with this study. The work of Lotfi (2018) which stated that the shell protein matrix is comprised of 70% protein ,and also, increasing the sulfate groups existing in the shell matrix significantly increases the Ca binding ability, which in turn may increase both shell percentage and specific gravity and overall shell quality.

CONCLUSION

The results indicate that high energy and high protein (HEHP) diets is suitable for optimum performance of Japanese quail in terms of weight gain and egg quality.

ABSTRACT
This study was conducted to estimate the variance components and heritability for birthweight and weaning weight, as well as the genetic and phenotypic correlations between these traits in N'dama and Muturu crosses at the University of Nigeria Nsukka (UNN) cattle herd. The study lasted for 6 months and the heritability and genetic correlation of the traits were estimated using Restricted Maximum Likelihood (REML) method of SAS mixed model. The direct heritability estimates obtained were 0.15±0.05 and 0.45±0.05 for birth weight and weaning weight respectively. The direct genetic correlation between the two traits was positive (0.53) between birth weights and weaning weights.
Keywords: Genetics, heritability, N'dama, Muturu and Correlation

INTRODUCTION
The beef cattle sub-sector plays important roles in the Nigerian economy, not only in terms of its contribution to the gross domestic products (GDP) but also contributes substantially to the supply of animal protein (FDLPCS, 2002 and Tewe, 2010). In the opinion of Grain de Sel (2010), Nigeria is by far the leading beef cattle producer in Central and West Africa with the cattle herds estimated at over 16 million heads, which is far ahead of Niger (8.7 million), Mali (8.2 million) and Chad (7 million).
However, Nigeria's rapidly growing population which is expected to reach 250+ million persons by 2030 (NLTP, 2019-2028), coupled with rising incomes and urbanization, are translating into increased demand for livestock products (FAO, 2018). Recent estimates suggest that, between 2010 and 2050, beef, poultry meat and milk consumption will increase by 117, 253 and 577 per cent, respectively (ASL2050 FAO, 2018). Hence, there is need to genetically upgrade the performance of our indigenous cattle species to raise the potential for higher meat yield.
Long (1980) opined that the genetic improvement of beef production systems is hinged primarily on two procedures which are; selection within breeds to enhance critical characters and selection among, and combination breeds to produce individuals that better fit production conditions and resources. N'dama and muturu which are predominant in the south eastern Nigeria produce minimally and are usually referred to as unimproved. However they have good adaptive traits that makes them hardy and resistance to certain environmental factors and diseases. Hence, they can be used in advanced beef cattle improvement programmes. Moreover, birth weight and weaning weight traits are recognized as important traits in determining economic efficiency of beef cattle (Oni et al 1988), and also an important selection criteria because of the ease with which they can be measured (Gregory 1965).
The effectiveness of breeding programmes depends on the accuracy of genetic and phenotypic parameter estimates, which include heritability and repeatability (Burrow, 2001). However, since the inception of breed improvement programmes in Nigeria, there has been no comprehensive analysis of the data generated either to obtain estimates of genetic parameters or to evaluate the genetic progress achieved in these populations. Such estimates are not only necessary for planning future breeding strategies but are also relevant for predicting response to selection and for evaluating genetic programmes. Although many genetic parameter estimates are now available in the literature from different breeds and production conditions, estimates of genetic and phenotypic parameters in pure breed indigenous cattle populations are scarce (Bosso et. al., 2002). Hence, the primary objective of this study is to estimate genetic parameters for birth weight and weaning weight of N'dama and Muturu crosses which will be used in subsequent genetic evaluation of the breed.
The objective of this study was to estimate the variance components and heritability for birthweight and weaning weight, as well as the genetic and phenotypic correlations between these traits in UNN cattle population.

MATERIALS AND METHODS

The study area

Data used in this study were obtained from the breeding and production records of beef cattle at the University of Nigeria Animal Science Farm, Nsukka. Nsukka lies within longitude 6˚45'E and 71E and latitude 7˚12.5'N (Ofomata, 1975) and on the altitude 447m above sea level. The climate of the study area is typically tropical, with relative humidity ranging from 65 – 80% and mean daily temperature of 26.8˚C (Agbagha et al., 2000). The rainy season is between April and October while dry season is between November and March with annual rainfall range of 1680 – 1700mm (Breinholt et al., 1981). The experiment lasted for three months.

Management of the herd

A total of 15 cows and 5 sires were used for the experiment. They were bred and managed properly through calving till weaning. Calving occurs all year round as no strict breeding season is enforced. Calves were weighed within 24 h of birth and thereafter weighed at bi-monthly intervals using a 100Kg capacity weighing scale. Calves were identified at birth and branded later, close to weaning. Calves were weaned at about 6 months of age. All animals were treated against ecto- and endoparasites and routine prophylaxis for trypanosomiasis and babesiosis was administered. The vegetation of the research station is described as guinea savannah type. The predominant grass species on UNN pasture are *Panicum maximum, Pennisetum purpureum* and *Cynodon dactylon* interspersed with legume species like *Centrosema pubesence, Mucuna sp., Mimosa sp.* and others.

Statistical analysis

Data were edited such that only animals with complete records on sire, dam and all fixed effects were used. The number of animals in the final data set were analysed by the MIXED model procedure of SAS (SAS University Edition 2019). The model used include the fixed effect of sex (male and female) and random effect of sire. Restricted maximum likelihood (REML) method of SAS mixed model was used to estimate the observable variance components due to sire (σ_s^2) and error (σ_w^2). Estimates of genetic correlations were obtained using varcomp procedure of Harveys computer program (Harvey, 1990). The programme also computed the genetic correlations and the appropriate standard errors of the estimated heritabilities.

$$h^2 = \frac{4\delta_s^2}{\delta_s^2 + \delta_w^2}$$

Where, h^2 is the sire heritability; δ_s^2 is the sire variance component and δ_w^2 is the error variance component.

$$rG = \frac{Cov\ (x\ y)}{\sqrt{\delta_s^2(x)\delta_s^2\ (y)}}$$

Where, *rG* is the genetic correlation; Cov (x y) is the genetic covariance of x and y components; δ_s^2 (x) is the sire variance of x component and δ_s^2 (y) is the sire variance of y component.

The detailed description of animals at UNN population is presented in Table 1 below.

Table 1: Descriptive statistics of the data

	Birth Weight	Weaning weight
No of records	15	15
No of sires	5	5
No of dams	23	23
Progeny per sire	3	3
Progeny per dam	1	1
Mean (kg)	10.77	58.29
Standard deviation	2.37	7.03
Coefficient of variation (%)	22	12.07

RESULTS AND DISCUSSION

Sex effect was not significant (P>0.05) for birthweight. However, there is significant difference (P<0.05) between male and female calf weight at weaning. Male calves weighed 6.87kg (11.8%) heavier. The result is in line with the work of Hopkins (1977), who observed an increased sex

differences with increasing growth rate, signifying that male animalse are more responsive to improvement in the environment. The levels of weight advantage of male calves recorded in this study are comparable to what can be estimated from the values of Tawah et al. (1993) in Gudali but lower compared with values estimated by Tuah and Danso (1985) for WASH and Ndama in the humid forest zone of Ghana where favourable rainfall regime allowed greater quantities of high quality forage to be produced throughout the year, thus improving the nutritional environment for greater expression of male calves' responsiveness to improved environment.

Variance components and heritability in UNN cattle population

The variance and heritability estimates for birth and weaning weights are presented in Table 3 below.

Table 2: Variance covariance components and estimates for heritability (± SD) for birth and weaning weights

	Birth Weight		Weaning weight
Variance-covariance estimates			
Additive direct variance	0.8		16.37
Error variance	4.7		19.89
Phenotypic variance	5.5		36.26
Phenotypic correlation		0.05	
Genetic correlation *rG*		0.53	
Heritability estimates			
Direct heritability	0.15 ± 0.05		0.45 ± 0.05
Total heritability	0.15		0.45

Heritability

The variance, covariance and heritability estimates for birth and weaning weights are presented in Table 2. The estimates were low to medium but are in agreement with values reported by other researchers. The heritability value of 0.15 ± 0.05 for Birthweight in this study was close to 0.149 reported by Peters *et al.* (1998) for the same breed in a similar environment but lower than 0.37 reported by Johnson *et al.*(1992). Estimates of direct additive heritability (hi) for weaning weight (0.38 + 0.18) are in agreement with results of Mackinnon et al. (1991). The increase in heritability estimate with increase in age obtained in this study follows the same trend noted by Fogarty (1995).

Correlation

Phenotypic and additive direct genetic correlation coefficients between birth weight and weaning weight were 0.05 and 0.53 respectively. While the phenotypic correlation coefficient was slightly lower than those from other studies, the genetic correlation coefficient was similar to literature values. The unweighted and weighted means obtained from a review by Koots et al. (1994), of all published studies on correlations between birth and weaning weights were 0.36 and 0.46 for phenotypic correlations and 0.47 and 0.55 for genetic correlations, respectively. The lower phenotypic correlation relative to genetic correlation is in agreement with the trend reported in the reviews by Woldehawariat et al. (1977) Mohiud- din (1993) and Koots et al. (1994). The moderate genetic correlation between birth and weaning weights indicates that selection for one trait will result in a moderate positive correlated response in the other trait.

CONCLUSION

Estimates of heritability indicate that additive genetic variance exists for these traits. Selection for these traits, therefore, is likely to result in genetic gain for growth in UNN cattle population under tsetse infection pressure in south-eastern Nigeria and in the humid zone of Africa in general. The high genetic correlations between birth weight and weaning weight indicates that birth weight could be used as a cost effective means for selecting for cattle with high post weaning weight. The differences between male and female calves for weaning was highly significant hence, it is important

for sex of calf to be correlated for in analysing preweaning calf data. Genetic improvement of indigenous West African cattle has been attempted in the past by crossbreeding with exotic breeds of cattle with little or no emphasis placed on selection. The estimates of genetic parameters obtained in this study indicate that if genetic improvement through selection for birth and/or weaning weight of indigenous cattle and their crosses is desired, there is high posibility for high genetic progress to be achieved.

ABSTRACT

The study was conducted at Federal College of Forestry, Jos. The objective of the study was to determine effects of age on egg number and egg weight in chickens. A total of 500 pullets were obtained from a reputable hatchery in Ilorin and received in Jos. They were brooded for six (6) weeks during which all recommended vaccines were and antibiotics were administered, they were further transferred to battery cage at fourteen weeks (14). Records were taken daily for total feed consumed per bird per day by weighing feed left over, mortality, egg lay, weight of egg (egg weight was measured using a digital scale) and clutch length. The experiment lasted for twenty (20) weeks from first day of lay. Birds were fed with predetermined weight of feed once a day. Commercial diet was used as the experimental diet. The result showed that a positive and strong significant ($P < 0.01$) correlation was observed between age of hen and weight of eggs ($r = 0.092$). Weak positive correlation ($P < 0.01$) was observed between age of hen and number of eggs ($r = 0.017$). From the finding of this study, it was concluded that, there was a positive relationship between age of birds and egg number. Positive relationship also exist between age of birds and egg weight. However it should also be noted that the correlation between age and egg weight was stronger than the correlation between age and egg number. Further research was recommended

INTRODUCTION

Poultry production is an important and diverse component of agriculture. Poultry are kept in most areas of the world and provide an acceptable form of protein to most people in the world. Many developed countries have adopted intensive poultry production system in order to meet protein demand for humans. Poultry are able to adapt to most areas of the world at relatively low price, they reproduce rapidly and have a high rate of productivity. Layer chicken hens are efficient egg producers.Breeds used for egg production are mostly based on leghorn and Rhode Island Red but selection and cross breeding have resulted in high productive laying hens (FAO, 1992). In Nigeria, poultry contributes about 15% of the total annual protein intake with approximately 1.3 kg of poultry products consumed per head per annum. In the past decades, there has been a recorded improvement in poultry production in Nigeria with its share of the Gross Domestic Product (GDP) increasing in absolute terms. The contribution of chicken egg and meat to the livestock share of the GDP increased from 26% in 1995 to 27% in 1999 with an increase in egg production alone accounting for about 13% during the period. In spite of the significance of the poultry industry to the national economy, poultry farms face challenges inimical to the growth of the industry. Poultry production in general is faced with low capital base, inefficient management, disease and parasite, housing and marketing problems, etc (Akintunde, *et al.,* 2015). Poultry production has become a fulltime job for many and is considered to be a commercially viable enterprise, contributing significantly to Gross National Product (GNP) (Nwagu *et al*, 2007b). Egg production is believed to have complex qualitative traits which are influenced by several factors such as breed, nutrition, age, weight of bird, management practices and environmental factors. Over the last decades, poultry management techniques in Nigeria have improved significantly, with rapidly increasing production. Under subtropical environments, growth rate as well as egg production are generally depressed by high ambient temperature (Bordas and Merat, 1984; Farooq*et al*, 2001). A significant interaction between environments and lines was found for laying traits, which indicated that the selected line was more sensitive to environmental changes than the control line for production level (Chen *et al.,* 2004). Poultry plays an important role in human nutrition, employment and income generation. Therefore the objective of the study was to determine the effects of Age on Egg number and Egg weight laying birds.

MATERIALS AND METHODS

The study was conducted at Federal College of Forestry, Jos. It is located in the central part of the Nigeria between latitude $8^{o}30^{|}$ and $10^{o}30$N and longitude $8^{o}20$ and $9^{0}30^{|}$E, with a surface area of about 9,400km^2. It has an average elevation of about 1,250 meters above sea level. A total of 500 pullets were obtained from a reputable hatchery in Ilorin and received in Jos. They were brooded for six(6) weeks during which all recommended vaccines were and antibiotics were administered, they were further transferred to battery cage at fourteen weeks (14). Records were taken daily for total feed consumed per bird per day by weighing feed left over, mortality, egg lay, weight of egg (egg weight was measured using a digital scale) and clutch length. The experiment lasted for 20 weeks from first day of lay. Birds were fed with predetermined weight of feed once a day. The experimental diet was of commercial origin.

RESULTS AND DISCUSSION

Table 1: Pearson Correlation Between Age and Weight of Eggs

		Age of birds (in weeks)	**Weight of eggs**
Age of birds (in weeks)	Pearson Correlation	1	
	Sig. (2-tailed)		
	N	4834	
Weight of eggs	Pearson Correlation	0.092**	1
	Sig. (2-tailed)	0.001	
	N	3975	3975

** Correlation is significant at the 0.01 level (2-tailed).

Pearson correlation between age and weight of eggs was presented in table 1. A positive and strong significant ($P < 0.01$) correlation was observed between age of hen and weight of eggs ($r = 0.092$). Also, Pearson correlation between age and number of eggs was presented in table 2. A weak positive correlation ($P < 0.01$) was observed between age of hen and number of eggs ($r = 0.017$). The finding of this study were in agreement with that of Anderle *et al*. (2014) and similar to Zanon *et al*. (2006).

Table 2: Pearson Correlation Between Age and Number of Eggs

		Age of birds (In weeks)	Number of eggs
Age of birds (in weeks)	Pearson Correlation	1	
	Sig. (2-tailed)		
	N	4834	
Number of eggs	Pearson Correlation	0.017**	1
	Sig. (2-tailed)	0.227	
	N	4831	4831

** Correlation is significant at the 0.01 level (2-tailed).

CONCLUSION AND RECOMMENDATION

From the finding of this study, it was concluded that, there was a positive relationship between age of birds and egg number. Positive relationship also exist between age of birds and egg weight. However it should also be noted that the correlation between age and egg weight was stronger than the correlation between age and egg number. Further research was recommended.

ABSTRACT
Raising goat requires more than knowledge of feeding, medication, breeding and various other routine management. Having a clearer understanding of buck mating behavior in the flock is necessary to ensure a good breeding program. One apparently healthy mature red Sokoto buck of 4 years old was exposed to two oestrus nulliparous does of 1 year-old to evaluate courtship behavior for 60 minutes in breeding pen. One hour video-tapping was copied into computer system and visualized to record frequencies and durations of reproductive behavioral events. Courtship behavior frequencies and durations were presented in figure 1 and 2 respectively. The result showed that foreleg kicks (12 times repeated) was the highest frequent courtship behavior displayed by the buck followed by snorts, nuzzling, chin resting and vocalization. Buck spent higher time (10.52 mins) without displaying courtship behaviors while nuzzling (6.36mins) and self-enurination (6.26 mins) was the highest courtship duration spent by buck while mounting without ejaculation (2.10 min) was the lowest time spent. The results showed that red Sokoto buck can be used to evaluate courtship ethograms and serve as a tool that will provide holistic ideas of modern reproductive behaviors for better and clear understanding of courtship behavior causes, its mechanism and complex interaction between the animals to both internal and external environments that influence such behaviors.
Key Words: Courtship, Ethogram, Buck, and Nulliparous Does

INTRODUCTION
The sexual behavior of goats is an important factor for flock breeding efficiency and productivity of goat farming. Many researchers have derived different ways and means to evaluate the breeding quality of the buck. The potential fertility of breeding males can be evaluated in the field by assessment of physical examination and genital tract examination, mating ability and semen quality evaluation (Kerketta *et al.*, 2013).

The "Ethology" is the observation and description of behavior that leads to improved understanding of its mechanism, function, development and evolution, while an "Ethogram" is a detailed description of the behavioral features of a particular species and collected behaviors that are distinguished according to their duration in "events" and "states" (McGreevy, 2004). The events are behaviors of instantaneous duration (e.g. vocalizations), which are best described by their frequency, while the states are behaviors of relatively long duration (e.g. feeding), which can be best described by their total or average duration. Therefore, a correct ethogram should include the frequency of events and the duration of states (McDonned, 2003).

OBJECTIVES OF THE STUDY
The objective of this study is to evaluate reproductive behaviors of buck exposed to two oestrus nulliparous does for 1 hour indoor breeding confinement.

MATERIAL AND METHODS
Experimental Site
The experiment was carried out in the small ruminant unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-ma. The site lies between latitude 12°27'18' North and 7°29'29' East and 605 meters above sea level with an average rainfall of 700mm within the Northern guinea Savannah zone (Gaddafi *et al.*, 2019)

Experimental Animal

A total number of three apparently healthy red Sokoto goats comprise of 1 buck and 2 oestrus nulliparous does of about 4 years old buck and 1 year old does respectively, was used in this study. The animals was housed in mating pen of about 7 x 5 mm^2 made up of blocks wells, concretized floor, metallic gate and windows with galvanized roofing sheet. Two oestrus does was identified by their behavioral displayed and introduced to the breeding pen for this trail.

Observations and Recordings

Two cameras were mounted in the well to enable 1 hour (60 minutes) video-taping. The video records was then transferred into computer and visualized for scoring frequency and durations of behavioral events of red Sokoto buck.

Sexual Ethogram for Red Sokoto Buck

Houpt, (2011) state that as the major stimulus for expressing sexual behavior is the presence of the partner, it is therefore very essential to bring a doe in estrus, near the mating pen for a limited time. Since the sampling rule is a behavioral sampling, therefore two estrus does were brought to the breeding pen and occurrence of the following mating behaviors were recorded: vocalization, self-enurination, flehmen, anogenital sniffing, foreleg kicks, tongue flicking, chin resting, snorts, mounting without ejaculation and mounting and ejaculation. The choice for video camera was to enable the animal to exhibit mating behavior naturally without observer distractions.

Table 1: Definition of Buck reproductive behaviors

Behaviors	Definition
Vocalization	Characterized by frequent louder bleating.
Self-enuranation	Downward turning of the head and shoulders towards the hindquarters and the emission of urine from the erect penis onto the face, beard and front legs.
Anogenital sniffs	Buck sniffs and licks the anal, vulva and other external genitelia.
Flehmen	When buck raise his head, curl his lip and wrinkled his nose.
Snorts	When buck forcibly produce exhalation sound/huffing.
Foreleg kicks	When buck kicked a doe`s back and shoulders with foreleg.
Nuzzling	When buck rub his nose to move the doe in cozy position.
Chin resting	Buck rises his forelegs and hanging his chest on the doe`s back.
Mounting without ejaculation	When buck chin resting properly, extrusion of penis without inserting into doe`s vagina.
Mounting with ejaculation	When resting, penis into vagina and ejaculation take place.
Non courtship behaviors	Walking, laying, feeding e.t.c.

RESULT

The courtship behavioral frequencies of red Sokoto buck exposed to two oestrus nulliparous does were presented in figure 1. The results revealed that foreleg kicks highest courtship behavior followed by snorts, nuzzling, chin resting, and vocalizations with a repetition frequencies of 12, 11, 10, 8 and 8 respectively. While anogenital sniffing (5), flehmen (4), mounting without ejaculation (4), self-enurination (3) and mounting with ejaculation (3) was the less frequent displayed behaviors observed during this study. 10 times were the frequency scores of other (non-courtship) behavior which characterized by standing without displaying any courtship behavior, lying down or walking away from the does.

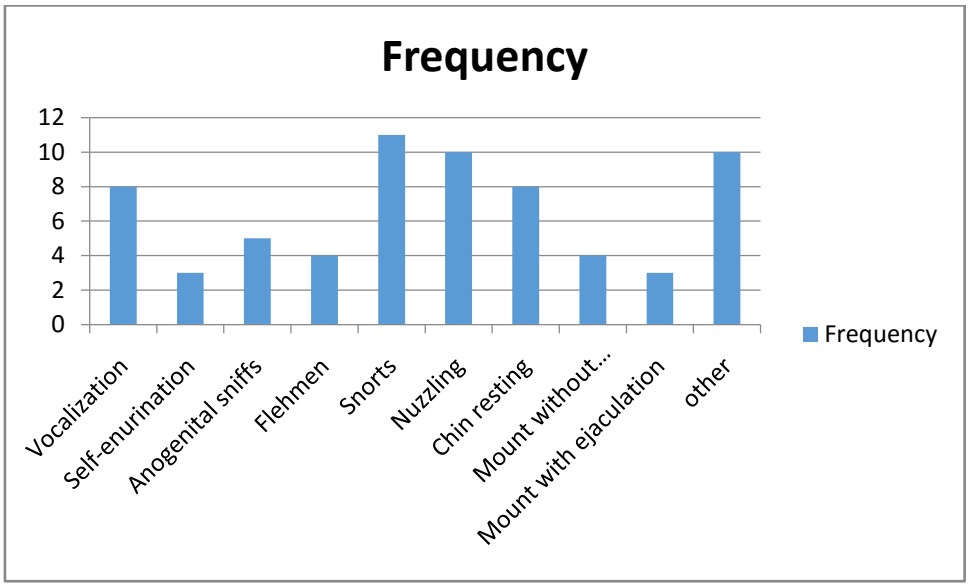

Fig. 1: Courtship Behavioral Frequencies of Red Sokoto Bucks Exposed to Two Oestrus Nulliparous Does

The time spent by buck on courtship behavior exposed to two oestrus nulliparous does were presented in figure 2. Non-courtship (other) behaviors was the highest times (10.52 minutes) by buck while the from the video recording, buck spent 6.36 minutes nuzzling, 6.26 minutes self-enurination, 4.50 minutes foreleg kicks, 4.19 minutes vocalization, 3.56 minutes chin resting, 3.15 minutes mounting with ejaculation, and 3.7 minutes anogenital sniffing. Buck spent less time displaying snorts (2.18 minutes), flehmen (2.17 minutes) and mounting without ejaculation (2.10 minutes).

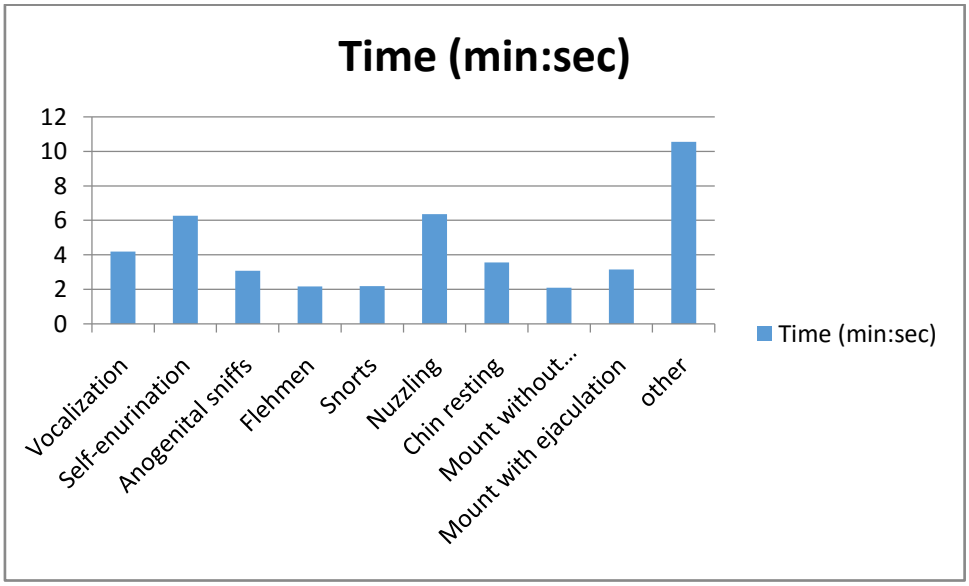

Fig. 2: Duration of Courtship behavior of Red Sokoto Buck Exposed to Two Estrous Nulliparous Does

DISCUSSION

The male domesticated goat (buck; *Capra hircus*) is popularly noted for his high libido and sexual vigor. Before mating, the male goat engages in several distinct behaviors that, as a whole, make up the courtship display (Longpre *et al.*, 2011). These behaviors include latency courting (vocalization, anogenital sniffing, nudging and flehmen) and copulatory (mounting and ejaculation) behaviors (Darwish and Mahboub, 2011). Vocalization, snorts, anogenital sniffing and flehmen are the first pre-

copulatory behaviors recorded in this study, were the buck begin by sniffing the doe`s vulva and urine. He then raises his head, extends his neck and raises his upper lip while moving his head from side to side. This is called the "Flehmen reaction". Snort and vocalization was probably a stimulator that will arouse the attention and likely induce osetrus of female goat. This agrees with the statement made by Vielma *et al.,* (2005) that buck vocalization may stimulate estrus in local anovulatory female goats during the anestrus period. From the research carried out by Delgachillo *et al.,* (2006) were one group of goats was joined with two sexually active bucks (SA groups, n= 6), the second group was exposed to buck vocalization (VOC group, n= 6) reproduced through a microphone-amplifier-loudspeaker system, the third group was isolated from any male stimulus (C group, n= 6). He concluded that those submitted to male vocalization displayed higher estrus than isolated group and similar estrus behavior with those exposed to sexually active male. He further suggests that male goat vocalization may induce estrus activity in anestrus female goats even though they do not seem to influence ovulation itself (Delgachillo *et al.,* 2006).

Flehmen and anogenital sniffing was the less pre-mating activity observed in this study which contradict Mondal *et al.,* (2005) study who reported that flehmen was the longest pre-mating activity in experienced buck. However, the flehmen and anogenital sniffings duration in this study are almost similar those reported by Kerketta *et al.,* (2013) who reported 2.18 minutes flehmen reaction and bucks treated groups with a sniffing time spent ranging from 3.44-3.58 minutes. Self-enuration behavior was observed both at the first introducing does to the breeding pen before and after copulation, this support the suggesting made by Price et al., (1986) that the self-enurination behavior is more likely to occur when the buck can view, but not breed an estrous. This may occur when the buck is separated from a female by a fence, or when the male is in the post-ejaculatory refractory period. It was also found that first contact and distance from the stimulus or the presence of another buck (especially when that buck is tending the female) increase the likelihood of self-enuration.
Buck displayed nuzzling behavior and spent more time to move and arrange the does in a comfortable and cozy position for mounting and these may be attributed to the mating inexperience nature of the does since they are nulliparous does. Similarly chin resting and mounting without ejaculation may be as a result of inexperienced nature of the does or complex interaction of buck`s internal and external environment. Because, Katz, (1987) reported that the sexual behavior of the male goat are dependent upon highly complex interaction between his internal and external environment. The buck`s external environment is comprised of his physical surroundings and social interactions. His physical environment is his surroundings, humidity, temperature, housing, topography e.t.c. His social environment is comprised of sexual, competitive, aggressive and communicative interactions with parents, siblings, other conspecifics, or animals of different species, including humans (Katz, 1987). The buck`s endocrine and nervous systems make up of his internal environment and also play a critical role in the activation of his sexual behaviors. It is, of course, both the buck`s internal and external environments that influence behaviors via highly complex interactions.
The result of this study revealed that high amount of time was spent by buck without displaying any courtship behavior, similar kerketta *et al.,* (2013) reported that the amount of time spent in standing without any activities was highest in a study with local Rottinkh goat bucks on mating behavior, libido score and semen biology.

CONCLUSION

The results showed that red Sokoto buck can be used intensively to evaluate courtship ethograms and serve as a tool that will provide holistic ideas and modern reproductive behaviors for better and clear understanding of the causes, its mechanism and complex interaction between the animals to both internal and external environments that influence such behaviors.

HAEMOGLOBIN AND MORPHOMETRIC POLYMORPHISM OF FOUR STRAINS OF DONKEY (*Equus asinus L.*) IN GAMAWA LOCAL GOVERNMENT AREA, BAUCHI STATE, NIGERIA.

Anene, M.G.; Mancha, Y.P.; Ibrahim, T. & Samaila, L. M.
Correspondence email: monoskilled4life@gmail.com ;Tel:+2348060888773
Department of Animal Production, Abubakar Tafawa Balewa University Bauchi, Bauchi State.

ABSTRACT
The study was conducted in 2018 (March to July). Blood samples and some morphometric characteristic of donkeys were taken in Gamawa Local Government Area (LGA) of Bauchi State, Nigeria. The aim was to describe the haemoglobin polymorphism and to characterize the genetic pool of four commonly kept strains (*Auraki*, *Duni*, *Fari* and *Idabari*) of donkeys in the study area. Eighty (80) matured donkeys were used for this research, comprising both sexes (39 males and 41 females), with 16 donkeys from each of five agro-ecological zones (Gamawa East and West, Udubo East and West and donkey market) of Gamawa. The red lysates were subjected to cellulose acetate electrophoresis and specific staining procedure to reveal the band patterns of the haemoglobin. The results revealed the presence of three genotypes (AA, AB and BB) with BB found only in *Fari* strain. The frequencies of A and B alleles were 0.925 and 0.075, respectively. The implication is that donkeys with AA genotype are more resistant to infections. Analysis of the morphometric measurements revealed that height at withers and neck circumference were significantly ($P<0.01$) correlated (0.514). Negatively lower correlation (-0.224) was significantly ($P<0.05$) found between lengths of ear and tail. Body length and neck measurements were significantly ($P<0.01$) Correlated (0.324 to 0.497). It could be concluded that, donkeys in Gamawa LGA of Bauchi State with A gene (*Auraki*, *Duni* and *Idabari*) can be selected for resistance and performance. Further study could be undertaken to evaluate the effects of genotypes on the productivity.
Keywords: Donkey, Haemoglobin, Polymorphism and Morphometric

INTRODUCTION
Donkeys are valued for their ability to survive under harsh conditions (Blench, 1990), yet they are often regarded as animals of low social status and neglected by research (Starkey, 1995). Nigeria is estimated to have about 800,000 heads of donkey (Mabayoje and Ademiluyu, 2014). Mainlyconcentrated in the North where they are used as pack animals (RIM, 1992). In south eastern Nigeria, donkeys are used as meat animals and about 16,000 donkeys are transported annually from the northern states for this purpose and these has become a major threat to donkey population (Blench, 2014). However, there are needs to conserve the existing population to avoid exilement. To this, haemoglobin is an important erythrocyte protein inherited by co-dominance in Mendelian fashion and has been reported to be a useful marker through which many economic traits (Akinyemi and Salako, 2010).

The genetically determined system of haemoglobin polymorphous in donkey provides an opportunities for using them as genetic markers that make it possible to conduct studies related to the genetic structure (Slavov *et al.*, 2004). Although these genetic markers and their mode of inheritance were clarified in most animals, information on donkeys are rather limited. This this, the study aimed to determine the haemoglobin and morphometric polymorphism of four Nigeria indigenous strains of donkeys in Gamawa Local Government Area of Bauchi State.

METHODOLOGY
Study Area
This research study was conducted in Gamawa Local government Area of Bauchi State, Nigeria (North Eastern Nigeria) bordering Yobe State to the East and Jigawa State to the west. It lies between latitude 12.13^0N, longitude 10.54^0E of the equator and 397 meters elevation above the sea level (Maps view, 2018). It has an area of 2,925km^2 and has a population of 286,388 as at 2006 census. The annual rainfall ranges between 700mm to 1600mm which start in May and ends in October. The rainy season months are from July to September and the dry season commence fully in November and end in April. The relative humidity ranges between 20- 30 % and the mean monthly temperature ranges between 26^0C to 39^0C (BSADP, 2017).

Research Animals

The animals used for this study were obtained from several small donkey holder flocks especially four strains predominant to the dry climates of the north. A total of eighty (80) animals, twenty (20) per strain – *Auraki*, *Duni*, *Fari* and *Idabari* were used. Sampled animals from these four strain comprised both sexeswithin breeding age group. Donkey management in the study area is dominated by semi extensive production system, in which donkeys are allowed to graze freely during the day time and kept on open enclosure during the night.

Data Collection

Blood collection

5ml of blood was collected from each of the sampled animals by jugular vein puncture using needle and syringe and put into sample bottles containing Ethylene Diamine Tetra Acetic acid (EDTA) as anticoagulant, properly labelled with respect to the different strains and sex and preserved in a cooler containing ice blocks from where they were transported to immaculate medical laboratory in Minna, Niger State for analyses.

Morphometric measurements

Flexible measuring tape was used to take the body measurement. During body measurement, animals were made to stand upright and restrained by assistants in such a way that their necks, heads and ears were stretched almost in a straight line. Each measurement was taken for at least two times and recorded to the nearest centimetre. Reference marks for body measurement according to the method of Salako (2006a) were adapted.

Head Length (HL), Ear length (EL), Neck length (NL), Neck circumference (NC), Height at Wither (HW), Body length (BL) and Tail length (TL) as defined by Salako (2006a)

Laboratory Analysis of Blood Collected

Blood Preparation

The blood samples were then washed with normal saline and haemolysed with distilled water to release the haemoglobin. The supernatant was removed after centrifuging at 3000 rpm for 5 min and the sample haemoglobin stored at refrigeration temperature pending electrophoresis.

Electrophoresis

The red cell lysate was impregnated on a cellulose acetate paper with a control, placed on the electrophoresis tank using forceps and subjected to electrophoresis according to the standard. The strips were run for 5 minutes at a constant voltage of 250v until a clear separation was observed. Interpretations were made based on the relative mobility of the haemoglobin bands towards the anode. The resulting electrophoregram showed haemoglobin bands distinct movement toward anodic end of the electrophoretogram (Boyers and Hinner, 1963).The genotype migrated was labelled as described by Boyers and Hinner (1963).

Statistical Analysis

Since only two alleles (A and B) were detected; then, haemoglobin genotype and gene frequencies were estimated as follows:

$$\text{Genotype frequency AA} = \frac{\text{No of individuals with AA}}{\text{No of idividuals sampled}} \text{ X } 100$$

$$\text{Genotype frequency AB} = \frac{\text{No of individuals with AB}}{\text{No of idividuals sampled}} \text{ X } 100$$

$$\text{Genotype frequency BB} = \frac{\text{No of individuals with BB}}{\text{No of idividuals sampled}} \text{ X } 100$$

Genotype frequency was estimated with respect to breeds and sex sampled. For the estimation of Gene frequency, the equation was adopted as thus;

P = (2NAA + NAB) / 2N and

Q = (2NBB + NAB) / 2N

Data collected for morphometric traits were subjected to Special Package for Social Science (SPSS 21.0), according to the method of Steel and Torrie (1980). The difference between the means were separated using Duncan Multipe range test (DMRT).

RESULTS AND DISCUSSION

Table 1: Distribution of haemoglobin types on strains and between sex of donkeys in Gamawa

Strain	N	Sex	N	AA	AB	BB
Auraki	20	Male	15	15	0	0
		Female	5	4	1	0
		Total	20	19	1	0
Duni	20	Male	8	7	1	0
		Female	12	10	2	0
		Total	20	17	3	0
Fari	20	Male	6	5	0	1
		Female	14	12	1	1
		Total	20	17	1	2
Idabari	20	Male	10	9	1	0
		Female	10	8	2	0
		Total	20	17	3	0

HL = Head Length EL = Ear Length, NL = Neck Length, NC= Neck Circumference,
HW =Height at Wither, BL = Body Length, HG = Heart Girth and TL = Tail Length
SEM: Standard error of means
abc: means with different superscript in row are significantly different (P<0.01; 0.05)
P-value: Probability level of significant.

Distribution of haemoglobin types on strains and between sex of donkey found in Gamawa Area of Bauchi State are shown in Table 1. Three haemoglobin genotypes were detected; two homozygotes (AA and BB) and one heterozygous (AB) which corresponds to the general observation of A and B alleles with their corresponding genotypes AA, AB and BB in different species (Tunon *et al*., 1989). Out of 20 from each strains, *Auraki* sampled had 19 AA Hb (15 males and 4 females), 1 AB Hb (1 female) and no BB Hb type was present. *Duni* had 17 AA Hb (7 males and 10 females), 3 AB Hb (1 male and 2 females) and no BB Hb type. *Fari* strain had 17 AA Hb (5 males and 12 females), 1 AB Hb (I female) and 2 BB Hb (1 male and I female) and *Idabari* strain had 17 AA Hb (9 males and 8 females), 3 AB Hb (2 males and 3 females) and no BB Hb type was present.

The presence of homozygote Hb BB genotypes of donkey disagreed with Salvaggi *et al.* (2015) who observed one haemoglobin types in Martina Franca donkeys and concluded that, it might not be readily apparent or is not widely distributed. Pearson and Ouassat (1996) believed that, the specific conditions of the African continent enabled donkeys to develop a typical habit thereby causing a change in its genotypes to enable them play key roles in order to survive in dry locations. Therefore, the predominant of Hb AA over Hb AB and Hb BB types among the four strains of donkey could be attributed to donkey adaptive feature for survival and genetic resistance to diseases as reported by (Wold *et al*., 2004). Donkeys appear to be less susceptible to a number of pathological conditions and diseases affecting horses and cattle. Similar report was documented by (Meutchieye *et al*., 2014).

Auraki strain had the highest genotypes frequency for AA with 95 %. *Duni*, *Fari* and *Idabari* had the same genotype frequencies of 85 % for AA. AB genotypes for the four strains showed that, *Duni* and *Idabari* had the highest genotypic frequency of 15 %, followed by *Auraki* and *Fari* with 5 %. BB genotypic frequency was not visible in *Auraki*, *Duni*, and *Idabari* but visible only on *Fari* strain with genotypic frequency of 10 %. The genotypic frequencies polled (all together) of the four strains of donkey were 87.5, 10 and 2.5 % for AA, AB and BB genotypes, respectively.

The gene frequencies A and B alleles among the four strains of donkey showed that, *Auraki* had the highest frequency (0.975) while Fari had the lowest (0.875) frequency of the A Allele. However, *Fari* had the highest gene frequency (0.125) while *Auraki* has the lowest (0.025) gene frequency of the B Allele. More so, they all obeyed Hardy Weinberg's equilibrium (P + Q = 1). Gene frequency of A allele on sex were higher on males (0.949) compared to females (0.902). More so, the B allele were higher in females frequencies (0.098) compared to males (0.051). There is not enough reason however, to conclude that sex has an effect on the disparity in B types.

Differences in the on strains among the qualitative traits of donkeys such as HL, NL, HG and BL could be attributed to genetic variations among the donkey strains. The study agreed with Ellis *et al*. (1994) who reported that, other body dimensions of the Zimbabwean donkeys as well as live weight indicated no major difference between male and female donkeys of similar maturity. However, there were no significant differences between EL, NC, SW, HW and TL in adult donkeys; this implied that, those donkeys were somewhat similar to Nigeria donkeys.

CONCLUSIONS

Gamawa donkeys haemoglobin polymorphism is defined by expression of three genotypes: two homozygotes (Hb AA and Hb BB) and one heterozygote (Hb AB). The phenotypization of the haemoglobin variants is determined by two co-dominant alleles, Hb A and Hb B. The allele Hb A registers a higher frequency than Hb B allele. Consequently, in the haemoglobin tables, the homozygotes Hb AA reaches a high incidence, the heterozygotes Hb AB have a middling frequency and the homozygotes Hb BB were less present. Finally, it could be suggested that the Hb AA type evident in the *Auraki* donkeys having the highest altitude, Gamawa local Government Area of Bauchi State, donkeys were favoured by natural selection, possibly for resistance against certain parasitic (internal and external) and some Haemo-parasitic infections.

The adult body size measurements of donkeys in Gamawa, Bauchi state Nigeria were head length (46.92cm), ear length (25.40cm), neck length (44.09cm), neck circumference (63,36cm), height at withers (104.89cm), heart girth (111.90cm), body length (107.21cm), and tail length (57.04cm).

There were some variations in the morphometric traits of the donkeys due to strain effects of which *Duni* donkey strain having the highest body length and heart girth compared with other strains.

The results of the study is however, subjected to some limitations being that the sample size for the analysis was rather too small and this is due to financial, constraints of the farmer not allow one to get access to the animals due to traditional believes, time as well as animal resources encountered during the course of this study.

RECOMMENDATIONS

The Hb type AA was predominant on the four breeds of donkey which then mean adaption in favour for hot tropical weather and tolerance to ticks and helminthic infections; in other words, hot tropical regions, farmers are therefore encouraged to take advantage of donkey production, since they highly resistance to various diseases compared to cattle and horse. More so, head length, neck length, heart girth and body length could be used in classifying donkeys into strains. Further studies could be carried out to evaluate the effect of genotype on their productivity.

ABSTRACT

A study was therefore carried out to assess the range of variation, within the various pigeon population in Bauchi metropolis, to ascertain the number of strains available. The data utilized from this study where generated from 58 household in Bauchi metropolises, Nigeria, between July 2016 and April 2017. Data on local names of the various strains and morphological parameters were collected. The morphological parameters measured included; Live weight (LW), breast Girth (BG), Body length (BL), shank length (SL), wing Span (WS) and Tail length (TL). Live weight was measured using an electronic weighing scale while the other body measurements were done with a measuring tape. All data collected on body measurements subjected to analysis of variance using the general linear model of IBM SPSS version 20.0 and where means differed Duncan Multiple Range Test was used to separate them. The study identified 22 unique strains of pigeons within Bauchi metropolis. Overall mean live weight of all pigeon strains was found to be 553.48g. The heaviest was the Mondain with an average LW of 1002.2g and while the Na gida strain had the least LW of 267.17g. Breast girth was also highest for the Mondain while the shantu fara had the smallest. However, the Romanian deck nail and the poulter ($p<0.05$) had the longest body. The males were heavier and had broader breast girth and longer body length than the females. Shank length was similar for all the strains. It was concluded that there is potential for future selection and breeding for intensive squab production.

INTRODUCTION

Pigeon farming is gaining popularity in the developing countries due to its ability to serve as a cheaper source of animal protein, thereby improving nutritional stability in the society. It also has the potential to enhance economic empowerment. Pigeon, apart from being extensively used for scientific research notably in genetics, parasitology, physiology and psychology, its meat has a gamy bird taste (Fajemilehin, 2017).

Apart from body weight, a number of conformity traits are known to be good indicators of body growth and market value of poultry (Ukwu *et al.,* 2014). Poultry breeders have tried to establish the relationship that exists between body weight and body linear measurements such as shank length, thigh length, keel length, body length, chest circumference and wing length. The relationships between these traits provide useful information on the performance and carcass value of the animals. The relationship between body weight and body linear measurements is important for selection in breeding programs for genetic improvement of the breed (Dzungwe *et al.,* 2018).

Over the years little attempt has been made to capture the variability in pigeons population within Bauchi metropolis. This has retarded breeding efforts as information on their potentials is lacking. This study was therefore carried out to assess the range of variation, within the various pigeon population in Bauchi metropolis, to ascertain the number of strains available.

MATERIALS AND METHODS

Bauchi State is located between latitudes 9° 3′ and 12° 3′ north and between longitudes 8°50' and 11° East of the equator with a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass. Rainy season starts between April and May and last up till October, while dry season commences in November and ends in March. The mean annual rainfall ranges from 800 to 1094mm, while the mean daily maximum temperature is about 33.5^0c. (IAR/BSADP, 1996)

The data utilized from this study where generated from 58 household in Bauchi metropolises, Nigeria, between July 2016 and April 2017. Matured pigeons were used for the study. The matured pigeons of breeding age where housed by the farmers in wooden or metallic cages or empty carton attached

externally to walls (open house type) with compartment of about 35 by 35cm usually in monogamous pairs. Supplementary feed where provided consisted of mixture of grains varying from millet, sorghum, and crushed maize to kitchen scraps once or twice a day, in some cases were highly priced birds are kept, they are fed chick mash.

Data on local names of the various strains and morphological parameters were collected. The morphological parameters measured included; Live weight (LW), breast Girth (BG), Body length (BL), shank length (SL), wing Span (WS) and Tail length (TL). Live weight was measured using an electronic weighing scale while the other body measurements were done with a measuring tape.

All data collected on body measurements subjected to analysis of variance using the general linear model of IBM SPSS version 20.0 and where means differed Duncan Multiple Range Test was used to separate them.

RESULTS AND DISCUSSION

Plates 1 to 22 shows the different strains of pigeons found within Bauchi Metropolis indicating a wide variation in the strains available. The study identified 22 unique strains of pigeons within Bauchi metropolis. Apart from the Na gida strain which is used for meat all the other strains were basically kept as ornamental birds. Table 1 show a summary of body measurements of the different strains. Overall mean live weight of all pigeon strains was found to be 553.48g which was higher than the average body weight of 283.32±1.43 g reported by Fajemilehin, (2017) but similar to the 340 - 680 g repored by NRC (1991). The heaviest was the Mondain with an average LW of 1002.2g and while the Na gida strain had the least LW of 267.17g. Breast girth was also highest for the Mondain while the shantu fara had the smallest. However, the Romanian deck nail and the poulter ($p<0.05$) had the longest body. A clear sexual dimorphism was noted; the males were heavier and had broader breast girth and longer body length than the females. The body length depicts bone growth while chest girth describes the muscularity of the birds (Fajemilehin, 2017). Shank length was similar for all the strains. The Romanian deck nail also had the widest ($p<0.05$) wing span. The Russia and England fan tail had the longest ($p<0.05$) tail length.

CONCLUSION

Twenty two distinct strains of pigeons were identified within Bauchi Metropolis, with this wide variation in biodiversity, there is potential for future selection and breeding for intensive squab production. Sexual dimorphism was also noted in the pigeon population with the males being heavier than the females. Further studies on molecular characterization and reproductive potentials of the pigeon population can be done.

ABSTRACT:
Animal feeds are potential reservoirs for cross contamination of microorganisms. This can lead to health concerns in animals as well as humans that consume the products. This study was conducted to analyze the microbial load in five selected broiler super starter feeds within Jos North LGA of Plateau State. Results obtained showed microbial contamination of all feed samples. Total plate count ranged from 0.88 to 1.28×10^5 CFU/g, coliform count ranged from 1.40 to 3.20×10^4 CFU/g, and fungal count 0.08 to 2.90×10^5 CFU/g. Bacteria species isolated from the feed samples were *Streptococcus feacalis, Proteus spp., Staphylococcus aureus, Pseudomonas aeruginosa* and *Salmonella paratyphi.* The presence of these pathogenic microorganisms in poultry feeds is indicative of the level of contamination. The study concluded that periodic examination of poultry feeds for biosafety can reduce or prevent cross contamination of poultry products.

Keywords: Microorganisms; poultry; feed; contamination; broiler

INTRODUCTION

Feed represents a major aspect of poultry production required for maintenance and productivity (Isiaku, 2015). Poultry feeds are contaminated during processing, handling, mixing and exposure to microorganisms. Onyeze *et al.* (2013) asserted that most poultry diseases occur as a result of consumption of contaminated feeds. Diseases such as dysentery, fowl cholera, *samonellosis*, *staphylococcosis*, *aflatoxicosis* amongst others are associated with ingestion of contaminated feeds (Aliyu *et al.*, 2016).

Irrespective of the adequacy of nutrients in formulated rations, microbial contamination can result in competition for ingested nutrients in the GIT, leading to poor performance (Idachaba, 2017). According to Aliyu *et al.* (2016), microorganisms also degrade nutritional value of feeds resulting in the production of toxins. The nature and presence of microorganisms in animal feeds should be a major concern to animal nutritionists and poultry farmers because they cause economic losses and affect animal health. Hence, this study focus on microbiological evaluation of selected commercial broiler super starter feeds in Jos North LGA of Plateau state.

MATERIALS AND METHODS

Area of Study

The study was carried out in Jos North LGA of Plateau State. It is located in Northern Guinea Savannah between longitude 8° 20'N and latitude 9° 30'E. The average temperature ranges between 21-25°C. The climate of Jos is cool due to its high altitude with average annual rainfall of 1,250 mm (Federal College of Forestry, 2017)

Sample collection

Five brands of broiler super starter feeds were purchased from retailers in Jos North LGA of Plateau State. Each feed sample was aseptically collected in triplicate in sterile plastic bags and labelled A, B, C, D and E.

Sample analysis
The feed samples were taken for analysis at the Microbiology Laboratory, Department of Microbiology, Faculty of Natural Science, University of Jos. They were cultured and isolated for bacteria species and fungal counts according to procedures described by Ochei and kolhatkar (2007).

Data analysis
Data obtained from microbial colony count was subjected to statistical analysis using the General Linear Model (GLM) procedure of SAS (2001) software for analysis of variance. Duncan multiple range test (Duncan, 1955) was used to determine differences between means.

RESULTS AND DISCUSSIONS

Microbial colony count in five (5) commercial broiler super starter feeds
Table 1 shows the microbial colony count in five (5) commercial broiler super starter feeds. All feed samples were contaminated by bacteria and fungi. Feed A showed significantly (P<0.05) lower total plate count compared to others while the highest was observed in feed sample B. Feed C showed significantly (P<0.05) lower coliform count compared to others while feed B showed the highest. Okgun *et al*. (2016) reported that broiler starter and chick mash feeds are easily contaminated by microorganisms. This according to the authors is due to their high protein contents which serve as growth factors for contaminating organisms. Uwaezuoke and Ogbulie reported that bacteria and fungi contamination of poultry feeds can result from exposure to microorganisms on field, in feed mills, during storage or poor sanitary practices in pens.

Table 1: Microbial colony count in five commercial broiler super starter feeds

Microbial count (CFU/g)	FEEDS					
	A	B	C	D	E	SEM
Total plate count (10^5)	0.88^a	1.28^d	1.11^c	1.05^b	1.12^c	0.01
Coliform count (10^4)	2.60^d	3.20^e	1.40^a	1.60^b	1.90^c	0.06
Fungal count (10^5)	0.08^a	1.21^c	2.90^d	1.00^b	1.16^c	0.03

abc = means with different superscript on the same row differs significantly, SEM- standard error of means, and CFU- coliform forming unit.

Culture media and biochemical tests for isolated bacteria species in five broiler super starter feeds
Table 2 shows the culture media and biochemical tests for isolated bacteria species in five broiler super starter feeds. Bacteria isolates of *Proteus sp.* was found in all feed samples and *Pseudomonas sp.* in feed samples A, B and D. This agree with reports of Anon (2001) and Veldman *et al*. (1995) who stated that enterobacteriaceae are common contaminants of poultry feeds. All feed samples were contaminated by *Staphylococcus aureus* while feed samples A, B and E were contaminated by *Salmonella sp.* Idachaba (2017) reported that *Staphylococcus aureus* and *Salmonella sp.* can cause acute or chronic infections in poultry and other animals. The author further stressed that microorganisms from poultry feeds can attach to intestinal epithelium, thus competing with host animals for ingested nutrients.

Table 2: Culture media and biochemical tests for isolated bacteria species in poultry feed samples.

							Triple sugar ion agar slant				
Feeds	Catalase	Coagulase	Urease	Indole	Oxidase	Motility	Slope	Butt	H_2S	Gas	Bacteria species
A	+	+	+	-	+	+	Red	Yellow	+	+	*Staphylococcus aureus, Proteus spp., Pseudomonas aeruginosa, Salmonela typhi.*
B	+	-	+	-	-	+	Red	Yellow	+	+	*Streptococcus feacalis, Proteus spp., Staphylococcus aureus, Pseudomonas aeruginosa, Salmonela paratyphi A.*
C	+	+	+	-	-	+	Red	Yellow	-	+	*Staphylococcus aureus, Proteus spp.*
D	+	+	+	-	+	+	Red	Yellow	-	-	*Staphylococcus aureus, Proteus spp., Pseudomonas aeruginosa.*
E	+	+	+	-	-	+	Red	Yellow	+	+	*Staphylococcus aureus, Proteus spp., Salmonela typhi.*

CONCLUSION

The study showed that all feed samples were contaminated by microorganisms (bacteria and fungi). This may be due to poor handling and storage practices of the feeds from field to the retail shops. Ingestion of such contaminated feeds can affect productive performance in chickens with residual effects affecting humans where meat is improperly cooked. The study concludes that there is a need to establish better quality control strategies for proper handling of feeds at retail shops and on-farm. Periodic examination of feeds for biosafety can reduce or prevent cross contamination of poultry products.

[2]Department of Animal Health and Production, University of Nigeria, Nsukka

ABSTRACT
The study was done to assess the dose response and ameliorative effects of resveratrol on trypanosomosis induced testicular changes in diminazene aceturate (DA) treated *Trypanosoma brucei* infected male dogs. Thirty male dogs were used for the study and were assigned into six groups (n=5). Group A was infected with *T. brucei*, not treated with (DA) and not supplemented with resveratrol. Group B was presupplemented with resveratrol (50 mg/kg) for 7 days, Infected with *T. brucei* and treated with DA (7 mg/kg). Group C was presupplemented with resveratrol (100 mg/kg) for 7 days, infected with *T. brucei* and treated with DA (7 mg/kg). Group D was presupplemented with resveratrol (200 mg/kg) for 7 days, infected with *T. brucei* and treated with DA (7 mg/kg). Groups B, C and D were postsupplemented with 50, 100 and 200 mg/kg of resveratrol for 14 days respectively. Group E was infected with *T. brucei* and treated with DA (7 mg/kg). Group F was the control
There were significant decreases ($p<0.05$) in the parasitaemia level and rectal temperature of dogs in group C when compared to other supplemented groups. There were significant increases ($p<0.05$) testosterone level, testicular weight and epididymal sperm reserve of dogs in group C when compared to other supplemented groups, DA alone and the infected untreated group.
In conclusion, this study indicated that resveratrol at the dose of 100 mg/kg may constitute a promising compound for the amelioration of male reproductive toxicity in DA treated *Trypanosoma* infected male dogs.
Keywords: Trypanosomosis, reproduction, diminazene aceturate, resveratrol

INTRODUCTION
Trypanosomosis is a protozoan disease caused by pathogenic blood parasites known as trypanosomes of the genus *Trypanosoma*. It is transmitted by tsetse flies of the genus *Glossina*. The disease is unique to Africa, affecting both human (human African trypanosomosis or sleeping sickness) and animals (animal African trypanosomosis or Nagana) (Radostits *et al*., 2007). The main species of importance in livestock are *T.vivax, T. Congolense* and to a lesser extent *T. brucei* causing Animal African Trypanosomosis (AAT) (Steverding, 2008).

Its common clinical manifestations are weight loss, anaemia, anorexia, lethargy, weakness and dullness. It has been reported that trypanosomosis causes severe reproductive disorders characterized by decrease in testosterone level and testicular degeneration in males (Sekoni *et al*., 2004; Raheem *et al*., 2009). Oxidative stress induced by trypanosome is the major cause of testicular damage in trypanosomosis, due to the overproduction of reactive oxygen species (Adamu *et al*., 2006; Steverding, 2008).
Resveratrol is a natural polyphenol found in nuts, grapes and red wine (Siemann and Creasy, 1992). It is known for its anti-inflammatory, antioxidant, analgesic, cardioprotective, anti-aging and neuroprotective roles (Giovannimi *et al*., 2001; Sinha *et al*., 2002; Bradamante *et al*., 2004). Valenzano *et al*., 2006 reported that resveratrol is able to decrease germ cell apoptosis in mice and rats.

MATERIALS AND METHODS
Trans-resveratrol of analytical grade was obtained from Candlewood Stars Incorporated, Danbury, USA and carboxymethylcellulose was obtained from the Department of Veterinary Physiology and Pharmacology, Faculty of Veterinary Medicine, University of Nigeria, Nsukka. Trans-resveratrol, due to its low solubility in water, was suspended in 10 g/L carboxymethylcellulose.

Trypanosome brucei was isolated from a dog with natural infection presented to Veterinary Teaching Hospital, University of Nigeria, Nsukka and experimental animals were infected intraperitoneally at a dose of 1.5×10^6 trypanosomes per milliliter of saline diluted infected blood.

Experimental design

Thirty male dogs were used for the study and were assigned into six groups (n=5). Group A was infected with *T. brucei*, not treated with (DA) and not supplemented with resveratrol. Group B was presupplemented with resveratrol (50 mg/kg) for 7 days, Infected with *T. brucei* and treated with DA (7 mg/kg). Group C was presupplemented with resveratrol (100 mg/kg) for 7 days, infected with *T. brucei* and treated with DA (7 mg/kg). Group D was presupplemented with resveratrol (200 mg/kg) for 7 days, infected with *T. brucei* and treated with DA (7 mg/kg). Groups B, C and D were postsupplemented with 50, 100 and 200 mg/kg of resveratrol for 14 days respectively. Group E was infected with *T. brucei* and treated with DA (7 mg/kg). Group F was the control

Determination of parameters

Parasitaemia was monitored using the wet mount method daily after infection, daily after establishment, daily after treatment for clearance and weekly post clearance up to 10 weeks for relapse. The numbers of infective trypanosomes were determined using the rapid matching method of Herbert and Lumsden (1976). Rectal temperature was determined using a digital clinical thermometer. Enzyme Linked Immunosorbent Assay Test Kit (Monobind Inc., Lake Forest, CA 92630, USA) was used for the determination of serum testosterone levels according to the method of (Dorfman and Shipley, 1956). The dogs were orchiectomized and lignocaine was the local anaesthetic used (2 mg/kg). The testicles from each dog were carefully dissected out, trimmed free of extraneous tissues and weighed with a weighing balance. Epididymal sperm reserve was determined using the haemocytometer method described by Amann, 1986.

RESULTS AND DISCUSSION

The significant decrease ($p < 0.05$) in the parasitaemia level of dogs supplemented with 100 mg/kg of resveratrol when compared to those supplemented with 50 mg/kg, 200 mg/kg and the infected unsupplemented groups suggests that resveratrol at the dose of 100 mg/kg has optimum protective effect against early establishment of trypanosomosis

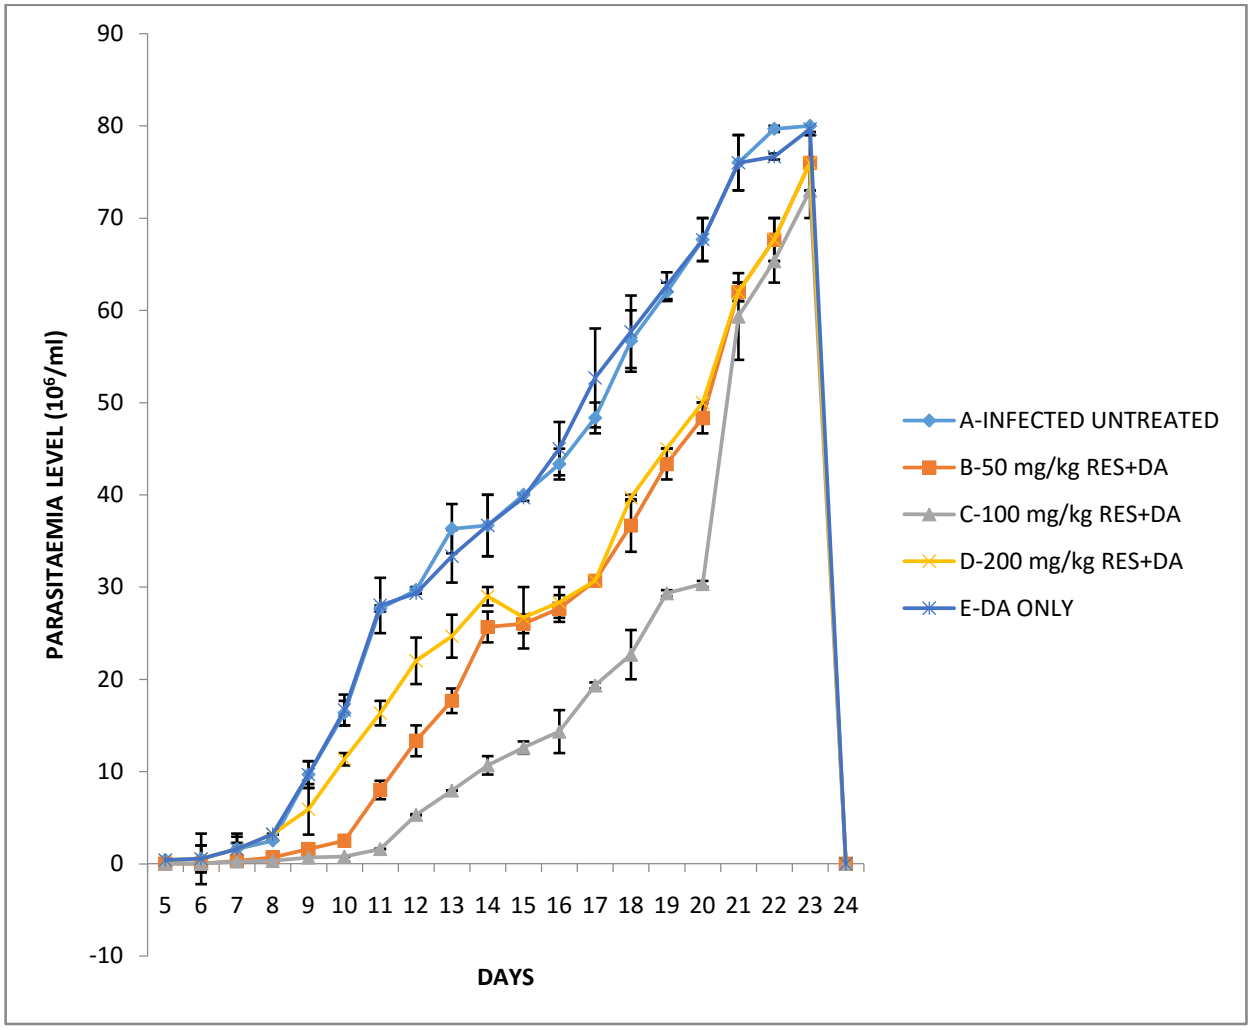

Figure 1: Effects of graded doses of resveratrol on parasitaemia levels of *T. brucei* infected male dogs
Key: RES – resveratrol, DA – diminazene aceturate

The significant increase ($p < 0.05$) in testosterone levels of dogs supplemented with 100 mg/kg of resveratrol when compared to those supplemented with 50 mg/kg, 200 mg/kg and the infected unsupplemented groups (Figure 2) may be that 100 mg/kg of resveratrol had a stimulatory effect on the secretion of gonadotrophins, the major endocrine regulators of spermatogenesis. The concentrations of FSH, which acts within the tubules to stimulate spermatogenesis, and LH, which signals the production of testosterone in Leydig cells have been reported to be enhanced by resveratrol (Juan *et al*., 2005)

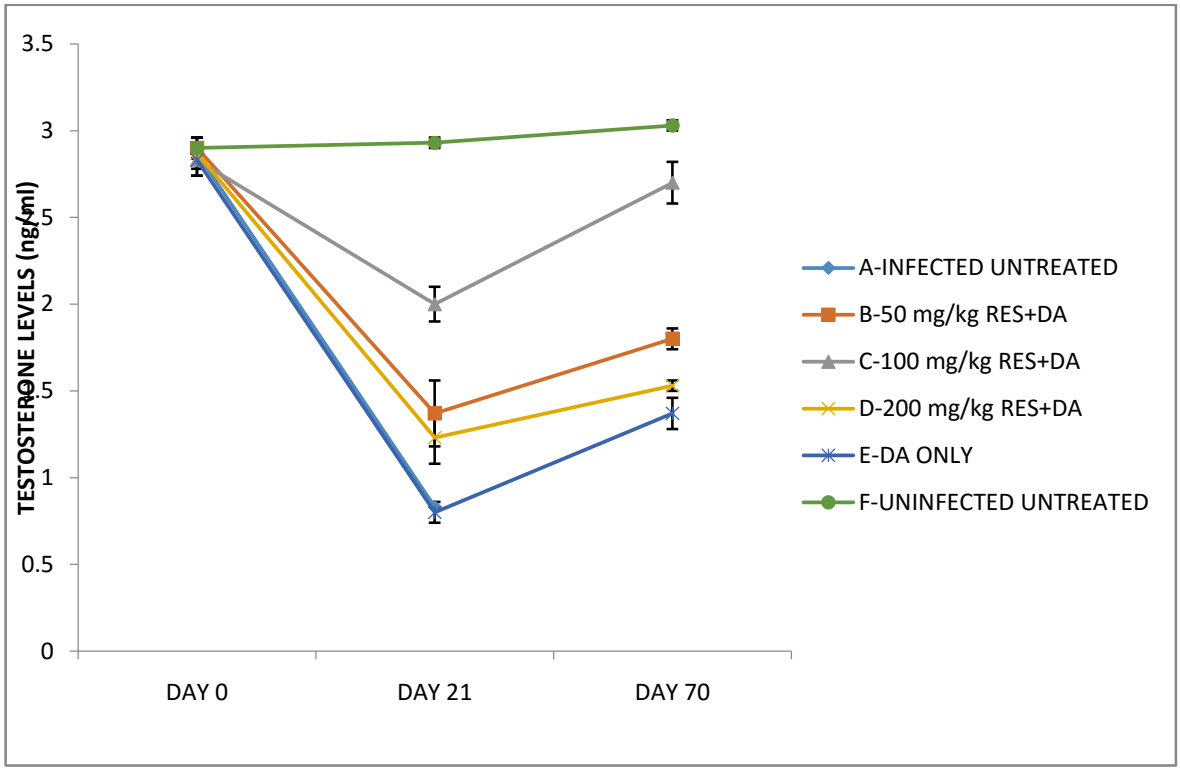

Figure 2: Effects of graded doses of resveratrol on testosterone levels of *T. brucei* infected male dogs
Key: RES – resveratrol, DA – diminazene aceturate

The significant increases ($p < 0.05$) in testicular weight and epididymal sperm reserve of dogs supplemented with 100 mg/kg of resveratrol and treated with DA when compared to those supplemented with 50 mg/kg and treated with DA, 200 mg/kg and treated with DA, treated with DA alone and the infected untreated (Table 1) may be due to significant increase in the testosterone level of 100 mg/kg supplemented group. It may also be due to antioxidant activity of resveratrol (Giovannimi *et al.*, 2001). Oxidative stress induced by trypanosome is the major cause of testicular damage in trypanosomosis, due to the overproduction of reactive oxygen species (Adamu *et al.*, 2006; Steverding, 2008; Losos and Ikede, 2012).

Resveratrol at the dose of 200 mg/kg produced negative effects in all the parameters determined which may be as a result of overdose. Resveratrol is an antioxidant and antioxidants at high concentrations have the opposite effect and act as pro-oxidants (Ramadori *et al.*, 2009; Minikawa *et al.*, 2011).
In conclusion, the findings from this study indicated that resveratrol, a phytochemical at the dose of 100 mg/kg may constitute a promising new compound for the amelioration of male reproductive toxicity in diminazene aceturate treated *Trypanosoma* infected dogs.

Table 1: Effects of resveratrol and DA on testicular weight and epididymal sperm reserve of *T.brucei* infected male dogs

Parameters	**Groups**					
	A-Infected untreated	B-50 mg/kg RESV+DA	C-100 mg/kg RESV+DA	D-200 mg/kg RESV+DA	E-DA only	F-Uninfected untreated
Testicular weight (g)	2.87 ± 0.06^{a}	3.26 ± 0.06^{b}	4.16 ± 0.13^{c}	3.06 ± 0.04^{b}	3.14 ± 0.12^{b}	3.34 ± 0.06^{c}
Epididymal sperm reserve (10^6/ml)	44.61 ± 3.17^{a}	122.59 ± 2.79^{b}	216.97 ± 8.91^{c}	100.61 ± 5.77^{d}	97.89 ± 4.05^{d}	221.93 ± 7.18^{c}

a, b, c, d - Different supercripts indicating difference between the mean ($p < 0.05$)

RECOMMENDATIONS

The findings from this study, encourages the use of moderate quantity of natural food stuff rich in resveratrol in preparing dog food.

ABSTRACT

This study was conducted in Kibiya Local Government Area to assess the incidence of high slaughter of small ruminant on moribund stage especially during the early set of rainfall. Data were gathered from 100 livestock's farmers, 54 Butchers and 45 veterinary personnel through the use of structured questionnaires and visual inspection record. Majority of livestock respondents were males (92%) and married (52%) with age range of 40-60 years (67%). About 48% of the respondents were keeping animals 0-5 years, with 50% mixed flock of sheep and goats; 35% goats only and 15% sheep only. The breeds kept were Red Sokoto goats (49%) and Yankasa sheep (50%). Extensive system of management was more popular and practiced (51%). The slaughter of small ruminant on moribundity/already slaughtered was more frequent (66%) and increased during raining season (June). the number of goats slaughtered (499) were twice the number of sheep (250) slaughtered, thus indicated that goats were more frequently slaughtered during the season. Among the reasons for slaughtered were either for lack of feedstuff, urgent need or selling at will. While others were slaughtered as a result of diseases and health related issues. Mostly postmortem was not done on slaughtered animals, thus is a potential health risk to meat consumers in the area of study. Therefore, farmers are advised to preserve crop residues that can be fed at late dry season; regular postmortem and meat inspection should be performed. It is recommended that appropriate extension services, government, livestock scientists and veterinary workers be put in place the awareness of economic benefits of small ruminant production and meat hygiene for safety of consumers.

Key words: Small ruminants; Moribundity; Postmortem; Slaughter; Rainy season

INTRODUCTION

Small ruminants, sheep and goat production is an important economic activity in Africa and are among major source of animal protein in Nigeria. It was reported that Nigeria has a livestock population of 24 million goats and 13.6 million sheep (Lawal-Adebowale, 2012). They are distributed all over Nigeria, for their ability to adopt to varieties of environmental conditions. Their rearing is an important occupation for the rural people especially less privileged communities and it is profitable venture for the resources, provided and are able to sustain them on spare vegetation unsuitable for feeding to other livestock (Ajala *et al.,* 1995). The production is characterized by extensive system of management and low productivity (Otchere *et.al.,* 1986). Therefore, improve in small ruminant is likely to improve the well-being of small holder farmers. The socio economic important of small ruminants in rural communities of Nigeria among others includes usage as a sources of ready cash and meat for house hold consumption, means of exchange for ready labour and usage during ceremonies festivities, religious rites have long been recognized. It is observed that there is annual occurrence of high slaughter of small ruminant on moribund stage at early set of raining season in Kibiya Local Government, which is a potential health risk to meat consumers the area. Therefore, this study was aimed to assess and identify root of the problem and offer possible solutions as it's continued will have direct effect on meat consumers and will cause huge economic losses in small ruminant production.

Materials and method

Study area

The research was conducted at Kibiya local government area of Kano state. It is located at the south-east part of the state, about 60km away from Kano metropolitan and it has a total area of 404km². Coordinate $11^0$32N $8^0$40E/ 11.533^{0}N 8.667^{0}E. The climate is classified as dry and wet, the rainy days last from mid-June to early October approximately (120-150 days) (Olofin *et al*., 2008). The local government has ten wards. According to 2006 census population is 136,736. The people of the area are predominantly Hausa/Fulani by tribe and are farmers that keep a good number of Small ruminants and poultry in addition to arable cropping. The soil of the area is predominantly rich sandy-loam with few types of clay soil around river bank suitable for the cultivation of wide range of crops, some of the food crops cultivated are G/corn, millets; maize, rice and sorghum are local consumption while groundnuts, tomatoes are produced for export and industrial purposes. Animals that are rearing are sheep, goats, cattle Etc.

Data collection

Data was collected by using: questionnaire and visual inspection records.

A total of three hundred well structural questionnaires were designed as sample materials. And one hundred (100) from each were designed and distributed to livestock's farmers, Butchers, and Veterinarians. The procedure of collecting the data remain the same throughout the study. Regular visit was made in the morning to slaughter locations: (from 8:00am – 11:00am) over a period of 3-months. At slaughter locations small ruminants were brought and number of animals slaughtered by butchers was recorded. Attention was paid to animals on moribund condition.

Data analysis

The data generated from questionnaire and the visual inspection records from slaughter units were Microsoft excel 2007 and SPSS version 16 for simple descriptive statistics and graph.

RESULTS AND DISCUSSION

The information of livestock farmers on Socio-economic characteristics, Types of animals kept and farming experience, reasons and condition of animals during slaughter at Kibiya local area is presented in Table 1. This study has shown that majority of the respondents (92%) were male indicating that males are more actively involved in livestock farming especially small ruminant production. The highest percentage in age of respondents range between 40 – 60 years (67%) indicating most of the farmers were middle age class; and 52% were married.

Source: Field survey June 2017 – August 2017

Around 48% of the respondents had experienced on livestock rearing (0-5 years), with 50% mixed flock of sheep and goats; 35% goats only and 15% sheep only. The breeds kept were Red Sokoto goats (49%) and Yankasa sheep (50%). Extensive system of managements was more popular and practiced (51%). The slaughter of small ruminant on moribundity/already slaughtered was more frequent (65%). The reasons for slaughtered of the animals includes lack of feedstuff, urgent need or selling at will. While others were slaughtered as a result of diseases and health related issues. It was observed that postmortem was not done on slaughtered animals, which is a potential health threat to meat consumers. Abdullahi et al (2019) reported menaces in management practices, processing and transportation of meat in the semi-arid of kano metropolis abattoirs. Kebede (2010) emphasized that meat hygiene services are functions in such a way as to satisfy consumers and at the same time safeguard public health and animal hygiene.

The result of the study revealed a total number of 1524 of small ruminants were slaughter from month of June to August, where are 525 sheep and 999 were goats, respectively. Out of the total small ruminant slaughtered 549 were on moribundity; 457 were slaughtered before arrival to slaughter slab; while remaining 518 were physically fit before slaughter. Muhammad et al (2007) reported that more prominent slaughtered of pregnant animal was occurred in early wet season (May – July).

Visual inspection record

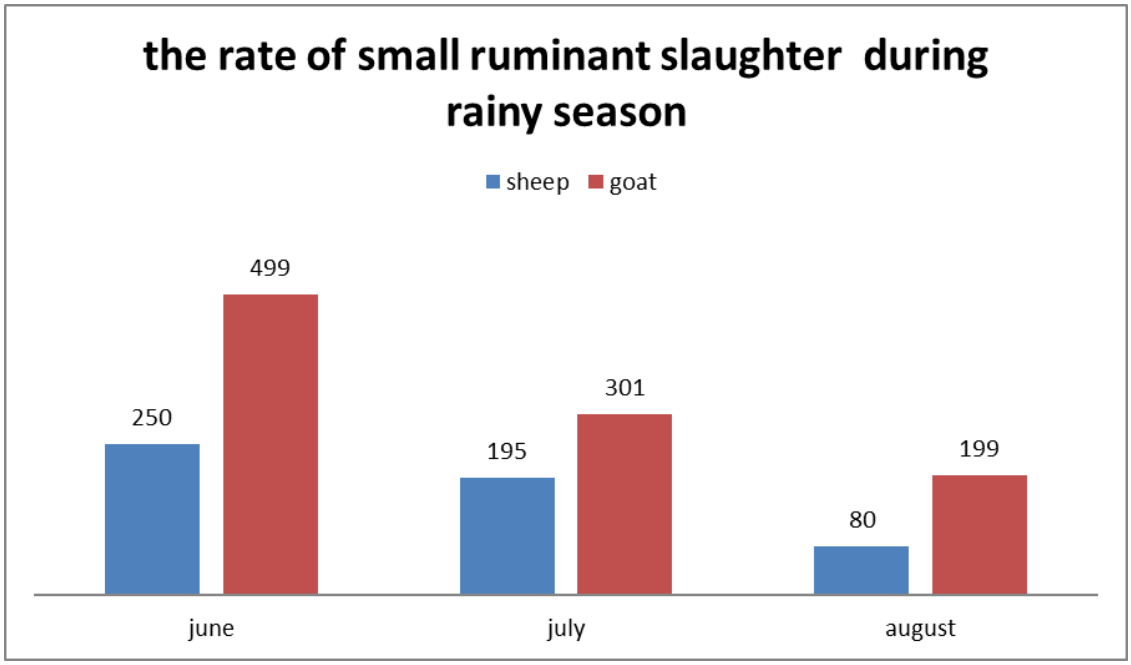

Figure 1 Number of small ruminants slaughtered in three months at Kibiya LGA of Kano State.

The chart above (figure 1) showed that at the month of June (month that rain started in Kibiya) there was high slaughter of small ruminant in the area especially goats (499), sheep (250). While in July goats (301), sheep (195) and in August goats (199), sheep (80) respectively. Kumar and Prasad (1986) and Somvashi et al (1992) reported that during the rainy season the majority of 6–12-month-old kids became dull, off-feed, weak, emaciated and anemic.

Conclusion And Recommendations

Most of the livestock's producer in the study area keeps their flock in free range system which graze on newly germinated grasses that caused diarrhea and other digestive disorder at early set of rainy seasons. It is concluded that livestock farmers in the area of study are keeping small ruminants which are facing problem of high slaughter of their stocks during raining season as a result of problem of feeding and disease as well as urgent need and selling at will of their owners.

RECOMMENDATIONS

To improve sheep and goat production in the area of study, effective extension education to farmers on animal health and production is greatly needed.

i. Livestock farmers should preserve their harvested crop residues to be used during scarcity.
ii. Livestock farmers are advised to keep their animals in intensive or semi-intensive system.
iii. Government should provide veterinary centers, livestock incentives and credit facilities.
iv. Postmortem and meat inspection should be carried out regularly for meat consumer health safety.

ABSTRACT
Moringa oleifera, a small size tree, which can grow to a height of 5 to 10 m. It survives in different climate of the world. It can grow under harsh climatic conditions without being much affected by drought. It tolerates different ranges of rainfall estimated at minimum 250 mm and maximum at over 3000 mm. It thrives on soil pH of 5.0 to 9.0. The trunk is soft with white corky and its branches has a gummy bark. It possesses tripinnate compound leaf with several small leaf legs. The flowers are white in colour and the three wings seeds are scattered by the winds. It is cultivated for its multiple utilities. Every part of Moringa is used for certain nutritional and/or medicinal propose. It is a good source of protein, vitamins, oils, fatty acids, micro and macro minerals elements as well as various phenolics, it was also reported to have anti-inflammatory, antimicrobial, antioxidant, and antihelmintic usefulness. Research on this precious herb may lead to the development of novel agents for various diseases to substitute the current antibiotics which are fast becoming ineffective. This review provides a brief overview about medicinal and Nutritional potentials of *Moringa oleifera* and its use as a component of modern medicine and broilers feed.
Key word: *Moringa oleifera,* anti-microbial, anti-oxidant, feed additive, broiler

INTRODUCTION
The presence of residues of antibiotics in poultry meat and meat products beyond maximum permissible limits is a matter of serious concern (Muaz *et al*., 2018). The use of antibiotics for animal products is also a global concern to world health organization (WHO, 2014) because there is increased emergence of antibiotic resistant pathogens due to sub-therapeutic use of antibiotic as growth promoters, which poses a serious hazard to human health (Torun *et al*., 2018). According to Brock Biology of Micro-organisms (2014), Antibiotic resistance (AR) is defined as the ability of an organism to resist the bacteriostatic or bactericidal effects of an antibiotic to which it was normally susceptible.

Justification
The need for the knowledge of a potential alternative to antibiotics in broiler production is consequential because its meat is usually ready for consumption at an average of 6 weeks. The avoidance of improper use of antibiotics and the prevention of its residual effect in meat is therefore the essence of this review.

Properties of Moringa Plant
Moringa oleifera is a well-known cultivated species in the genus Moringa, (family Moringaceae) under the order Brassicales. It is also known as drumstick tree, horseradish tree, and ben oil tree or benzoil tree or miracle tree (Arora *et al*, 2013). It can grow under harsh climatic conditions without being much affected by drought (Morton, 1991). It tolerates different ranges of rainfall estimated at minimum 250 mm and maximum at over 3000 mm. Palada and Chang (2003) reported that it thrives on soil pH of 5.0 to 9.0. *Moringa oleifera* trunk is soft with white corky and its branches has a gummy bark. It possesses tripinnate compound leaf with several small leaf legs. The flowers are white in colour and the three wings seeds are scattered by the winds (Anwar and Bhanger, 2003; Prabhu et al., 2011). The plant is native to South Asia and Western Africa (Alnidawi *et al*, 2016).

Nutritional properties

Moringa leaves or derivatives are not easily consumed by chickens but about half the protein content can be extracted in the form of a concentrate and added to chicken feed (Price, 2007). According to Fuglie, (2000) phytase can be added to Moringa leaves to break down phytate leading to increased absorption of phosphorusin in chicken diet.

The leaves have been seen to exhibit high contents of vitamin A, C, and E (Hekmat *et al*, 2015), on dry matter basic it contains dry matter (DM) 93.63% to 95.0 %, crude protein (CP) 17.01 % to 22.23 %, carbohydrate 63.11 % to 69.40 %, crude fiber (CF)6.77 % to 21.09 %, crude fat (EE) 2.11 % to 6.41 %, ash (total mineral) 7.96 % to 8.40 %, gross energy 14.790 (MJ/kg), and fatty acid 1.69 % to 2.31 % [58–60].

Medicinal properties of *Moringa oleifera*

Moringa oleifera has enormous medicinal potential, which has long been recognized in the Ayurvedic and Unani system (Mughal *et al*., 1999). Nearly every part including root, bark, gum, leaf, fruit (pods), flowers, seed, and seed oil have been used for various ailments in the indigenous medicine (Odebiyi and Sofowora, 1999). The seed and leaves have been broadly use in human food industry and health related issues (Fahey, 2005). Furthermore, the seed powder of M. oleifera contains polyelectrolytes, which are the most important active ingredients for water purification. Alnidawi *et al*., (2016) conducted an experiment with a view to examining the effects of *Moringa oleifera* leaf on health status in broilers.it was discovered that total cholesterol content was lower with higher level (at 15 % and 20 %) of *Moringa oleifera* inclusion in broiler diets. Similarly, high-density lipoprotein cholesterol (HDL) content in serum was increased and low-density lipoprotein cholesterol (LDL) was decreased with higher level of supplementation of *Moringa oleifera* in broiler.

Antimicrobial Effects

In a recent study, aqueous extracts of *Moringa oleifera* was found to be inhibitory against many pathogenic bacteria, including *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli*, and *Pseudomonas aeruginosa* in dose dependent manner (Saadabi and Abu Zaid, 2011). It was also found to be inhibitory against *Mycobacterium phlei* and *B. subtilis.* Its Leaf extract was found to be effective in checking growth of fungi *Basidiobolus haptosporus* and *Basidiobolus ranarums* (Nwosu and Okafor, 1995).

Anti-inflammatory properties

According to Amit Mittal (2017), investigation shows that aqueous extract of Moringa oleifera leaves (200 mg/kg) exhibited anti-inflammatory activity in all models for inflammation. It was therefore construed that the anti-inflammatory effect might be due to active constituents (flavonoids, tannins, rhamnose, xylose, galactose, arabinose, galacturonic acid) that are present in the aqueous extract of Moringa oleifera leaves.

Anti-oxidant properties

Using different methods of extraction, it was discovered that ethanol and methanol extracts of *Moringa oleifera* exhibited the highest level of anti-oxidant property with 66.8 %, and 65.1 % respectively (Lalas and Tsaknis, 2002; Siddhuraju and Becker, 2003). Bajpai *et al*., (2005) and Siddhuraju and Becker, (2003) discovered that the bioactive compounds of phenolics (such as quercetin and kaempferol) are responsible for antioxidant activity.

Table 1: Some pharmaceutical compounds found in *Moringa oleifera*

S/N	Compounds	Method of Extraction	Application	Reference
1	Pterygospermin	Solvent extraction followed by MIC Analysis	antibacterial and fungicidal effects	Rao *et al*. 2008
2	4-(4'-O-acetyl-a-L-rhamnopyranosyloxy) benzyl isothiocyanate, 4-(a Lrhamnopyranosyloxy) benzyl isothiocyanate, niazimicin, benzyl isothiocyanate, and 4-(a Lrhamnopyranosyloxy) benzyl glucosinolate, Anthonine and Spirochin	Solvent extraction followed by MIC Analysis	Antibacterial	Fahey (2005), Busani *et al*., (2012), Nwosu and Okafor (1995)

CONCLUSION

Herbal plants have considerable promise in health promoting effects in poultry because they contain substances which are considered potential alternatives to antibiotics. Medicinal potential of *Moringa oleifera* is difficult to cover in a single article. This review has provided a glimpse of *Moringa oleifera* applications for performing appraisal of this promising medicinal plant. Although, many bioactive compounds have been discovered from *Moringa oleifera*, these discoveries is in infancy. Future rigorous studies can lead to the detection, and commercialization of *Moringa oleifera* bioactive compounds as a remedies for several poultry broilers ailments. This review shows that *Moringa oleifera* could be successfully used as an environmentally friendly feed additive in broiler chicken to promote growth as well as boost their immune system because of its richness in essential vitamins and minerals. *Moringa* leaf meal can be used safely at levels of 5% to 20% in broiler diets without deleterious effects on their performance.
The future study should focus on the uses of *Moringa oleifera* in relation to a pathogen challenge as well as dosages. Further review on *Moringa oleifera* as an alternative for antibiotics should be considered for laying hen for the production of organic meat and egg.

ABSTRACT

The study was conducted at the Poultry Unit of the Teaching and Research Farms of Oyo State College of Agriculture and Technology, Igboora, Nigeria.A total number of 96 day old unsexed broiler chicks were purchased from a reputable farm at Ibadan for the experiment. At 8 days of age, birds were weighed and randomly allotted into 4 feeding treatments of 3 replicates consisting of 8 birds in a completely randomized design (CRD).T1 control, T2 (30 ml of AVGE + 1 litre of water), T3 (60 ml of AVGE + 1 litre of water), T4 (90 ml of AVGE + 1 litre of water).The experiment lasted for 49 days. The results obtained show that aloe vera gel extract (AVGE) supplementation in water significantly ($p<0.05$) affected Packed cell volume (PCV) (%), haemoglobin (Hb) (g/dL), red blood cells (RBC) ($x10^9$/dl), heterophil, lymphocyte, monocyte eosinophil as well as basophil. White blood cells (WBC) **(**$x10^3$/dl) was however similar ($p>0.05$) across the treatment group. PCV was observed to be highest at T3 (24.83) while T1 (24.00), T2 (24.00) and T4 (24.17) show no difference in the means obtained. Similarly, RBC was observed to be highest at T3 (2.64) and lowest at T4 (2.39) while T1 and T2 had comparable significant means of 2.49 and 2.52 respectively. Hb was also observed to be highest at T3 (9.14) while T1 (8.79), T2 (8.79) and T4 (8.62) had comparable mean value across the treatment. Heterophil was however highest at the control T1 (42.00) while there were no differences in the means obtained in T2 (37.33), T3 (38.33) and T4 (40.67). WBC also had ranged values between 10.55 – 11.47 (T3 – T2) across the treatment groups. It can be concluded from the study that the groups treated with Aloe vera gel extract showed better significant haematological properties when compared to the control groups. It is thus recommended that farmers can adopt the use of 60 ml of aloe vera gel extract in oral supplementation as an alternative to commercial antibiotics.

Key words: Broiler, Aloe vera gel extract, PCV, WBC, RBC

INTRODUCTION

Antibiotic growth promoters have been helpful in improvement of growth performance and feed conversion ratio in poultry (Izat *et al*., 1990; Dibner and Buttin, 2002 and Miles *et al*., 2006) However, constant treatment of poultry with antibiotic may result in residues of these substances in poultry products and bacteria resistance against treatments in human body. Due to such threats to human health, use of antibiotics in poultry is banned (Hinton, 1988; Botsoglou and Fletouris, 2001; Alcicek *et al*., 2004 and Owens *et al*., 2008). Many studies have been carried out on using additives, including herbs, as alternatives to antibiotics, with direct or indirect effects on intestinal micro-flora, in poultry products (Taylor, 2001). *Aloe vera is* used as a multi-purpose medicine with anthelminthic, antimicrobial, anti-inflammatory and anti-oxidative properties. They also contain carotenoids, vitamins, terpernoids and phenols among other compounds (O'Brien *et al*., 2011). They are used in treating newcastle disease, internal parasites, fowl typhoid, coccidiosis, gall sickness and inflammation (Dold and Cocks, 2001). Apart from the above, anti-mutagenic effects and anti-hypersensitivity effects of *Aloe vera* have also been reported by some researchers (Strickland and Ulijaszek, 1993). With numerous properties, *Aloe vera* is among the most well-known herbs. Thus, the study aim to examine the use of oral supplementation of *aloe vera* gel without commercial antibiotics and multivitamin on the haematological indices of broiler chicken

MATERIALS AND METHODS

The study was carried out at the Poultry Unit of the Teaching and Research Farms of Oyo State College of Agriculture and Technology, Igboora, Nigeria

Preparation of 50 % *Aloe vera* gel extract

Fresh Aloe leaves were harvested from Igbo-ora community and environs. Aloe gel infusion was prepared accordingly to the method of Durrani *et al*. (2008). The leaves were washed with clean water to remove dirt. Aloe Vera gel was extracted from 1kg leaves manually by making a cut on the leaves with a pocket knife. The gel was scooped out with a small spoon and drained into in a beaker. A 50% concentrated infusion was prepared by taking 500 ml of fresh gel in a glass bottle and 500 ml of boiled water at room temperature was poured on it. The bottle was then agitated for about 5-7 minutes to ensure thorough mixing, after which it was kept for 30 minutes to 40minutes at room temperature prior to use. The homogenized gel extract was prepared at intervals of two (2) days and served to the animals fresh according to treatments.

EXPERIMENTAL PROCEDURE

A total number of ninety-six (96) day old unsexed broiler chicks were purchased from a reputable farm at Ibadan for the experiment.At 8 days of age, birds were weighed and randomly allotted into 4 feeding treatments of 3 replicates consisting of 8 birds in a completely randomized design (CRD). T1 control, T2 (30 ml of AVGE + 1 litre of water), T3 (60 ml of AVGE + 1 litre of water), T4 (90 ml of AVGE + 1 litre of water).Treatment 1 served as the control which contained vitalyte and antibiotics, representing the common commercial drug supplement that is usually made available to birds.

Table 1: Composition of the basal diet (%)

Ingredient	**Starter (1-21 days)**	**Finisher(22-49 days)**
Maize	58.00	63.80
Soybean meal	34.50	28.40
Soya oil	3.30	3.70

Hb (g/dl)	8.79^{ab}	8.79^{ab}	9.14^{a}	8.62^{ab}	0.20
WBC (x10^{3})	10.72	11.47	10.62	10.55	0.46
Heterophil (%)	42.00^{a}	37.33^{b}	38.33^{b}	40.67^{ab}	2.13
Lymphocyte (%)	57.33^{ab}	60.33^{a}	58.33^{ab}	57.00^{ab}	2.24
Monocyte (%)	0.67^{ab}	0.33^{b}	1.33^{a}	0.67^{ab}	0.23
Eosnophil (%)	0.00^{c}	1.67^{ab}	2.00^{a}	1.33^{ab}	0.31
Basophil (%)	0.00^{b}	0.33^{a}	0.00^{b}	0.33^{a}	0.09

^{a,b,c} Means on the same rows with different superscript differs significantly ($p< 0.05$) * PCV – Pack cell volume, Hb – Haemoglobin, RBC –Red blood cells, WBC – White blood cells SEM= Standard Error of the Mean

The table shows that aloe vera gel extract (AVGE) supplementation in water significantly ($p<0.05$) affected Packed cell volume (PCV) (%), haemoglobin (Hb) (g/dL), red blood cells (RBC) (x10^{9}/dl), heterophil, lymphocyte, monocyte eosinophil as well as basophil. White blood cells (WBC) **(**x10^{3}/dl) was however similar ($p>0.05$) across the treatment group. PCV was observed to be highest at T3 (24.83) while T1 (24.00), T2 (24.00) and T4 (24.17) show no difference in the means obtained. Similarly, RBC was observed to be highest at T3 (2.64) and lowest at T4 (2.39) while T1 and T2 had comparable significant means of 2.49 and 2.52 respectively. Hb was also observed to be highest at T3 (9.14) while T1 (8.79), T2 (8.79) and T4 (8.62) had comparable mean value across the treatment. Heterophil was however highest at the control T1 (42.00) while there were no differences in the means obtained in T2 (37.33), T3 (38.33) and T4 (40.67). WBC also had ranged values between 10.55 – 11.47 (T3 – T2) across the treatment groups.

DISCUSSION

It was observed that the PCV values obtained from all treatments fell within the normal range of 24.00-45.20% for healthy chickens as reported by (Mitruka and Rawnsley, 1997) this indicates that AVGE supplementation was suitable and adequate for broiler chickens, and the birds were not anaemic and that the dietary protein is of good quality (Schalm *et al.*, 1975). Since the blood is often time used as a physiological index or indicator for diseases diagnosis, nutrition status and health condition of the birds. Olafedehan *et al. (*2010) reported that blood acts as a pathological reflector of the status of exposed animals to diseases and other conditions. Isaac *et al.*, (2013) reported that animals with good blood composition were likely to show good performance. Mhonzya (2002) reported that haemoglobin and packed cell volume levels are normally higher in a well-nourished than poorly fed animal. But since all the levels of AVGE supplementation did not fall below the range then it implies there was no case of anaemia in the birds. The values obtained in RBC indicate also that the red blood cells were not reduced by the AVGE supplementation which also shows that the diet also allows for proper oxygen and carbondioxide transport. This supports Ojhas *et al*., (2011) who stated that oral administration of aloe vera gel extract significantly increased the RBC count. As reported by Isaac *et al.* (2013), red blood cell is involved in the transport of oxygen and carbon dioxide in the body. Thus, a reduced red blood cell count implies a reduction in the level of oxygen that would be carried to the tissues as well as the level of carbon dioxide returned to the lungs (Ugwuene, 2011; Soetan *et al.*, 2013 and Isaac *et al*, 2013). From the findings, lymphocytes and heterophiles showed significant difference ($P<0.05$). Iraql (2014) reported improvement of broiler chicken immune system and significant increase of lymphocytes and heterophiles with garlic extract supplementation due to immune-stimulant effect of garlic. The significant effect of most parameters

measured at 60 ml of AVGE + 1 litre of water in this study suggests that it may be an appropriate level of inclusion.

CONCLUSION AND RECOMMENDATION

It can be concluded from the study that the groups treated with Aloe vera gel extract showed better significant haematological properties when compared to the control groups. It is thus recommended that farmers can adopt the use of 60 ml of aloe vera gel extract in oral supplementation as an alternative to commercial antibiotics.

ABSTRACT
Antioxidant supplementation can alleviate stress arising from the environment, production systems, and animal functional metabolic activities at different physiological stages. Therefore, in this study, a microalga known as *Chlorella vulgaris* was supplemented to rabbits as an antioxidant at different physiological stages while their performances and oxidative stress attenuation mechanisms were monitored. In the prepubertal and gestation phases, forty rabbits were investigated; in the lactation phase, 35 rabbits with equal number of kits were studied while in the non-reproducing phase, forty rabbits were studied. At each phase of the study, rabbits were divided into five groups and rabbits in each of the groups were individually supplemented with 0, 200, 300, 400 and 500 mg *Chlorella vulgaris* biomass per kg bodyweight as Control, T1, T2, T3, and T4 groups respectively. There was significant effect of the supplementation on the rabbits' weight gain ($p < 0.05$), reproductive index ($p < 0.05$), feed intake ($p < 0.05$), carcass traits and meat yield ($p<0.05$), antioxidant enzymes activities and gene expression patterns ($p < 0.05$). Evaluation of these outcomes led to the conclusion that the microalga supplementation led to improved performances of the rabbits and protected the rabbits against oxidative stress at different physiological reproductive stages, hence it was recommended as suitable antioxidant supplements for rabbits while its suitability as antioxidant in other food producing animals was suggested.
Keywords: Antioxidants, *Chlorella vulgaris*, gene expression, oxidative stress and rabbits.

INTRODUCTION
Reproduction is arguably a metabolic and performances burden to animals as some group of scientists agreed it is a burden while some claimed it is not; however, either agreed or disagreed, reproduction is known to increase animals' nutrients demands in breeding animals as well as the modification of the alimentary tract in response to the increase in nutrients demand and intake (Hammond, 1997). It is also agreed upon that there is always an increase in the thermoregulatory demand of breeding animals which usually get extremely higher during lactation period due to the need by animals to produce milk for consumption of the younger ones (Heldmaier *et al*. 2004).
Reproductive specific to rabbits is that there is usually a reduction in physical activities in breeding does compared with dry does (Fernandez-Carmona *et al*. 2010). It was also reported that there is bone loss due to increased calcium supply to the foetus and offspring during gestation and lactation periods (Sarli *et al*. 2005). All these complications are almost inevitable in food producing animals due to reproduction or functional production performances; however, underlying these complications is oxidative stress a condition of imbalance between prooxidant and antioxidant in animals occasioned by rigourous energy demand and other activities which occur all the time to keep an animal suitable for production; therefore exogenous antioxidant aimed at enhancing internal antioxidant defence system become modern animal production exploit. In this study, a microalga rich in antioxidant was supplemented to rabbits in fulfillment of exogenous antioxidant supplementation hypothesis.

MATERIALS AND METHODS
In the prepubertal and gestation phases, forty rabbits were investigated; in the lactation phase, 35 rabbits with equal number of kits were studied while in the non-reproducing phase, forty rabbits were studied. At

each phase of the study, rabbits were divided into five groups and rabbits in each of the groups were individually supplemented with 0, 200, 300, 400 and 500 mg *Chlorella vulgaris* biomass per kg bodyweight as Control, T1, T2, T3, and T4 groups respectively. Approval for use of the animals and the experimental protocol was obtained from joint approval of Institutional Animal Ethics Committee (IAEC) of National Institute of Animal Nutrition and Physiology, India and Committee for the Purpose of Control and Supervision on Experiments on Animals (CPCSEA), India. The animals fed commercial rabbits feed and provided with water *ad-libitum* (Table 1); while they were supplemented with microalgae biomass intake as antioxidant supplements. The animal house was maintained at normal room temperature while electric blowing fan was provided for emission of excess heat generated and prevention of stickiness.
The prepubertal stage lasted for 60 days, gestation 35 days, lactation 21 days, and non-breeding stage 120 days; during each of the stages, blood was obtained from each animal through puncturing of auricular vein using 26G needle and 2mL hypothermic syringes (Hindustan Syringes & Medical Devices (P) Limited, India). Blood samples were collected early morning between 6.30 and 8.30 am and the animals were hand restrained while surgical spirit was used for wiping (Om Shiva Pharma Industries, India). Blood samples collected were allowed to clot at room temperature before they were transported on ice pads to the laboratory for serum separation. Clear serums were obtained by centrifuging whole blood at 2000 rpm (Remi NEYA 16R, REMI India); the centrifuge was done at 4 ^{o}C for 15 minutes period for each sample and the serums were obtained into Eppendorf tubes packed in cryo box (Tarsons Products Pvt. Ltd, India) then stored at -80 ^{o}C for downstream analysis. Concentration of malondialdehyde in the serum was used as marker of lipid peroxidation was assayed according to procedures described by (Ohkawa *et al*, 1979). Serum biochemical parameters including enzymes such as alanine aminotransaminase (ALT), aspartate aminotransaminase (AST), creatinine, alkaline phosphatase (ALP) and bilirubin were determined using commercial kits; while antioxidant enzymes activities, gene expression patterns and other analysis were carried out as described in Sikiru *et al*, 2019a, Sikiru *et al*, 2019b and Sikiru *et al*, 2019c respectively.

RESULTS AND DISCUSSION

The supplementation of *Chlorella vulgaris* has antioxidant in this study significantly led to improvements in the rabbit production and functional performances; from feed intake, growth rate, carcass traits and oxidative stress protection via reduction of oxidative stress biomarkers and enhanced antioxidant enzymes activities as presented in the tables 2 to 6 below. The findings as revealed in this study gave a strong support to practical use of microalga *Chlorella vulgaris* as in rabbits because it improved the rabbits performance through attenuation of oxidative stress products of lipid peroxidation, enhanced antioxidant activities using its components including carotenoids and polyphenols for prooxidants scavenging, these finding agreed with earlier studies on the alga as reported (Pieretti and Meineri, 2009) who stated that it improved feed nutrients digestibility and promotion of growth rates; similarly, the microalga was also reported to improved meat qualities, reproductive performance and functional attributes of rabbits and mice models (Meineri *et al*, 2009; Kang *et al*, 2004). This study demonstrated that oxidative stress is an inevitable biochemical process in animal performance and its implications transcend beyond physiological loss to economic loss; meanwhile, supplementation of microalga *Chlorella vulgaris* in this study ameliorated the production inefficiencies as well as enhanced the animals' physiological performances and also showed molecular oxidative stress protection through up-regulation of antioxidant genes through expression modification.

Table 1: Nutritional compositions of the basal feed fed to the rabbits at all stages of the experiment

Parameters	Amount	Units

ABSTRACT
This study was conducted on the basis of radiant hope in medicinal plants' efficacy to solve health and nutritional problems in livestock production. Standard procedures were adopted in the determination of phytochemicals, proximate and mineral constituents of *Hibiscus asper* and *Hibiscus sabdariffa*. Saponins, tannins, flavonoids, terpenoids and steroids were present in both plants. These are indispensable for the body systems and physical well being. The quantitative phytochemicals were found to be more in *H. asper* than *H. sabdariffa*. Proximate values for moisture (12.163 ± 0.060), ash (11.709 ± 0.042), fat (9.579 ± 0.090), crude protein (13.903 ± 0.086) and crude fibre (1.418 ± 0.065) in *H. asper* were higher than that of *H. sabdariffa*. The metabolizable energy in *H. asper* was 3109 Kcal/Kg while that of *H. sabdariffa* was found to be 3107 Kcal/Kg; making the plants to a veritable source of energy. *H. asper* had higher values of Sodium (27.400), Potassium (72.500), Magnesium (10.480), Iron (0.670), Copper (0.280), Zinc (1.027), Phosphorus (3.130), compared to *H. sabdariffa.* Insignificant quantity of Lead (0.010 ppm) was detected in *H. asper* and none in *H. sabdariffa,* showing that the two plants are safe from lead poisoning. It was concluded that *H. asper* and *H. sabdariffa* are medicinal plants that can be of inestimable value in livestock production if the leaves can be exploited for drug and feed formulation.

Key words: Phytochemical, proximate composition, minerals, medicinal plants, livestock

INTRODUCTION
The universe offers plethora of plants with medicinal and nutritional properties. This has given radiant hope to the scientists all over the world that medicinal plants have the potentials to solve disease and nutritional challenges in animal production. The incessant problem of antibiotic resistance in livestock production can also be mitigated through administration of medicinal plants in drinking water or incorporation into their feed. The usage of leaf meal in broiler diets was reported by Oloruntola *et al.* (2016). It was reported by Ukorebi *et al*. (2019) that 10% dietary level of *Gongronema latifolia* (Utasi) leaf meal supported normal health by enhancing the blood building capacity and performance of broiler chickens. Wumnokol *et al*. (2019) reported the inclusion of Acha (*Digitaria exilis* Staph) grains in the diet of broiler chickens as beneficial on the haematological parameters. Despite the inexhaustible well of medicinal plants, innumerable species of them are yet to be exploited satisfactorily. *Hibiscus asper* and *Hibiscus sabdariffa* are two medicinal plants of high pharmacological and nutritional value that are yet to be meaningfully tapped. They belong to the genus Linnaeus of the family Malvaceae. It was reported that the plants from this family are good source of fibres, medicine, tea and oil (Ayanbadejo *et al*., 2012). Although, many researchers have worked on the seeds and calyxes from the plants in poultry nutrition but there is a great dearth of information on the use of the leaves (leaf meal) for drug formulation or nutritional purpose in livestock production in Nigeria. Hence, the essence of studying the phytochemical, proximate and mineral constituents of air-dried leaves of these two medicinal plants.

MATERIALS AND METHODS

Plant samples collection and preparation

Fresh leaves of *Hibiscus asper* and *Hibiscus sabdariffa* were harvested from Goshen Community, off Aule Road Akure, Ondo State Nigeria in September, 2019. The plants were properly identified taxonomically at the Department of Forestry and Wood Technology of the Federal University of Technology, Akure. The leaves were gently rinsed in distilled water to get rid of dirt and thereafter air-dried for fourteen days until constant weight was achieved. Air-dried leaves were ground in Thomas Willey machine® to fine powder and stored in air tight containers prior the time of the analyses at 4^0C.

Phytochemicals, proximate and minerals analyses

The phytochemicals and proximate analyses of the plant extracts were carried out at the Chemistry Department Laboratory, School of Sciences of the Federal University of Technology, Akure (Trease and Evans, 2005; AOAC, 2006). The results were obtained in duplicates and expressed as means ± SD using IBM SPSS Statistics version 23. Metabolizable energy was determined using the Janssen formula (Janssen, 1989).The minerals analysis was done in a reputable commercial Laboratory in Akure, Ondo State with the usage of AAS Buck Scientific 210 VGP & FP 902 Laboratory instrument.

Results and Discussion

The results of the phytochemical constituents, proximate and mineral composition of the two plants are shown in Table 1, 2 and 3. As seen in Table 1, *H. asper* and *H. sabdariffa* contained saponins, tannins, flavonoids, terpenoids and steroids. Glycosides were present in *H. asper* but absent in *H. sabdariffa*. Phlobatannins, alkaloids and anthraquinonoes were absent in the two plants. This agrees with the reports of Sulaiman *et al*. (2014) and Gbadamosi *et al*. (2018), that *H. sabdariffa* contained tannins, saponins, terpenoids and steroids while *H. asper* is very rich in flavonoids, tannins, saponins and cardiac glycosides respectively. The qualitative analysis of the phytochemicals showed that *H. asper* had higher values than *H. sabdariffa* in all the phytochemicals present in them. The phytochemicals in plants give them their medicinal value that has been tapped into by man and animals over the ages. According to the report of Osuntokun and Olajubu (2014), phytochemicals have the ability to prevent diseases in man and animals. They have the potential to alleviate the possibility of urinary tract infections (Bongoni *et al*., 2013).

Table 1: Phytochemical constituents of air-dried leaves of *H. asper* and *H. sabdariffa*

Phytochemicals	***H. asper***	***H. sabdariffa***	***H. asper***	***H. sabdariffa***
Saponins	+	+	8.000±0.257	6.727±0.257
Tannins	+	+	3.845±0.000	3.153±0.008
Flavonoids	+	+	2.619±0.005	1.550±0.005
Terpenoids	+	+	39.415±0.038	25.053±0.038
Steroids	+	+	8.042±0.018	4.371±0.018
Glycosides	+	-	12.476±0.046	ND
Phlobatannins	-	-	ND	ND
Alkaloids	-	-	ND	ND
Anthraquinones	-	-	ND	ND

Where (+) = present, (–) = absent and ND = not detected. Values are expressed as means ± SD.

Table 2: Proximate analysis of air-dried leaves of *H. asper* and *H. sabdariffa*

Parameters (%)	***Hibiscus asper***	***Hibiscus sabdariffa***
Moisture	12.163 ± 0.060	9.166 ± 0.234
Ash	11.709 ± 0.042	10.594 ± 0.532
Fat	9.579 ± 0.090	8.439 ± 0.243
Crude protein	13.903 ± 0.086	8.965 ± 0.355
Crude fibre	1.418 ± 0.065	0.885 ± 0.123
Carbohydrate	51.192 ± 0.274	62.309 ± 0.333
ME (Kcal/Kg)	3109	3107

Values are expressed as means ± SD of duplicate determination. ME = Metabolizable energy

Table 3: Mineral composition of air-dried leaves of *H. asper* and *H. sabdariffa*

Minerals (ppm)	***Hibiscus asper***	***Hibiscus sabdariffa***
Sodium (Na)	27.400	24.900
Potassium (K)	72.500	58.200
Calcium (Ca)	12.940	17.100
Magnesium (Mg)	10.480	10.130
Iron (Fe)	0.670	0.420
Copper (Cu)	0.280	0.250
Manganese (Mn)	0.074	0.095
Lead (Pb)	0.010	ND
Zinc (Zn)	1.027	0.780
Phosphorus (P)	3.130	2.420

Where ppm = part per million and ND = Not detected

The proximate analysis (Table 2) revealed *H. asper* values for moisture (12.163 ± 0.060), ash (11.709 ± 0.042), fat (9.579 ± 0.090), crude protein (13.903 ± 0.086) and crude fibre (1.418 ± 0.065) to be higher than that of *H. sabdariffa*. However, *H. sabdariffa* value for carbohydrate (51.192 ± 0.274) was higher than that of *H. asper*. Metabolizable energy in *H. asper* and *H. sabdariffa* were 3109 and 3107 Kcal/Kg respectively. This is even higher than the metabolizable energy in some of the commercial feed ingredients. The ash value for *H. asper* (11.709 ± 0.042) in this study was higher (3.27±0.06) than that reported by Gbadamosi *et al*. (2018) and conversely for the crude protein and crude fibre (lower). This may be attributed to the effect of geographical location. The low crude fibre obtained from *H. asper* (1.418 ± 0.065) and *H. sabdariffa* (0.885 ± 0.123) is a factor for effective digestibility of the leaves from these plants if incorporated as leaf meal into livestock diets. Consequently, it was observed from Table 3 that *H. asper* had higher values of Sodium (27.400 ppm), Potassium (72.500 ppm), Magnesium (10.480 ppm), Iron (0.670 ppm), Copper (0.280 ppm), Zinc (1.027 ppm), Phosphorus (3.130 ppm), compared to *H. sabdariffa.* Generally the two plants are rich sources of minerals because they are found in appreciable quantities. Lead (Pb) that was found in the plants in trace amount is required by the body in little or less quantity (lead is poisonous). According to Okwu and Okwu (2004), elevated level of lead (Pb) in the body is hazardous to the body systems. This justifies one of the reasons medicinal plants are used for various purposes all over the world.

CONCLUSION

Based on the results obtained from this study (phytochemicals, proximate and mineral composition) *H. asper* and *H. sabdariffa* are medicinal plants whose potentials can be explored by phytopharmaceutical industries and animal nutritionist for drug and feed formulation respectively. The ability of the leaves of these plants' to re-grow quickly after plucking is a credited plus to them.

Recommendations

Further studies: antimicrobial and antifungal properties are to be determined *in-vitro*. Analysis of the amino-acid profile of the plants, isolation of bioactive compounds (GC-MS) and *in-vivo* experiments with animals are also very important to be carried out.

ABSTRACT
The objective of the study was to establish the relationship existing between haematological parameters by predicting the packed cell volume (PCV) of chickens from the other haematological variables in a study that was conducted at the Federal University of Technology, Akure Teaching and Research Farm. A total of 120-day old chicks of four strains were purchased from reputable Farm at 30 chicks per strain and used for the study that lasted eight (8) weeks. The experiment was arranged in a completely randomized design and the birds were distributed into four treatments according to their strain. Each group was replicated three times at 10 birds per replicate. The birds were fed experimental diet *ad-libitum* containing 23% crude protein and 2685.49Kcal/kg metabolizable energy during the period of the experiment. Adequate health preventive measures were ensured during the period of the study. At the end of the experiment, blood samples were collected from 12 birds per strain and were analyzed on computer using SAS (2008). Results showed that haematological parameters were highly significant ($p<0.01$) among the four chicken strains. Coefficient of determination (R^2) was highest in Haemoglobin for Naked neck breed with the value of 99.84%. Haemaglobin had the higher accuracy of prediction. This function was best with Marshall broilers compared to other chicken strains used for the study. White blood cells generally contributed low to PCV. It was concluded that Red Blood Cell (RBC) was the best predictor of PCV from other haematological variables across the chicken strains. Haematological parameters could be used to predict PCV in chickens and they could be used to assess the well being of poultry birds. This could help to generate baseline information necessary for breeding plans and improvement of the Nigeria Indigenous chickens.

Keywords: Indigenous, relationship, prediction, haematological parameters and improvement,

INTRODUCTION

Traditional poultry production in Nigeria is practiced in rural and semi-urban areas where conditions permit settlement of life. The household poultry production system is based on scavenging indigenous domestic chickens which may be accompanied by pigeons, guinea fowls, ducks or turkeys. Indigenous birds are usually raised as scavengers in an open yard, scratching and picking on the grounds (Ravi-Kumar *et al*., 2002). Analysis of haematological parameters of chickens is essential for the diagnosis of various pathological and metabolic disorders. It can be used as a diagnostic tool in order to assess the health status of an individual and/or a flock. Haematological changes are commonly used to determine the body status and to assess the impact of environmental, nutritional and/or pathological stresses.

Haematological parameters provide valuable information on the immune status of animals (Kral and Suchy, 2000). Such information, apart from being useful for diagnostic and management purposes, could equally be incorporated into breeding programmes for the genetic improvement of indigenous chickens. It is desirable to know the normal physiological values under local conditions for proper management, feeding, breeding, prevention and treatment of diseases. Meager information about the local ecotypes of birds and their characterization are available in the literature and no reliable data describing traditional poultry production are available. However, normal haematological information on Nigerian indigenous birds is hardly available in the literature as researches on these chickens had rarely been carried out. The present study was designed to partly rectify this deficiency and to provide baseline data on haematological parameters of some indigenous chickens in Nigeria.

MATERIALS AND METHODS

The study was carried out at Teaching and Research Farm, Livestock Section (Poultry Unit) of the Federal University of Technology, Akure, Ondo State, Nigeria with Latitude 07° 16^1 and 07° 18^1 N and Longitude 05° 09^1 and 05° 11^1 E. There is a unimodal rainfall pattern which starts from April to October and average of 1556mm per annum. The average ambient temperature was about 30 - 32°C and relative humidity of 80% (Climate data, 2018).

A total of 120-day old chicks were purchased from reputable farms in Abeokuta and Ibadan, Ogun and Oyo States of Nigeria. Thirty (30) chicks of each strain were procured and used for the study that lasted eight (8) weeks. The strains were normal feather, naked neck, frizzle feather and Marshall Chickens. The experiment was arranged in a completely randomized design (CRD) and the birds were distributed into four treatments according to their strain. Each strain was replicated three times at 10 birds per replicate. The birds were fed experimental diet *ad-libitum* containing 23% crude protein and 2685.49Kcal/kg metabolizable energy. Adequate health preventive measures were ensured during the period of the experiment. At the end of the experiment, 2ml blood samples were collected from twelve (12) birds per strain and emptied into well labelled ethylene diamine tetra acetate (EDTA) bottles. These blood samples were taken to the haematology Laboratory of the Department of Animal Production and Health of the University for Laboratory analyses of haematological parameters using Lamb (1981) procedure. All blood samples were collected at about the same time. The blood collection tubes were kept on ice pack in cool containers to avoid denaturing of proteins and were taken to the laboratory within 2 hours of collection. The haematological parameters studied were: packed cell volume (PCV), erythrocyte sedimentation rate (ESR), red blood cells (RBC), haemoglobin concentration (HBC) and the differential white blood cell (Heterophils, Basophils, Eosinophils, Monocytes and Lymphocytes). The blood constants (mean corpuscular haemoglobin concentration, Mean cell haemoglobin and Mean cell volume) were determined using standard formulae.

Data generated were analyzed on computer using SAS (2008) version 13 statistical software. Where significant differences were observed, means were separated using appropriate subroutine of the same statistical package. The statistical model used was:

$Yij = \mu + Ti + \epsilon ij$

Where

Yij= Haematology of jth bird in the ith strain (j = 1- 30)

μ = General mean

Ti = Fixed effect of the ith strain (i = 1- 4)

ϵij = Residual error

RESULTS AND DISCUSSION

The estimation of PCV from other haematological parameters in Table 1 showed that most of the haematological parameters were highly significant ($p<0.01$) among the four strains with Erythrocyte Sedimentation Rate (ESR), Mean Cell Volume (MCV), Mean Cell Haemoglobin (MCH), Basophils (BAS), Haemoglobin (HB), Red Blood Cell (RBC), Eosinophils (EOS) and Monocytes (MON), while the Table equally revealed that Lymphocyte (LYM), Mean Cell Haemoglobin Concentration (MCHC) and Heterophil (HET) were not significantly different ($p>0.05$). Generally, the coefficient of determination (R^2) was highest in Haemoglobin (HB) for Naked neck (NN), Normal feather (NF), Frizzle feather (FF) and Marshal broiler (MB) with the various values 99.84 %, 99.81 %, 99.97 % and 99.94 % respectively and lowest in MCHC for NN with 0.00, BAS and EOS for NF with 0.00, EOS for FF with 0.10 and HET for MB with 0.21 as shown in Table 1. The function was best described in Marshall Broilers compared to other chicken strains used for the study.

On the estimation of PCV from other haematological variables, Red blood cells (x_2) had the highest contribution to the value of PCV in all the strains used in this study. Low contribution from the White blood cells showed that the experimental birds were clinically free from infectious micro-organisms (peters

et al., 2011) during the period of the study. On the basis of coefficient of determination (R^2), Haemaglobin (x_3) had the higher accuracy of prediction. Generally, all the haematological parameters were highly significant ($p<0.01$).

CONCLUSION AND RECOMMENDATIONS

The present study showed that the estimations of PCV from the other haematological parameters were generally significant across the strains used in the study. The estimation of Packed Cell Volume (PCV) from other haematological parameters using linear function revealed that Red Blood Cell (RBC) was the best predictor of PCV among the strains. Haemoglobin (x_3) had the highest accuracy of predictions based on the values of coefficient of determination (R^2). Packed Cell Volume (PCV) could be used to determine the health and immunological status of chickens.

In general, the result showed that haematological parameters could be used to predict the PCV of poultry birds. They could also be used to assess the well being of poultry birds vis-a-vis their health and physiological status. This study would help to generate baseline information necessary for breeding plans and improvement of the Nigeria Indigenous chickens. It was recommended that government and stakeholders should provide adequate funding for researches on indigenous chicken production.

ABSTRACT

A case of sarcoptic mange infestation in a 6-month-old Yankasa ewe weighing 22kg was presented to the student fellows in large animal section of Medicine Speciality, College of Veterinary Surgeon of Nigeria, A.B.U Zaria study centre during a routine ambulatory visit to a sedentary Fulani herd in Tohu village in Zaria LGA, Kaduna State. The infested ewe was in a flock of 13 sheep reared alongside with a herd of cattle. Physical examination revealed crusty lesions and areas of alopecia around the face, ear and limbs. Vital parameters were within normal range. Skin scrapping, blood and faecal samples were collected and taken to the Entomology, Clinical pathology and Helminthology laboratories of the Ahmadu Bello University Veterinary Teaching Hospital for identification of mites, helminthes and haemogram respectively. The laboratory results indicated a sarcoptic mite, marked eosinophilia and hyporoteinaemia while no parasite was observed in the faecal sample. Sarcoptic mange was diagnosed and the ewe was treated twice with ivermectin at one-week interval. The ewe apparently recovered after 2 weeks and the client was advised to treat all sheep in his farm.

Keywords: Sarcoptic mange, Ewe, Ivermectin, Tohu village.

INTRODUCTION

Sarcoptic mange is highly contagious skin disease caused by a mite and is transmitted most frequently by direct contact with infected animals (Taylor *et al.,* 2007; Reichard, 2016). The mite, *Sarcoptes scabiei* var *ovis* infests sheep and is quite hardy and can survive off the host animal in a home environment at room temperature for 1-6 days (Ahmed *et al.,* 2015). The parasite, *S scabiei* var *ovis* is zoonotic (Provet, 2013) and animals in poor condition appear to be most susceptible. This mite lives permanently in the superficial layers of the skin and disease occurs as a result of the irritation caused by the presence of the parasite in the skin, or, most often, due to an allergic (hypersensitivity) reaction in the host. It infests non-wooly skin, usually on the head and face (Rahbari, 2009*).* Clinical signs do occur from 3-6 weeks after infection with the mite. The lesions manifest with formation of crusts and intense pruritus, excoriation, crusts, lichenification and secondary alopecia on face and ears and secondary bacterial infection and thickening of the skin in chronic cases (Reichard, 2016). Self-trauma is due to scratching and biting. Female mites form shallow burrows in the lower stratum corneum of the skin and lay eggs in tunnels under the skin. They hatch in 3-8 days and then develop into larvae, nymphs and finally adults. The whole of the lifecycle takes 17-21 days and is completed on the host animal (Radostits *et al.,* 2006). Affected animals have decreased reproduction, meat gain, and milk yield (Wall and Shearer, 2001). Diagnosis is made by examination of deep skin scrapings and identifying mites, eggs or mite faeces (Ogundiyi *et al.,* 2012). The itchy pruritus can be controlled using anti-inflammatory drugs (e.g. corticosteroids), antibiotics may be needed if secondary bacterial infection is present, anti-seborrhoeic shampoos are also helpful to cleanse the skin (Provet, 2013). Positive diagnosis can be made only by scraping lesions on the sheep with a scapel blade and observing the mites in the scrapings. The present case reports the natural infestation of *S. scabei* in a sheep and its therapeutic management with Ivermectin at field condition.

MATERIALS AND METHODS

History and physical examination

A 6-month-old Yankasa ewe weighing 22kg from a flock of 13 sheep with history of crusty lesion on the face was presented to the student fellows in large animal section of Medicine Speciality, College of Veterinary Surgeon of Nigeria (CVSN), Ahmadu Bello University, Zaria study centre during a routine ambulatory visit to a sedentary Fulani herd in Tohu village in Zaria LGA, Kaduna State. History revealed that the lesions were noticed about 4 weeks prior to the visit. The animal was managed on an extensive system of management and had no medical history. Physical examination revealed crusty lesions and areas of alopecia around the face, ear and limbs (Plate I). The rectal temperature was 38.8□C; pulse 108 beats per minute, and the respiratory rate was 16 breaths per minute. The differential diagnoses were: mange, dermatophilosis, pediculosis and ring worm. However, on a closer examination of the lesions, the tentative diagnosis became mange. This was due to the fact that scabs in dermatophilosis can easily be peeled off, in pediculosis, there are no crusts and the lice or their nits would have been visible. Also in ring worm, the lesions would have been circumscribed. Blood and rectal faecal samples were collected and sent to Clinical Pathology and Helminthology laboratories respectively for screening. To arrive at a confirmatory diagnosis, deep skin scrapping at the periphery of the lesion was collected and sent to the Entomology laboratory for possible mite identification. The ewe was treated with Ivermectin (Ivomec®) subcutaneously at the rate of 0.2mg/kg b. wt. and was repeated after 1 week. The animal recovered completely after 2 weeks of revisit. Thus, there was complete resolution of the mange in respect of skin texture i.e; disappearance of crusts and subcutaneous appearance of fresh and shiny skin with hairs.

Plate I. Sarcoptic mange Yankasa Ewe with crusty lesions/alopecia on the face, ears and limbs

RESULTS AND DISCUSSION

Entomology laboratory:

The microscopic examination revealed presence of *S. scabiei* mites which was differentiated by rounded mouth parts, absence of eyes/stigmata, short posterior legs, presence of empodial claws and pulvillus on first two pairs of legs, presence of transverse ridges on dorsal surface of the body (Wall and Shearer 2001).

Helminthology Laboratory:
No parasite found in the faecal sample.
Clinical pathology laboratory result
Table I: Haemogram of a 6-month–old Yankasa ewe with sarcoptic mange in a sedentary Fulani herd in Tohu village in Zaria Local Government Area of Kaduna State

Parameter	Patient's Value	Reference range
PCV %	22	24-50
Hb g/dl	7.3	8-15
WBC x 10^9/l	7.1	4-12
Neutrophils %	30	10-50
Lymphocytes %	54	40-75
Monocytes %	06	0-6
Eosinophils %	28	0-10
Total protein g/dl	5.4	6-7.9

The primary signs observed in the present case are similar with that of Murthy *et al*. (2013) and they included pruritis, excoriation, crusts, lichenification and secondary alopecia on face and ears. The affected area was intensely excoriated because of itching, scratching and biting. Treatment was carried out with two shots of Ivermectin at 1 week interval because initial injection could only kill the mites but not the unhatched mite eggs. This perhaps may be due to inability of the drug to penetrate the thick egg shell and also due to its specific site of action (nervous system), Ivermectin may not be effective against the younger stages of the parasite inside the egg because the nervous system is not yet developed. However, administration of the second injection treats any newly hatched mites (Currie and McCarthy, 2010; Sharma and Signal, 2011). Administration of ivermectin has been reported to be effective in the treatment of mange in several countries (Sargison *et al.,* 1995; Sharma and Signal, 2011). All vital parameters of the animal were within the normal range showing that there is no systemic involvement in the condition. It is worthy of note that the result from clinical pathology examination showed marked eosinophilia indicating a high antigenic stimulation by the mites due to their burrowing activities and also due to the effect of their saliva and excreta (Sharma and Signal, 2011; Ameen *et al*., 2012). The animal had a body condition score of 2 on a scale of 5 which agrees with the reports of Lughano and Dominic (2006), who reported that animals with mite infestation become emaciated and die out of exhaustion probably due to abstinence from grazing and constant scratching of body. This may explain the slightly low packed cell volume (PCV) and hemoglobin (Hb) values observed (Table 1). This finding agrees with the observation of Hafeez *et al*. (2007), who reported that Hb and PCV in mange infested animals is lower than normal. Also, poor body condition is usually associated with undernourishment which leads to decline in immunity and susceptibility to pathogens including ectoparasites (Taylor *et al*., 2007). The hypoproteinaemia observed

may be associated with protein deficiency due to malnutrition and loss of plasma protein caused by dermatitis (Ameen *et al*., 2012).

CONCLUSION AND RECOMMENDATION

The treatment of the ewe twice with ivermectin at one week interval against sarcoptic mange was effective. The ewe recovered completely after 2 weeks of treatment. The client was advised to treat the rest of the flock in the farm because Sarcoptic mange is contagious. The environment should also be treated in case mites have dropped off into bedding or floor coverings. Animal owners and veterinarians should consider mite control in sheep as part of routine control of ectoparasites.

ABSTRACT
This study was carried out to investigate the effect of ginger (*Zingiber officinale)* on antioxidant status of turkey poults. A total number of ninety-six (96) two-weeks old American Bronze turkey poults were divided into four treatment groups in completely randomized design with a total of 12 experimental unit. The poults were assigned at the rate of 24 per treatment in 3 replicates of 8 poults per replicate. Ginger was washed, sliced, sundried and ground into fine particles. The test ingredient was used to compound the diets at different inclusion levels of 0, 0.2, 0.4 and 0.6%. A basal diet (turkey starter) was compounded for the period of the experiment (14day to 56day). Blood samples (3 turkey poults per treatments) were collected through the jugular veins at the termination of the experiment into heparinized bottle for antioxidant enzymes determination. The glutathione peroxidase (GPx) activity significantly ($p<0.05$) increased in the turkey poults fed diets supplemented with 0.2, 0.4 and 0.6% ginger. Significant ($p<0.05$) increased superoxide dismutase (SOD) activity was recorded at 0.2, 0.4 and 0.6% ginger when compared to 0% (control diet). Catalase (CAT) activity significantly ($p<0.05$) increased in turkey poults fed 0.6% ginger supplemented diets when compared to the other diets. It can be concluded that ginger when used as supplement in turkey poults diets at the rate of 0.6% can combat oxidative stress by enhancing the SOD, GPx and CAT activities.

Keywords: Ginger, Turkey poult, Antioxidant, Herbs, Growth promoters

INTRODUCTION
The use of antibiotic growth promoters in livestock and poultry production has been in vogue for many years due to the emergence of drug resistance microorganisms, side effects of antimicrobials and the harmful residual toxicity effect of drugs observed in food chain (Mahima *et al*., 2013). The valuable sources of medicines are currently in increasing demand and popularity on which about 80% of people in developing countries still rely for their primary health care (Verma and Singh, 2008).People are now aware of the limitations of synthetic drugs and chemicals in terms of higher cost, anticipated toxicity and adverse effects (Adu *et al*., 2009). On the other hand, the natural medicines are more suitable for animal health care with the benefits of total safety. In this era of food safety concern, emerging antibiotic resistance and residual effects in food products can play wonderful role for safeguarding health of humans and animals (Hashemi and Davoodi, 2012). Nowadays, there has been an increase in demand for natural antioxidants in food due to its health benefits against oxidative stress and several diseases. Plant derived antioxidants are gaining more demand in poultry nutrition because their meat has high content of polyunsaturated fatty acid and susceptible to lipid oxidation (Christaki, 2012). Spices like cinnamon, nut meg, ginger etc have been shown to have antioxidant properties as they contain the compounds such as polyphenolics, flavonoids and terpenoids (Botsoglou *et al.*, 2013). Studies showed that the active ingredients of herbs (ginger) have strong antioxidant effects including neutralization of superoxide, hydrogen peroxide and nitric oxide either by scavenging radicals or by increasing the production of glutathtion peroxidase (GPx), superoxide dismutase (SOD) and catalase (CAT) (Yarru *et al*., 2009). Ginger contains some important metabolites and alkaloids like gingerol, shogaol, gingerdione and other phenolic compounds which have antioxidant properties (Zhao *et al*., 2011). Ginger is the rhizome of the plant *Zingiber officinale* consumed as a delicacy, medicine or spice (Botsoglou *et al*., 2002). (Al-Amin *et al*.,2006) reported that a study conducted in-vitro tests show that the ginger extract might control the quantity of free radicals and the peroxidation of

lipids. The aim of the present study was to evaluate the role of ginger on the antioxidant enzyme status in turkey poults.

MATERIALS AND METHODS

The test ingredients ginger powder (*Zingiber officinale*) used for this study was purchased at the local market, Ado-Ekiti. The test ingredient was washed, sliced, sundried and ground into fine particles. It was used to formulate the diet at different inclusion levels of 0%, 0.2%, 0.4% and 0.6%. A basal diets (turkey starter) was formulated for the period of the experiment (14day to 56day) to meet the NRC (1994) requirements for turkey poults. Thereafter, the basal diet was divided into four (4) diets. Diet 1 contained 0% of ginger supplementation, diet 2 was supplemented with 0.2% of ginger, diet 3 was supplemented with 0.4% while diet 4 was supplemented with 0.6%. Ninety-six, two (2) weeks old American Bronze turkey poults breed were randomly distributed to four dietary treatments (8 turkey poults per replicate); 24 poults per treatments) in a completely randomized design (CRD).Eight (8) birds were housed in their respective pen, they were fed ad-libitum throughout the period of the experiment (42days). On the last day of experiment (42day), blood samples collection (3 turkey poults per treatments) was done in the morning after the birds were starved overnight into a heparinized tube which was kept in ice to provide hemolysate for determination of activity of antioxidant enzymes superoxide dismutase (SOD) (Misra and Fridovich, 1972), glutathione peroxidase (GPx) (Rotruck *et al*., 1973) and catalase (CAT) (Aebi, 1974). All data collected were subjected to analysis of variance using SPSS version 20. Duncan's Multiple Range Test of one way ANOVA was used to analyse the mean differences of the same parameters, significant differences were considered where necessary at a level of ($P<0.05$**).**

RESULTS AND DISCUSSION

The effect of dietary ginger on antioxidant parameters of turkey poults is presented in Table 1. The Glutathion peroxidase (GPx) value was significantly ($p<0.05$) higher in birds on diets 2,3,4 than the values recorded for birds on control diet suggesting that ginger supplementation at 0.2, 0.4 and 0.6% significantly increased the activities of GPx. There was a significant ($p<0.05$) increase in the values of superoxide dismutase (SOD) in birds fed the test ingredients (diets 2,3 and 4). The highest value of SOD was recorded for birds on diet 4 while the lowest value of SOD was recorded for birds on control diet. The catalase (CAT) values recorded for birds on diet 4 was significantly ($p<0.05$) higher than the values recorded for birds on other diets. Ginger contains some important metabolites and alkaloids like gingerol, shogaol, gingerdione and other phenolic compounds which have antioxidant properties (Zhao *et al.*, 2011). In addition, the positive effects of antioxidants properties of phytochemicals to poultry on oxidative status parameters was reported by Akbarian *et al*. (2016).

Table 1: Effect of ginger on antioxidant parameters of turkey poults fed experimental diets

	Diets				
	1	2	3	4	± SEM
	Ginger inclusion				
Parameters	Control diet				
GPx (µ/mol)	4.47^{c}	10.73^{b}	11.04^{b}	11.71^{a}	0.88
SOD (%)	40.50^{d}	44.88^{c}	55.66^{b}	60.21^{a}	0.05
CAT (mg/g)	225.31^{a}	257.02^{b}	261.24^{b}	285.18^{a}	0.62

GPx: glutathione peroxidase; SOD: superoxide dismutase; CAT: catalase.Means with different superscript on the same row differ significantly (P<0.05)

Abstract
This paper presents a short review of the effects of activated charcoal (AC) on different aspects of poultry performance. Activated charcoal is a solid, porous, tasteless and black carbonaceous material prepared from a variety of carbon containing materials, including agricultural residue. In powder form it acts as adsorbent for many toxins according to physical and chemical nature of the precursor. Several studies reviewed showed AC, as a non-digestible and cheap substance that may be of benefit to poultry gut health, growth and laying performance, especially in the tropics where microbial degradation of feed is a major threat.

Keywords: Activated charcoal, poultry performance, broilers, layers

INTRODUCTION

Feed remains the most important component of the cost of production in the intensive poultry sector. Several biotechnology techniques are currently being used to reduce cost and increase poultry productivity. One of the viable methods has been the use of growth promoters such as prebiotics to improve feed efficiency and poultry health. These substances do not contribute to the nutrient needs but are rather used to control pathogenic organisms in the gut. This is desirable in view of the fact that the gut is one of the major organs determining the performance of birds and the economics of production, with the profile of intestinal microflora playing a significant role in gut health. However, most of these substances or natural growth promoters are not readily available to Nigerian poultry farmers who are mostly small-scale producers. Therefore, cheaper alternative additives like activated charcoal and clay minerals (Thacker, 2013) which could be produced on the farm or supplied from a nearby cottage industry will be of value to farmers.

Activated charcoal also called activated carbon or biochar is a solid, porous, tasteless and black carbonaceous material prepared from a variety of carbon containing materials, including agricultural residues. Activated charcoal when ground into fine powder acts as an adsorbent for many toxins with the absorbance being dependent on pore size, surface area, concentration and chemical nature of the precursor (Yahya *et al.*, 2015). Awad *et al.* (2009) reported that adding activated charcoal to poultry diet can help recover the intestinal integrity, improve gut health and thus increase nutrient availability and absorption. Currently, the use of activated charcoal in poultry production is an emerging research area that is still generating the needed literature for ultimate on-farm application. There is therefore the need to articulate what is currently known, especially as it applies to poultry production in the tropics.

This paper presents a short review of the effects of activated charcoal on different aspects of poultry performance.

EFFECT ON GROWTH, HAEMATOLOGY AND SERUM CHEMICAL PROFILES

Growth is an increase in mass of a living substance and so, weight change can be considered an index of growth. Odunsi *et al.* (2007) supplemented wood charcoal into broiler starter and finisher diets and reported that body weight gains and feed conversion ratio (FCR) were significantly better in the control group than those fed charcoal based diets. This is in agreement with the report of Kutlu *et al.*(2001) that charcoal supplementation reduces feed intake and feed conversion ratio, with the reduction being attributed

to higher bulk density of charcoal supplemented feed (Evans *et al.*, 2015). Majewska and Zaborowski (2003) however reported that AC supplemented birds were 1- 6.5% heavier, 5.9% better in their FCR and 1.6% better in their survival rate than the control group. Dim *et al.* (2018) reported that the final body weight, average daily weight gain and FCR were better in birds on 6% AC inclusion than other groups after 56 days trial period similar to the reports of Kutlu *et al.* (1999).

Dim *et al.* (2018) also noted that WBC count and PCV were not affected at both the starter and finisher phases, while haemoglobin concentration (Hb) and RBC count were significantly improved while cholesterol and lipoprotein levels were significantly reduced, probably due to the ability of the birds on AC to maximally utilize the vitamin-mineral premix in the diet. No significant differences in high density lipoprotein (HDL) and triglycerides were observed across the treatment groups. Majewska *et al.* (2009) reported that dietary supplementation of AC at 0.3% did not significantly affect RBC, WBC, Hb and PCV values of broilers fed aflatoxin-B1 contaminated feeds. Majewska *et al.* (2002) had used charcoal as feed additive to raise turkeys and reported non-significant differences in the serum biochemical indices.

EFFECT OF ACTIVATED CHARCOAL ON CARCASS QUALITY

.Kutlu *et al*. (2001) reported that wood charcoal significantly increased the carcass weight, carcass yield and carcass ash and fat contents in broiler chickens. However, charcoal inclusion to the diet did not affect carcass dry matter and protein contents significantly. Majewska and Zaborowski (2003) reported that carcass yield, liver, spleen and kidney weights did not show any major variations among the treatment groups though the broiler fed 7.5% wood charcoal had the least percentage carcass yield and abdominal fats. While cut-up parts did not vary across the groups, the lung, heart and gizzard showed slight changes among the treatment groups when compared with the control. This showed that wood charcoal used in the study had no major physiological effects on tissue and organ development and functions when compared with the control. However, a positive development in the reduction of abdominal fat deposition in broilers fed wood charcoal based diets was noticed when compared to the control group. These results with respect to subcutaneous and abdominal fat deposition could indicate lower intake of dietary energy with charcoal inclusion in the diet (Kutlu *et al.*, 2001). This means that as the charcoal level in the diet increases, FCR and fat excretion increases, while fat deposition also reduces.

EFFECT OF ACTIVATED CHARCOAL ON LAYING PERFORMANCE AND EGG QUALITY

The addition of beneficial feed additives such as AC to the diet can help recover the intestinal integrity, improve gut health and thus increase nutrient availability and absorption (Awad *et al.*, 2009) which result to increased laying performance. A mixture of bamboo charcoal powder and bamboo vinegar has been shown to induce a significant increase in egg production by stimulating intestinal functions of laying hens in the early phase of production (Yamauchi *et al.*, 2010). These were attributed to the beneficial effects of the product in promoting intestinal functions which may help to absorb and assimilate more nutrients. In late phase of production, Rattanawut *et al.* (2017) supplemented with the commercial bamboo vinegar, SuperBob® at 0, 0.5, 1.0 and 1.5% inclusions to the basal diet. They reported no significant differences between the groups with respect to egg shell weight, yolk colour and Haugh (an index of albumen quality).

Kutlu *et al.* (2001) studied the effects of dietary oak charcoal on laying performance using Hyline breed fed a standard commercial layer diet and supplemented with 0, 10, 20 and 40g ground wood charcoal per kg. There was no effect on egg weight, albumen weight, yolk weight, shell weight, shell thickness and shape index. However, AC supplementation reduced the number of cracked eggs in a dose-related manner which is attributed to the absorption capacity of charcoal for dietary fat and its excretion. Increased fat excretion promoted by charcoal probably enhanced mineral utilization, particularly calcium which promotes shell formation in the shell gland. Charcoal supplementation induced a non-significant reduction in feed intake, egg production and FCR. The lower feed intake was possibly due to higher bulk density and blackening of the diets by charcoal and decrease in palatability (Jindal *et al.*, 1994).

EFFECT OF ACTIVATED CHARCOAL ON EXCRETORY PRODUCTS

Studies by Plank *et al.* (1990) revealed that wood charcoal increased fat excretion which is expected in view of its binding effect on fat, fat soluble substances and noxious substances that may interfere with digestion. This increased fat excretion could be beneficial in preventing the malfunctioning of the GIT associated with poor fat digestion as a result of limited bile synthesis in young birds. This result in addition to reduced carcass fat content and abdominal fat weight suggest reduced intake of dietary energy sources with charcoal inclusion in diet (Kutlu *et al.,* 2001). In other words, as the charcoal level in the diet is increases, the FCR and fat excretion increases, while fat deposition in the body decreases.

Activated charcoal inclusion in the diet reduces nitrogen free extract excretion while markedly increasing fiber excretion in a dose-dependent manner (Duke, 1986). This means that increased levels of AC in high fiber diet will increase fiber consumption and excretion. The major constituents of dietary fibre are cellulose, hemicellulose and lignin which are poorly digested by birds (Kutlu *et al.,* 2001). Activated charcoal also increases carcass ash content in a dose-dependent manner and this is a reflection of the increased mineral intake (Duke, 1986).

Effect of activated charcoal on gastrointestinal tract histomorphology and Ecology

Activated charcoal as an adsorbent has the potential to condition the cell membranes, reduce surface tension by eliminating gases and toxins in the GIT to improve absorption and utilization of nutrients (Majewska *et al.,* 1999). Broiler chickens fed 1% bamboo charcoal diet recorded the highest body weight with the jejunal villus height and area being higher than those of other groups (Xia *et al.,* 2004). Increased villus height is indicative of a greater absorptive surface area and a better capacity of absorbing available nutrients. Villus height is increased by enhanced efficiency of digestion and absorption in the small intestine due to increased population of beneficial bacteria that supply nutrients and stimulate vascularization and development of the intestinal villi (Gilmore and Ferreti, 2003). Choct (2009) reported a shorter villus when the counts of pathogenic bacteria increased in the GIT, which results in fewer absorptive and more secretory cells. It has been suggested that there is a strong correlation between gut structure and type of feeding materials and that villus height can be used to predict weight gain. A commercial charcoal product, Nekka-Rich®, was fed as prebiotic to leghorn chickens and it was able to significantly reduce the Salmonella recovered from the large intestine and faecal samples.

CONCLUSION

Activated charcoal, a non-digestible and cheap substance may be of benefit to poultry gut health, growth and laying performance, especially in the tropics where microbial degradation of feed is a major threat.

ORGAN AND CARCASS WEIGHT VARIATION IN *EIMERIA TENELLA* INFECTED BROILER CHICKENS TREATED WITH METHANOL EXTRACT OF *PARKIA BIGLOBOSA* ROOT BARK

Garba M. U.

[1] Department of Veterinary Physiology and Pharmacology, Faculty of Veterinary Medicine, University of Nigeria Nsukka, Enugu, Nigeria; matthias.ugwuoke@unn.edu.ng (*Corresponding Author)*

ABSTRACT

The experiment was designed to evaluate the effect of methanol extract of *Parkia biglobosa* root in *Emeria tenella* infected broilers. One hundred and fifty broilers grouped into 6 groups (n = 25) were used for the study as follows: infected treated with extract (A), infected treated with amprolium (B), infected untreated (C), uninfected untreated; (control) (D), uninfected treated with extract (E), and uninfected treated with amprolium (F). Each broiler was infected at 28 days of age with 20,000 infective *Eimeria tenella oocysts* and treated at day 7 post infection with either extract or Amprolium at a dose rate of 200 mg/ml in drinking water for 7 days. Carcass and Organ weights were measured at 35 days of age. The results showed significant difference in the carcass and organ weights (P>0.05) between the groups. This study proved that the root bark of *Parkia biglobosa* has no adverse effects on organs of treated broilers, instead improved carcass weight and ameliorated clinical signs of bloody diarrhea associated with *Eimeria tenella* infection in broilers.

Keywords

Broilers, Coccidiosis, Organs, *Parkia biglobosa*, Weight.

INTRODUCTION

Coccidiosis is one of the most economically important prevalent parasitic diseases which has adversely affected the growth and fortune of poultry farmers worldwide (Gharekhani et al., 2014). Coccidiosis affects virtually all domestic and wild species, causing signs such as paleness, diarrhea with or without blood, poor feed conversion, weight loss, and in severe cases even death. *Eimeria*, protozoan parasites of the Phylum Apicomplexa are considered the main risk to avian production since they are the causative agent of avian coccidiosis (Blake *et al*., 2015). Avian coccidiosis is caused by seven species of *Eimeria*, which parasitize chickens intestine. According to a recent estimate, the global cost of the protozoan to the poultry industry is estimated to be over USS 2.4 billion per annum (Ola-Fadunsin *et al*., 2017). In Nigeria, the disease is caused by *Eimeria tenella, E. necatrix, E. bruneti, E. acervulina, E. mitis* and *E. praecox* (Jatau *et al*., 2012). These species have predilection sites in the different parts of gastrointestinal tract.The management comprises of ionophorous compounds (ionophores) and synthetic drugs (chemicals). However, the increased occurrence of resistance against routine anticoccidial drugs, the toxic effects of these chemicals on poultry and the development of drug residues in poultry meat and egg (Goetting et al., 2011) have left the poultry industry with a renewed challenge for coccidiosis prevention and control. These have propelled the search for alternative strategies among which plant products provide a good alternative. Some of these plants are indigenous to Nigeria and may serve as a source of foreign revenue when exported to developed economies where people are becoming more aware of the toxic effects of using chemotherapeutic agents in producing animal protein. *Parkia biglobosa* is one of such plant alternatives. The stem bark of *P. biglobosa* has been reported to have some coccidiostatic activities (Maikai *et al*., 2007) and antimalarial effects (Traore *et al*., 2013). The stem bark is used for treating hypertension (Karou *et al*,, 2011) and listed as having wound healing properties in South-Western Nigeria (Adetutu *et al.*, 2013). A decoction of the root is used in the treatment of coccidiosis by natives in western Nigeria (Olanipekun, 2014). There is no data on the anticoccidial activity of the root bark extract of *P. biglobosa* in

broiler chickens. In this study, the anticoccidial activity and the effect of methanol extract of *P. biglobosa* root bark was evaluated in broiler chickens experimentally infected with *Eimeria tenella* oocysts.

RESULT

Carcass yield and organ weight

Data on body weight, carcass weight/dressed and parts of the broilers are shown in Table1. It is observed that among the infected groups, the body weight was higher in the *P. biglobosa* treated group A (3.2 kg/broiler) and the amprolium treated group B (3.2 kg/broiler). The infected but untreated group C had the least body weight (2.7 kg/broiler). In the uninfected broilers, group E (*P. biglobosa* treated) recorded a higher body weight (3.4 kg/broiler), followed by the amprolium treated group F (3.3 kg/broiler) and lowest the untreated group D (3.1 kg/broiler). In the results, it was also observed that among the infected groups the carcass yield was higher in group A (2.8 kg/broiler), followed by B (2.6 kg/broiler) and lowest C (2.4 kg/broiler) (Table1). Among the uninfected groups, D (untreated) recorded 2.5 kg/broiler, E (P. biglobosa treated) and F (amprolium treated) recorded 2.6 and 2.8 kg/broiler, respectively.

DISCUSSION

The slight difference observed by the decrease in weight of the carcass parts (thigh, back and neck, wings) in group C and D (Table 1) may be due to the lack of treatment of the broilers with either the *P. biglobosa* or amprolium. Also significant weight difference ($P < 0.05$) existed in group B among the weight of the organs, where the liver (1.8%), heart (0.6%) and the spleen (0.2%) weighed more than those in the other groups as shown in Table 1. The variation in weight of the organs in group B may be due to a compensatory mechanism in relation to treatment with amprolium and the coccidian infection. *Eimeria tenella* is a very pathogenic chicken coccidia that parasitize caecum of young chickens and is characterized by acute onset manifested by clinical signs of bloody diarrhea due to invasion of the mucosal lining of the caecae by the second generation merozoites and the associated microscopic changes due to coccidiosis which include congestion of the mucosa of the intestine, diffuse or patchy haemorrhagic enteritis, lymphocytic and mononuclear cells infiltration of the intestinal mucosa and sloughing of epithelial lining (McDougald and Reid,1997). Also, it is a known fact that the weight of organs in broilers is indicative of the response of birds to the feed intake in relation to their age or growth of broilers. The weight of organs in broilers also reflects the anatomical response of broilers to the type of diets consumed, such as the use of whole grains in feed or large high fibre particles (Atteh, 2004).

Table 1: Organ and Carcass body weight (%) of broiler chickens treated with *Parkia biglobosa* and Amprolium after infection with *Eimeria tenella* oocysts

Group Parameters	A Infected	B Infected	C Infected	D Uninfected	E Uninfected	F Uninfected
Average live Body weight (Kg/broiler)	3.2[b]	3.2[b]	2.7[a]	3.1[b]	3.4[b]	3.3[b]
Carcass/dressed weight (kg/broiler)	2.8[b]	2.6[b]	2.4[a]	2.5[b]	2.6[b]	2.8[b]
Carcass/live body weight ratio (%)						
Breast/chest	23.3[b]	22.2[b]	23.1[b]	23.2[b]	23.1[b]	23.2[b]
Thigh/legs	22.4[b]	22.0[b]	22.5[c]	20.8[a]	22.7[b]	23.2[b]
Back/neck	21.8[b]	21.1[b]	20.8[a]	22.2[b]	22.1[b]	22.3[b]

Heart	0.6	0.8	0.4	0.6	0.5	0.6
Spleen	0.2	0.3	0.2	0.2	0.1	0.2
Intestines, etc.	8.3	10.2	12.1	11.3	10.7	9.2

*****Means within the horizontal line, followed by different lower-case superscripts are significantly different ($P < 0.05$). Group A- treated with *P. biglobosa* extract, B-treated with amprolium, C and D- not treated, E- treated with *P. biglobosa* extract, F- treated with amprolium.

CONCLUSION

In conclusion, this study has shown that the methanol extract of *Parkia biglobosa* root bark may have improved the carcass yield of broilers and also ameliorates clinical signs of bloody diarrhea consistent with *Eimeria tenella* infections in broiler chickens. The root bark of *P. biglobosa* has no harmful or adverse effect on the organs of treated broilers with or without *Eimeria tenella* infection. It is recommended that further research on the potential use of the root bark of *P. biglobosa* for the control of coccidiosis in broiler chickens be carried out. *P. biglobosa* root bark may be recommended to poultry farmers in the absence of conventional anticoccidial drugs.

ABSTRACT
Animal welfare has arisen in society to express ethical concerns about the quality of life experienced by animals, particularly animals used in production agriculture.Although animal welfare studies originate more in developed countries, the topic is also emerging in developing nations. Animal welfare could be determined in terms of biological functioning that measures reactions to stress, including plasma levels of glucocorticoids, catecholamines, prolactin and endorphins, as well as heart rate and brain levels of neurotransmitters. Geographical and human conditions in sub-Saharan Africa suggest the welfare of trade animals for slaughter are negatively affected and that this also negatively affects meat quality and hence have economic impact. Nigeria has a Criminal Code which includes regulations on animal protection, that regulat markets bodies and road check points to monitor the welfare of trade cattle. Field reports indicate that these regulations are rarely – if ever – enforced.

Keywords: Animal welfare, trade cattle, agriculture, Nigeria

INTRODUCTION

Animal welfare concerns the state of an animal relative to the environment in which it lives. In recent times, animal welfare as a term, has arisen in society to express ethical concerns about the quality of life experienced by animals, particularly animals that are used in production agriculture. The term is therefore not one that necessarily expresses a scientific concept, nevertheless, because scientific methodsare used to identify, interpret and implement societal concerns about animal quality of life issues, animal welfare has become established as a scientific field (Duncan, 2004).

Thus, animal welfare has now become measurable characteristics of an animal at a particular time or during a period (Grandin, 2015).Still animal welfare remains a complex and emotional topic which is difficult to define and assess. For example, the handling, loading, transporting and unloading of animals can have very substantialeffects on their welfare and meat quality, which may be given different interpretations by different stakeholders. Therefore, there is the need to monitor welfare issues associated with trade animal handling and transportation, especially in developing countries were such topics are considered novel.

This paper reviews the concept of animal welfare and the current situation in trade cattle in Nigeria.

SCIENTIFIC PERSPECTIVES OF ANIMAL WELFARE

Animal welfare concern has become well established in many industrialized countries, particularly in the last 50 years. Increased ethical concerns about animal farming for food production and increased attention to animal rights drive these developments safeguard animal welfare (Fraser *et al.*,1997) that has led to regulations on the production, transport, and slaughter of farm animals (Caporale*et al.*, 2005). Scientific research on animal welfare issues has also increased, especially in response to public concerns about intensive production systems (Grandin, 2015). Although animal welfare studies originate more in developed countries, the topic is also emerging in developing nations (Mugande and Croney, 2019). In applying animal welfare approaches developed in industrialized countries in developing countries, theremay need to consider the economic, cultural and religious peculiarities of such countries (Mugande and Croney, 2019).

The scientific assessment of animal welfare involves measurements that capture different viewpoints on what constitute a good quality of life for animals. Development of scientific disciplines relevant to animal welfare has a long history and has been summed to include animal husbandry, animal science, veterinary

medicine and behavioral science, which contribute to the understanding of welfare problems of transport of farm animals to slaughter location (Grandin, 2015). Welfare is affected by many factors, as expressed by the five Freedoms (freedom from fear and distress; freedom to express normal behavior; freedom from hunger and thirst; freedom from discomfort; and freedom from pain, injury and distress) (Widowski *et al.,* 2016). It is also affected by the fact that people vary in the emphasis that they place on physical aspects, mental aspects and naturalness. Therefore, science has to cope with this complexity by applying a systematic approach to the asking of questions, and yielding answers that, as information accumulates from one or more comparable situations, are increasingly reliable and generalizable (Smith and Grandin, 2004). Similarly, scientific measurements of animal welfare have been shown to include health and biological fitness, the motion or subjective experiences of animals as well as ability to perform natural or specie-typical behavior pattern (Widowski *et al.,* 2016).

It is now understood that welfare and product quality are related and that poor welfare practices will result in inferior meat quality. Welfare varies on a scale from very good to very poor. Health is also an important part of welfare, while feelings, such as pain, fear and various forms of pleasure, are components of the mechanisms for attempting to cope and so should be evaluated where possible in welfare assessments (Broom, 2008). Where an individual is failing to cope with a problem, it is said to be stressed. Stress is an environmental effect on an individual, which overtaxes its control systems and reduces its fitness or appears likely to do so (Broom and Johnson, 2000). Welfare may be considered in terms of the subject experiences of animals or in terms of biological functioning that measures reactions to stress including plasma levels of glucocorticoids, catecholamines, prolactin and endorphins, as well as heart rate and brain levels of neurotransmitters(Broom, 2008).

Animal Transportation and Welfare

Around 60 billion animals are reared for food each year worldwide, most of which are transported for slaughter, often for long distances, both within and between countries. This massive movement of live animals takes place against a background of increasing concern and understanding of factors that affect animal welfare during transportation and increasing awareness that animal welfare may be correlated with food safety and quality. Physical welfare problems caused by transportation include injury, disease and stress which may be detected from behavior and from physical effects such as failure to grow or from physiological measurements (Ukwu, 2013). Transported animals may die or mortality may be increased by high or low temperatures, by long journey times and by transporting very young animals(Hong *et al.,* 2019).

Evidencesof mental welfare are usually based on whether animals have what they want and whether they are suffering. For example, many preferences of animals may be frustrated by transport, both to avoid conditions such as vibration and noise, and to express normal behavior(Hong *et al.,* 2019). Forms of suffering caused by transport include hunger, thirst, discomfort, pain, frustration, fear and distress (Appleby *et al.,* 2008), which generally increase with time of deprivation or exposure, such as during long-distance transport. In order to reduce the adverse effects on food animals and the economic losses encountered during animal transportation, The EU developed the Welfare of Animal Transport Order 1997, which allows a maximum journey time of 19 hours that must include a one-hour break for food, water and rest after each 8-9 hours.

EFFECTS OF TRANSPORTATION ON TRADE ANIMAL WELFARE

The necessity of transportation in trade animal production for meat cannot be over emphasised as the need to transport food animals occurs essentially in commercial agriculture and to a lesser extent in the rural or subsistence sector. Animals areusually moved due to marketing, slaughter, re-stocking, and drought areas to better grazing and change of ownership. It involves several stages starting with gathering of animals from farms, driving or trekking them to markets, where they are gathered in corrals and pens, loading them

into vehicles, transporting them to the slaughterhouse, unloading them, and then driving them to lairage pens and to slaughter (Gallo *et al.,* 2018). For trade animals that go through livestock markets, the whole processes get repeated several times as they are not directly from farm to slaughter(Appleby *et al.,* 2008). According to Minka and Ayo(2009), geographical and human conditions in sub-Saharan Africa suggest that in many occasions, the welfare of trade animals for slaughter are negatively affected and that this also negatively affects meat quality and hence have economic impact. Therefore, animal welfare improvement is necessary to reduce suffering in food animals, which will better the conditions of the livestock and the safety of the handlers.

EFFECT OF ANIMAL HANDLING ON TRADE ANIMAL WELFARE

Inappropriate handling of trade cattle during the entire transport operation as loading, journey time and unloading can be more stress-inducing than the transportation itself. Arney and Aland(2010) reported that improper handling due to poor welfare causes impairment of meat quality, not only through mechanical damage to the carcase, but also through chemical changes in the meat, such as reduced pH and the consequences of high levels of cortisol, which is released during periods of stress. The risk of injury and stress during handling of livestock can be high, causing financial loss to producers, transporters and the slaughterhouse (FAO, 2002).

Gallo *et al.* (2018) reviewed the standard regulation for handling trade animals in South America countries that cover production systems, transport and slaughter, with the general aim of acknowledging that farm animals are sentient beings and that there is a need to reduce pain and unnecessary suffering in them. The regulation for industrial production systems as outlined by the EU includes indicationsregarding feeding, health, and housing conditions; with specific prohibitions during handlinglike hitting, pricking, or grabbing animals as well as trainingobligations. These make it compulsory to have at least one person trained as an animal handler ineach productive system (Gallo *et al.,* 2018).

Loading of animals into a transport vehicle has been reported as one of the most stressful procedures and a critical point within the general transport process, which interfere with animal welfare (Miranda *et al.,* 2009). The standard for maintaining welfare is that the stockmen are trained in animal handling, understanding when the animals are calm and that the infrastructure is adequate, particularly loading ramps (Gallo *et al.,* 2018).

WELFARE OF TRADE CATTLE IN NIGERIA

The welfare of trade cattle in Nigeria is an issue worth reviewing because the livestock production approach employed by the farmers is usually the traditional system of production. This system involves traditional methods of production, including health and marketing. (Okoli*et al.,* 2005). Livestock is exchanged not only between northern markets but also between the northern and southern parts of Nigeria (Okoli and Kalla, 2008). The welfare concerns of trade cattle in Nigeria therefore rise from ativities in the local markets in the north, handling and disease management as well as the long distance journey during road transportation to the markets in the South (Minka and Ayo, 2009). These processes expose trade cattle to environments that cause injuries, sickness, fear agitations and in some cases death.

Nigeria has aCriminal Code (amended 1991), which includes regulationson animal protection that regulations markets bodies and road check points to monitor the welfare of trade cattle (Appleby *et al.,* 2008). Owners guilty of cruelty to animals are first given the option of a fine, and arenot liable to imprisonment unless they are unable to pay the fine. Field reportsindicate that these regulations are rarely – if ever – enforced (Appleby *et al.,* 2008).

ABSTRACT
This study was conducted to assess the level of Aflatoxin B_1(AFB1) contamination in poultry eggs, feeds and litters collected from six (6) randomly selected farms at Malumfashi Local Government Area of Katsina State. A total of number of 36 samples were analysed for AFB_1. This comprised of three (3) feeds samples and three (3) eggs samples were collected from each farm. The AFB_1concentrations (µg/kg) in all the samples was analysed using ELISA kits. The *Aspergillus flavus* was the most prevalent Fungus followed by *Aspergillus niger*. The mean concentration of AFB_1 in poultry feeds was 15.93±1.53 µg/kg and the least was 5.27±1.31 µg/kg. Approximately 83% of the feed samples were having AFB_1 contamination above 5.00 µg/kg as recommended by FAO for animal feeds. Thus, farmers should frequently test their livestock feeds for aflatoxins and eggs should also be properly screened before consumption.

Keywords: Fungi, Aflatoxin, Poultry eggs, Malumfashi

INTRODUCTION
Mycotoxins cause illness and mortality in domestic animals fed moldy feedstuffs. These acute intoxications can have devastating effects and are difficult to diagnose and treat because the suspect feed may be consumed before it can be tested (CAST, 2003). It has been estimated that more than five billion people in developing countries worldwide are at risk of chronic exposure to aflatoxins through contaminated foods (Strosnider *et al*., 2006). In many parts of Africa, the need to eat outweighs other considerations such as food safety, and as such, this has made food-borne intoxications to be a serious problem in many respects. It was reported that about 40% of the productivity in birds was lost to diseases in developing countries but was most likely due to diseases exacerbated by aflatoxins (Bennett, 2003). Darwish *et al*.(2014) reported that aflatoxins are the most common mycotoxins (43.75%) in Africa followed by fumonisin (21.87%), ochratoxins (12.5%), zearalenone (9.38%), deoxynevalenol (6.25%) and beauvericin (6.25%). Darwish *et al*.(2014) reported that there is high levels of aflatoxin in samples collected from several African countries including South Africa, Lesotho, Egypt, Tunisia, Morocco, Sudan, Tanzania, Zambia, Uganda, Kenya, Ethiopia, Nigeria, Ghana, Benin, Mali, Togo and Bourkina Faso. Aflatoxin B_1 have been given considerable attention because of their demonstrated carcinogenic potential and hepatotoxic effects in both humans and animals (Fouad *et al*., 2019; Negash, 2018; Daodu and Adebowale, 2016). There has not been sufficient report on aflatoxin contamination in poultry feeds and eggs at Malumfashi local government area of Katsina State. Thus, this study provided a baseline data on aflatoxin contamination in poultry feeds and eggs produced by poultry farmers in Malumfashi Local Government Area of Katsina State.

MATERIALS AND METHODS
Study location
Malumfashi is one of the notable Local Government Areas of Karadua Zone, Katsina State of Nigeria. It is located at 11°48′N 7°37′E11.800°N 7.617°E, with a total area of 674 km2 (260 and a population of 182,920 (NPC, 2006).

Sampling method
In this study 18 industrial eggs and 18 feeds samples from 6 different poultry farms (randomly selected out of 66 farms) with 3 replicates (in each replicate 3 eggs and 3 feed samples). Aflatoxin-B1 concentration in these samples was determined via ELISA techniques.

Aflatoxin b_1 determination procedures materials used
Microplate of 96 wells; Micropipette; Weighing balance; Incubator with in-build digital shaker; Laboratory Blender; Conical flasks; Beakers; pH meter; Measuring cylinder; Filter paper; Voxtex mixer; Pipette tips; ELISA Reader (BIO-RAD); Magnetic Stirrer; Orbit-Shaker

Aflatoxin B_1 quantification procedures
The quantification of aflatoxin B_1 was done using ELISA technique following the protocol.

RESULTS AND DISCUSSION
The distribution of the fungal isolated from the feed samples is presented in Table 1. The result showed that the feed samples were infected more with Aspergillus *flavus* with 94.4% followed by *Aspergillus niger with* 61.1% while the occurrence of *Penicillium* was found to be the least (33.3%). These findings are similar with those reported by D'Mello (2004) and Sivakumar *et al*. (2014). This might be due to the use of infected feed ingredients and feed storage system. *Aspergillus spp* are known to thrive better in high temperature and humidity (D'Mello, 2004).

Table 1: Distribution of isolated fungi from feed samples across the selected farms

Farms	No of samples	Fungi Isolated from feed samples				
		Aspergillus niger	***Aspergillus flavus***	***Fusarium***	***Penicillium***	***Rhizopus***
A	3	1	3	2	1	2
B	3	1	3	2	1	0
C	3	1	3	1	2	2
D	3	2	2	3	1	0
E	3	3	3	0	1	2
F	3	3	3	0	0	2
Total	18	11	17	8	6	8

Figure 1 above shows the level of AFB_1 contamination across the feed samples that were analysed. The highest mean concentration of AFB_1 was detected in Farm A with about 15.93µg/kg (±1.53 µg/kg) and followed by Farm C with a mean concentration of 15.47 µg/kg (±2.46 µg/kg). Farm F has the least AFB_1 concentration with a mean of 5.27 µg/kg (±1.31 µg/kg). These variations might be as a result of differences in the feed ingredients and their feed management systems. Similar levels of AFB_1 contamination in animal feeds have been reported from different parts of the world (Pereira *et al.*, 2019). Kana *et al*. (2013) also reported AFB_1 concentration of 2 – 23 µg/kg for layer feeds and 2 – 52 µg/kg for broiler feeds in Cameroun.

Figure 1: **shows the level of AFB_1 contamination across the feed samples**

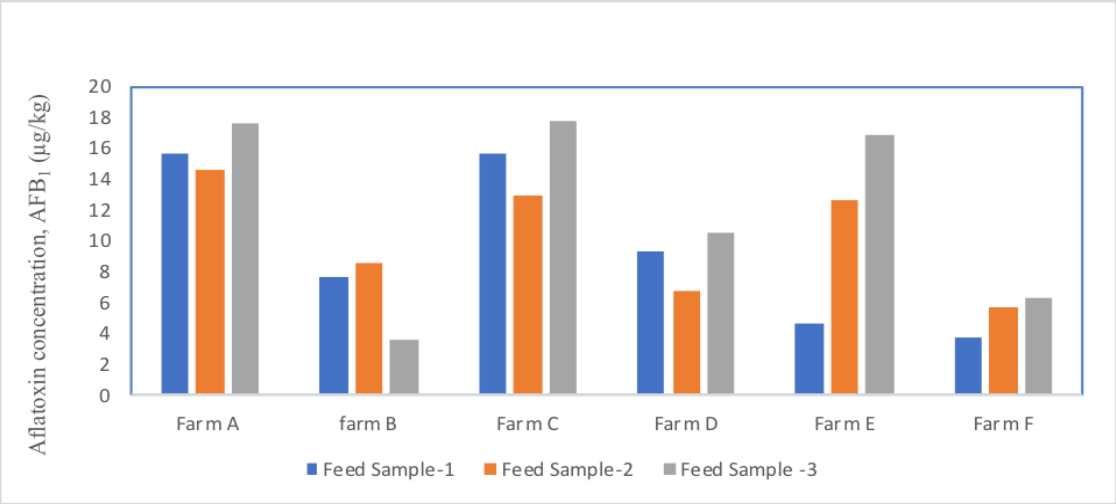

Table 2 shows the distribution of isolated fungi from egg shell swabs across the selected farms in Malumfashi. *Aspergillus flavus* had the highest occurrence (88.9%) in the egg shell while the least obtained was *Penicillium* with 16.7%. This contamination of the egg shells might be as a result of the contact between the eggs and feeds after laying. Similarly, Eggshell contamination may be initiated due to the conditions of egg acquisition, that is, the quality of straw and feed, the presence of dust, temperature and moisture (Lukasz *et al.,* 2018). We can suppose that the eggs produced in the deep litter indoor housing, free-range or even organic systems are at the highest risk of contamination with microscopic fungi

Table 2: Distribution of isolated fungi from egg shell swabs across the selected farms in Malumfashi

Farms	No of samples	Fungi Isolated from egg shell swabs				
		Aspergillus niger	**Aspergillus flavus**	**Fusarium**	**Penicillium**	**Rhizopus**
A	3	2	3	3	1	0
B	3	3	2	2	1	2
C	3	1	2	1	0	0
D	3	1	3	2	1	0
E	3	0	3	0	0	3
F	3	1	3	0	0	3
Total	18	8	16	8	3	8

CONCLUSION AND RECOMMENDATIONS

Aspergillus flavus was found to be the most predominant Fungus contaminating poultry feeds and commercial table eggs. The highest mean concentration of AFB_1 obtained in this study was 15.93µg/kg (±1.53 µg/kg) and the least was 5.27 µg/kg (±1.31 µg/kg) for the poultry feed samples. Poultry farmers should check their feeds for moulds before offering them to their livestock and eggs should be properly screened for aflatoxin contamination before selling them to consumers. More research is still needed to developed a general regulation template for an acceptable level of Aflatoxin in eggs and poultry feeds.

ABSTRACT

Unethical practice in handling and slaughtering of cattle is on the increase in Nigerian abattoirs. Proper handling and prevention of stress in animals prior to slaughter avails good carcass. The study was carried out at Akinyele international Cattle Market abattoir in Ibadan for a period of five consecutive weeks. information were gathered on the restraining methods, slaughtering style, slaughtering interval and processing interval from 7.00am – 7.00pm daily using direct observation with the aid of checklist. Data were subjected to descriptive statistics using frequencies and percentages. Out of the 1839 slaughtered cattle observed at the facility during the period of the study, a total number of 1584 cattle (87.2%) were slaughtered without restraining while 255 were restrained before slaughter. A total of 1635 cattle (89%) were bled by slashing through the neck while 11% were slaughtered by piercing narrowly with knife. Most cattle (72.2%) were slaughtered within the first 5 minutes of arrival at the abattoir while a larger number of cattle slaughtered were also processed within the first 1-5 minutes. It could be concluded that cattle handling and slaughtering practices at Akinyele International Market were unethical. Slaughtering should therefore be done humanely, cattle should be properly restrained before bleeding and allowed to bleed well before the commencement of singeing or further processing.

INTRODUCTION

In the recent time, there is an increasing concern on the unethical practices in Nigerian abattoirs especially the way animals are handled before slaughtereing. Cattle marked for slaughtering are handled with little or no human feelings. Akinyemi *et al*. (2013) reported that some cattle handlers are of the opinion that cattle intended for slaughter should require little or no care since they will eventually end up slaughtered. This mentality is uncalled for, because how animals are handled will eventually have effect on the quality of meat obtained from such animals. Voisinet *et al.* (1997) reported that agitation and excitement of cattle during handling results in significant lower weight, tougher meat and more border line dark cutters. Such carcass might also not command consumer's preference.

Cattle are often slaughtered without restraining during exsanguination which could result in animal struggling and stress. However, Tenneseen and Morrigan (1999) noted the advantages of restraining before slaughtering to include effective physical appraisal of body conformation of animals marked for slaughter, efficiency of livestock handling and processing facilities. Also, different slaughtering styles that could inflict pain on animals are used during slaughtering exercises in the abattoirs.

There is limited information on pre-slaughtering handling and pattern of slaughtering in most Nigerian abattoir. The study was therefore designed to observe the slaughtering handling processes of cattle at Akinyele International Cattle Market, Ibadan.

MATERIALS AND METHODS

The transient-abattoir located within Akinyele International Cattle Market, Ibadan (AICM) was used for the study. This study was carried out from 7am-7pm for a period of five consecutive weeks (Monday to Sunday). Data were collected on the restraining methods, slaughtering style, slaughtering interval and processing interval. Direct observation with the aid of check list was used to obtain relevant data. Data obtained were analysed using descriptive statistics of SPSS 2020.

RESULTS AND DISCUSSION

Presented in Table 1 is the restraining and slaughtering methods of cattle at the AICM market. The study revealed that most of the cattle brought for slaughtering were not restrained before slaughter. The high

population of cattle slaughtered without restraining might be that most of the butchers are either ignorant or negligent of the ethics and importance of restraining or careful handling of animals prior to slaughter. It could also be that most of the cattle brought for slaughtering are weak and recumbent in nature with limited ability to struggle during slaughtering as observed on the field. Voisinet *et al*. (1997) reported that agitation and excitement of cattle during handling results in significant lower weight, tougher meat and more border line dark cutters. Slashing was the slaughtering method mostly used which is commendable. It was recorded that some butchers bled cattle by piercing narrowly the throat (Fig 3) as against the general practicing of slashing, such practice is unethical as the event is stressful and could inflict severe pain on the animals. Cattle were directly observed to be struggling for life over a period of time. Warris (1984) reported that animals should be rendered unconscious prior to bleeding and that bleeding should be with severe cut.

Table 1: Slaughtering pattern of cattle at Akinyele international cattle market, Ibadan

	Restraining methods (%)				Slaughtering style (%)			
	Restraining		Unrestrained		Slashing		Piercing	
Breeds	Frequency	%	Frequency	%	Frequency	%	Frequency	%
White Fulani	118	6.4	676	36.8	698	38.0	96	5.2
Red Bororo	92	5.0	552)	30.0	585	31.8	59	3.2
Gudali	42	2.3	323	17.6	319	17.4	46	2.5
Kuri	3	0.1	33	1.8	33	1.8	33	0.2
	255		1584		1635		204	

Source : Field survey 2018

The time interval between arrival of cattle and slaughtering at the AICM market is as shown in Figure 2. Most Slaughtering occurred within the first 1-5 mins of cattle arrival at the abattoir all through the period of the study. It was observed that the cattle were not fasted overnight and rested in the lairage and there was no stuning to render them unconscious. It was also observed that butchers were in a hurry to slaughter the weak and recumbent cattle that were about to give up so as to prevent economic loss on the part of the owner. Komolafe *et al*. (2019) reported that butchers are mostly in a hurry to slaughter several animals in order to make more money. Also, butchers might also want to quickly display meat for sale so as to prevent left over of meat as means of preservation are not readily available. Wolterdorf and Troeger (1987) encouraged that the time interval to move from lairage and slaughtering should be as short as possible as long waiting times are stressful., This is consistent with the observation in this study where most

slaughtering activities were done within a short period, although there was no presence of lairage in the study area.

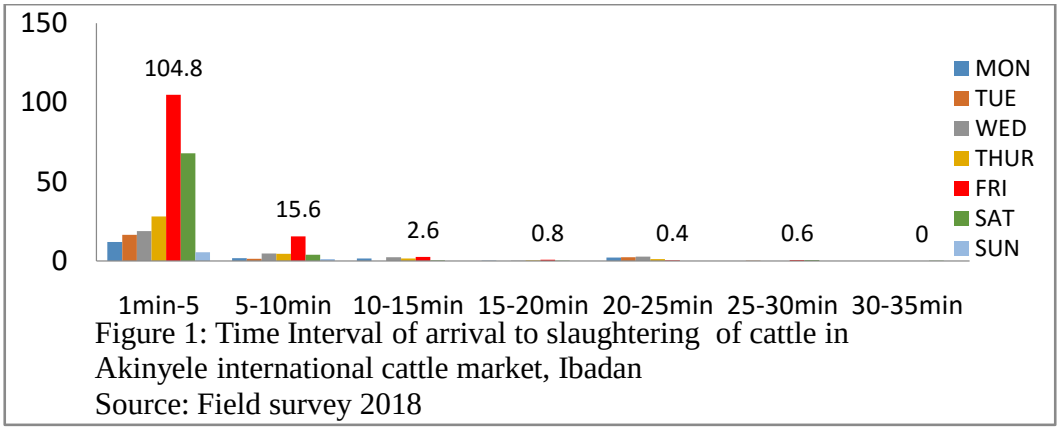

Figure 1: Time Interval of arrival to slaughtering of cattle in Akinyele international cattle market, Ibadan
Source: Field survey 2018

The time interval between slaughtering and processing is presented in Figure 2. It was observed that processing of cattle slaugtered began within the first 1-5 minuite of slaughtering. Proper bleeding and animals complete quietness was not achieved before singeing commences. This practice is unethical and a serious height of cruelty as cattle were mostly observed to struggle for life when set ablazed (Singeing with kerosene) before they eventually die.. The likely reason for this cruel act might be as a result of the general believe among cattle handlers that animals can be handled without special care since they are not humans. Warris (1984) however reported that no animal should be bled when conscious and no carcass processed until nervous reflexes disappear.

Plate 1: A picture showing slashing and piercing methods of cattle slaughtering at Akinyele abattoir
Source: Field survey 2018

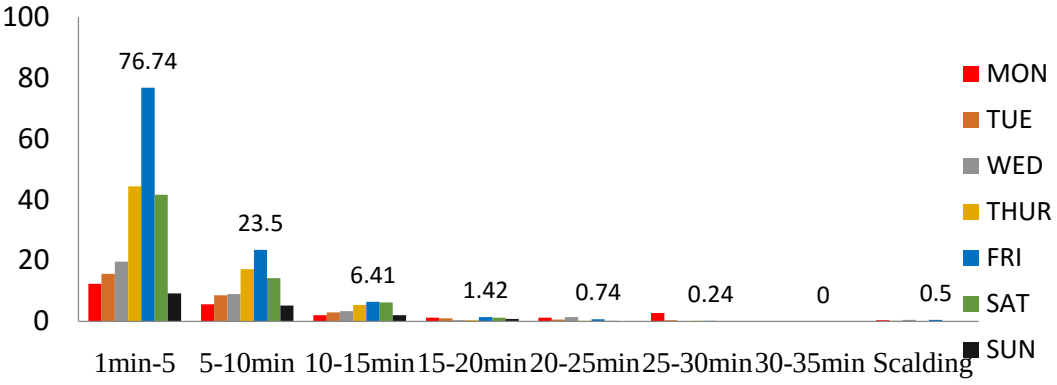

Figure 2: Interval between slaughtering and processing of cattle in Akinyele international cattle market, Ibadan
Source: Field Survey 2018

CONCLUSION

The study showed that most of the cattle brought into Akinyele Cattle Market were not restrained and while some were unethically slaughtered. The study also revealed that the time interval between arrival and slaughtering and slaughtering to processing was 1-5 minute.

RECOMMENDATION

Cattle is expected to be slaughtered humanely, properly restrained before bleeding and allowed to bleed well before the commencement of processing

DETECTION OF ANTIMICROBIAL DRUG RESIDUES IN MEAT FROM BUNAJI CATTLE SLAUGHTERED IN MINNA MODERN ABATTOIR

***L.L Mande, J.Y. Adama, A. Usman**

Department of Animal Production, School of Agriculture and Agricultural Technology, Federal University of Technology P.M.B 65, Minna, Niger State Nigeria

Corresponding authors E-mail; mandelawal46@gmail.com

ABSTRACT

Antimicrobial drug residues are of global health concern in many countries of the world, with Nigeria reporting occurrence of residue contamination of edible animal products beyond FAO and WHO permissible levels. The occurrence of antimicrobial drugs residues in meat in Minna modern abattoir was investigated during this study, 56 meat samples were collected from 56 Bunaji cattle slaughtered in the abattoir at 2weeks intervals for period of 4months (April – August 2019) . Antimicrobial inhibition test was adopted with zone of inhibition measured in millimetres (mm), samples below 1mm were considered negative. 29(51.78%) samples were tested positive with zone of inhibition at various levels of residue (12mm, 13mm, 15mm, 17mm, 19mm and 20mm), which signified high levels of residue. Samples from female's cows had the highest number 20(68.90%) and values at 20mm. Ages between 6-10 years had 17(58.62%) while the lowest residue was recorded at older animals above 10 years 5(17.24%). This result indicated that consumers in Minna metropolitan are predisposed to health hazards due to the presence of antimicrobial residue, this emphasis the need for effective prevention of infectious diseases, general enlightenment on the withdrawal periods, and establishment of antimicrobial residues monitoring unit in Minna.

Keywords – Antimicrobial residue, Meat, Microbial inhibition test, Abattoir, Minna

INTRODUCTION

Drug administration to domestic animals requires not only consideration of its effect on the animals but also the effect on humans who consume the product from such animals. Antibiotics are natural product of microorganisms or identical synthetic products or similar semi-synthetic products that inhibit the growth of or destroy microorganisms (Karbis, 2007). In animal health practice, antibiotics are widely used as therapeutic prophylactic or as growth promoting agents (Donoghue, 2003). Antibiotics are of different types, with various pharmacokinetic activities which often neglected during slaughter, and hence become potential hazard to human. The presence of antibiotics in meat and other food of animal origin is one of the most important indices for their safety to human consumers (Kozanova *et al.*,2001). Many livestock farmers administer antibiotics indiscriminately for purposes of treating or preventing an ailment or as growth promoters without cognisance of the need to consult an expert for necessary advice, such animals are often slaughtered without recourse to the withdrawal period, even if they used the same drugs as animal health personnel's. The Indiscriminate use of antibiotics in livestock has raised serious public health concern globally, especially in sub-Sahara Africa and particularly Nigeria (Shehu, 2018).

Drug residue arises when treated animals are slaughtered without recourse to pharmacokinetics of the specific drug administered, this situation usually occur with prolonged administration and over dosage of antimicrobial agent, especially if these animals are slaughtered immediately,(vinedresser, 1989)as cited by (Gabriel *et al.* 2012). Toxic level of antimicrobial residues in food animals are known to cause divers health hazards to susceptible unsuspecting human consumers. (Gabriel *et at.*,2012).

Cattle command a prominent position in our meat supply which constitute of about 45% of meat industry. Presently cattle population in Nigeria has been estimated as 15.3million (Umar, 2007).

Bumaji cattle are the most predominant and wide spread of all Nigeria cattle breed, they represents 37% of the national herd (Alphosus,Akpa, Barje and Adamu, 2012). About 800-1000 cattle, sheep and goat are slaughtered daily across Niger state (Dukku, 2018), the abattoir where these animals are largely slaughtered and processed for public consumption, contributed immensely to the economic development of states. In Nigeria as in many other countries, the veterinary structure are not strong (Fau, 2004) and are characterised by indiscriminate usage of veterinary drugs such as antibiotics, which are readily avaailable and obtainable over the counter as well as every rural cattle market, which make it easily accessible to different categories of livestock handlers including the nomadic pastoralist and the middle men. With this development it implies that correct dosage and withdrawal period are not usually adhered to, and hence meat safety quality assurance cannot be granted, Olatoye and Ogundipe, (2009).

MATERIALS AND METHOD

EXPERIMENTAL SITE

The samples were collected from Minna abattoir located along Tayi village in Minna Niger state of Nigeria. Minna the capital city of Niger state is situated on a latitude 9 3105 and longitude 7 421 north, with annual rainfall of 1,200-1,300mm and mean temperature of 38-40c the area has an altitude of 1,46m above sea level in the northern guinea savannah vegetation zone of Nigeria it is characterised by two season, the wet season (April - October and dry season November -march). NSFCO/ ADP.,(2015).

SAMPLES COLLECTION

Fifty six (56) Beef samples weighing 50g were collected from 56 slaughtered white Fulani cattle in Minna modern abattoir for a period of 4 months, (April - August 2019) at 2 weeks intervals, with emphasis to breed, age sex and time intervals, Samples were properly packed and labelled in a polyethylene and refrigerated at -20^0C

SAMPLE ANALYSIS;

MICROBIAL INHIBITION TEST

An adapted microbial inhibition test was employed to screened samples for evidence of antimicrobial drug residues as described by Huber et al, (1969). Mueller Hinton Agar (MHA) was prepared in plates according to manufacturer`s instruction. *Bacillus subtilis* ATCC 6633 was used as test organism. Plates were inoculated with the test organism by dipping sterile cotton swab sticks into the suspension of test organism until saturated. The MHA plates were then gently but thoroughly swabbed uniform to achieve a lawn of confluent growth and allowed to dry for 5 minutes. The extract from the sample were tested by dipping sterile 1.2 mm diameter *whatmann* filter paper disc into the juice extract, until saturated, excess sample were allowed to drained, then, *whatman* filter paper disc containing 30ug of oxytetracycline Hcl was used as control discs, placed at the centre of the plates with test discs at the periphery of the plate and incubated at 37 degree for 18 – 20 hrs, after which presence or absence of zone of inhibition and that of the disc was calculated. Any disc with a difference of >1mm was considered positive.

DATA ANALYSIS;

The data obtained was subjected to descriptive statistical analysis, for the variations between occurrence of drug residues between sex and Age groups, using SPSS version 16.0, (2010)

RESULTS AND DISSCUSSION

Out of the 56 meat samples from 56 cows of different sex and age that were screened for antimicrobial drug residues during this study, 29(51.78%) tested positive under zone inhibition test ranging from 13mm to 20mm, indicating presence of antimicrobial drug residue in the samples; 27(48.21%) were tested negative less than 1mm. All samples were collected from Bunaji cattle in Minna abattoir. The overall results from this study indicated a high incidence (51.78%) of antimicrobial residues in the meat consumed by the public in Minna metropolitan The results is higher than the reported incidence of 46% residue in beef in Oyo state, (Akinwumi, 2012); 16.11% reported by (Dipeolu and Alonge 2002); 33.1% obtained in

broilers (Kabir *et al*,.2004); 25% reported in milk (Yusuf *et.al*., 2017). However the result is lower than 89.3% reported from kidney and urine (Gabriel *et. at.*, 2012) and 79.74% in edible beef (Olatoye and Ogundipe, 2009). **Table 1** Shows distribution of residue on Sex of the cows that were tested positive, 9(31.02%) were males, 3 samples had highest value of 19mm while 1 sample had lowest value of 12mm, females recorded highest antimicrobial residue of 20(68.96%), 2 samples had highest zone inhibition value of 20mm while 1 had lowest of 12mm, the study recorded high incidence of residues on females (68.9%) than males (39.01%), 2 females had high zone inhibition value of 20mn. **Table 2** shows variation on Age, 7(26.3%) were between 1-5 years, 17(53.62%) were between 6-10 years and 5((17.24%) where above 10 years. At 1-5 years 2 samples had highest value of 19mm and the lowest value of 13mm, highest value of 20mm was found at 6-10years and above 10 years respectively, From the result 6-10 years shows 58% residual values than other age groups the result agreed with that reported by (Zeenatudeen, 2015) on milk.

Table 1 Distribution of antimicrobial drugs residue based on Sex of cow under zone inhibition above 1mm detectable limit

Sex	**Meat sample**	**12mm**	**13mm**	**15mm**	**17mm**	**19mm**	**20mm**	**Total**
Male	9	1	1	4	1	3	0	9(31.02%)
Female	20	1	4	4	6	3	2	20(68.96%)
Total	29	2	5	8	7	6	2	29(100%)

Table 2; Distribution of antimicrobial drugs residue based on Age of cows under zone inhibition above 1mm detectable limit

Age years	**Meat sample**	**12mm**	**13mm**	**15mm**	**17mm**	**19mm**	**20mm**	**Total**
1-5	7	Nil	Nil	3	2	2	0	7(24.13%)
6-10	17	1	4			3	1	17(58.52%)
Above 10	5	Nil	1	3	5	1	1	5(17.24%)
				2	Nil			
Total	29	1	5	8	7	6	2	29

CONCLUSION;

The high percentage of meat with antimibrial residues obtained from this study indicated that, consumers in Minna metropolitan are predisposed to health hazards due to the presence of antimicrobial residue in meat in slaughtered animals from the abattoir, this emphasis the need for the enforcement of antimortem inspection, effective prevention of infectious diseases, general enlightenment on the withdrawal periods, and establishment of antimicrobial residues monitoring unit in Minna.

KAEMPFEROL IMPROVED LIVER ENZYMES IN TWO WEEKS OLD BROILER CHICKENS WITH EXPERIMENTAL *EIMERIA TENELLA* INFECTION

***Muhammad, Y[1]., Jatau, I. D[2]., Chiroma, M. A.[3] Umar, A.M[1]., & Dahiru, M[1]**

ABSTRACT

The effect of kaempferol on the concentration of liver enzymes in two weeks old broiler chickens with experimental *Eimeria tenella* infection was evaluated in this study. Sixty day old broilers were randomly allotted into six groups (I-VI) of ten broilers each and brooded for two weeks. At exactly two weeks of age, broilers in group I served as non-infected control. Broilers in groups II- VI were infected with *Eimeria tenella* sporulated oocyst (10^4/ml) via oral inoculation. After infection was established, broilers in groups II-IV were treated *per os* with 1 mg/kg, 1.5 mg/kg and 2 mg/kg of kaempferol respectively. Broilers in group V were treated for five days with amprolium, 1.25 g/Lin drinking water. Broilers in group VI served as infected untreated control. Five days post infection; all broilers were sacrificed by severing their jugular veins. Blood sample was collected from each broiler in a plane sample container devoid of anticoagulant so as to harvest serum for serology. Concentration of liver enzymes (ALT, AST and ALP) in the serum was determined. Data obtained were analyzed using pad prism version 5.0. There were statistically significant ($P<0.05$) reductions in the mean values of liver enzymes (ALT AST, ALP) in groups II, III and IV in a dose dependent manner when compared to group VI. It was observed in this study that kaempferol improved the serum level of liver enzymes and reduced the level of pathology in the liver and caecum of broilers infected with *Eimeria tenella* in this study, and therefore recommends that it should be incorporated in bird's feed.

Key words: Amprolium, Broilers, Diminazene aceturate *Eimeria tenella*, kaempferol, liver enzymes,

INTRODUCTION

Each year, over 50 billion chickens are raised as a source of meat, accounting for over one-third of protein food for humans (Bampidis *et al*., 2005), however, this practice is often confronted by so many problems of avian coccidiosis (Coccidia subclass) (Chapman *et al*., 2010). So far, nine Eimeria species, *E. acervulina, E. brunetti, E. maxima, E. necatrix, E. praecox, E. mitis, E. tenella, E. mivati, and E. hagani,* have been identified from chickens (Chapman *et al*., 2010). These parasites can infect and multiply within the mucosal epithelia in different parts of bird guts, which cause severe gut damage (i.e., inflammation, hemorrhage, diarrhea, etc.), morbidity, and mortality (Calderon-montana *et al.,* 2011). It also causes a global loss of over 2.4 billion US dollars in the poultry industry, including poor growth performance, replacement of chicks, and medication (Lilleheoj and Trout, 1996). Anticoccidial chemicals, coccidiocides, coccidiostats, and ionophores, have long been used as a mainstream strategy to control avian coccidiosis in modern poultry production and birds have developed resistance to them (Chapman, 2014)

Antioxidant compounds like kaempferol are well known to have a cellular protective action against oxidative stress and reduce the severity of *Eimeria tenella* infection by altering the degree of intestinal lipid peroxidation[1].(Allen *et al.,* 1998). Most of the antioxidants occur as dietary constituents[3], as shown by many researches, antioxidants deposited in broiler meat following oral ingestion delay lipid peroxidation in the muscles and improve it quality (Bampidis *et al*., 2005),, these important role, made us conduct this study with aim of determining the ameliorative effect of kaempferol in stress induced by experimental *Eimeria tenella* infection in two weeks old broiler chickens.

MATERIALS AND METHODS

Study area

This research was conducted in the Departments of Animal Health and Production (poultry unit), Binyaminu Usman Polytechnic, Hadejia, Jigawa State, Nigeria ($10^0$02' 28.14'' E Longitude and $12^0$27' 12.49 N Latitude)

Drugs, Sources and Preparations

Kaempferol was sourced from whitehead scientific (pty) limited, South Africa, it came along with the following details; CAS number (520-18-3), Catalog number (3603), EC number (208-287-6) and batch number (3).

Eimeria tenella Isolate

The *Eimeria tenella* isolate used in this study was obtained from the parasite bank of the Department of Veterinary Parasitology and Entomology, Ahmadu Bello University, Zaria. The oocysts were propagated in two week-old coccidian-free chickens before use. The unsporulated oocysts collected from the caecal content on the seventh day post-infection was purified and preserved in 2.5% potassium dichromate solution to induce sporulation at 28° C. The sporulated oocysts were kept at 4° C until use.

Experimental birds and grouping

Sixty day old broiler chicks obtained from a reputable hatchery were used in this study. The chicks were randomly allotted into six groups (I-VI) of 10 birds and brooded for 2 weeks on concrete floor (using wood shaven as litter material) under strict biosecurity measures and as routine were adequately vaccinated against Newcastle disease and infectious bursal disease. They were fed with commercial broiler feed (Vital feed®) and water which were provided *ad libitum*.

Experimental infection and treatments

At exactly two weeks of age, birds in Groups II-VI were orally inoculated with 10^4 sporulated oocysts of the *E.tenella* isolate, and then treated as follows:

Group I: Birds in this group served as non-infected control.
Group II: Birds in this group were treated with 1 mg/kg of kaempferol *Per os* for 5 days.
Group III: Birds in this group were treated with 1.5 mg/kg of kaempferol *Per os* for 5days.
Group IV: Birds in this group were treated with 2 mg/kg of kaempferol *Per os* for 5 days.
Group V: Birds in this group were treated with 1.25 g/L of amprolium in drinking water for 5 days.
Group VI: Birds in this group served as infected untreated control.

Determination of Serum level of liver enzymes

Serum level of alanine amino transferase (ALT), aspartate amino trasferase (AST) and alkaline phosphatase (ALP) were determined using chemical auto-analyzer (Bayer® Clinical Chemistry Analyzer, Germany) as described by manufacturer.

Statistical Analysis

Data obtained were expressed as means ± standard errors of mean (S.E.M), subjected to one-way analysis of variance (ANOVA) and compared with Tukey post-hoc test. The level of significance was set at $p< 0.05$.

RESULTS

Effect of Kaempferol on the Activities of Liver Enzymes

Figure 1 shows the effect of kaempferol on the activities of liver enzymes in two weeks old broilers challenged with *Eimeria tenella.* There were significant ($P < 0.05$) increases in mean AST, ALT and ALP

values in the infected untreated broilers (group VI) when compared with the infected broilers and treated with different doses of kaempferol (group II, III and IV) and those that were treated with Amprolium (group V). But no significant (P>0.005) difference in the mean values of AST, ALT and ALP was observed in broilers treated with 2 mg of kaempferol and those that were treated with amprolium.

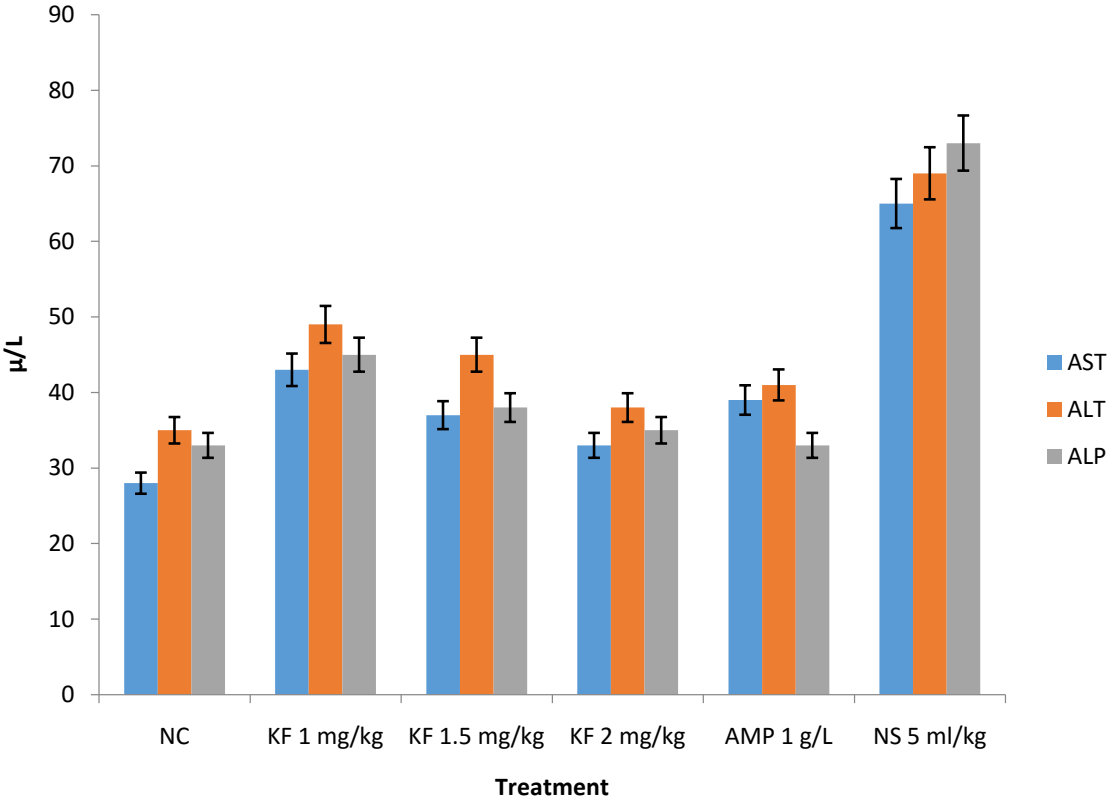

Figure 1: Effect of kaempferol on the activities of liver enzymes (ALT, AST, ALP).

Key: NC=Neutral control, KF=Kaempferol, AMP= Amprolium and NS=Normal Saline
P≤0.05 considered significant.

DISCUSSIONS

The present study revealed significant reduction in the concentration of liver enzymes (ALT, AST and ALP) in groups (II, III and IV) treated with kaempferol when compared to infected untreated broilers (group VI). No significant difference in the concentration of liver enzymes (ALT, AST and ALP) was recorded between group III, IV and V.

The increased levels of ALT, AST and ALP in the infected untreated broilers agrees with the earlier reports of Srivastava *et al.*,2012, who attributed the elevation of ALT, AST and ALP to inflammation in the host, particularly of the liver. Another possibility of increased levels of ALT and AST is the activities of free radicals generated at different stages of the infection (Murali, 2014). Therefore, serum levels of ALT and AST are two of the most useful indications of liver cell injury, although the AST is less liver specific than is ALT (Kim and Choi, 2013). Oyewale 1991) attributed the increase in the liver enzymes to inflammatory condition involving liver and gatro-intestinal tract[18]

CONCLUSION AND RECOMMENDATION

It was therefore concluded in this study that, the oral administration of kaempferol had ameliorated stress induced by the experimental *Eimeria tenella* infection in two weeks old broilers via improving the serum level of liver (ALT, AST and ALP) enzymes

ABSTRACT

Prudent antibiotic usage in poultry boosts productivity and limits emergence and spread of antibiotic-resistant organisms, especially zoonotic pathogens, transmissible through the food chain. A nation-wide survey to determine the pattern of antibiotic administration in poultry was conducted among 2,402 randomly selected poultry farmers,in12 of the 36 States ofthe federation; using structured questionnaire.Finding showed thatcritically important antimicrobials, belonging to the WHO lists of '*Highest'* and '*High'* priority antibiotics, were administered sub-therapeutically; for prophylaxis and growth enhancement purposes. Many diseases that warranted the antimicrobial administration were of viral etiology. Only 64.2% of the farmers administered the drugs based on veterinary doctors' prescription while62.3% of them did not observe recommended withdrawal period after the drug administration. Enlightenment of the farmers on the benefits of prudent agricultural use of antimicrobials is imperative; for sustainable poultry production and to curtail development and dissemination of antimicrobial-resistance pathogens.

KEYWORDS: antibiotics, antibiotic-resistance, poultry diseases, poultry farms

INTRODUCTION

The poultry subsector is the most commercialized and the fastest growing agribusiness in Nigeria.The growth in the poultry industry may be attributed to prudent use of antimicrobials in combating most infectious diseases, inimical to poultry production in the tropics (Njoga*et al.,* 2018). Good antibiotic steward in food-animal production has also curtailed spread of zoonotic pathogens and transmissible through the food chain. Prudent agricultural use of antibiotics involves administration of the appropriate drug, for the right disease, at the appropriate dose, all through the recommended period of time. Chemotherapeutic and prophylactic uses of antibiotics in poultry production are well recognized; but use of sub-therapeutic doses for growth promotion purposes, is rapidly gaining popularity in Nigeria(Chinwe*et al.,* 2014). Upsurge in demand for foods of animal origin, occasioned by boom in human population and increase in middle class income in most developing countries, aredriving the sub-therapeutic usage; to cater for the shortfall in available animal protein, in a record short time.

Sub-therapeutic use of antibiotics to fast-track poultry production is associated with emergence and spread of antimicrobial-resistant pathogens, which may worsen the animal's health problem or may be transmitted to humans via the food chain. Adebowale*et al.* (2016) reported that poultry farmers incur up to 35%

additional cost of production, due to treatment of antibiotic-resistant bacteria. Other imprudent antibioticusage such as non-observance of withdrawal period (WP) facilitates accumulation of antimicrobial residues in poultry products, which could reach the human populations through the food chain (Njoga*et al*., 2018). Consumption of antimicrobial residues in edible animal products predisposes to health problems including, allergy in sensitized individuals, bone marrow depletion or aplastic anemia, disruption of normal intestinal flora infavour of pathogenic bacteria, toxicity and carcinogenicity (Nisha, 2008; Njoga*et al.*, 2018).

This nation-wide study was therefore carried out to determine the antibiotic usage pattern in poultry farms in Nigeria. This will guide policy formulation for preservation of the therapeutic efficacy, for sustainable poultry production and to safeguard public health.

MATERIALS AND METHODS

Structured and pretested open-ended questionnaire was used to obtain information ontypes and pattern of antimicrobial drug usage in poultry; as well as the diseases that warranted the drug administration.

A total of 12 states, 24 agricultural zones (AZ) and 2, 402 poultry farms were randomly selected and surveyed. At first, four of the six geopolitical zones, namely Southeast, Southwest, North-central and Northwest were purposively selected for the study, based on the history of high poultry production activities. In each selected zone, three states and two AZs per state were selected by simple random sampling. The same sampling method was used to select at least 100 poultry farms from each selected AZ, based on the consent the farm owners to participate in the study and accessibility of the farm.

RESULTS

The classes of antimicrobials administered and percentage of farmers involved were: tetracycline (25.4%), aminoglycosides (18.5%), macrolides (14.8%), quinolone and fluoroquinolone (14.8%), chloramphenicols (11.3%), sulfonamides (8.5%) and penicillin and betalactam (6.8%).The diseases that 'necessitated' antibiotic treatment in farms surveyed were not only of bacterial etiology and included: Newcastle (31.7%), coccidiosis (21.3%), gumboro (26.4%), salmonellosis and colibacillosis (13.4%).Only 64.2% of the farmers administered the drugs based on veterinary prescription. On the purpose of the drug administration, 36.2% used the drugs for treatment, while 36.7% and 27.1% administered it for prophylaxis and growth promotion purposes respectively. Majority (62.3%) of the farmers who administered these drugs did not observe the recommended WP thereafter.

DISCUSSION

The high rate of antibiotic administration (63.8%) for non-therapeutic purposes in this study is in tandem with the 68.5% found in South Africa (Eagar *et al.*, 2013). Farmers may have resorted to non-therapeutic use of antibiotics as a 'quick fix' or compensation for poor management practices observed in the farms surveyed. This may explain why critically important antibiotics, including second generation fluoroquinolone (ciprofloxacin) were used for prophylaxis in some farms.

Occurrence of antibiotic-resistant bacteria due to non-chemotherapeutic use of antibiotics has been reported in chicken in Nigeria (Chinwe*et al.*, 2014). Sub-therapeutic administration of antibiotics, is an important factor in the epidemiology of emergence and dissemination of antibiotic-resistant bacteria (Njoga*et al.*, 2018), transmissible through the food chain. Cognizant of the fact that egg is sometimes consumed raw in Nigeria (Onyenweaku*et al.*, 2018); these resistant-organisms can easily reach the human population via consumption of infected raw eggs or undercooked poultry products. Even when the

emerged antibiotic-resistant organism is not zoonotic, it may transfer its resistance genes to zoonotic organisms; for onward transmission to humans (Van den Bogaardand Stobberingh, 2000).

The practice of administering un-prescribed antibiotic drugs in poultry farms is unethical and may be to save cost of veterinary services, in order to probably maximize profit. This 'cost saving' habit, without recourse to the negative implications on human and animal health is counterproductive. When people who are not formally trained in veterinary clinical practice administer un-prescribed antibiotics to food animals, the likelihood of incorrect doses and other chemotherapeutic errors; that may adversely affect the pharmacokinetics of the drugs is most probable. These, no doubt, facilitate emergence and spread of antibiotic-resistant bacteria, and accumulation of antibiotic residues, beyond safe levels in poultry products or the environment.

The continued use of chloramphenicol in poultry, after over two decades of its prohibition for systemic administration, due to its complicity in aplastic anaemia, is most unfortunate. Easy access to veterinary antibiotics in Nigeria, exemplified by its sell as over-the-counter, including those classified as '*Highest'* and '*High'* priority antibiotics, may be contributory to the continued use. Most importantly, lack of legislation against this practice and obvious inadequate implementation of the available veterinary drug laws in Nigeria are to be blamed.

CONCLUSION AND RECOMMENDATION

There is extensive imprudent administration of antibiotics in poultry in Nigeria. Thisunderscores the urgent need to enlighten the farmers on the benefits of prudent use of antibiotics inpoultry production and disease management. Discontinuation of sale of essential antibiotic as over-the-counter drug and strict implementation of veterinary drug laws is imperative; to safeguard the therapeutic efficacy for sustainable poultry production and to preserve public health.

ASSESSMENT OF CHANGES IN PHYSIOLOGICAL PARAMETERS AND IMMUNE MARKER LEVELS IN ANIMALS PRESENTED FOR SLAUGHTER AT IKPA NSUKKA SLAUGHTER ABATTOIR

Ogbanya K.C., Eze C. A., Okereke N. H. & Chukwu C. C.
Department of Veterinary Surgery, Faculty of Veterinary Medicine
University of Nigeria, Nsukka
Corresponding author e-mail: kenneth.ogbanya@unn.edu.ng (08036027640).

ABSTRACT

The objectives of the study were to determine the changes in physiological parameters such as heart rate, pulse rate, respiratory rate and rectal temperature) and to assess the changes in immune marker levels like total leucocyte count, differential leucocyte count and neutrophil/lymphocyte ratio) of animals presented for slaughter at Ikpa slaughter slab. Physiological parameters of the cattle were determined using conventional methods. Blood was collected from 40 cattle at two stages: 1) pre-slaughter and 2) during slaughter. A significant increase in the physiological parameters at slaughter compared to the pre-slaughter in the both sex groups of the bovine species was noted. A slight increase in the neutrophil/lymphocyte ratio in the different sex groups at pre-slaughter and slaughter were observed. However, the increase was not statistically significant. It can be concluded from this study that changes in vital parameters (heart rate, pulse rate and respiratory rate) are more indicative of acute stress which is associated with slaughter processes in Ikpa abattoir

Keywords: stress, haematology, cattle, slaughter, physiological parameters.

INTRODUCTION

Stress is defined as the biological response elicited when an animal perceives a threat to its homeostasis (Moberg, 2000). Stress can also be defined as adverse effect in the environment or management system which forces changes in the animal's physiology or behavior to avoid physiological malfunctioning and assist the animal in coping with its environment (Ferguson and Warner, 2008). Stress leads to fight or flight response, so an animal can experience faster pumping lungs, increase heart rate, higher blood pressures and endorphins flooding the body. Also appetite, libido and immune system is shut down in order that energy is diverted to muscle to prepare for flight (Ranabir and Reetu, 2011). Animals can be stressed by either psychological factors (hunger, thirst, separation from group, mixing with unfamiliar group or novelty), physical factors (such as restraint, handling, fatigue or injury) and environmental factors (temperature and noise) (Etim and William, 2013). The main stressors in an animal's life are danger, illness, pain, accident, synthetic chemicals, inappropriate diet, weaning, confinement, isolation, overcrowding, change in routine, change in environment and over-stimulation (Etim and William, 2013).

Biological response to a stressor is used as an indicator of stress (Kumar *et al.*, 2012). Vocalisation, restlessness, fight, pain, refusal to move, increase in heart, blood pressure variability and increase in respiratory rate as behavioural indicator for stress (Broom, 2003). Endocrine Indicators used in determining acute stress level include corticotrophin-releasing hormone, catecholamine (epinephrine and norepinephrine), cortisol, adrenocorticotropic hormone, oxytocin, vasopressin, prolactin, glucagon, serotonin, opiates and gonadotrophins (Sapolsky, 2000).

Immune indicators that can be used in determining stress include increase in neutrophil/lymphocyte ratio and blood monocyte count (Sapolsky, 2000). Biochemical markers used in determining the level of acute stress in animals include urea level, glucose level, packed cell volume (PCV), total protein albumin,

creatinine kinase level (CK), aspartate transaminase (AST), lactate level, alkaline phosphatase (ALP) and blood potassium level (Calamari *et al*., 2003; Lay and Wilson, 2004; Abeni *et al*., 2007).

The objectives of the study were to evaluate the changes in physiological parameters (heart rate, pulse rate, respiratory rate and rectal temperature) and to assess the changes in immune marker levels (total leucocyte count, differential leucocyte count and neutrophil/lymphocyte ratio) of animals presented for slaughter at Ikpa slaughter slab.

MATERIALS AND METHODS

The rectal temperature was measured using a clinical thermometer (Naylor *et al*., 2010).

The heart rate was measured using a stethoscope (David and Dumitrascu, 2017).

The pulse rate of the animals was determined by placing the thumb on superficial arteries and the pulsating effect of the vessel was counted as beat in a minute (Tibballs and Russell, 2009). The respiratory rate of each animal was determined by calculating the number of movements of the flank in a minute (Legates *et al*., 1991).

Blood sample was collected from the jugular vein using sample bottle containing ethylene diamine tetraacetic acid (EDTA) from the animals 48 hrs before slaughter and during slaughter at the abattoir. Total white blood cell count was obtained using the haemocytometer counting method and while thin blood smear made on clean grease-free glass slides for differential leukocyte count were stained following the Leishman technique and enumerated by the meander counting method (Thrall and Weiser, 2002).

RESULTS

Changes in values of heart rate, pulse rate, respiratory rate and rectal temperature at pre-slaughter and at slaughter in the different sex groups of Bovine were reported in the table 1.

Table 1: Mean table 1: Changes in Bovine vital parameters (pre and at slaughter).

PARAMETER	Group	48 hr pre-slaughter	Slaughter
Heart rate (bpm)	**Male**	80.00±7.48[a]	**112.50±2.87[b]**
	Female	51.33±1.76[a]	**64.00±2.31[a]**
Pulse rate (bpm)	**Male**	79.00±6.61[a]	**113.50±9.00[b]**
	Female	49.33±2.67[a]	**74.67±7.42[b]**
Respiratory rate (cpm)	**Male**	33.00±2.52[a]	**47.00±1.00[b]**
	Female	30.67±1.33[a]	**41.33±3.53[b]**
Rectal temp (°C)	**Male**	37.55±0.09[a]	**38.48±0.13[b]**
	Female	38.63±0.18[a]	**38.60±0.06[a]**

Different superscript [a, and b] in rows indicate a significant difference at $p<0.05$.

Changes in value of total leucocytes, neutrophils, lymphocytes, monocytes, eosinophils and neutrophil/lymphocyte ratio in the male and female groups of Bovine at 48 hr pre-slaughter and at slaughter were shown in the table 2.

Table 2: Mean changes in Total and Differential WBC at pre-slaughter and at slaughter (Bovine).

PARAMETER	Group	48 hr pre-slaughter	Slaughter
Total leucocyte (*10^3/µl)	**Male**	8.10±0.85[a]	**8.24±0.47[a]**
	Female	6.93±0.75[a]	**8.63±0.85[a]**
Neutrophils (*10^3/µl)	**Male**	3.67±0.56[a]	**4.05±0.31[a]**
	Female	3.24±0.30[a]	**4.16±0.35[a]**
Lymphocytes (*10^3/µl)	**Male**	3.73±0.20[a]	**3.80±0.11[a]**
	Female	3.51±0.63[a]	**4.14±0.59[a]**
Monocytes (*10^3/µl)	**Male**	0.55±0.11[a]	**0.33±0.13[a]**
	Female	0.18±0.10[a]	**0.28±0.05[a]**

	Female	0.00±0.00[a]	**0.05±0.05[a]**
Neutrophil / Lymphocyte ratio	**Male**	0.97±0.10[a]	**1.07±0.08[a]**
	Female	0.97±0.16[a]	**1.02±1.31[a]**

Different superscript [a, and b] in rows indicate a significant difference at $p<0.05$.

DISCUSSION

The significant increase in the physiological parameters (heart rate, pulse rate, respiratory rate and rectal temperature) in the both sex groups of the bovine species at pre-slaughter and slaughter could be as a result of fear perceived by the animals during handling and restraint at slaughter. These changes also were observed by Apple *et al*. (2005) in a work done on the effect of handling and restraint on cattle. Catecholamine and cortisol are released during stressful conditions and they will lead to an increase in levels of vital parameters in other to maintain homeostasis (Sontag *et al*., 2010). The significant variation in the heart and pulse rates and rectal temperature between the male and female groups of the bovine specie could be as a result of sex differences in stress response. Bale and Epperson (2015) reported that sex differences in stress response can be found at all stages of life and these differences is related to the organizational and activational effects of gonadal hormones (testosterone and estrogen) and also to the various genes found on the sex chromosomes. In this study, the male group responded more to stressors associated with slaughter than the female group. This was also observed in the work done on pigs by Morta-Rojas *et al*. (2006) who showed that male animals are more susceptible to changes in vital signs associated with stress than the female because the male animals are more excited and aggressive.

The increase in neutrophil/lymphocyte ratio in the different sex groups at pre-slaughter and slaughter in this study could be as a result of increase in level of neutrophil and decrease in level of lymphocyte. Elevated levels of glucocorticoids have been reported to lead to an increase in the level of neutrophils and a decrease in level of lymphocytes resulting in variations in total leukocyte level (Davis *et al*., 2008).

CONCLUSION

It can be concluded from this study that changes in vital parameters (heart rate, pulse rate and respiratory rate) are more indicative of acute stress which is associated with slaughter processes in Ikpa abattoir. From this study there was no significant changes in total and differential leukocyte counts.

RECOMMENDATION

Animals should be given enough rest while they are kept in lairage before slaughter to avoid stress in these animals. Also proper handling of animals should be adopted by Butchers during slaughter to avoid stressing them which could affect the quality of meat.

ABSTRACT
The main objective of this descriptive and cross-sectional study was to determine the common radiographic features of claws with gross disorders using abattoir samples. A total of 40 claws were collected from Nsukka abattoir. The claws were examined for identification of different types of gross lesions. Two radiographic exposures, dorso-plantar and lateral views of each of the claws were taken and evaluated for radiographic changes. The prevalence of infectious and non-infectious claw disorders was 55% and 45% respectively. White line disease (WLD), sole ulcer and horn heel erosion were the most prevalent gross lesions with 35%, 30% and 20% prevalent rates respectively while bulb ulcer and wall fissure were the least occurred claw disorders with 5% and 5% occurrence Infectious claw disorders (55%) had a relatively higher occurrence than the non-infectious disorders (45%). The most prominent radiographic abnormalities were noted in the second (PII) and third phalanxes (PIII) region. The radiographic changes were: increase in joint width (10%) subluxation of pedal bone joint (5%), exostoses (5%) of the pastern (PII) bone, sinking pedal bane (15%) in which the bone was displaced slightly ventrally away from the dorsal wall of the claw. Concurrent appearance of more than one radiographic feature in a single claw was noted in the claw samples.

Key words: cattle, foot, claw disorder, radiograph

INTRODUCTION
Claw disorders are either infectious or non-infectious (Greenough, 2007). Claw disorders in dairy animals cause a great deal of economic loss in terms of milk production and reproduction losses (Booth *et al.*, 2004; Garbarino *et al*., 2004; Singh *et al*., 2011). Claw disorders have been found to be the cause of more than 90% of all lameness cases observed in dairy cattle (Murray, *et al.,* 1996). Lameness in animals has emerged as the most severe problem in recent years, at organized farms. It is considered to be the third most expensive health problem of dairy animals after mastitis and infertility (Esslemont, 1990), having adverse effect on their welfare. Lameness is considered to be a major welfare and economic problem both in beef and dairy farming. Economically, lameness due to lose in milk yield, weight and fertility and increases the risk of culling (Reyher *et al*., 2011; Hogeveen *et al.,* 2011). Because of the low level of farmer's knowledge, training and awareness, the risk of claw disease not being discovered until the clinical condition becomes very obvious. The chances of restoring the productivity of the animal, its milk yield or weight gain, depend largely on rapid medical or surgical treatment, the course of which relates directly to accurate diagnosis and appropriate treatment (Hogeveen *et al*., 2011). Radiography as a diagnostic tool is often necessary and in most cases, useful to reach to a diagnosis (Ahmed and Shekidef, 2012). The objectives of the study were to macroscopically and radiographically examine claw disorders of the culled cattle at Nsukka Abattoir.

MATERIALS AND METHODS
The Ikpa Nsukka market abattoir and the slaughter slab was purposively selected because the abattoir maintains a regular slaughter of cow. Post-mortem hindlimb digits with gross claw disorders were amputated and collected for assessment. The choice of hindlimbs was based on the fact that hindlimbs have been reported to be responsible for a higher percentage of foot lameness in cattle (Hernandez *et al.*

2002). A total of 20 cow-feet of the hindlimbs (40 claws) with claw-related lesions were macroscopically and radiographically examined.

Macroscopic examination of the claw

The claws were thoroughly washed, assessed for macroscopic lesions identification. The weight-bearing surface of the claws were examined for any gross claw lesions. Excessively overgrown claws were trimmed using hoof knife to effectively reduce their sizes. The horn of the sole was trimmed with a hoof knife to expose any underlying claw lesions and any observable claw lesions recorded accordingly.

The claw lesions were photographed using a digital camera (Sony DSC-S80, 4.1Mega Pixels).

Radiographic assessment of the claws disorder was using standard radiographic techniques (Beige and Bakir, 2005).

Radiographic examination of the claw

The collected feet were transported to the Radiology Unit of the Department of the Veterinary Surgery and Radiology, UNN for radiographic examination. Lateromedial and dorsoplantar views were obtained using exposure factors of 20 mAs, 80-88kV and FFD of 70 cm. The obtained radiographs were interpreted properly.

Data management and analysis

Presence or absence of a particular lesion were recorded as "1" (meaning "Yes" for presence of a claw lesion), and "0" (meaning "No" for absence of a claw lesion). Percentage distribution of the lesions were computed as: Proportion of the number of positive observations of each lesion type divided by the total number of feet sampled, multiplied by 100 to express it as a percentage.

Results

A total of 20 cows had been enrolled at the end of the study period and had complete data observations. White line disease (WLD) sole ulcer (SU) were the most prevalent claw disorders with 35% (7/20) and 30% (6/20), respectively, while bulb ulcer and wall fissure were the lest occurred claw disorders with 5% (1/20) and 5% (1/20) occurrence (table 1). Infectious claw disorders (55%) had a relatively higher occurrence than the non-infectious disorders (45%) (table 2).

Radiographic changes

The most prominent radiographic abnormalities were noted in the third phalanx (PIII) region of the culled cows. The radiographic changes were: increase in joint width (10%), subluxation of pedal bone joint (5%), exostoses (5%) of the pastern (PII) bone, sinking pedal bane (15%) in which the bone was displaced slightly ventrally away from the dorsal wall of the claw. Pedal bane changes were observed to be more severe in the lateral claws than medial claws. Concurrent appearance of more than one radiographic feature in a single claw was noted in the law samples. Prevalent rate of various radiographic features and cows with laminitis were summarized in tables 3 and 4.

Table 1: Prevalent rate of different claw disorders in 20 abattoir feet (40 claws) samples.

Claw Disorders	No of Occurrence	Percentage of Occurrence
White line disease (WLD)	7	**35%**
Sole Ulcer (SU)	6	**30%**
Horn Heel Erosion (HHE)	4	**20%**
Wall fissure (WF)	1	**5%**
Digital dermatitis (DD)	2	**10%**
Bulb Ulcer (BU)	1	**5%**
Total	**20**	**100**

Table 2: Prevalent rate of infectious and non-infectious claw lesions.

Type of claw infection	Number of occurrence	Percentage of Occurrence
Infectious	11	**55%**
Non-infectious	9	**45%**
Total	**20**	**100**

Table 3: Prevalent rate of radiographic features of 20 abattoir feet (40 claws) with claw disorders

Radiographic lesion	Occurrence	Prevalence X/20 x 100/1
Increase joint width	2	**10%**
Subluxation of the pedal bone	1	**5%**
Sinking pedal bone	3	**15%**
Exostosis of the pastern bone	1	**5%**
Total	7	**35%**

Table 4: Prevalent rate of laminitic and non-laminitic cows

Animal	No of occurrence	Prevalent (6/20 x 100/1
Laminitic cow	6	**30**
Non-laminitic cow	14	**70**
Total	20	**100**

DISCUSSION

Claw lesions such as heel erosion, white line separation and sole ulcer have been incriminated as major underlying predisposing cause for development of laminitis in cattle (Nocek, 1997; Beige and Bakir, 2005). The high prevalence rate of white line disease (35%), sole ulcer (30%) and heel horn erosion (20%) observed in this current study almost proportionally compares with the 30% prevalence rate of laminitis seen among the examined cows. This observation supports works of other researchers who have previously employed presence of, heel erosion, white line separation and sole ulcer for the diagnosis of laminitis in cattle (Greenough and Vermunt, 1991; Bergsten, 1994; Beige and Bakir, 2005).

In this study, all the cows with sole ulcer and horn heel erosion were radiographically confirmed to be laminitic. This linkage is likely to be attributed to the fact that the initial phase of the pathogenesis of

laminitis involves changes in pododermal microvasculature, which results in vascular tissue damage and subsequently manifest as ulcer in the sole (Nocek, 1997; Hirschberg and Plendl, 2005). Sole ulcer is probably the main sign that can be used to diagnose subclinical phase of claw lesions particularly laminitis. The results of this study indicated that cows with laminitis have more than one associated claw lesion and deformity. This report is consistent with the previous findings which stated that laminitis is a predisposing cause of lesions such as sole ulcers, white line separation, heel erosion and double soles (Nocek, 1997, Beige and Bakir, 2005).

White line separation was mostly found on the lateral claw of the hind limbs. White line separation has been reported previously to be attributed to the fact that white line is the weakest point of impact which is likely to succumb and fissure under pressure insults (Baggott and Russell, 1981).
High prevalence rate of infections of the claw observed in this study might be attributed to poor environmental hygiene in the cattle environment. Presence of infectious digital dermatitis (10%) which is also known as digital papillomatosis or "hairy warts" in cows suggested a managemental factor in its aetiological predisposition. Unhygienic environment would promote development and spreading of this contagious lesion (Weaver, 1993). Results of this study indicate that laminitis in cows can tentatively be predicted by presence of some claw deformities. This predictive association between claw deformities and laminitis is supported by findings of others (Greenough, 1987; Ebeid, 1993; Weaver, 1993).
Claws affected with infectious digital dermatitis had narrowed medial pedal bone. This finding is related to the findings of Nguhiu-Mwangi *et al.* (2007) who reported narrowing of pedal bones in extremely deformed chronic laminitic claws of dairy cows. However, narrowing of the pedal bones could be due to an osseous dissolution resulting from osseous necrosis (osteosis). One of the causes of osteosis is associated with nutrition and oxygen especially when there is compromise of local blood supply (Jubb *et al*., 1993). Exostosis of the pastern bone was also observed in the claws affected with digital dermatitis. Similarly, Maclean (1970), reported in the exostosis of the pedal bone in claws with chronic laminitis. The cause of exostosis could be attributed to periostitis (inflammation) of the pedal bane following prolonged inflammatory stimuli in chronic laminitis. The outgrowths or projections seen on the pastern bone could be a result of exostosis (Jubb *et al*., 1993).

The cause of rotation of phalanges (mainly third phalanx) in this study could be attributed to damage of the laminar tissue attaching the pedal bone to the dorsal aspect of the claw. Rotation of phalanges usually leads to joint angulation.

In conclusion, radiographic examination revealed that typical changes of chronic laminitis were among the most common pathological features recorded.

ABSTRACTS

This study was carried out to determine the haematopoietic potential of the methanolic extract of *Tetrapleura tetraptera* in male albino rats. Twenty five rats weighing between 147 and 166 g were used for the study. Anaemia was induced by daily removal of 2ml of blood per 100g body weight for ten days. Thereafter, the animals were administered with the extract for seven days. The rats were treated with 50mg/kg, 100mg/kg and 200mg/kg respectively for groups A - C while groups D (negative control) and E (positive control) received 5 ml/kg of water. Results showed successful induction of anaemia. There were significant increases in the erythrocytic parameters after administration of the methanoloic extract of *T. tetraptera*. The concentration dependent increase in the PCV, HBC, RBC, MCH and MCHC in the groups treated with the extract when compared with the untreated groups suggests that the extract possesses some haematopoietic potentials.

Key words: Anaemia, haematopoitic, *Tetrapleura tetraptera*, haematology, rats.

INTRODUCTION

Anaemia is a decrease below normal of the erythrocyte count and/or haemoglobin concentration. It is not a disease in itself, but a sign of disease (Coles, 1986; Fry and Mc Gavin, 2012). The daily production of erythrocytes in healthy individuals equals their destruction with the result that circulating red blood cell (RBC) values are always within the normal range for the species. Anaemia occurs due to inability to maintain this equilibrium as a result of excessive destruction or loss. Anaemia is one of the major syndromes commonly encountered by veterinarians in practice especially in Africa due to the abundance of the causative agents in the environment, climatic factors that favour their proliferation and survival, and poor management practices which favour the spread of infectious disease agents. Clinical manifestations of anaemia include pallor of the mucus membranes of the mouth and pharynx, the conjunctivae and lips, cyanosis and dilation of peripheral vessels as occurs in shock, tachycardia and polypnea, mainly after exercise, weakness, poor stamina and fever if caused by infectious agents especially bacteria (Coles, 1986). The severity of the anemia is determined by the nature of blood loss. It is acute if a large volume of blood is lost within a short period of time as occurs in trauma and chronic when small amount of blood is lost over a long period of time due mainly to gastro-intestinal parasites, ectoparasites, ulcerations of the gastrointestinal tract and neoplasm. Also, anaemia can result from destruction of erythrocytes or reduced erythrocyte lifespan. Destruction of red blood cells can be due to toxins, chemicals, haemoparasites or immune reactions while decreased red blood cell production may be due to nutritional causes such as iron deficiency, lack of vitamin B12 and bone narrow neoplasm (Kerr, 2002).

Herbal medicines are presently becoming popular in treatment of diseases because conventional medicines are expensive and associated with side-effects (Atawodi *et al*., 2014). Several plants have been found to exhibits haematinic effects (Muriithi *et al*., 2015).

Tetrapleura tetraptera is a medicinal plant of the *Fabaceae* family. It is generally found in low land forest areas of tropical Africa. The fruits consist of a fleshy pulp with small brownish black seeds. It is used traditionally as spice and in management of convulsions, leprosy, inflammation and rheumatism (Ojewole

and Adesina, 1983; Nwawu and Akali, 1986; Okwu, 2003; Aladesanmi, 2007). It also exhibited antibacterial activities as well as good wound healing effects (Ekwenye and Okorie, 2010; Effiong *et al*., 2014; Oguoma *et al*., 2015). It has also been shown to be very potent against larvae of *Anopheles gambiae* (Aina *et al*., 2009). However, while some reports recorded good haematopoietic potentials (Muriithi *et al*., 2015), others claimed that the plant is haemolytic (Odesanmi *et al*., 2010). This study was therefore designed to further evaluate the effects of the methanolic pod extract of *T. tetraptera* on haemorrhagic anaemia in rats.

Materials and Methods

Twenty five male albino rats were used for the study. They were obtained from a laboratory animal house in Osisioma L.G.A. of Abia State. They were randomly divided into 5 groups of 5 rats each. The rats were kept in metal cages in the laboratory animal house of the Department of Veterinary Pathology, MOUAU for two weeks and feed (Vital feed) and water given *ad libitum.* After acclimatization, anaemia was induced by daily removal of 2ml of blood per 100g body weight for ten days (Ihedioha and Daniel-Igwe, 2014).

Dried fruits of *T. tetraptera* were purchased from a local market (Orie Ugba) in Umuahia, Abia State. The fruits were washed with distilled water and dried for 7 days. They were later ground into small coarse particles and stored in airtight containers prior to extraction.

Extraction: Extraction was by cold maceration. Ground fruit (500 grams) was soaked in one litre of absolute methanol and was agitated every 3 hours for 3 days (72 hours). It was filtered with Whatman's filter paper into a beaker and oven dried at 39°C with a yield of 90.2g crude extract.

Yield was calculated as follows:

$$\text{Percentage yeild} = \frac{19.2g}{20.500g} \text{ x } 100 = 18.04\text{g}$$

Haematological analyses were carried out immediately after collection and standard procedures were followed for the assay of all parameters. Packed cell volume (PCV) was determined by the microhaematocrit method, while haemoglobin concentration (HBC) was determined by the Cyanomethaemoglobin method (Schalm et al., 1975; Coles, 1986). Red blood cell (RBC) and total white blood cell (WBC) counts were carried out by the haemocytometer method while the mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and mean corpuscular haemoglobin concentration (MCHC) were calculated using the standard formulae and the differential WBC count was determined by the Leishman method (Schalm *et al*., 1975; Coles, 1986).

Data Analysis

Data generated were subjected to analysis of variance (ANOVA) and variant means were separated using the least significant difference (LSD) method using SPSS statistical package version 16.0. Significance was accepted at (P<0.05) probability level.

Results

The results are presented in table 1. After induction of anaemia, the mean PCV, HBC and RBC count of groups A - D were significantly lower ($p< 0.05$) when compared with group E (control). The mean corpuscular volume (MCV) of groups A - D were significantly higher ($p< 0.05$) when compared with group E (control). However, the mean HBC count of group C was significantly higher ($p< 0.05$) when compared with groups B and D. The mean corpuscular haemoglobin (MCH) of groups A - D were significantly lower ($p< 0.05$) when compared with group E (control) but group C was significantly higher ($p< 0.05$) when compared with groups A and B. The mean corpuscular haemoglobin concentration (MCHC) of groups A, B and D were significantly lower ($p< 0.05$) when compared with groups C and E (control) and no significant difference ($p> 0.05$) between groups C and E. There were no significant ($p> 0.05$) variations in all the white blood cell values in all the groups. Also, there were no significant ($p> 0.05$) variations in the mean values of the plasma protein except group C that was significantly higher ($p< 0.05$) when compared with groups B and E (control). There were no significant ($p> 0.05$) variations in the

mean body weights of all the groups. After administration of the extract, the mean PCV of all the groups were higher when compared with group D but only group A was significant ($p< 0.05$). The mean HBC values of groups C and D were lower when compared with other groups but were only significant ($p< 0.05$) when compared with groups A and B. The mean red blood cell count (RBC) of all the groups were higher when compared with group E (control) but only group D was significant ($p< 0.05$). The MCV values of groups A - D were all higher when compared with group E but only group D was significant ($p< 0.05$). There were no significant ($p> 0.05$) variations in the MCH and MCHC, white blood cell and mean plasma protein values. Also, there were no significant ($p> 0.05$) variations in the mean body weights of all the groups.

PCV - Packed cell volume; HBC - Haemoglobin concentration; RBC - Red blood cell; MCV - Mean corpuscular volume; MCH - Mean corpuscular haemoglobin; MCHC - Mean corpuscular haemoglobin concentration, WBC- White blood cell.

DISCUSSION

The significant reduction in PCV, HBC and RBC in all the groups bled indicated that anaemia was successfully induced. This is in agreement with Ihedioha and Daniel-Igwe (2014) who reported daily removal of 2 ml of blood per 100g for 10 days for successful induction of anaemia with minimal or no mortality. The increase in MCV values after induction of anaemia indicates presence of macrocytes which are mainly reticulocytes (Coles, 1986; Kerr, 2002). This also shows bone marrow response to the anoxic condition created by the continual removal of blood (Chulilla, 2009). The decreased values of PCV, HBC, RBC and MCHC and increased MCV indicates a macrocytic normochromic anaemia. The significant increase in the PCV. HBC , RBC, MCH and MCHC in the groups treated with the extract when compared with the untreated group (D) suggests that the extract possesses some haematopoietic potentials.

Tetrapleura tetraptera had been reported to contain abundance of iron which is used by the bone marrow for haemoglobin production (Aladesanmi, 2007). Iron also helps many enzymes that are essential for growth, healing, immune function and DNA synthesis (Basta, 1979). This finding supports the folkloric usage by women after delivery in most parts of Africa including Nigeria.

ABSTRACT

Body condition score (BCS) is an important tool used for the assessment of health status of goats. This study evaluated the relationship between varied body condition scores of goats and the activities and levels of certain serum biochemical markers of liver disorders (SBMLD). The study was a cross sectional survey of slaughter goats in Ikpa abattoir, Nsukka, Enugu state, Nigeria. Each goat was tagged and evaluated for body condition. Prior to slaughter, blood samples were collected and sera obtained for assay of aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, gamma glutamyltransferase activities, and albumin and cholesterol levels. After clinical examination, 114 (94.21 %) of the goats were considered apparently healthy while 7 (5.79 %) were not healthy. Correlation of BCS with SBMLD indicated that cholesterol correlated positively and strongly ($r = 0.861$, $p = 0.028$).The cholesterol values of goats with body condition scores of 2.5 - 4 were significantly ($p<0.05$) higher than those with body condition scores of 1. It was concluded that the body condition score was directly related to the serum cholesterol values.

Keywords: Biochemical markers of liver disorder; Body condition scores; Nigerian breeds of goats

Body condition scores (BCS) assessment is a very critical tool in evaluating the body conditions of goats. It shows the available fat reserves that can be utilized in time of stress, suboptimal nutrition and high energy demand (Villaquan *et al.,* 2008). Body condition scores assess the extent of fatness or thinness with the use of a scale based on 5-point (Edmondson, *et al.,* 1989). The BCS can be useful in management of feed (Gillund *et al*., 2001). It affects health, reproduction and production (Dechow *et al*., 2002).

Nigerian breeds of goats are mainly Red Sokoto goats and relatively smaller proportion of Sahel goats and West African Dwarf goats (Ngere *et al*., 1984). Goats are veritable source of milk, meat and fur. Ill health occasioned by both infectious and non-infectious agents has been a major challenge in the livestock industry. Some of these ailments may lead to emaciation and changes in body conditions and these will ultimately affect production and reproduction (Heinrich and Isler, 1989).

Serum biochemical markers of liver damage are those parameters assayable from serum and can aid in diagnosis of liver disorders. These analytes include AST, ALT, ALP, GGT, albumin, cholesterol e.t.c (Ozer *et al*., 2008). The parameters such as AST and ALT are enzymes resident in hepatocytes. They ooze out into the circulation upon hepatic injury, and serve as indication of liver damage. In the same vein, enzymes such as ALP and GGT reveal damages to the hepatobilliary system since they (GGT and ALP) are ubiquitous in the epithelial lining cells of hepatobilliary system. Their increased serum activities therefore are a pointer to hepatobilliary disorder (Friedman *et al,* 2003). However, analytes such as cholesterol and albumin are synthesized by liver. Reductions in their serum levels indicate defective production by hepatocytes (Thapa and Walia, 2007).

There is dearth of information on the possible relationship between the BCS and liver damage in Nigerian breeds of goats. The aim of this study was to evaluate a relationship between these serum biochemical markers of liver disorder and body conditions of the goats and by extension, their health status.

Materials and Methods

Animals
Nigerian breeds of trade goats presented for sale and slaughter at the Ikpa Abbatoir Nsukka, Enugu State, Nigeria were used for the study.

Study design
The study design was a cross sectional survey. Research visits to the Abbatoir were made 2 times a week for period of 12 weeks (January-March, 2019). Before slaughter, the goats were physically examined to determine the body condition score and the health status using the method of Villaquiran *et al*., (2008).

Sample collection
Blood samples were collected from the jugular veins of the goat at the point of slaughter into clean test tubes devoid of anticoagulant. Sera were harvested by centrifugation at 3, 000 g for 10 mins. Thereafter, the clear supernatants were aspirated with the aid of clean syringe.

Body condition score assessment
The method of Villaquiran *et al*., (2008) was used to determine the body condition scores of the goats. The method uses a 5-point scale with 0.5 increments. Score of one (1) represents a very thin goat devoid of fat reserves while a score of five (5) shows an overweight goat. The goats were firstly visualized to determine whether they were emaciated or not, strong or weak. The state of the backbone and whether the flank was hollow and the ribs clearly visible or not were all determined. The amount of muscle and fat were determined in the lumbar area by running fingers on the lumbar processes attempting to grasp the fingertips. Attempts were also made to pinch fat covering the sternum, rib cage and the intercostals spaces.

Assay of biochemical parameters
The serum aspartate aminotransferase activity was determined by the Reitman-Frankel spectrophometric method (Reitman and Frankel, 1957; Colville, 2002). The serum alanine aminotransferase activity was determined by the Reitman-Frankel spectrophometric method (Reitman and Frankel, 1957; Colville, 2002). The serum alkaline phosphatase activity was determined by the phenolphthalein monophosphate method (Klein *et al.*, 1960; Colville, 2002). Gamma glutamyltransferase (GGT) activity was done following a Spectrophotometric method according to Theodorsen and Strømme, 1976 and Colville, 2002. The serum albumin was determined by the bromocresol green method (Doumas *et al*., 1971; Colville, 2002). The serum cholesterol was determined by cholesterol oxidase-perioxidase method (Allain *et al*., 1974; Colville, 2002). The AST:ALT ratio (De Ritis ratio) was calculated by dividing the AST activity with the corresponding ALT activity.

Data analyses
One-way analysis of variance (ANOVA) was used to compare data on the serum biochemical markers of liver disorders of the goats with varied BCS. Duncan's Multiple Range post hoc test was used to separate the variant Means. Spearman Rank correlation was used to correlate the BCS and the serum biochemical markers of liver disorders. Probability levels were set at $p<0.05$. Results were presented in tables and charts as means± standard error of the mean.

Results

Table 1: Serum biochemistry parameters of goats with varied body condition scores

PARAMETERS	BODY CONDITION SCORES					
	1 (N=9)	2 (N=31)	2.5(N=17)	3(N=31)	3.5(N=20)	4 (N=13)

CHOLES (mg/dl)	64.57 ± 3.88^{a}	73.71 ± 2.63^{ab}	75.92 ± 2.61^{b}	90.38± 3.13^{c}	84.07 ± 2.53^{bc}	90.47± 4.99^{c}

Different superscripts a, b, c across the same row indicates significant difference at P< 0.05.

Persistent and significant increases were observed in cholesterol values as the body condition scores improved from thin to obese while specified trends were not observed in other parameters measured.

Key: AST=Aspartate aminotansferase; ALT= Alanine aminotransferase; AST:ALT= Ratio of AST to ALT; ALP=Alkaline phosphatase; GGT=Gamma glutamyl transferase; ALB=Albumin; CHOL=Cholesterol. 1-Emaciated, 2=Thin, 3-Moderate, 4-Fat, 5-Obese

DISCUSSION

Gamma glutamyltransferase activities and cholesterol levels showed significant differences (P<0.05) in relation to body condition scores. Cholesterol showed consistent and significant increases as the body condition scores improved. The goats that were rated 4 and 3 (Normal) had significantly higher cholesterol levels compared with those rated 1, 2 (thin) and 2.5 (normal). Similar results had earlier been reported in a study by Roche *et al*., (2009) and Duricic *et al.*(2017). However, the results of this study are at variance

with those of Barbosa *et al*., (2009). Body condition score has been accepted as an effective, simple and reliable method to help assess reproductive efficiency (Duricic *et al*., 2017). Some researchers have noted that breed, age, sex, nutrition and environmental condition are among the key factors that affect body condition scores (Aktas *et al*., 2011;Samardzija and Vince, 2013). The effect of GGT revealed that the goat with score of 1 (thin goats) had a statistically higher activity of GGT. There is dearth of information on the relationship between body condition scores and the level of activity of GGT. GGT is a marker enzyme for hepatobiliary dysfunction (Thapa and Walia, 2007). It is thought that probably the goats with body score of 1 (thin or emaciated) may probably have some level of hepatobiliary dysfunction.

CONCLUSION

The results of this study showed that goats with high body condition score indices had higher serum cholesterol levels compared to the thin goats implying that the body condition score in goats could give a rough estimate of cholesterol levels.

ABSTRACT

The study surveyed the types and utilization of ethno-therapeutic remedies on some diseases of sheep in Maiyama Local Government Area. Sixty (60) sheep keepers were interviewed from four (4) districts in the study area using a structured questionnaire. Results on demography, experience and flock size indicated that majority of the sheep keepers are males (91.67%) and are between the age of 61 and above, with 1 – 5 years rearing experience. Results on ethno therapeutic practice indicated that most of thesheep keepers use both traditional and conventional remedies (45%) for the treatment of livestock diseases have practiced for the past 11-20 years (38.34%). Results on alternative therapeutic remedies indicated that the majority of sheep keepers use conventional remedies (83.34%) more than traditional remedies. Result shows that the sheep keepers source their ethno therapeutic remedies from the market. The common diseases affecting livestock in the study area were identified to include diarrhoea, foot and mouth disease, milk reduction, placenta retention, ecto-parasites, muscular weakness, worm or internal parasites, dysentery, mange, catarrh, pox, contagious ecthyma, mastitis, constipation, respiratory disorder, and foot pain. The ethno-therapeutic remedies commonly used were *Khaya senegalensis*, roasted maize ,salt and warm water ,*Grewia mollis, Hibiscus esculentus, Balanites aegyptraca,* dried grasses, *Poliostigma thoningi,Azadiracta indica,Guirrea senegalensis, Parkia biglobossa (*locust bean*),* wood ash, cow dung , donkey faeces, groundnut oil, shea butter, *Citrus aurantifolia, Carica papaya, Mangifera indica* and *Adansonia digitata*. It was concluded that though the sheep keepers in the study area practice ethno-therapy, they however utilize more conventional drugs for treating their animals.

Keywords: Utilization, Ethno-Therapeutic, Remedies, Diseases, Sheep

INTRODUCTION

Ethno-therapeutic research is defined by Carkle (2005) as the systematic investigation and application of animal or veterinary folk knowledge of curing, healing and managing livestock. Traditional veterinary drugs are very important in developing countries, where conventional remedies for animal health care are inaccessible or unaffordable to poor rural farmers (Mc Carcle,2005). About 80% of the people in the world today rely on folk (or traditional medicine) for treating both human and animal diseases and infections (Sindhu *et al*., 2010).

According to the United States or United Nations food and Agricultural organization (FAO) the lack of drugs to treat diseases and infections results in losses of 30 – 35% in the breeding sector of many developing countries where poor animal health remains the major constraint to increase production (FAO, 2002). Problem of service delivery of conventional veterinary drugs to such locations in developing countries are often exacerbated by multitude of other factors and that these factors have contributed to maintaining traditional veterinary treatment practices in these countries (Muhammad *et al.,* 2005). The extension of conventional medical veterinary service is particularly different and costly in developing world nations where necessary infrastructure (roads, clinics, labs, cold chains etc.) is poorly developed and where much of the populace and its livestock reside, in remote rural areas or may be nomadic or transhumance (Carkle and Green, 1998).

Nonetheless, much effort is needed in research and integration of the ethno-therapeutic practice activities in developing countries (Mathians *et al*.,, 1997). In many native and local stock raising communities, if not all, a considerable proportion of useful ethno – knowledge and traditional animal health delivery system is available for a wider use by rural and peri – urban communities (Wabzala *et al.,* 2005). However, there is still a wide gap Because traditional native medical practices have been in most cases either discontinued or greatly modified, there is much about them that will never be known (Lawrence, 1998). There is scarce documented information on the traditional medicine used in treating some sheep disease in this part of the country. Hence, the main aim of this research is to evaluate the ethno-therapeutic remedies of sheep in Maiyama Local Government area, Kebbi stste, Nigeria.

Materials and Methods

The experiment was carried out at Maiyama Local Government Area in Kebbi state Nigeria .In this study, a survey method was used. Structured questionnaires were administered to solicit responses from the respondents. A population of this study included sixty (60) sheep keepers drawn from four (4) districts in Maiyama Local Government area. The purposive sampling technique was used to select sixty respondents across Maiyama local government area. The questionnaires were administered to the respondents in order to aid responses on the ethno-therapeutic remedies of some diseases of sheep in the study area.

Data Collection

Data were collected on demographic characteristics, years of experience and practice of ethno therapeutic remedies, level of utilization of traditional medicine, methods of utilization, types of ethno-therapeutic remedies and their mode of utilization, common diseases found and other necessary information useful to the study.

Data analysis

The data collected from respondents was analyzed through the use frequency distribution tables, and sample percentage.

RESULTS AND DISCUSSION

Demography, Experience and Flock size of sheep keepers in Maiyama Local Government Area

Results on Table 1 shows the distribution of respondents according to demographic characteristics, experience in sheep keeping and flock size. The result indicated that majority (91.67%) are males and they are within 61 and above years (33%). Most of them have 1-5years experiences in sheep keeping (31.67%) and the people that possess sheep are (35%) and they are within 11-20 years of experience in sheep keeping.

Table 1: Demography, Experience and Flock size of sheep keepers in Maiyama Local Government Area

S/N	Question	Responses			
1.	Gender	Male	Female		
		55(91.67%)	5(8.34%)		
2.	Age	20-30years	31-40years	41-60years	61and above
		10(16.67%)	13(21.67%)	17(28.34%)	20(33.34%)
3.	Years of experience in sheep keeping	1-5years	6-10years	11-20years	21 and above
		16(31.67%)	14(23.34)	19(35%)	14(23.34%)
4.	Numbers of sheep possessed	1-5years	6-10years	11-20years	21 and above
		12(20%)	14(23.34%)	21(35%)	13(21.67)

Source: Field survey, 2019.

From the result, it was observed that male (91.67%) were involved in sheep rearing more than female. This might be as a result of the scarcity of the income and resources of female. The 11-20 years (35%) experience could indicate that sheep keeping has been an old practice of most households in the communities. Majority of the respondents having 21 sheep might be as a result of lack of or the scarcity of income and resources of farmers to ncrease flock size which conforms to the claim that most animals are owned by resource poor farmers (Dharani *et al.,* 2015)..

Ethno Therapeutic Practices of Sheep Keepers in Maiyama Local Government Area

The results on able 2 indicated that the majority of respondents are using conventional remedy (35%) better than traditional remedy and they have been using it for 11-20 years (38.34%) and the effect of the traditional remedy are quick recovery (55%) and their sources of traditional remedies are free (51.67%) when treating their animals.

Table 2:- Ethno-therapeutic practice of sheep keepers in Maiyama local government area.

S/N	Question	Responses		
1.	With what do youuse in treating you sheep orsick sheep?	Traditional remedy 12(20%)	Conventional remedy 21(35%)	Both 27(45%)
2.	For how long have you been using traditional remedies?	1-10years 18(30%)	11-20years 23(37.34%)	>12 19(31.67%)
3.	What are the results of using trationalremedies?	Quick recovery 31(51.67%)	Not recovery 27(45%)	
4.	What is your source of traditional remedies	Free 31(51.67%)	market 29(48.28%)	

Source:Field Survey, 2019

The respondents used both traditional and conventional remedy for disease treatment. This might be as a result of lack of awareness on ethno-therapy. While majority of respondents have been practicing ethno-therapy for up to 11-20 years (37.34%), they reported that quick recovery (51.67%) is usually observed when they used traditional remedy. Majority of respondents reported that the traditional remedies are sourced free (51.6%) probably as a result of its natural existence in the study area.

Alternative Therapeutic Remedies of Sheep Diseases in Maiyama Local Government Area.

The results on Table 3 shows that the majority (83.34%) of the respondents uses conventional remedies. And also utilizes conventional remedy (55%) better than traditional remedies in treating sheep diseases.

Table 3: Alternative therapeutic remedies of sheep keepers in maiyama local government area.

S/N	Question	Responses	
1.	Do you use conventional remedies?	Yes 50(83.34%)	No 10(16.67%)
2.	Between traditional and conventional remedies which one do you used regularly?	Traditional remedy 27(45%)	Conventional remedy 33(55%)

Source: Field survey, 2019

Based on the findings of the current research, most of the respondents in the study area are using conventional remedies to cure or prevent sheep from various diseases. This might be as a result of complicated mode of utilization of traditional remedies since there is no standard composition or dosage which could limit its utilization. The respondents also reported that they utilize conventional remedies regularly (55%) more than ethno-theraphy which could be as a result of lack of its complete reliability (Jacob *et al*., 2004).

Common Diseases and their Ethno therapeutic Remedies in Maiyama Local Government Area.
The results in Table 4 indicated that the most common diseases affecting livestock in the area are diarrhea, foot and mouth diseases (FMD), milk reduction, placenta retention and ecto-parasite (like lice, tick, mites) Muscular weakness worm/Intestinal parasite (i.e. endo-parasite (Haemanchus, worms. Helminthes), catarrh, contagious ecthym (Orf), conjunctivitis, mastitis, foot pain, respiratory disorder, mange infestation and constipation. The ethnotherapeutic remedies that respondents are using in curing, treatment and preventing disease and illness of their animals are *Khaya senegalensis*, (Mahogany) roasted Maize, salt and warm water, *Grewia mollis* (Kamomowa), *Hibiscus esculentus* (Okra), *Balanites aegytraca* root (aduwa) dried grasses *Poliostigma thonigil* (camels foot), *Azadirachta indica* (Neem tree), *guirrea senegalensis* (sabara) *Pakia bigiobossa* (locust bean tree), wood arsh, cow dung, donkey faeces, ground nut oil, shea butter, *citrus aurantifolia* (lime oranges) *carica papaya* (paw paw), *Mangifera indica* (mango tree) and *Adansonia digitata* (Baobab tree).

Table 4: Common Diseases and their Ethno therapeutic Remedies in Maiyama Local Government Area.

S/N	Name of Diseases	Ethno therapeutic remedies and they are used
1.	Diarrhoea	* Using *Khaya senegalensis* bark (mahogany) and drench the animal. * Using *Adansonisa digitata* (baobab tree and give to the animal in fresh or dried form. * Using *citrus aurantifolia* (lime orange) leaves * By using *Magnifera indic*a and drench the animal give to the animal.
2.	Foot and mouth disease	*By roasting of maize and give to the animal. *By washing the affected area with warm water and salt.
3.	Milk reduction	*By using *Grewia molllis* leaves (Kamomowa) and pound and extracts are drench to the animal. *By giving small amount of fresh maize to the animal.
4.	Placenta retention	*By *using Hibiscus esculentus* (okra) pound and dry the stem and extracts are drench to the animal. *By using *Balanites aegyptraca* roots (aduwa) and extracts are drench to the animal.
5.	Ectoparasite (lice)	*By burning the dried leaves of *carica papaya* (pawpaw) and pour on the body of infected animal. *By burning the leaves of *Guirea senegalensis* (sabara) and smoke the animals with fumes.
6.	Muscular weakness	*By tie of the affected area with the twigs of polistigma thoningii (camel's foot Kalgo)
7.	Internal parasites	*By using Azadirachta indica bark (neem tree or dogonyaro) and drench the animal.
8.	Dysentery	*by using *Azadirachta indica* tree (neem tree) leaves and bark and drench the animals.
9.	Mange	*By rubbing of engine oil on the affected area 0f the body. *By using shea butter oil on the affected area.
10.	Catarrh	*By smoking the fumes of *Azadiracta indica*(Neem tree) in the animal premises.
11.	Pox	*Mix half a cup of salt with I litre of warm water and wash the affected area. *By using seed of *Azadirachta indica* and make paste and aply to the affected area.
12.	Contagious ecthyma	*By using salt and warm water to wash the affected area. *By using *Acacia nilotica* pods and mix with water and wash the affected area.
13.	Mastitis	*By making paste of non-poisonous wood ash and rub to the affected udder and massage. *By burning dung of cattle and donkey faeces and apply to the udder and massage.
14.	Constipation	*By drenching small amount of groundnut oil.
15.	Respiratory disorder	*by sucking a rhizome of a *Zingiber officinale* (ginger) in water and drench the animals
16.	Foot pain	*By using locust bean seed and make paste and rub the affected area properly.

Source: Field survey, 2019

CONCLUSION

The majority of sheep keepers were male (91.67%) with 1-5yaers working experience, having between 11 – 20 heads of sheep. The ethno-therapeutic remedies identified were *Khaya senegalensis (*mahogany*),* roasted maize ,salt and worm water ,*Grewia mollis (*kamomowa*), Hibiscus esculentus (*okra *), Balanites aegyptraca (*aduwa*),* dried grasses, *Poliostigma thoningi (*camels foot*) ,Azadiracta indica (*neem tree*)* ,*Guirrea senegalensis (*sabara*), Parkia biglobossa (*locust bean*),* wood ash, cow dung ,donkey faeces, groundnut oil , shea butter , *Citrus aurantifolia (*lime oranges*), Carica papaya (*pawpaw*) , Mangifera indica (*mango*)* ,and *Adansonia digitata (*baobab tree*).* The sheep keepers practices ethno-therapy but are utilizing more conventional drugs for treating their animals.

PREVALENCE, ECONOMIC IMPACT ANALYSIS AND VIABILITY OF HYDATID CYSTS IN BOVINE SLAUGHTERED IN SELECTED ABATTOIRS WITHIN KADUNA METROPOLIS

Vantsawa P. A., Dibal D. M. & Ossai E. I.
Department of biological sciences, Nigerian Defence Academy, Kaduna.

ABSTRACT
A cross sectional study aimed at determining the prevalence, cyst characteristics and estimating the financial loss due to cystic echinococcosis (hydatidosis) in cattle slaughtered at Tudun-wada abattoir, Kakuri (Makera) abattoir, Kawo abattoir and Sabon–Tasha abattoir, all within Kaduna metropolis, was carried out from January to July, 2019. Out of the 160 cattle examined (40 from each abattoir), 21 (12.2 %) were found to harbor visible hydatid cysts. Significantly higher infection ($p < 0.05$) was detected in cattle with moderate body conditions than animals with forward and fat body condition score. No significant variation was observed with regards to sex of animals. Cysts were found to be distributed in the lung, liver, kidney, spleen and heart as follows 42.9%, 38.0%, 4.76%, 9.50% and 4.76% respectively. Out of 36 hydatid cysts examined, 17 (47.22%), 14 (38.88%) and 5 (13.88%) were found to be small sized, medium-sized and large- sized respectively. Likewise, out of 36 cysts assessed, 18 (50%) were fertile, 4 (11.11%) sterile and 14 (38.8%) were calcified. Of the 18 fertile cysts subjected for viability test, 12 (27.7%) were viable while 8(22.2%) were non viable. Moreover, assessment of annual economic loss due to bovine hydatidosis in Kaduna metropolis from organ condemnation and carcass weight loss was estimated at 17,862,348(NGN).Despite the moderate magnitude of infection detected currently, there seems to be an existing socio economic situation favorable for hydatidosis and hence it remains one of the most important diseases warranting serious medical and veterinary attention.

Keyword: Echinococcosis, cysts, abattoir, fertile, viability.

INTRODUCTION
Hydatidosis is a parasitic zoonotic disease caused by the metacestode of the tapeworm *Echinococcus spp* (Magaji *et al.,* 2011). It is one of the limiting factors in food animal production and hampers the realization of adequate meat supply to meet the ever increasing demand of animal protein by human population (Ogunsan *et al*., 2000).

Three broad morphological forms of *Echinococcus* are recognized clinically; *Echinococcus granulosus* which causes cystic Echinococcosis; *E. multilocularis* which causes alveolar Echinococcosis and *E. oligarthrus* which cause polycystic Echinococcosis. The definitive hosts of *E granulosus* are the dogs while the intermediate hosts are the domestic ungulates and man (Luka, 2009). The adult hydatid worm which resides in the small intestine of a definitive host produces gravid proglottids which release eggs that are passed out in feces of the host (mostly dogs). The eggs are then ingested by an intermediate host (cattle). The eggs then hatch in the small intestine of the cattle, releasing an oncosphore that penetrates the intestinal wall and moves through the circulatory system into organs such as lungs, liver, kidney, spleen and the heart where they develop into cyst which then slowly enlarges, creating protoscolices and daughter cyst. (Schantz,1990; Biu and Abagwe, 2001). Hydatidosis has a worldwide distribution and causes considerable economic losses and public health problems in many countries including Nigeria and other pastoral range and areas of the world (Tijani *et al*., 2010; Jenkins, 1998).

Lack of adequate control policy, uncontrolled movement, trading of animals and their product and difficulties in early diagnosis enhance the distribution of the disease (NAHIS, 2004).

Infection is often associated with economic losses due to livestock mortality, morbidity, and organ and meat condemnation at meat inspection. It also poses a serious threat to public health where close association exists between dogs, man and food animals (Kebede *et al*., 2009).

Many tropical countries are hydatitosis endemic and this poses a threat to development. There is paucity of information on hydatidosis in domestic livestock and most of the documented reports are based on postmortem findings from abattoirs, thus mitigating public health intervention measure in this regard. The aim of this research is to determine the prevalence of cystic hydatidosis in bovine slaughtered in four selected abattoirs within Kaduna metropolis.

Materials and Methods

This study was conducted in four selected abattoir within Kaduna metropolis: Tudun Wada, Kakuri, Sabon Tasha and Kawo. The animals comprise of cows slaughtered in the abattoirs. The information on the breed of the cow, age, sex and body count score were obtained through the administration of questionnaires. Sample size was determined using the formula of Thrusfield (2005) as follows:

$$N= \frac{(1.96)^2\ (pexp\ )(-pexp\ )}{d^2}$$

Where Pexp = expected prevalence

N= Total number of sample size

D = Required precision.

A total of 160 that is 40 from each abattoir were randomly sampled and examined for the presence of the hydatid cysts. All organs harboring hydatid cysts were partially or totally condemned and judged according to guideline on meat inspection for developing countries.

According to their size, hydatid cysts were then classified as small (<4cm), medium (4-8cm) and large (>8cm). The cysts was considered fertile when the protoscolices were present and seen as white dots on the germinal epithelium, direct and indirect losses were considered in the determination of economic loss due to hydatidosis. The direct loss was calculated based on condemned organs (lungs, liver, heat, spleen and kidney) and the indirect loss was obtained on the basis of live weight reduction due to hydatidosis. All data obtained were subjected to statistical analysis using SPSS and Chi Square. All value of ($P<0.05$) is considered significant.

RESULTS

The result of relative distribution of the cysts in different organs of the cattle is shown in table 1. The relative prevalence of the cysts is more in the lungs followed by the liver with 42.9% and 38.0% respectively. The least occurrence was in the heart and spleen with 4.76% each.

The status of cysts from different organs of the cattle slaughtered in the four abattoirs is presented in table 2. In the lungs there were eight cases of fertile viable cysts which represent 47.05% , non–viable were six which represents 35.2%, two cases of sterile which represent 11.76% and one case of calcified which represent 5.8%.

Only one case of viable cysts in the liver occurred which represent 7.14%. No case of non –viable and sterile cyst was found in the liver. There were 13 calcified cases which represent 92.8%. All the cases occurred at 33.3 % in the kidney which the exception of the calcified. In the spleen and heart, one case each of non- viable and sterile occurred respectively.

The economic loss due to *Echinococcus* infestation was estimated to be N17, 862,348. This was as a result of organ condemnation and weight loss by animal. In this study a total of 17 lungs averaging 1.2kg; 14 livers with average of 3.5kg; three kidneys with an average of 0.6kg and one heart with an average of 0.7kg were discarded due to infestation with hydatid cysts. These constitute a loss to the farmers as the average cost of 1kg of meat in the market was N1350.00.

DISCUSSION

The prevalence of hydatidosis of 12.2% in this study is closer to the 15.4% reported by Dada *et al*., (1980). However lower than the findings of 20.5% reported in Kano by Luka *et al*., (2009) and 24.3% reported from southwest Nigeria by Oyeduntan (2014). Differences in culture, social activity, animal husbandry system, lack of proper removal of infectious carcasses and attitude to dogs in different region could be factors that contributed to the variation in prevalence in different areas of the country. The higher prevalence of cysts in lungs and liver in this study agree with the work of Njoroge *et al*., (2002) and Eckert (2004) who observed hydatid cysts in domestic animals. This could be due to possession of great capillaries which is usually encountered by the migrating echonococus onchosphere which adopt the portal vein route and primarily negotiate hepatic and pulmonary filtering system sequentially before any other peripheral organ is involved. It is also possible that the hexacanth embryo can enter the lymphatic circulation and be carried through the thoracic duct to the lungs in such a way that the lungs may be infected before the liver. The fertile cyst of 50% observed in this study is in agreement with the study by Kebede *et al*., (2009). This higher fertility rate highlights the hazard that these animals perpetuate in the cycle of hydatidosis when slaughtered and the raw offal fed to dogs and other wild carnivores. The economic loss of N17, 862,348 due to hydatidosis is enormous and could be curtailed to boost the profit merging farmer.

CONCLUSION AND RECOMMENDATION

From this study, hydatidosis is an important disease of cattle in Kaduna metropolis and its surroundings, causing substantial losses due to condemnation of organs and weight loss in infected livestock. Much attention and resources should be channeled to research in order to curtail the mode of transmission of this parasites from definitive host to intermediate hosts and vice – versa.

Health workers should be empowered to enlighten the abattoirs operation on the claim of transmission of hydatitosis. They should also increase inspection visits and monitoring of abattoirs activities to avoid illegal consumption of hydatid infected organs. Anti–helminthic drugs should be made available to bovine farmers in order to eliminate the parasites.

ABSTRACT
Straw used as bedding materials serves both as recreational and nutritional substrates for pigs and has been reported to improve swine welfare. The aim of this study was to investigate the influence of maize straw on the growth performance and behaviour of weaner pigs. Thirty-six (large white x Landrace) weaner pigs were randomly distributed into four treatments (concrete floor, maize straw at 0.1m, 0.2m and 0.3m depth) with each treatment having three replicates and three pigs per replicate. Data were collected on growth parameters and behavioural indices. There was significant ($p<0.05$) difference in interaction effect on feed conversion ratio (FCR) across the bedding types and depth. Pigs on concrete floor had FCR of 4.72 that was significantly ($p<0.05$) greater than 3.83, 3.53 and 3.49 found in pigs on 0.1, 0.2 and 0.3m depth of maize straw bedding, respectively. There were significant ($p<0.05$) differences between pigs on concrete flooring and those on maize straw enriched bedding for final body weight (FBW), weight gain and feed conversion ratio (FCR). Overall levels of measured behavioural activity differed between the treatments; where animals on maize straw spent significantly higher time on exploratory behaviours, while they spent considerably lower time on manipulative oral behaviours. It can be concluded that pigs reared on maize straw bedding, particularly at 0.3m depth performed more exploratory behaviour, less aggressive behaviour, and had better welfare.
Keywords: Behaviour, Enrichment, Growth Performance, Maize Straw, pigs.

INTRODUCTION
Animal welfare jointly with environmental and food safety are the major challenges of agriculture (Hotzel *et al*., 2005). Intensive indoor-systems are often made up of barren slatted concrete floors with no rooting material. These systems promote boredom and frustration for pigs by precluding the expression of behaviours, which are exhibited, by pigs under normal circumstances (Studnitz *et al*., 2007). In pig farming, welfare conditions should be especially observed at critical stages such as weaning, when piglet performance may be affected by behavioural, physiological, immunological and microbiological changes (Molino and Balbino, 2010). Environmental enrichment by provision of objects or substrates capable of satisfying the behavioural needs of pigs is a major method to combat animal welfare problems. These objects or materials have the ability to reduce the amount of time pigs spend on harmful social behaviours. The effects of enrichment can be examined in different approaches such as behaviour and performance of pigs in enriched environments compared to those in barren environments. These aspects all offer insights on how environmental enrichment improves pig welfare. This study therefore explored existing knowledge concerning environmental enrichment and its effect on behaviour and growth performance of weaner pigs housed in maize straw enriched pen.

MATERIALS AND METHODS
The experiment was carried out at the Piggery Unit of the Teaching and Research Farm, University of Ibadan, Ibadan, Oyo State. Thirty-six (Land race X Large white) weaner pigs were used for a 35-day research. Pigs were randomly distributed into four treatments (concrete floor, maize straw at 0.1, 0.2 and 0.3m depth) with each treatment having three replicates and three pigs per replicate. Data were collected on the growth performance of the pigs. Behavioural activities of pigs in each pen were also recorded at day 2 and 34 using direct observation method. Time spent on different activities was observed 3 times for 2 hours, starting from 1000h and ending at 1200h. In each pen, 1 focal pig was selected. The same focal pig

was observed throughout the trial. Data obtained were analyzed using descriptive statistics and analysis of variance (ANOVA) as described by (SAS, 1990), while means were separated using Duncan Multiple Range Test of the same statistical package.

RESULTS

Table 1: Effect of floor type and depth on growth performance of weaned pigs raised on concrete and maize straw enriched floor

Floor type	Depth	Initial weight(kg)	Final weight (kg)	Weight gain (kg)	Feed intake (kg)	FCR
Concrete	0	5.21	8.55	3.34	15.73	4.72[a]
Maize	0.1	5.30	9.43	4.13	15.71	3.83[b]
	0.2	5.33	9.58	4.25	14.97	3.53[b]
	0.3	5.25	9.41	4.16	14.51	3.49[b]
SEM		0.43	0.33	0.21	0.49	0.17

[a,b] Means of treatments along a column with different superscript differed significantly (P<0.05). SEM- standard error of mean, FCR- Feed Conversion Ratio

The performance characteristics of growing weaners housed in maize straw bedded pens are as shown in Table 1. There was significant ($p<0.05$) difference in feed conversion ratio (FCR) of weaned pigs. Pigs on concrete floor had FCR of 4.72 that was significantly ($p<0.05$) greater than 3.83, 3,53 and 3.49 found in pig on 0.1m, 0.2m and 0.3m maize straw bedding depth, respectively. There was no significant ($p>0.05$) different among the FCR of pigs on maize straw bedding.

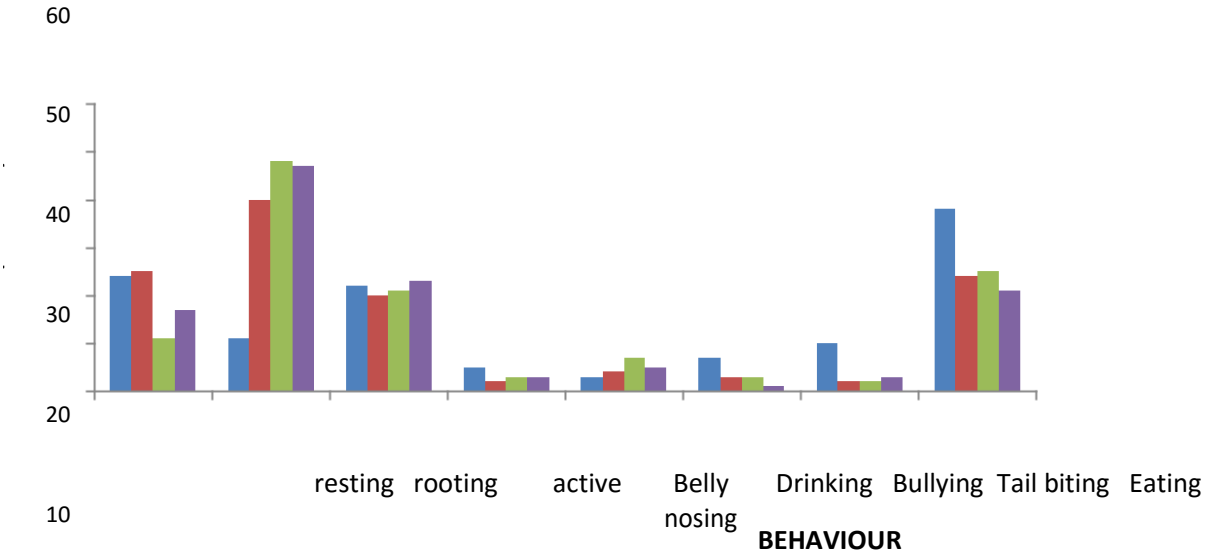

Figure 1: Behavioural activities of weaned pigs on concrete floor and maize straw bedding at 0.1, 0.2 and 0.3m depth at Day 2.

Figure 1 shows behavioural activities of newly weaned pigs on concrete floor and enriched floor with maize straw at 0.1, 0.2 and 0.3m depth at day 2. There was a variation in behavioural activity across the treatments.

Resting time of 24mins, 25mins, 11mins and 17mins was noted for pigs on concrete floor and enriched floor with maize straw at 0.1, 0.2 and 0.3m depth respectively. Pigs on concrete floor spent 11mins rooting which was considerably lower in comparison with pigs on maize straw bedding of 0.1m, 0.2m, 0.3m which spent 40mins, 48mins and 47mins respectively. Belly nosing frequency of 5mins, 2mins, 3mins and 3mins were noted for weaned pigs on concrete floor, and 0.1m, 0.2m and 0.3m, maize straw bedding depth, respectively.

Drinking and bullying activities frequency varied across the treatments from concrete floor, and 0.1m, 0.2m and 0.3m, maize straw bedding depth with 3mins and 7mins; 4mins and 3mins; 7mins and 3mins; and 5mins and 1mins, respectively.

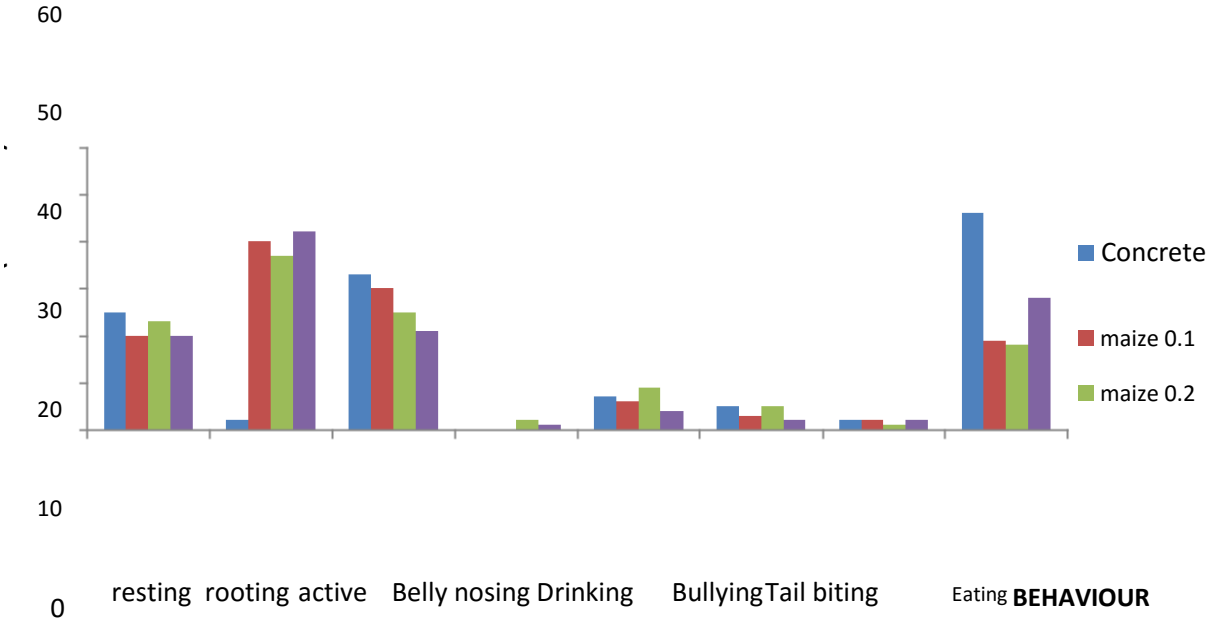

Figure 2: Behavioural activities of weaned pigs on concrete floor and maize straw bedding at 0.1, 0.2 and 0.3m depth on day 34.

Shown in figure 2 is the behavioural activities of weaned pigs on concrete floor and enriched floor with maize straw at 0.1, 0.2 and 0.3m depth for day 34. There was variation in the frequency of time spent on behaviour of weaned pigs on concrete floor and 0.1m, 0.2m and 0.3m depth of maize straw bedding.

Weaned pigs on concrete floor spent 25mins resting, while those on 0.1m and 0.3m maize straw bedding spent 20mins resting and pigs on 0.2 maize straw bedding spent 23mins. Less than 10mins was observed to have been spent by pigs on concrete floor to engaging in rooting activity, while those on 0.3m. 0.2m and 0.1m depth of maize straw bedding spent 42mins, 37mins and 40mins, respectively on rooting activity.

Active time was observed to be on the decline from 33mins, 30mins, 25mins to 21mins for pigs on concrete floor, maize straw enriched bedding of 0.3m, 0.2m and 0.1 depth, respectively.

Pigs on 0.2m maize straw enriched bedding spent 9mins of the observation time drinking and those on concrete floor spent 7mins, while those on 0.1m and 0.3m depth of maize straw bedding had 6mins and 4mins of the observation time drinking.

Pigs on concrete floor and 0.2m depth of maize straw bedding had 5mins of their observation time on bullying activity while those on 0.1m and 0.3m depth of maize straw bedding had 3mins and 2mins spent on bullying activity respectively.

Pigs on concrete floor had 46mins spent on eating activity while those on 0.1m, 0.2m and 0.3m had 19mins, 18mins and 28mins, respectively on eating activity.

DISCUSSION

The lack and absence of manipulation materials with the lack of space is a unique source of poor welfare and low production in intensive system of pig rearing (Studnitz *et al*., 2007). This reflects high frequency of behaviour redirected to objects and other animals in the pen causing pigs severe problem like skin lesion (Turner *et al*., 2006), cannibalism (van de weerd *et al*., 2005), physiological stress (Chaloupkova *et al.*, 2007) and lower product quality (Beattie *et al*., 2000). Maize straw as environmental enrichment substrate seems to comply with several of the characteristics necessary to maintain the interest of pigs for a relatively long period, such as being ingestible, chewable, odorous and rootable (van de Weerd *et al*., 2003).The choice of maize straw for this study was due to its availability and easy access as crop residues due to maize being an important and staple food in the country.

Feed conversion ratio (FCR) was found to be better than in pigs reared on maize straw beddings compared to those on concrete floor. Some differences, though, were found in the behaviour of the animals reared on concrete floor and the three different maize straw depths. Pigs kept on maize straw enriched bedded pens were found to have better weight changes compared to those on concrete floors. The performance of pigs is crucial as it reflects their response particularly to feed given and their living environment. Beattie *et al.* (2000) observed that pigs in enriched environments had higher growth rates, which was attributed to higher average daily feed intake. Furthermore, pigs in an enriched environment had a better feed conversion ratio (FCR) than their counterparts from barren environments. The predisposition to increase stress levels on concrete floor could be the reason why these pigs had lower performance rates than pigs in enriched environments. Barnett *et al*. (1992) reported that higher levels of stress adversely affected FCR. At high temperature, pigs reduce their feeding time (Collin *et al*., 2001). Feeding behaviour differ between pigs on concrete floor and those on maize straw bedding. Furthermore, there were differences in the time spent resting as influenced by temperature differences between floor types and bedding depth as this would be expected to influence the animals' thermal comfort (Hyun *et al*., 2005). Fraser (1985) found that while under cool conditions growing pigs prefer to lie on straw, at higher temperatures they prefer bare floors. Thus because of the tropical condition of the study, pig exhibit higher frequency of resting on concrete floor while lesser time resting on maize straw bedding that raise thermal stress in the animal as a result of heat of fermentation from the decomposing maize straw. Excessive temperature, as a result of fermentation of the substrate, could result in heat stress, reducing voluntary feed intake and weight gain of pigs (Quiniou *et al*., 2000)

CONCLUSION AND RECOMMENDATION

Maize straw helped in manipulating the behaviour of weaned pig which is important in welfare improvement of the pigs. It was revealed that the maize straw is a good rooting and welfare-friendly material that has a larger capacity to stimulate explorative behaviour of pigs. Also, it is a good absorbent material providing dry surface for pigs. Better pig production performance with improved weight changes and feed conversion ratio was noted with pigs on maize straw enriched pens. It can be recommended that pigs should be reared on 0.3m depth maize straw enriched pen as it improves exploratory behaviour of pigs and promotes better welfare of the pigs by reducing or eliminating aggressive behaviour.

INCIDENCE OF FOETAL WASTAGE IN CATTLE SLAUGHTERED AT THE BAUHI ABATTOIR, BAUHI STATE

***Samaila, L. M; Sanusi, M.; Mbap, S. T & Anene M. G.**
Department of Animal Production, Abubakar Tafawa Balewa University, Bauchi.
Correspondence authors email: lulumaje@gmail.com; 08141198458

ABSTRACT
A total of 10,201 foetuses were wasted within a seven year period studied (2011 – 2017). Majority of the foetuses encountered were in 2013 (1,848) followed by 2011(1,818). The year 2016 had the lowest rate of foetal wastage. Monthly increase at the abattoir arise in the months of September, July, January and December 922, 929, 950 and 968 respectively with the highest peak in June1013 throughout the study period. The late rainy season (July-September) had the highest rate of foetal wastage while the late dry season had the lowest. The results indicated a high level of slaughtering of pregnant cows in the abattoir studied. Therefore concerted efforts like routine veterinary checks and interventions among trade animals is needed in order to reduce the high level of foetal wastage in the country. Also, livestock owners should be educated on the seasonal breeding patterns of cattle in order to avoid selling cows during the calving season. It also gave insight to need for strategic planning and decision-making on animal food security in Bauchi State.

Keyword*: Foetal wastages, cattle, Bauchi abattoir, slaughtered.*

INTRODUCTION
Selling of cattle to livestock market is a common practice to farmers for the purpose of getting income. To get good prices, farmers always select animals by visual assessment, looking at body size (well-nourished and fat animals) and sell them to cattle traders in livestock markets. Because of limited veterinary and extension services in rural areas, farmers just sell animals without knowing their pregnancy status. The majority of cattle traders buy animals for slaughter and sell meat. Studies in many African countries show that many local cattle slaughtered in different slaughter-houses are pregnant (Zulu *et al*., 2013; Nantongo *et al*., 2013; Bakari, 2016 and Hassan *et al*., 2016). This leads to foetal wastage which otherwise would have increased the cattle herds that ultimately increase the protein supply to the ever increasing human populations in African countries like Nigeria.

The attendant embryonic and foetal wastages due to this practice consequently query the efficiency of *ante-mortem* and the rationale for converting pregnant animals to beef, mutton, chevon, pork, offal and other meat types. It also challenges the ethical or moral act of slaughtering pregnant animals in situations where there is no law supporting the practice. In most cases, meat consumers are even unaware or denied the right to know the status of the animal that is converted to meat they eat. In Nigeria, there is lack of legislation strictly regulating abattoir construction and operation. In many states of the federation there are no modern abattoirs where proper ante-mortem examination of slaughtered animals is practiced to eliminate slaughtering of pregnant cows. The greatest effects about slaughtering pregnant cows lies in the fact that herd population sizes are reduced and enormous economic wastages are involved, leading to colossal reduction in the national herd, loss of dairy products as well as supply of poor quality meat product to the general public (Alhaji, 2011; Ardo *et al*., 2013;Hassan *et al*., 2016 and Bakari, 2016). This study was carried out to investigate the incidence of foetal wastage in cattle slaughtered at the Bauchi Abattoir, Bauchi State for the period of 7 years.

MATERIALS AND METHODS

Study area

The study was conducted in Bauchi abattoir, Bauchi district of Bauchi state, Nigeria. Bauchi is the state capital of Bauhi state, located at latitude 9° 3′and $12^0$3'N and longitude 8° 5′and 11^0E.The geographical area is largely inhabited by people whose main occupation is subsistence agriculture including the rearing of animals(ruminants) others are artisans and civil servants.

Data processing and statistical analysis

The primary raw data was collected and processed by the use of descriptive statistics (percentage and ratio). Chi-square test was also employed to test association between foetal wastage and years, months and seasons using SPSS version 21.

RESULTS AND DISCUSSION

The result of this investigation showed that 19.17% of slaughtered cattle were pregnant in Bauchi abattoir, that is, for every five slaughtered cows, one could be pregnant; this showed the extent of reproductive loss. The proportion of cows slaughtered pregnant varied considerably among countries and breeds; 22.1% in Cameroon cows (Ndi *et al*., 1993), 15 % in Mali (zebu cows) (Wilson and Traore, 1988), 38.7% in New Zealand (dairy cows) (Lawton *et al*., 2000), and 23.5.% in UK (dairy cows) (Singleton and Dobson, 1995; Sheldon and Dobson,2003) respectively. and States; 2.6% in Kano (Bakari, 2016) and 40.70% in Lafia (Hassan *et al*., 2016). However, the incidence of pregnant cows slaughtered in Bauchi abattoir was higher in comparison with some countries' reports. Singleton and Dobson, (1995) reported that, the reasons why so many pregnant cows were slaughtered at abattoirs might include disease eradication schemes, economic factors such as the calf price, the cash flow of an individual farm, nutritional factors such as the availability of pasture and the effects of a dry season. However, these factors may be different among livestock production situations, breed and area.

Table 1 shows the annual incidence of foetal wastage in Bauchi abattoir. A total of 10,201 foetuses were wasted within ten year period. Majority of the foetuses encountered were in 2013 (1848) followed by 2011 (1818). The year 2016 had the lowest rate of foetal wastage (905). The possible reason for the peak in foetal wastages in 2013 and subsequent fall could not be easily ascertained but often cattle are sold to meet the need for money to send children to school and meet some other domestic needs. The implication of this finding was that 19.17% of the future productive herd was lost to this practice which would adversely affect the development of cattle production in and around Bauchi. The higher percentage observed in this study could be associated with lack of enforcement of legislation against slaughtering of pregnant cows. The percentage of foetal wastage 19.17% in this study was higher than 8.2% obtained by Nwakpu *et al.* (2007), 9.15% by Fatemi *et al*. (2008), 9.87 by Ardo *et al*. (2013) and 2.6% by Bakari (2016).

The findings in this study also showed that one foetus was wasted for every five cows slaughtered. This ratio is higher than the findings of 1:14 by Fayemi *et al.* (2012) at four abattoirs in Ogun State, 1:11 by Nwakpu*et al.* (2007) in Ebonyi State of Nigeria.The unnecessary disposal of many pregnant cows represented a major economic loss and an important source of herd wastage to the industry (Sheldon and Dobson, 2003)

Table 1: Annual incidence of foetal wastage in cows slaughtered at Bauchi Abattoir, Bauchi State, Nigeria from 2011-2017

Years	TCTS	TBS	TCS	TFW	POFW (%)	TCS:TFW
2011	14926	7065	7861	1818	23.13	4:1

Keys: TCTS = Total number of Cattle slaughtered, TBS = Total bulls slaughtered, TCS = Total cows slaughtered; TFW= Total number of foetuses wasted, POFW=Percentage of foetal wastage.

Table 2 shows the monthly increase of slaughtered animals at the abattoir, there was a rise in the months of July, January, December and June 929,950,963 and 1013 respectively with the highest peak in June 1013. The rise in the months of June and July showed that the rains were just about to begin and these periods are usually characterized by drought, hunger which expose animals to poor nutrition, diseases especially gastrointestinal parasitism and as such to forestall losses due to natural death or diseases, farmers prefer to sell their animals. Many authors have reported that most cattle sold for slaughter during the dry season were females (Abdulkadir *et al.*, 2008; Alhaji and Odetokum, 2013). The rise in wastage in December and January of most of the years may be related to the festivals and ceremonies during this period. There was a peak of foetal wastage in June with a significant difference between months and foetal wastage at $P \leq 0.05$.

Key: *11-17 means 2011 - 2017*

Table 3 shows the seasonal variation in the rate of foetal wastage in this abattoir. The incidence of foetal wastage was more in late rainy season than others and a significant difference between Seasons and foetal wastage was observed at $P \leq 0.05$.The highest incidence in the late rainy season could be due to disease especially gastrointestinal diseases or shortage of money during this periodas much has been invested in farming.

Table 3: Seasonal Variation of Foetal Wastage at Bauchi abattoir, Bauchi State 2004 -2013

CONCLUSIONS

This showed that the foetal wastage was quite alarming and effort should be geared towards instituting routine veterinary checks including pregnancy diagnosis at cattle control posts and abattoirs. In addition adequate infrastructural facilities including ultra-scanners that will ensure adequate pregnancy diagnosis should be provided to aid quick detection of pregnant animals during inspection. Drastic efforts should be made to increase future domestic meat supply in order to reduce or halt the incidence of slaughtering pregnant cows.

ABSTRACT
Good health management fosters high productivity in animal husbandry; the study looked at the health condition of livestock raised by crop farmer in Fashola farming community, Oyo, Nigeria. Fifty–eight well structured questionnaire were administered using a snowball sampling techniques to crops farmers that raised livestock. Data collected were analysed using descriptive statistic. The mean flock sizes were 9.2, 6.3, 5.7, 4.7, 4.0, 3.3 and 1.0 for chicken, goat, turkey, sheep, duck, cattle and pig, respectively. *Peste des petits ruminante* was reported by 52.4% of the respondents while 21.4% reported Newcastle Disease. Highest mortality of 5.4 was found in goats while cattle and pig had zero mortality. About 81.1% of the livestock keepers sought veterinary intervention when animals were sick and 3.8% salvage the animals. The study showed high mortality of goats and local chickens as a result of *Peste des petits ruminante* and Newcastle diseases outbreaks in the study area.
Keywords: Newcastle, *Peste des petits ruminante,*Mortality, Ailment

Introduction
Food production in Nigeria is basically in the hands of small scale farmers who are spread all over the country. These farmers are faced with diverse challenges such as predominance of primitive techniques, limited use of biological and chemical technology (Adesoji, 2002). Above all, inconsistency in rainfall pattern, prolonged dry season posed by climate change led to crop failure and consequently affect yield.
Although, some of the crop farmers are engaged in other secondary occupations (Ajayi *et al*., 2019) which can help to cushion the effect of low crop yield for better livelihood. Animal husbandry has been found to be a complimentary occupation due to the symbiotic relationship between the two enterprises. The waste from one enterprise is a resource in the other enterprise.

However, livestock production in Nigeria is faced with challenges such as housing, health and feeding (Doma *et al*., 1999) and good health management practice is pivotal to sustainable animal production. Studies have shown high incidence of diseases as a major constraint associated with animal production resulting in economic losses due to stunted growth, weakness, poor reproductive performance or death in livestock (Jawara, 1990). The study assessed the health condition of animals raised by crop farmers domiciled in Fashola farming community, Oyo.

Materials and methods
The Study was carried out in Fashola farming community, Oyo, located in Oyo West Local Government Area of Oyo State, Nigeria. The area shares boundaries with Orire Local Government in the North, Akinyele Local Government in the South, Iseyin Local Government in the West. The area was purposefully chosen because of the ecological conditions that are suitable for crop-livestock production systems. Individual interview was carried out for data collection using a well structured questionnaire to 58 respondents who were basically crops farmers that raised livestock using a snow ball sampling technique. The questions were translated from English to Yoruba language for the respondents and recorded in English Language. Descriptive statistics such as frequencies and mean were used to analyse the data.

RESULTS AND DISCUSSION

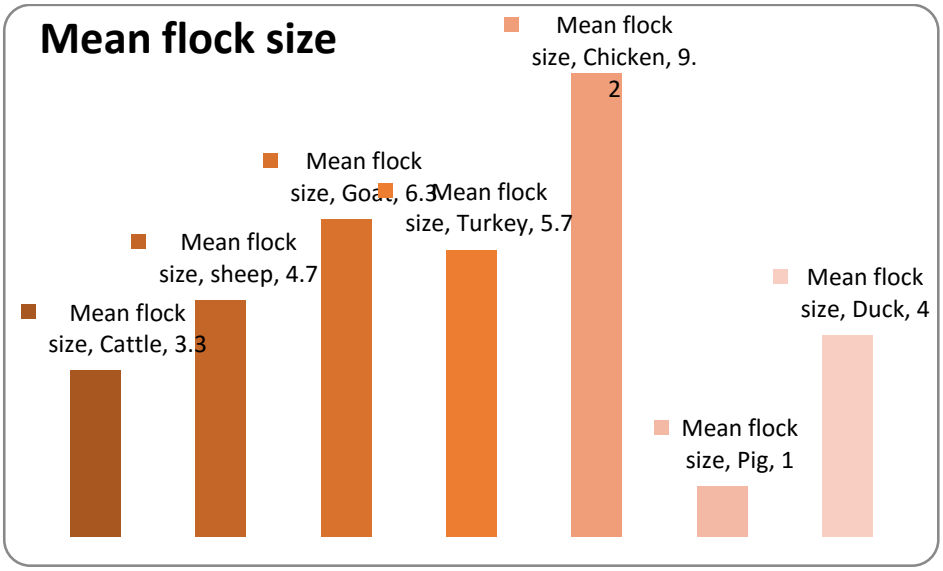

Figure 1: Mean flock size of livestock raised in Fashola farming community, Oyo

(Source: Field survey, 2018)

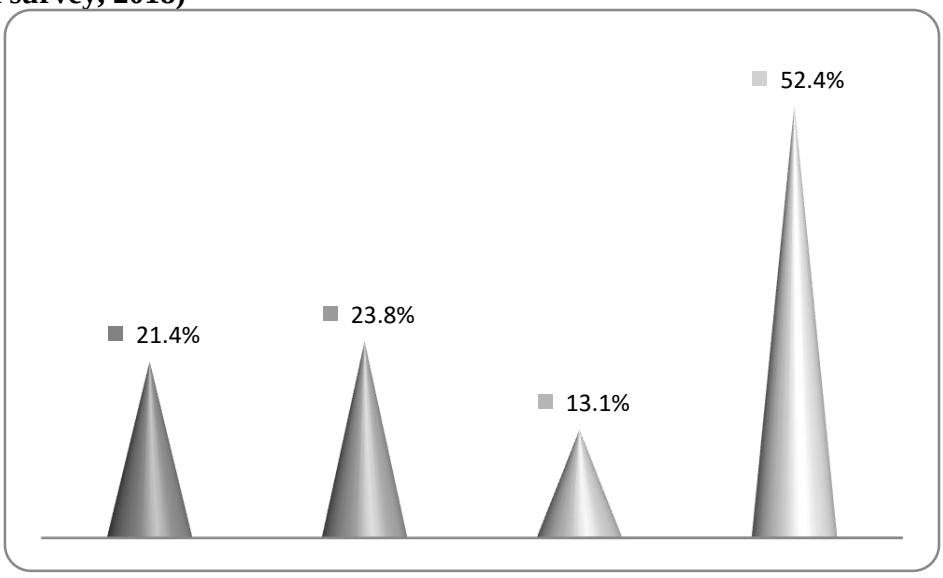

Figure 2: Common ailment affecting livestock in Fashola farming community, Oyo.
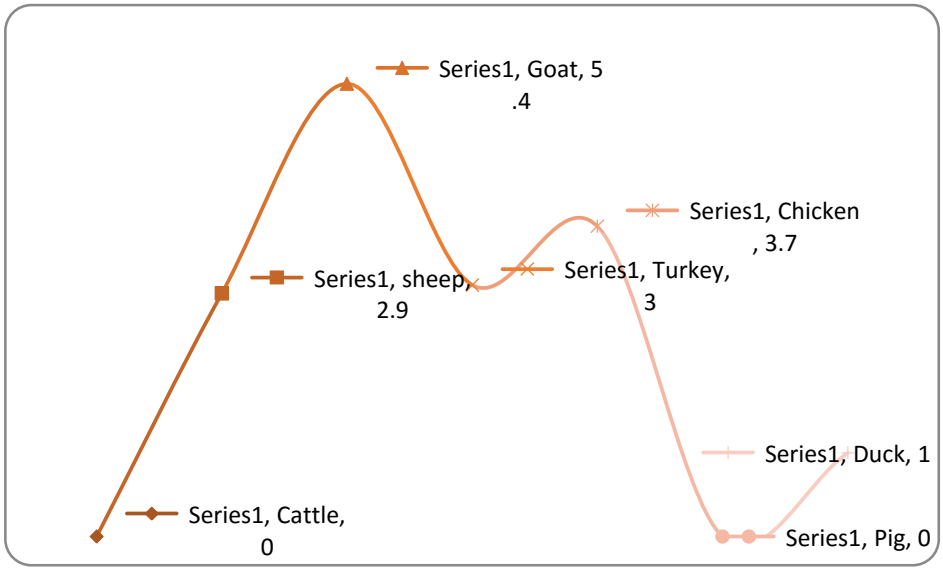
Source: Field survey, 2018
***Multiple responses**



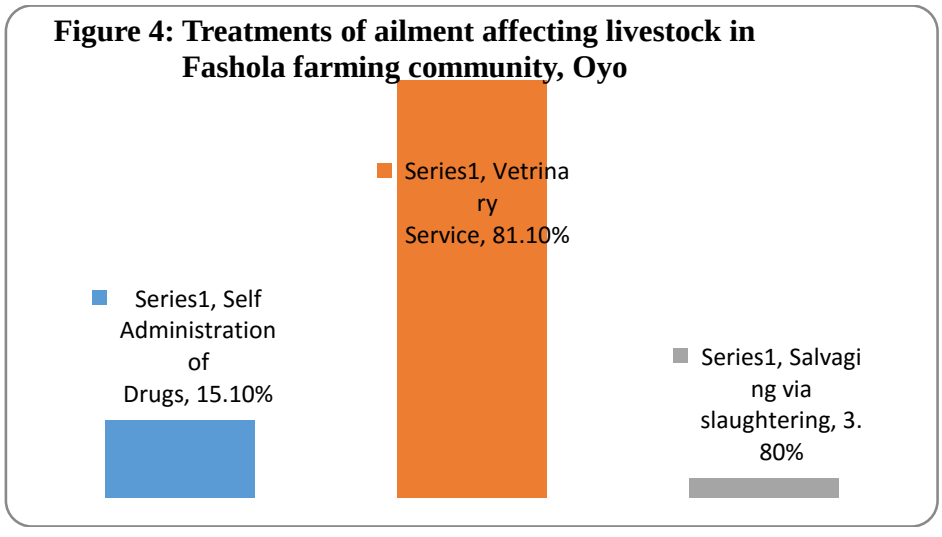


Figure 3: Yearly average mortality rate of livestock raised in Fashola farming community, Oyo. Source: Field survey, 2018

Source: Field survey, 2018

Figure 1 shows the mean flock size of livestock raised in the study area. Local chickens had the average flock size of 9.2 followed by goats which was 6.3 and pig (1) was the lowest. The high population of chickens and goats could be due to the production system adopted by the farmers as majority of the animals were raised on free range. This system of production requires low capital and less managerial involvement. Common ailment affecting livestock in Fashola farming community, Oyo is shown in figure 2. The study revealed that *Peste des petits ruminante* (PPR) was the commonest reported by 52.4% of the respondents while 21.4% reported Newcastle

Disease (ND). PPR and ND are viral diseases that affect goats and local chickens, respectively. The widespread of these viral diseases could also be attributed to the production system as little attention is given to the vaccination of the animals to prevent the occurrence. The yearly average mortality is represented in figure 3. Goats had the highest mortality of 5.4 followed by chickens (3.7). This high mortality can be due to the production system adopted in the study area as less attention is given to vaccination of animals until they come down with ailment. Moreover, Newcastle Disease is reported to be the most prevalent and fatal disease of poultry (Kingori *et al*., 2010). Figure 4 represents the treatments of ailments affecting livestock raised by farmers in Fashola farming community. The study revealed that 81.1% of the livestock keepers relied on veterinary intervention when the animals are sick. About 15.1% were involved in self-administration of drugs to animals while 3.8% salvage the animals for consumption when the animals are sick as reported by Aklili, 2007.

CONCLUSION

The study revealed that *Peste des petits ruminante* (PPR) and New castle diseases were the predominant diseases common to livestock in the study area. The attitude of "not vaccinating animals" was observed among farmers and led to the high percentage of mortality of goats and poultry.

ABSTRACT
A survey on the incidence of common poultry diseases was carried out in five selected poultry farms in Owerri North and Owerri West Local Government Areas of Imo State for the period of January 2013 to December 2017. The diseases investigated include: Newcastle disease, Infectious Bursal disease, Coccidiosis, Fowl typhoid and Chronic Respiratory disease. The farms were Lambert Farm and Engrobic farms in Owerri West Local Government Area; Odimara farms, Ben and Baba Khojo farms and Chiawuotu farms in Owerri North. Data were collected in the selected farms on percentage mortarlity rates of each disease. The prevalence of Coccidiosis was slightly higher than other diseases investigated. Newcastle Disease recorded 1.22% of total percentage mortatily, Infectious Bursal Disease recorded 0.6%, Coccidiosis recorded 1.24%, Fowl typhoid recorded 0.58% and Chronic Respiratory Disease recorded 0.38%. Most of the diseases occurred during the rainy season [April to October] of the years. Most of the poultry farmers were male and within the age range of 32-50 years. Poor management, inadequate diagnostic facilities, improper vaccine handling, self medication coupled with harsh weather conditions were responsible for the distribution pattern. It therefore becomes imperative for poultry farmers to instituite and intensify biosecurity measures inorder to minimize emergence and transmission of these diseases.

Keywords; Poultry diseases, percentage mortality, prevalence, biosecurity measures.

INTRODUCTION
Poultry industry in Nigeria occupies a prominent position as a major source of animal protein and economic empowerment of the resource poor segments of the society. [Udedibie and Opara 1998]. USDA [2013] currently rated Nigeria as the leading country in Africa with respect to egg production, but the fourth in broiler chicken production. According to F.A.O. [2010], Nigeria presently is far from meeting her domestic demand when compared with that of the developed countries. Nigeria 'per capita daily protein consumption/intake' for instance is estimated to be 45.4g as against F.A.O recommended minimum of 53.8g.

Poultry disease has however, been identified as one of the major barriers to expansion of poultry industry in Nigeria [Okere *et al*., 2014; Okoli *et al.*, 2001, 2003; Okoli and Ebere, 2002]. The cost of disease treatment and control tends to increase the cost of production of poultry, hence reducing the profit earned by the poultry farmers. This thereby leads to a hike in purchase of poultry and their products, out of the reach of the common man [Okere *et al.*, 2018]. These poultry diseases are barriers to sustainable poultry production all over the world.

This study will therefore, identify the incidences of the aforementioned diseases, analyse the level of losses reached by these diseases and make appropriate recommendations on how to ameliorate the problem.

MATERIALS AND METHODS
Five selected poultry farms were investigated; Lambert Farms and Engrobic Farms in Owerri West Local Government Area; Odimara Farms, Ben and Baba Khojo Farms and Chiawuotu Farms in Owerri North. Information on the locations of existing poultry farms were obtained from Owerri north and Owerri west local government secretariats. The five poultry diseases investigated were Newcastle disease, Infectious Bursal disease, Coccidiosis, Fowl typhoid and Chronic Respiratory disease. The farms were selected based on existence of farm records, production consistency and efficiency and large population. Mortality rate percentages were determined.

METHOD OF DATA COLLECTION AND ANALYSES

Magazines, journals and internet were the secondary sources of data while the primary sources of data were the farm disease survey records [health records], detailed questionnaires and interviews. Simple descriptive statistical model was employed in the analysis of work using tables, bar charts and graphs.

RESULTS AND DISCUSSION

Table 1 shows the average yearly incidence of the various poultry diseases in all the farms in the two local government areas of Imo State for the period of five years; January 2013 – December 2019.. Figure 1 shows the average percentage mortality of selected poultry diseases from farms in Owerri north and Owerri west local government areas of Imo State for the period January 2013 –December 2017. Newcastle disease recorded the highest percentage mortality of 0.21%.in Lambart farms for the five years. Fowl typhoid recorded the highest percentage mortality of 1.91% in Ben and Baba Khojo farms. Newcastle diease also had the highest percentage mortality of 0.77% in Odumara farms for the five years. In Chiawuotu farms, Coccidiosis recorded the highest percentage mortality rate of 2.58%. Newcastle disease recorded the highest percentage mortality of 2.12% for the five years in Engrobic farms. The average yearly incidence of the various diseases in all the five farms from January 2013 to December 2017 showed that Coccidiosis was the most prevalent in the farms with an average percentage mortality rate of 1.24% while chronic respiratory disease recoded the lowest average percentage mortality of 0.38%. This result agrees with Okere [1999], who reported the incidence of Coccidiosis as the highest [3.4% mortality] amongs five poultry diseases investigated in Imo State. Generally, incidences of these diseases were low in the five farms for the five years investigated, but the effects were devastating. The result of the study showed that Coccidiosis, Newcastle disease and Gumboro disease were the most prevalent in the study area. This is in agreement with Adene [2000] and FAO [2008] who suggested that throughout the world, Newcastle disease, Gumboro [IBD] and Coccidiosis are considered as the most important. It was also observed from the results of the questionnaire that disease outbreaks were mostly during the rainy season [May – October] in accordance with the report of Unamba -Opara [2018]

Table 1: Average yearly incidence of the various poultry diseases in all the farms in Owerri north and Owerri west local government areas of Imo State from January 2013 – December 2017

		2013	**2014**	**2015**	**2016**	**2016**	**TOTAL**
Newcastle Disease	Number of birds stocked Number of dead birds % Mortality	6000 105 1.75	6450 83 1.3	6350 72 1,13	7050 66 1.03	6400 66 1.03	32250 392 1.22
Infectious Bursal Disease	Number of birds stocked Number of dead birds % Mortality	6000 39 0.65	6450 36 0.56	6350 48 0.76	7050 35 0.5	6400 37 0.57	32250 195 0.6
Coccidiosis	Number of birds stocked Number of dead birds % Mortality	6000 90 1.5	6450 78 1.21	6350 75 1.18	7050 78 1.11	6400 79 1.2	32250 400 1.24
Chronic Respiratory Disease	Number of birds stocked Number of dead birds % Mortality	6000 24 0.24	6450 20 0.31	6350 27 0.43	7050 25 0.35	6400 26 0.41	32250 122 0.38
Fowl Typhoid	Number of birds stocked Number of dead birds % Mortality	6000 52 0.87	6450 35 0.56	6350 21 0.33	7050 42 0.6	6400 36 0.56	32250 186 0.58

CONCLUSION AND RECOMMENDATION

In conclusion, Newcastle disease, Infectious bursal disease, Coccidiosis, Chronic Respiratory disease and Fowl Typhoid have been majorly responsible for a number of economic losses to poultry farmers in Owerri north and Owerri west local government areas of Imo State with Coccidiosis recording the highest percentage mortality. It was therefore recommended that strict vaccination and medication schedule be adhered by the farmers, coupled with adequate keeping of health records.

ABSTRACT
To study the relationship between cellular immune response and humoral immune response of chicks to Infectious Bursal Disease (IBD) vaccination, four groups of chicks vaccinated with IBD vaccine were bled 3 weeks post vaccination (PV).Their whole blood samples were used for total and differential White Blood Cells (WBC) count to determine number of lymphocytes per ml of their blood, while their sera were used for Qauntitative Agar Gel Precipitation Test (QAGPT) to assess antibody titre. Least AGPT titre that gave zero mortality to IBDV challenge was also determined.
Correlation existed between humoral immune response with mean antibody (AGPT) titre, 9 ± 2.06 and cellular immune response with mean lymphocytes count (Per ml) ,216,500 ± 20,900 ($p < 0.05$). From AGPT titre 8 (about 200,000 lymphocytes per ml of blood) and above, there was zero mortality to IBDV challenge.

Key words: Humoral immunity, Cellular immunity, AGPT Antibody titre, IBD.

INTRODUCTION

Infectious Bursal Disease (IBD) is a very important economic problem in Nigeria (Akoma and Baba, 1975, Abdu et al, 2001)(I.W. Musa, L. Sai`du and E.S. Abalaka, 2012. Economic Impact of Recurrent Outbreaks of Gumboro Disease in a Commercial Poultry Farm in Kano, Nigeria. *Asian Journal of Poultry Science, 6: 152-159.*) and in most poultry producing countries of the world (Okoye, 1984). The disease is very contagious (Benton et al, 1967) and causes high mortality (Annon, 1977)(Islam, M.T and M. a. Samad, 2004. Mortaity in chicks associated with economic impact and prospect of layer chicks rearer package programme of the participatory livestock development project in Bangladesh. Int. J. Pout Sci, 3: 119 - 123). Infected chickens that do not die of IBD are often immunosupressed and so, die of secondary infections (Okoye and Aba – Adulugba, 1988)(Rev. sci. tech. Off. int. Epiz., 2000,19(2), 527-543 Infectious bursal disease (Gumboro disease) T.P.van den Berg, N. Eterradossi, D. Toquin & G. Meulemans). Control of IBD is very difficult because of antigenic variations of the causative virus (Mcferan et al, 1980, Aghakehan et al, 1996, Roji and Cerne, 1997). Most countries are now adopting different measures to improve control of IBD. In China, a mixture of yolk IgG and hyperimmune serum is used in prevention and treatment of IBD (Lin – Yusher et al,1997). Haddad et al (1997) reported that USA has used a combination of IBDV strain 2512 and bursal disease antibodies to produce IBDV – BDA complex vaccine which has proved protective even when chicks with maternal antibodies are vaccinated.
In Nigeria. main method of control for IBD is mass vaccination of chicks with live atenuated IBD virus vaccine. IBD often occurs in the country, at times, even among vaccinated flocks (Ezeokonkwo, 1997). A recent serosurvey of day old chicks hatched in Nigeria also showed they lacked maternal antibodies against IBD.There is therefore need for regular evaluation of immune response of vaccinated flocks, especially, parent stock hens.

Viral vaccines provoke immune responses to protect vaccinated animals (White,1984).Immune response is either humoral (mediated by antibodies) or cellular, through lymphocytes (Paul, 1989). Both cellular and humoral immune responses are specific to the invading antigen (Roitt,1994, Stites et al, 1994) and develope cuncurrently

(Janeway and Travers,1994). So, assessment of any of the two, may give indication of ability of vaccinated animals to resist infection by the antigen.

Serologic tests used to assay IBD antibody titres of avian species include Radioimmunoassay (RIA), Enzymeimmunoassay (EIA), PolyAcrylamide Gel Eletrophoresis (PAGE) and Agar Gel Precipitation Test (Roitt,1994, Stite, et al, 1994, Abbas et al, 1994, Herbert, 1994).

Some of these tests are sophisticated and expensive. Most farms and laboratories in developing countries can not afford them for routine assessmet of immune responses of vaccinated animals. Heamatology to determine lymphocyte count is simpler and cheaper. Agar Gel Precipitation Test (AGPT) is also a simple qauntitative serologic test (Herbert,1974).

It was therefore thought useful to compare AGPT titres of IBD vaccinated chicks with their cellular immune response (lymphocytes count) to see if differential lymphocyte count can give a good assessment of immunity against IBDV in vaccinated flocks.

MATERIALS AND METHODS

Four groups, each of 10 chicks vaccinated at 10 days of life were bled 3 days post vaccination. Part of each blood sample was used for differential lymphocytes count while the remaining portion was allowed to clott for serum used for Qauntitative Agar Gel Precipitation Test as described by Herbert (1974). The mean lyphocytes count and mean AGPT titre were compared by correlation co – efficient.

In a second experiment, 6 groups, each of 10 chicks, were vaccinated with IBD vaccine on their tenth day of life.Conditions, such as, medication with multivitamins before and after the vaccination, day of bleeding post vaccination and administration of booster vaccination were varried for the groups in order to get different immune levels in the different groups of chicks.A sevent group was not vaccinated and served as control. Blood was collected from each group for serum before they were challenged with one drop (I/O) of a virulent IBD virus (NVRI, Vom, Nigeria) per chick.

The sera were used for QAGPT to determine antibody titre for each group while the chicks were observed for clinical signs and for mortality.

RESULTS

There was correlation between mean AGPT tire (9 ± 2.06) and 216,500 ± 20,900 per ml got as mean lymphocytes count ($P < 0.05$).

The AGPT titres and lymphocyte counts are as on table 1.

Mortality was 100% for a group with AGPT titre zero, 80% for a group with titre 1 and 70% when titre was 2. Groups with AGPT titres of 8, 16, ≥ 32 and another ≥ 32 had zero mortality each.

Table 1: AGPT titres and Lymphocyte counts of chicks vaccinated with IBD vaccine.

AGPT Titre	Lymphocyte Count(Per ml).
8	212,000
4	168,000
16	270,000
8	216,000

AGPT Titre of chicks vaccinated with IBD vaccine was directly related to their lymphocyte count ($P < 0.05$).

DISCUSSION

The association of humoral immune response (AGPT antibody titre) and cellular immune response (lymphocyte count) seen in this experiment is in agreement with reports of Roilf (1991) and Stites et al (1994) that when an antigen enters a host, the host`s Antigen Presenting Cells (APC) diggest the antigen and present its peptides to the host`s T – cell receptors so that the body produces both cellular and humoral immune responses specific to the antigen. Humoral and cell mediated immunity develope cuncurrently (Janeway and Travers, 1994).

Most laboratories in Nigeria and in other countries in the tropics where IBD causes more mortality (Annon, 1977) run differential WBC count routinely. So, it may be easy to educate poultry farmers especially those who keep parent stocks to check immune responses of their flocks after IBD vaccination by assessing number of lymphocytes per ml of blood of vaccinated chickens.

Since least protective antibody titre was AGPT 8 and from result of the first experiment, two groups with AGPT 8 gave lymphocytes of 212,000 and 216,000 per ml of blood, lymphocyte counts of 200,000 and above may protect chicks against IBDV challenge.

ABSRACT
A case of lumpy skin disease in a 7-year old Bunaji bull was presented to the Postgraduate students of the College of Veterinary Surgeon of Nigeria (CVSN), Ahmadu Bello University, Zaria, who were on an Ambulatory visit to some sedentary cattle herds in Tohu village in Zaria LGA. The chief complaints were swellings on different parts of the skin and reduced feed intake. Physical examination revealed pyrexia with rectal temperature of 39.9□C, rapid respiratory rate and pulsation of 36 cycles per minute and 90 beats per minute. Other signs included generalized circumscribed firm nodules on the skin especially the neck region, oedema of the limbs, reluctant to move, pale ocular membrane, mucopurulent nasal discharges, and superficial lymphadenopathy. Lumpy skin disease (LSD) was tentatively diagnosed based on the history and clinical signs observed. A non-specific treatment management protocol targeted at preventing secondary bacterial complications using a combination therapy of antibiotic and anti-inflammatory agent was carried out. Incidentally, the bull apparently recovered and was sold for slaughter. Therefore, a combination therapy as a management protocol aimed at preventing LSD complications and saving the life of the affected bull has been relatively successful using antibiotic and anti-inflammatory agent.
Keywords: Clinical management, Lumpy skin disease, Bunaji bull

INTRODUCTION
Lumpy skin disease (LSD) is a transboundary viral disease of cattle caused by a lumpy skin disease virus (LSDV) in the genus *Capripoxvirus* of the family Poxviridae (Woods, 1988). Lumpy skin disease virus is closely related antigenically to sheep and goat poxviruses (Tulman *et al.,* 2002). The LSD is a notifiable disease and it affects calves and adult cattle (Brown and Torres, 2008) resulting to great economic losses due to damage to the hide, reduced milk yield, mastitis, infertility, abortion and sometimes death arising from secondary bacterial complications (Ahmed and Dessouki, 2013). Biting flies and ticks play the most important role in spreading the virus (Sevik and Dogan, 2017). Calves can be infected by drinking milk from an infected cow. The disease can also spread through the saliva of infected animals when they use the same drinking trough (Carn and Kitching, 1995). The disease causes emaciation, temporary or permanent loss of milk production, lowered or complete loss of fertility in bulls and cows, abortion as well as permanent damage to hides (Ali *et al*., 1990)**.** There is a significant decrease in red blood cell count, haemoglobin concentration and packed cell volume interpreted as a macrocytic hypochromic anaemia (Neamat-Allah, 2015). The disease can be confused with demodecosis, besnoitiosis, oncocercariasis, insect bite allergies, dermatophilosis, bovine virus diarrhoea/mucosal disease, bovine malignant catarrhal fever and rinderpest (Radostits *et al* 2007).
There is no specific treatment for LSD. However, non-specific treatment management protocol can be achieved using antibiotics, anti-inflammatory agents and vitamin injections. This type of management protocol is usually directed at treating the secondary bacterial infections, inflammation and fever, as well as improving the appetite of the animal (Salib and Osman, 2011, CFIA, 2011). Prevention through vaccination and biting fly repellants are the cheapest and best method of control of the disease. However, animals that recovered from a natural infection of LSD, are immuned and therefore need not to be vaccinated. (OIE, 2004). Consequently, calves, less than 6 months old born to LSD vaccinated cows or to cows that have recovered from natural infections, need not to be vaccinated (Prozeesky and Barnard, 1981; OIE, 2004). In cases of outbreaks, isolation and prohibition of animal movements, slaughtering of all sick and infected animals, proper disposal of dead animals, cleaning and disinfection of premises and farm implements along with vector control in premises should be carried out (World Organisation for Animal Health, 2012).

CASE REPORT

On 26 September 2018, the Postgraduate student fellows in large animal section of Medicine Speciality of the CVSN, A.B.U Zaria study centre were on an Ambulatory visit to Tohu Village in Zaria L.G.A where a 7-year-old Bunaji bull weighing 400kg from a herd of 27 cattle was presented with complaints of swellings on the skin and not feeding well. The herd was on extensive management system and the onset of the problem was 4 days prior to presentation. The bull and afew other members of the herd were physically examined. Vital parameters of the bull showed rectal temperature to be 39.9° C, respiratory rate 36 cycles per minute and pulse rate 90 beats per minute. Clinical Signs observed on the bull included generalized firm cutaneous nodules especially around the neck region, oedema of the limbs, reluctant to move, superficial lymphadenopathy, mucopurulent nasal discharges, rapid respiration and pneumonia (Plate I). Based on the above signs, LSD, demodecosis, dermatophilosis and urticaria were considered as differential diagnoses. However, a tentative diagnosis of LSD was made based on the history and the severity of the clinical signs. Blood sample was collected for haemogram and faecal samples for routine oocyst and helminths screening to the Clinical Pathology and Helminthology/Protozoology Laboratories of the Ahmadu Bello University Veterinary Teaching Hospital, Zaria respectively.

Laboratory Investigation Results

Blood sample of the bull taken to Clinical Pathology Laboratory for haemogram indicated macroytic hypochromic anaemia with eosinophilia while the faecal samples to Helminthology and Protozoology Laboratories revealed Strongyle eggs ++ and Coccidia oocyst + respectively. The skin nodule tissue and serum samples for viral isolation and serology to be send to the Virology Research Laboratory of the National Veterinary Research Institute, Vom were not taken as the client could not afford the cost.

Case Management and Clinical Outcome

The bull was administered 20% tetracycline at 20mg/kg deep i.m (8000mg) and dexamethasone 0.2mg/kg (80mg) x 3/7 i.m as symptomatic treatment and the bull was dewormed with albendazole suspension 7.5mg/kg p.os (3000mg). Since the cutaneous lesions on the bull hasn't ruptured, a 5% cypermethrin at 10ml/100kg body weight as pour-on was applied on the dorsum from the base of the tail to the cranium of the bull in order to repel biting flies from transmitting the infection to other members of the herd whom the pour-on was also applied on. On the 2nd and 3rd day of the treatment, the owner reported that feed intake by the bull had improved. The vital parameters especially the rectal temperature were near normal. Consequently, 3 days after the treatment there was a remarkable improvement such that fever, anorexia, oedema of the limbs, respiratory signs and other deviations subsided, but the skin still had some lumps.

B= skin noodle

DISCUSSION

Lumpy skin disease (LSD) is an economically important disease of cattle and can produce a chronic debility in infected cattle. The symptoms observed in the present case were in agreement with those reported by Radostits *et al*. (2007). Lumpy skin disease causes multiple circumscribed firm nodules on the body, including the muzzle, nostrils, head, neck, back, limbs, scrotum, perineum, udder, eyelids, nasal and oral mucosa (Ali *et al.*, 1990). Nodules can also develop in gastrointestinal tract, especially the abomasum as well as the trachea and lungs, resulting in primary and secondary pneumonia. Lameness may occur from inflammation of the tendons, and severe swelling of the brisket and legs. This lameness can be permanent with severe damage to tendons and joints from secondary bacterial infections (Kahn and Line, 2008). Permanent damage may occur to teats and mammary glands due to secondary bacterial infections and mastitis. Abortion and intrauterine infection are possible; temporary or permanent sterility in both bulls and cows may occur (CFIA, 2011). Therefore, systemic antibiotic and anti-

inflammatory drugs are obligatory for the skin lesions, pneumonia and inflammatory reactions in order to avoid further complications and economic losses (Abutarbush *et al*., 2015).

In the current case, 20% oxytetracycline was administered against bacterial and the coccidial oocyst infections (Danbirni *et al*., 2017) while dexamethasone was administered to suppress inflammatory reactions such as pain, fever and oedema as well as 10% albendazole suspension as a routine deworming against strongyles. The administration of 5% cypermethrin as a pour-on was to repel or kill biting flies and ticks from further spreading the disease from the infected bull to the other apparently healthy members of the herd. Consequently, 3 days after the treatment, there was a remarkable improvement of the bull's health such that fever, anorexia, oedema of the limbs, respiratory signs and other deviations apparently subsided. However, the skin still had some lumps. On the 5th day of the clinicians' visit to the herd, the client reported that all the clinical signs were no longer visible except for the cutaneous nodules and scars and he decided to sell the bull to a butcher for fear of spreading the disease to other members of the herd. As such, the clinicians could not take the picture of the recovery stage of the bull on the 5th day. The client was then, advised to be using pour-on on apparently healthy animals anytime he noticed biting flies or ticks in order to prevent arthropod vectors of LSD within the herd and to routinely deworm the herd as well as to report promptly any sick animal to the nearest Veterinary facility.

CONCLUSION

Lumpy skin disease is a transboundary, notifiable cattle viral disease of great economic importance characterized by distinct circumscribed firm nodular lesions affecting primarily the hide, hence reducing the quality.

A combination therapy as a management protocol aimed at preventing LSD complications and saving the life of the affected bull has been relatively successful using antibiotic and anti-inflammatory agent.

ACKNOWLEDGEMENT

The authors acknowledged the herdsman for his verbal consent and response during follow up of the treatment.

DETECTION OF ANTIMICROBIAL DRUG RESIDUES IN MEAT FROM BUNAJI CATTLE SLAUGHTERED IN MINNA MODERN ABATTOIR

***L.L Mande, J.Y. Adama, A. Usman**

Department of Animal Production, School of Agriculture and Agricultural Technology, Federal University of Technology P.M.B 65, Minna, Niger State Nigeria

Corresponding authors E-mail; mandelawal46@gmail.com

ABSTRACT

Antimicrobial drug residues are of global health concern in many countries of the world, with Nigeria reporting occurrence of residue contamination of edible animal products beyond FAO and WHO permissible levels. The occurrence of antimicrobial drugs residues in meat in Minna modern abattoir was investigated during this study, 56 meat samples were collected from 56 Bunaji cattle slaughtered in the abattoir at 2weeks intervals for period of 4months (April – August 2019) . Antimicrobial inhibition test was adopted with zone of inhibition measured in millimetres (mm), samples below 1mm were considered negative. 29(51.78%) samples were tested positive with zone of inhibition at various levels of residue (12mm, 13mm, 15mm, 17mm, 19mm and 20mm), which signified high levels of residue. Samples from female's cows had the highest number 20(68.90%) and values at 20mm. Ages between 6-10 years had 17(58.62%) while the lowest residue was recorded at older animals above 10 years 5(17.24%). This result indicated that consumers in Minna metropolitan are predisposed to health hazards due to the presence of antimicrobial residue, this emphasis the need for effective prevention of infectious diseases, general enlightenment on the withdrawal periods, and establishment of antimicrobial residues monitoring unit in Minna.

Keywords – Antimicrobial residue, Meat, Microbial inhibition test, Abattoir, Minna

INTRODUCTION

Drug administration to domestic animals requires not only consideration of its effect on the animals but also the effect on humans who consume the product from such animals. Antibiotics are natural product of microorganisms or identical synthetic products or similar semi-synthetic products that inhibit the growth of or destroy microorganisms (Karbis, 2007). In animal health practice, antibiotics are widely used as therapeutic prophylactic or as growth promoting agents (Donoghue, 2003). Antibiotics are of different types, with various pharmacokinetic activities which often neglected during slaughter, and hence become potential hazard to human. The presence of antibiotics in meat and other food of animal origin is one of the most important indices for their safety to human consumers (Kozanova *et al.*,2001). Many livestock farmers administer antibiotics indiscriminately for purposes of treating or preventing an ailment or as growth promoters without cognisance of the need to consult an expert for necessary advice, such animals are often slaughtered without recourse to the withdrawal period, even if they used the same drugs as animal health personnel's. The Indiscriminate use of antibiotics in livestock has raised serious public health concern globally, especially in sub-Sahara Africa and particularly Nigeria (Shehu, 2018).

Drug residue arises when treated animals are slaughtered without recourse to pharmacokinetics of the specific drug administered, this situation usually occur with prolonged administration and over dosage of antimicrobial agent, especially if these animals are slaughtered immediately,(vinedresser, 1989)as cited by (Gabriel *et al.* 2012). Toxic level of antimicrobial residues in food animals are known to cause divers health hazards to susceptible unsuspecting human consumers. (Gabriel *et at.*,2012).

Cattle command a prominent position in our meat supply which constitute of about 45% of meat industry. Presently cattle population in Nigeria has been estimated as 15.3million (Umar, 2007).

Bumaji cattle are the most predominant and wide spread of all Nigeria cattle breed, they represents 37% of the national herd (Alphosus,Akpa, Barje and Adamu, 2012). About 800-1000 cattle, sheep and goat are slaughtered daily across Niger state (Dukku, 2018), the abattoir where these animals are largely slaughtered and processed for public consumption, contributed immensely to the economic development of states. In Nigeria as in many other countries, the veterinary structure are not strong (Fau, 2004) and are characterised by indiscriminate usage of veterinary drugs such as antibiotics, which are readily avaailable and obtainable over the counter as well as every rural cattle market, which make it easily accessible to different categories of livestock handlers including the nomadic pastoralist and the middle men. With this development it implies that correct dosage and withdrawal period are not usually adhered to, and hence meat safety quality assurance cannot be granted, Olatoye and Ogundipe, (2009).

MATERIALS AND METHOD

EXPERIMENTAL SITE

The samples were collected from Minna abattoir located along Tayi village in Minna Niger state of Nigeria. Minna the capital city of Niger state is situated on a latitude 9 3105 and longitude 7 421 north, with annual rainfall of 1,200-1,300mm and mean temperature of 38-40c the area has an altitude of 1,46m above sea level in the northern guinea savannah vegetation zone of Nigeria it is characterised by two season, the wet season (April - October and dry season November -march). NSFCO/ ADP.,(2015).

SAMPLES COLLECTION

Fifty six (56) Beef samples weighing 50g were collected from 56 slaughtered white Fulani cattle in Minna modern abattoir for a period of 4 months, (April - August 2019) at 2 weeks intervals, with emphasis to breed, age sex and time intervals, Samples were properly packed and labelled in a polyethylene and refrigerated at -20^0C

SAMPLE ANALYSIS;

MICROBIAL INHIBITION TEST

An adapted microbial inhibition test was employed to screened samples for evidence of antimicrobial drug residues as described by Huber et al, (1969). Mueller Hinton Agar (MHA) was prepared in plates according to manufacturer`s instruction. *Bacillus subtilis* ATCC 6633 was used as test organism. Plates were inoculated with the test organism by dipping sterile cotton swab sticks into the suspension of test organism until saturated. The MHA plates were then gently but thoroughly swabbed uniform to achieve a lawn of confluent growth and allowed to dry for 5 minutes. The extract from the sample were tested by dipping sterile 1.2 mm diameter *whatmann* filter paper disc into the juice extract, until saturated, excess sample were allowed to drained, then, *whatman* filter paper disc containing 30ug of oxytetracycline Hcl was used as control discs, placed at the centre of the plates with test discs at the periphery of the plate and incubated at 37 degree for 18 – 20 hrs, after which presence or absence of zone of inhibition and that of the disc was calculated. Any disc with a difference of >1mm was considered positive.

DATA ANALYSIS;

The data obtained was subjected to descriptive statistical analysis, for the variations between occurrence of drug residues between sex and Age groups, using SPSS version 16.0, (2010)

RESULTS AND DISSCUSSION

Out of the 56 meat samples from 56 cows of different sex and age that were screened for antimicrobial drug residues during this study, 29(51.78%) tested positive under zone inhibition test ranging from 13mm to 20mm, indicating presence of antimicrobial drug residue in the samples; 27(48.21%) were tested negative less than 1mm. All samples were collected from Bunaji cattle in Minna abattoir. The overall results from this study indicated a high incidence (51.78%) of antimicrobial residues in the meat consumed by the public in Minna metropolitan The

results is higher than the reported incidence of 46% residue in beef in Oyo state, (Akinwumi, 2012); 16.11% reported by (Dipeolu and Alonge 2002); 33.1% obtained in broilers (Kabir *et al*,.2004); 25% reported in milk (Yusuf *et.al*., 2017). However the result is lower than 89.3% reported from kidney and urine (Gabriel *et. at.*, 2012) and 79.74% in edible beef (Olatoye and Ogundipe, 2009). **Table 1** Shows distribution of residue on Sex of the cows that were tested positive, 9(31.02%) were males, 3 samples had highest value of 19mm while 1 sample had lowest value of 12mm, females recorded highest antimicrobial residue of 20(68.96%), 2 samples had highest zone inhibition value of 20mm while 1 had lowest of 12mm, the study recorded high incidence of residues on females (68.9%) than males (39.01%), 2 females had high zone inhibition value of 20mn. **Table 2** shows variation on Age, 7(26.3%) were between 1-5 years, 17(53.62%) were between 6-10 years and 5((17.24%) where above 10 years. At 1-5 years 2 samples had highest value of 19mm and the lowest value of 13mm, highest value of 20mm was found at 6-10years and above 10 years respectively, From the result 6-10 years shows 58% residual values than other age groups the result agreed with that reported by (Zeenatudeen, 2015) on milk.

Table 1 Distribution of antimicrobial drugs residue based on Sex of cow under zone inhibition above 1mm detectable limit

Sex	**Meat sample**	**12mm**	**13mm**	**15mm**	**17mm**	**19mm**	**20mm**	**Total**
Male	9	1	1	4	1	3	0	9(31.02%)
Female	20	1	4	4	6	3	2	20(68.96%)
Total	29	2	5	8	7	6	2	29(100%)

Table 2; Distribution of antimicrobial drugs residue based on Age of cows under zone inhibition above 1mm detectable limit

Age years	Meat sample	12mm	13mm	15mm	17mm	19mm	20mm	Total
1-5	7	Nil	Nil	3	2	2	0	7(24.13%)
6-10	17	1	4			3	1	17(58.52%)
Above 10	5	Nil	1	3	5	1	1	5(17.24%)
				2	Nil			
Total	29	1	5	8	7	6	2	29

CONCLUSION

The high percentage of meat with antimibrial residues obtained from this study indicated that, consumers in Minna metropolitan are predisposed to health hazards due to the presence of antimicrobial residue in meat in slaughtered animals from the abattoir, this emphasis the need for the enforcement of antimortem inspection, effective prevention of infectious diseases, general enlightenment on the withdrawal periods, and establishment of antimicrobial residues monitoring unit in Minna.

ORGAN AND CARCASS WEIGHT VARIATION IN *EIMERIA TENELLA* INFECTED BROILER CHICKENS TREATED WITH METHANOL EXTRACT OF *PARKIA BIGLOBOSA* ROOT BARK

Garba M. Ugwuoke[1*]

[1*] *Department of Veterinary Physiology and Pharmacology, Faculty of Veterinary Medicine, University of Nigeria Nsukka, Enugu, Nigeria; matthias.ugwuoke@unn.edu.ng (*Corresponding Author)*

ABSTRACT

The experiment was designed to evaluate the effect of methanol extract of *Parkia biglobosa* root in *Emeria tenella* infected broilers. One hundred and fifty broilers grouped into 6 groups (n = 25) were used for the study as follows: infected treated with extract (A), infected treated with amprolium (B), infected untreated (C), uninfected untreated; (control) (D), uninfected treated with extract (E), and uninfected treated with amprolium (F). Each broiler was infected at 28 days of age with 20,000 infective *Eimeria tenella oocysts* and treated at day 7 post infection with either extract or Amprolium at a dose rate of 200 mg/ml in drinking water for 7 days. Carcass and Organ weights were measured at 35 days of age. The results showed significant difference in the carcass and organ weights (P>0.05) between the groups. This study proved that the root bark of *Parkia biglobosa* has no adverse effects on organs of treated broilers, instead improved carcass weight and ameliorated clinical signs of bloody diarrhea associated with *Eimeria tenella* infection in broilers.

Keywords: Broilers, Coccidiosis, Organs, *Parkia biglobosa*, Weight.

INTRODUCTION

Coccidiosis is one of the most economically important prevalent parasitic diseases which has adversely affected the growth and fortune of poultry farmers worldwide (Gharekhani et al., 2014). Coccidiosis affects virtually all domestic and wild species, causing signs such as paleness, diarrhea with or without blood, poor feed conversion, weight loss, and in severe cases even death. *Eimeria*, protozoan parasites of the Phylum Apicomplexa are considered the main risk to avian production since they are the causative agent of avian coccidiosis (Blake *et al*., 2015). Avian coccidiosis is caused by seven species of *Eimeria*, which parasitize chickens intestine. According to a recent estimate, the global cost of the protozoan to the poultry industry is estimated to be over USS 2.4 billion per annum (Ola-Fadunsin *et al*., 2017). In Nigeria, the disease is caused by *Eimeria tenella, E. necatrix, E. bruneti, E. acervulina, E. mitis* and *E. praecox* (Jatau *et al*., 2012). These species have predilection sites in the different parts of gastrointestinal tract.The management comprises of ionophorous compounds (ionophores) and synthetic drugs (chemicals). However, the increased occurrence of resistance against routine anticoccidial drugs, the toxic effects of these chemicals on poultry and the development of drug residues in poultry meat and egg (Goetting et al., 2011) have left the poultry industry with a renewed challenge for coccidiosis prevention and control. These have propelled the search for alternative strategies among which plant products provide a good alternative. Some of these plants are indigenous to Nigeria and may serve as a source of foreign revenue when exported to developed economies where people are becoming more aware of the toxic effects of using chemotherapeutic agents in producing animal protein. *Parkia biglobosa* is one of such plant alternatives. The stem bark of *P. biglobosa* has been reported to have some coccidiostatic activities (Maikai *et al*., 2007) and antimalarial effects (Traore *et al*., 2013). The stem bark is used for treating hypertension (Karou *et al*,, 2011) and listed as having wound healing properties in South-Western Nigeria (Adetutu *et al.*, 2013). A decoction of the root is used in the treatment of coccidiosis by natives in western Nigeria (Olanipekun, 2014). There is no data on the anticoccidial activity of the root bark extract of *P. biglobosa* in broiler chickens. In this study, the anticoccidial activity and the effect of methanol extract of *P. biglobosa* root bark was evaluated in broiler chickens experimentally infected with *Eimeria tenella* oocysts.

RESULT

Carcass yield and organ weight

Data on body weight, carcass weight/dressed and parts of the broilers are shown in Table1. It is observed that among the infected groups, the body weight was higher in the *P. biglobosa* treated group A (3.2 kg/broiler) and the amprolium treated group B (3.2 kg/broiler). The infected but untreated group C had the least body weight (2.7 kg/broiler). In the uninfected broilers, group E (*P. biglobosa* treated) recorded a higher body weight (3.4 kg/broiler), followed by the amprolium treated group F (3.3 kg/broiler) and lowest the untreated group D (3.1 kg/broiler). In the results, it was also observed that among the infected groups the carcass yield was higher in group A (2.8 kg/broiler), followed by B (2.6 kg/broiler) and lowest C (2.4 kg/broiler) (Table1). Among the uninfected groups, D (untreated) recorded 2.5 kg/broiler, E (P. biglobosa treated) and F (amprolium treated) recorded 2.6 and 2.8 kg/broiler, respectively.

DISCUSSION

The slight difference observed by the decrease in weight of the carcass parts (thigh, back and neck, wings) in group C and D (Table 1) may be due to the lack of treatment of the broilers with either the *P. biglobosa* or amprolium. Also significant weight difference ($P < 0.05$) existed in group B among the weight of the organs, where the liver (1.8%), heart (0.6%) and the spleen (0.2%) weighed more than those in the other groups as shown in Table 1. The variation in weight of the organs in group B may be due to a compensatory mechanism in relation to treatment with amprolium and the coccidian infection. *Eimeria tenella* is a very pathogenic chicken coccidia that parasitize caecum of young chickens and is characterized by acute onset manifested by clinical signs of bloody diarrhea due to invasion of the mucosal lining of the caecae by the second generation merozoites and the associated microscopic changes due to coccidiosis which include congestion of the mucosa of the intestine, diffuse or patchy haemorrhagic enteritis, lymphocytic and mononuclear cells infiltration of the intestinal mucosa and sloughing of epithelial lining (McDougald and Reid,1997). Also, it is a known fact that the weight of organs in broilers is indicative of the response of birds to the feed intake in relation to their age or growth of broilers. The weight of organs in broilers also reflects the anatomical response of broilers to the type of diets consumed, such as the use of whole grains in feed or large high fibre particles (Atteh, 2004).

CONCLUSION

In conclusion, this study has shown that the methanol extract of *Parkia biglobosa* root bark may have improved the carcass yield of broilers and also ameliorates clinical signs of bloody diarrhea consistent with *Eimeria tenella* infections in broiler chickens. The root bark of *P. biglobosa* has no harmful or adverse effect on the organs of treated broilers with or without *Eimeria tenella* infection. It is recommended that further research on the potential use of the root bark of *P. biglobosa* for the control of coccidiosis in broiler chickens be carried out. *P. biglobosa* root bark may be recommended to poultry farmers in the absence of conventional anticoccidial drugs.

ABSTRACT
This study was designed to investigate the Ethno–Veterinary Medicine (EVM) use approaches of camel keepers at Kazaure Local Government Area of Jigawa State, Northwest Nigeria. Thirty (30) structured questionnaires were administered to purposively selected camel keepers and data generated were subjected to descriptive statistics. Majority (43.00%) of the respondents had over 50 years of experience in keeping camel, while the most common herd size (70.00%) was between 5–10 camels. *Dermatophilosis* (37.00%) was most prevalent disease condition while with common diseases while observable signs of diseases (70.00%) were scratching of the body. The disease was also more prevalence in the rainy season (46.67%). EVM (60.00%) remain the major animal healthcare approach adopted by the camel keepers while route of drugs administration (26.00%) were topical application. Since EVM remains a widely accepted animal healthcare option among the camel keepers at the study location, further studies should be carried out to elucidate the actual practice of the camel keepers.
Key words: Camels, *dermatophilosis*, diseases, ethno–veterinary medicine

INTRODUCTION
Camels are very tough, energetic and healthy animals, but, like other animals, they still required care and maintenance (Scott, 2009). Inspite of this, there are still some infections that affects the camels both externally and internally (Kent, 2001). Animal health, production and management in the tropics are facing a serious set–back as a result of inadequate facilities and inputs to keep the system of production at sustainable level. In most of the tropical countries, camel (*Camelus dromedarius*) owners do not patronize available conventional veterinary services due to the believe that camels are hardy and resist disease conditions to some extent (FAO, 2001). EVM practices are however common among the pastoralists across the world and have been found to be effective despite recent difficulties (Kent, 2001). Camel keepers also exploit EVM approaches sto treat their animals suffering from various degrees of infection across different seasons of the year (Scott, 2009). In this context, there is need to elucidate information on the current EVM approaches and practices at specific location in Nigeria, since such information could add to what is known, and could also be useful in policy formation on the subject matter.
The objective of this study therefore to determine of EVM use approaches by camel keepers in Jigawa State, Northwest, Nigeria.

MATERIALS AND METHOD
The study was conducted at Kazaure Local Government Area of Jigawa State. The State covers an estimated land area of 22,410 square kilometers and shares boundary with the Niger Republic to the North, Katsina, Kano and Yobe States to the west, south and east respectively. The
population of the State was 4,348,649 during the 2006 national head count (NPC, 2006). Jigawa State is located in the Sudan savannah vegetation belt that is characterized by hot and dry climatic conditions. The hottest temperature ranges from 20.6^0C to 32^0C while the annual rainfall is 687mmHg (JARDA, 2006). The livestock types kept in the area include: cattle, camel, sheep, goat and poultry. Camels are particularly are particularly kept in the area as tough and hardyfor burden bearing, meat and milk.

Data collection

The study lasted for three (3) weeks. Thirty (30) structured questionnaires were administered to purposively administered to camel keepers at Kazaure Local Government Area of Jigawa State, Nigeria to capture their biodata, camel production experiences, diseases prevalence and treatment approaches.

Data analysis

The data collected were summarized and analyzed using simple descriptive statistics (Frequencies and Percentages).

RESULT AND DISCUSSION

Biodata of the respondents

Biodata of the respondents were presented in Table 1. Majority (33.33%) of the respondents fell within the age range of 41–60 and >60 years. This is in agreement with Ghude *et al.*, (2012) who reported that camel production in Northern Nigeria not a practiced by younger generations. All the camel keepers were males while most (83.00%) were engaged in both into crop and camel production and only 10.00% engaged into camel keeping only. Also, 83.00% of the camel keepers in the study area attended Islamic schools while only 17.00% obtained primary school leaving certificate.

TABLE 1: Personal data

Parameters	Frequency	Percentage
Age		
0 – 20	3	10.00
21 – 40	7	23.34

Experience in camel production

Table 2 showed that 43.00% of the respondents had over 50 years experience in camel keeping followed by 41–50 years as identified by 33.00%. Most of them were engaged in pastoral practice from childhood. Although they may not own their herds at younger age but they participate fully in all the activities as earlier reported by Wilson, (1998). Herd size is small in the study area with 70.00% of keepers possessing between 5–10 camels and only

17.00% owned more than 30 camels respectively. Camel herd size in the Tropics and some Asian countries is small due to the practice of subsistence agriculture (Wilson, 1998).

TABLE 2: Experience in camel production

Parameters	Frequency	Percentage
Years of experience		
0 – 10	-	-
11 – 20	2	7.00
21 – 30	5	17.00

Diseases experience and Season of the disease infection

In Table 3, the camel keeping experience in identifying various diseases and infections were presented. A skin infection (*Dermatophilosis*) was more prevalence in camels as identified by 37.00% of the respondents followed by 33.00% that identified ecto–parasites. The observable signs included scratching of the body (70.00%) and loss of appetite (13.00%). According to Kent, (2001), tick infestation is the major camel health problem that causes substantial economic losses, particularly in tropical and subtropical countries where approximately 80% of the world's dromedary camel population is raised. Higher prevalence of infection was observed during early rainy season (46.67%) and late dry season (23.33%). An improved veterinary treatment protocol that includes improved hygiene and general supportive treatment decreases the significance of such skin disease in camels and enhances response of animals to the utility activities (Scott, 2009).

TABLE 3: Diseases experience and season of the disease infection

Parameters	Frequency	Percentage
Types of diseases affecting camels in your area		
Endo – parasites	3	10.00

Treatment applied (method of application) and types of drugs used

Table 4 shows the treatment/methods and types of drugs used by camel keepers in treating *dermatophilosis*. Sprinkling, spray and dusting methods was largely practiced as indicated by 43.00% of the respondents followed by 26% who used application (rubbing) method. This is in agreement with the report of FAO, (2008) that the application method and administration of ethno veterinary drugs (EVDs) is through the use of traditional methods are usually done through the use of traditional methods. EVDs were adopted and in use as indicated by 60.00% of the camel keepers, while 26.67% seemed to avoid any use of medication. This is in agreement with the report of Kent, (2001) that tropical and in some Asian countries extensively exploits EVDs in the treatment of camel diseases.

TABLE 4: Treatment/method applied and types of drugs used

Parameters	Frequency	Percentage
Method of administering the treatment		
Oral	5	17.00

CONCLUSION AND RECOMMENDATION

Most of the camel keepers at Kazaure Local Government Area of Jigawa State employ EVM in the healthcare of their animals. Since EVM remains a widely accepted animal healthcare option among camel keepers at the study locations, further studies should be carried out to elucidate the actual EVM practice of the camel keepers.

Paper for oral presentation under the monogastric nutrition sub-theme

ABSTRACT

This study accessed the effects of dietary inclusion of Gut Balance Booster™ (GBB) on performance of weanling pigs. Twenty four six week old weaned pigs of mixed sexes were randomly assigned into two groups of 12 piglets each. They were fed diet A (normal starter diet without GBB) and diet B (starter diet with GBB at 200g/kg). Feed intake, weight gain, feed conversion ratio (FCR), haematology, serum lipid profile, faecal egg count, shedding of selected bacteria and cost-benefit of the additive were determined. Results showed that there was no significant difference ($p \leq 0.05$) in daily feed intake, FCR and weight gain. However, the values favoured the supplemented group (1.16±0.10 vs.1.06±0.13kg; 2.61±0.34 vs. 3.04±0.23; 485.29±59.12 vs. 355.00±40.30g). Haemoglobin, PCV, RBC and WBC and Lymphocyte counts were higher in group B. Lipid profile showed no significant difference ($p \leq 0.05$) in the two groups. The GBB reduced faecal strongyle eggs output, *salmonella species* and increased *Bacillus subtilis* and *Escherichia coli*. Net gain due to GBB supplementation within the experimental period was ₦221,508 ($613.60). It was concluded that in pigs, dietary inclusion of GBB at starter phase improves gut health, growth performance and is cost beneficial.

Keywords: Swine, antibiotics, feed additives, growth performance, cost benefits.

INTRODUCTION

Antibiotics are used in animal feed to maintain and improve animal performance and prevent /control enteric pathogens (FAO, 2016). However, consumption of the animal products can result in bacterial resistance in human pathogens and this led to its ban in 2006 by the European Union. Following this ban, researches focused of developing alternative to antibiotic feed additives to enhance livestock performance (Thacker, 2013). Organic acids, enzymes, probiotics, prebiotics, antimicrobial peptide and phytogenic compounds have widely been recognized as potential alternatives (Yang *et al.*, 2015). Strong odour, poorly understood mode of action, complex chemical composition, unpredictable effects of individual compounds, low availability and stability in gastro-intestinal tract limit the use of feed additives singly, particularly the phytogenics (Stevanović, 2018). Gut Balance Booster™ (GBB) contains Zinc, Benzoic acid, Calcium, Sodium butyrate and essential Oils. According to the manufacturer, in broilers, where it is recommended to be used within the first 35 days of life, it supports gut health by stimulating the growth of gut microvilli, and excretion of enzymes that improves nutrient absorption. The objective of this study was to assess if dietary inclusion of GBB™ could serve as an alternative to antibiotics growth promoter in swine diet.

MATERIALS AND METHODS

Experimental animals, husbandry and diet

Experimental animals comprised 24 weanling pigs of mixed sexes, progeny of three sows and one boar and aged six weeks. They weight ranged between 8.50 to 10.00kg. They were acclimatized for two weeks during which they were identified and given some prophylactic treatment. The experimental diet was formulated using following NRC (1998) nutritional requirements for swine.

Animal care:

Animal studies were carried out following the guideline of the ethical procedure of the Animal Use and Care Committee of the Faculty of Veterinary Medicine, University of Nigeria (FVM-UNN-IACUC-2019-056).

Experimental design:

Following the acclimatization period, the 24 animals were randomly divided into two groups A and B with 12 piglets in each. They were fed diet A (normal starter diet without GBB) and diet B (starter diet with GBB at 200g/kg).

Daily feed was determined as the difference between amount of feed fed and the amount left over in 24 hours while the feed conversion ratio (FCR) was determined by dividing feed intake by weight gained within the same period.

Packed cell volume pigs was determined by microhaematocrit method (Coles, 1986), Haemoglobin concentration was determined by the cyanomethemoglobin method (Jain, 1986) using SP6-500UV spectrophotometer (PYE UNICAM, England). Red blood cell and total WBC counts were enumerated using the Leishman stained blood smear and the different cells of the leucocytes series counted by the longitudinal counting method. The total and differential leukocyte counts, and red blood cell counts were carried out using an improved Neubaeur haemocytometer method (Coles, 1986). The lipid profile which include LDL, H DL, VLDL, Triglycerides and Cholesterol were determined using Biosystemtest kits (Biosystem, S.A Costa Brava 30 Barcelona, Spain).

The feacal egg count was done using faecal floatation technique. Where large egg numbers were involved, McMaster technique was employed for quantitative analysis. Microbial populations were determined by serial dilution (10^{-1} to 10^{-10}) in anaerobic diluent before inoculation onto petri dishes of sterile agar and enumerated as previously described (Singleton, 2004). Cost-benefit analysis (CBA) was carried out using cost benefit ratio (BCR); a basic financial tool.

Statistical

Statistical analyses were done using the SPSS program (SPSS Inc., Chicago, IL). Data from the study was analyzed with Independent t-test between the groups. Level of significance was taken as $p \leq 0.05$.

Results

There was no significant difference ($p \leq 0.05$) in the performance output of the weanling pigs fed with Gut Balance Booster™ supplemented diet when compared to the control group. However, the values from feed intake, weight gain, FCR, and final body weight were higher in the test group. There was no significant difference ($p \geq 0.05$) in the haematological profile of the pigs. However, the values obtained in HB, PCV, RBC and WBC count, and Lymphocyte counts were also higher in group B. Triglycerides, LDL and VLDL were higher in the test group than group A. The GBB reduced faecal strongyle eggs output (106.00 - 0.00epg), *salmonella species* (4.9×10^4 - 2.9×10^4cfu/ml) and increased *Bacillus subtilis* (1.4×10^4 - 2.8×10^4 cfu/ml) and *Escherichia coli* (2.7×10^4 - 3.1×10^4cfu/ml). Net revenue due to GBB supplementation within the experimental period was ₦221,508 ($613.60).

DISCUSSION

This study revealed that growth performance of the supplemented group was better compared to the control group. This is in line with the observation of Bühler (2009) that showed that dietary benzoic acid had an influence on fattening duration, though comparative analysis did not result in statistical significance. Optimal performance is only possible when enough nutrients are absorbed. The antimicrobial effect of organic acids can reduce the microbial population in the gut and thus competition for nutrients (Richards *et al*., 2005). The growth performance in this experiment is also in line with Han and Thacker (2010) who demonstrated more rapid growth for pigs fed with Zinc oxide supplemented diet. This data supports previous studies which demonstrated that pharmacological doses of zinc oxide stimulate performance in weanling pigs (Hill *et al.*, 2000). Similarly, the study revealed that growth performance of the supplemented group was better compared to control group This is in line with the observations of other researchers that have shown the beneficial health effects of combining probiotic and Sodium

butyrate to have positive effects on livestock production parameters such as weight gain, feed intake, and FCR (Abonyi 2018). Dietary content can affect the blood profile of healthy animals. The determination of haematological indices in this study was to determine any possible negative effects of the additive including leucograme abnormalities. This was in line with the report of Isaac *et al*. (2013) that hematological components which consist of RBCs, WBCs or leucocytes, platelets, haemoglobin and are valuable in monitoring food toxicity as well as the health status of farm animals. Values for haematological profile studied were within normal range for pigs. In like manner, probiotics were reported to have no adverse significant effect on the erythrocytes, PCV, haemoglobin concentration, MCV, MCH and leucocytes of rabbit (Ezema and Eze, 2010).
The lipid profile showed a reduction in values of cholesterol and triglycerides in the treatment group compared to the control. The work is in line with Favier *et al.* (1995), who reported reduced cholesterol levels in experimental guinea pigs.

According to Ooi and Liong (2010), feed additives such as probiotic and/or prebiotics have been widely assessed for their effects on lipid profiles of livestock such as total cholesterol, LDL, HDL and triglycerides. However, not all trials have yielded conclusive results as was observed in this trial.

In this study, GBB recorded some anthelmintic effect. To the best of our knowledge no other study has shown that this additive or its components reduce helminth burden in pigs.

This is a pioneer work done with GBB on weanling pigs and hence, is the first time the use of the additive has been put under cost benefit analysis. The result obtained however showed a significant increase in the profit margin, giving a net gain due to its dietary inclusion in pig starter diet to be ₦221,508 ($613.60).

CONCLUSION.
Diet B stimulated more positive influence on the production parameters we investigated by improving their gut health through reducing harmful and increasing beneficial bacterial load and anthelmintic effect. This suggests that GBB could be an alternative to antibiotic growth promoter in weanling pigs. More studies are recommended to elucidate GBB's appropriate inclusion level and potentials in reducing worm burden in pigs.

ABSTRACT
A total of 1331 faecal samples were collected to determine the prevalence of gastrointestinal parasites of donkeys in Darazo, Ganjuwa and Ningi Local Government Areas of Bauchi State, Nigeria. Season, Body Condition Score (BCS), and other parameters were considered. Samples were analyzed using standard coprological methods. The overall prevalence of 52.7% and five species of parasites were identified including: Strongyles (34.3%), *Gastrodiscus spp* (2.4%), *Strongyloides* (19.6%). *Trichonema spp (42.3%), Tricodontophorus* (1.3%). Body Condition Score, age and season have significant influence on the parasitic burden ($p<0.05$). Donkeys in the localities should be strategically treated against parasitic infection to enhance their condition and welfare.

INTRODUCTION
In remote rural areas of Northeastern (NE) Nigeria where modern transportation is infrequently available, the contribution of donkeys in agriculture is imperative. Donkeys suffer a number of health and other welfare difficulties especially in the rural areas. Gastrointestinal helminths are among the most serious health problems of donkeys in Africa. High prevalence of internal parasites of donkeys has been reported from African countries (Pandey *et al.*, 1994, Abdullahi *et al.*, 2010, Umar, 2013,). Despite these comprehensive reports, little information is available from this part of the country and hence one of the aims of this study.

MATERIALS and METHODS
The study was conducted in Darazo, Ningi, and Ganjuwa Local Government Areas (LGAs) of Bauchi Sate northeastern Nigeria. The state occupies an area of 49,119 Km^2 representing about 5.3% of the Nigeria's total land mass. There are two climatic seasons: rainy (May – September) and dry (October – April) in the state (Maleka, 2006). Three major livestock markets; one in each of the LGA were visited twice each season. The study animals comprised of 1331 (605 – males, 726 – females) donkeys of five different ages. Animals were randomly selected at the markets and grouped according to some measurable parameters (age, BCS) estimated using standard methods (Coombs, 2002, Pearson and Quassat, 1996). Faecal samples were collected from the rectum and transferred into labeled polythene bags and transported to the laboratory in a cooler containing ice blocks. The collected samples were analyzed using direct faecal smear, and floatation techniques at the National Veterinary Research Institute (NVRI) Parasitology Laboratory, Bauchi. Eggs were further examined microscopically. The modified McMaster and Bearman techniques were used to count the helminth eggs (epg) (Urquhart *et al.* 1996). Data was analyzed using descriptive statistics, Chi-square test and one-way ANOVA. Microsoft Excel (XP 2007) and SPSS 17.0 (2007) were used for the analysis.

RESULTS
The study showed an overall prevalence of 52.7%. Prevalence among the LGAs was similar in Darazo (54.4%) and Ganjuwa (59.5%) but significantly ($P<0.05$) different in Ningi (44.2%). The prevalence was also significantly ($P< 0.001$) higher in rainy (84.4%) than dry (23.2%) season and between young (55.3%) and old donkeys (44.8%). These findings were however; lower than the previous studies of other researchers in the neighboring states. In 2010 Abdullahi *et al.* reported a prevalence of 86.32% and in 2013, 67.88% was recorded by Ibrahim. The variation could be due to differences in year, mode and locations of studies. The study conducted by Ibrahim (2013) in Yemaltu Deba L.G.A of Gombe State was in rainy season and involved working donkeys only, while the present study considered the two seasons but did not classify the donkeys into working or trade. Prevalence rates were similar between males (51.7%) and female donkeys (53.6%). This might be due to the absence of gestation and lactation in the female donkeys. In general, it was speculated that sex is a factor that influences the prevalence

of gastrointestinal and other parasites of mammals (Pal and Qayyum, 1992). However, there was significant (P<0.001) differences across different categories of BCS with only 3.9% recorded in category V (obese) and as high as 95.7% in the BCS – I (thin) donkeys. The reason might be associated with the fact that animals with poor BCS have weak immunity and as a result they could not resist the parasitic burden when compared with animals of good BCS (Sapkota, 2009). Five different types of parasites were identified in the study which were almost present in all the three LGAs: *Trichonema spp (42.3%),* were highest followed by Strongyles (34.3%), *Strongyloides* (19.6%) *Gastrodiscus spp* (2.4%), *Tricodontophorus* (1.3%) (Tab. 1). Mixed infestation was observed in 47.9% of the donkeys. This was in line with the previous reports in the Nigeria and other countries (Jajere *et al*., 2016).

Table 1: Occurrence and species distribution of gastrointestinal parasites of donkeys in 3 Local Governments Areas (LGAs) of Bauchi Sate, NE Nigeria

LGA	**N**	**No. positive**	**(%)**
Ganjuwa	445	265	59.5
Darazo	445	242	54.4
Ningi	441	195	44.2
Total	**1331**	**702**	**52.7**
Species			
Strongyles		241	34.3
Strongyloides		138	19.6
Trichonema spp		297	42.3
Gastrodiscus spp		17	2.4
Tricodontophorus spp		9	1.3
Total		**702**	**100**

CONCLUSION

Donkeys will continue to play crucial roles in the livelihood of Nigerian farmers particularly in the rural areas. Parasitism, and other ill-health identified in this study, will remain a persistent treat to the health and welfare of these animals. Donkeys in the localities should be strategically treated against parasitic infections. Owners need to be educated on the basic principles of health management of donkeys. Research on donkeys should be included in priority lists of sustainable animal production in the country.

ABSTRACT
The study was conducted from 15th April to 31st July 2019 in Paikoro Local Government Area of Niger State, Nigeria; with the aim of determining the types, prevalence and intensity of ticks infestation in small ruminants production and identifying the major risk factors. Clinical examination and laboratory analysis were made on 160 sheep and 160 goats. The collected raw data were analyzed using software package SAS (Version 2010). Out of 320 sampled animals 67.2% (215/320×100) were found to be infested with one or more of tick species. The prevalence ticks observed were *Rhipicephalusevertsievertsi* 70(21.9%), *Amblyommavariegatum* 59(18.4%), *Boophilusdecoloratus* 40(12.5%), while *Hyalommaanatolicumexcavatum* 36(11.3%) and *Rhipicephaluspulchellus* 26(8.1%) were the minor species of ticks observed on goats and none on sheep were recorded in the study area. The infestation rate of tick in species, age and body condition scored (BCS) were significantly varied (P<0.05), however in sex (P> 0.05). In conclusion, the high prevalence in tick infestation becomes a threat to small ruminants production in the study area, therefore, further studies is recommended on the epidemiology of tick infestation, tick borne diseases as well as tick related risk factors on small ruminants production; as these may provide a benchmark to design appropriate prophylactic and control measures of tick infestation in the study area.
Key words: Small Ruminant, Infestation, Tick, Prevalence, Paikoro.

INTRODUCTION
Sheep and goats farming is one of the most important features of agriculture, which has contributed significantly towards the growth and development of the national economy of Nigeria. They play significant roles in the livelihood of rural households, where they are largely the property of women and their children (5). They provide a vast range of products and services, such as meat, milk, hairs and skin, horns, bones, manure, security gifts, religious ceremonies as well as production of drugs (11, 2).

Ticks infestation on sheep and goats reduce their ability to provide the above mentioned products and services. It could lead to noticeable economic losses to farmers due to loss of efficiency, death, and skin diseases. They are described to cause a wide range of diseases such as painful sore, mechanical tissue damage, bowel, loss of weight, loss of blood, and in strict conditions death of infested animals often followed by socioeconomic implications (7, 9). Apart from the direct effect of tick infestation on small ruminants' production and efficiency, ticks can harbor multiple pathogenic agents; patient can be infected with multiple pathogens at the same time, there by making diagnosing and treatment to be difficult (14). Despite these serious strikes no animal, the significance and incidence of tick infestation on small ruminants has not been assessed in Paikoro Local Government Area of Niger State, Nigeria. Therefore, the aim of this study was to determine the types, prevalence and intensity of ticks' infestation on small ruminants' production in Paikiro Local Government Area of Niger State, Nigeria, with a view to suggesting control measures for increasing efficiency of livestock and other meat producing animals.

MATERIALS AND METHODS
Study Location
Paikoro Local Government Area is one of the Local Government areas in Niger State, Nigeria. It has its administration headquarter situated in Paiko town about 25km south of the state capital Minna. It is located in the eastern region of the state, it lies within longitude 9°26'N and 6°38'E and latitude 9.433°N and 6.633°E. It has an area of 2,066km^2 (798 sq. mi) and a population of 158,086 which comprises of 79,399 males and 78,779 females at the 2006 census (6). Annual rainfall is between 1,100mm to 1,300mm with a mean temperature of 37°C during the dry season.

For the collection of data, a random sampling technique (12) was applied to gather the data on tick prevalence from eight wards out of eleven wards in 160 sheep and 160 goats in Paikoro Local Government Area of Niger State, Nigeria from 15th April to 31st July 2019. All the information required such as species, sex, age and body condition score were recorded on the predesigned proforma.

Prior to collection of ticks, animals were restrained properly and their whole body was thoroughly examined for the present of tick following which they were manually collected using hand with gloves. The collected ticks were preserved in 70% ethanol in labeled plastic vial and were taken to animal biology Laboratory, Federal University of Technology (FUT), Minna, for ticks' identification with the aid of stereomicroscopy using identification key described by (15).

All data were analyzed using Statistical Package for Social Science (SPSS) Software (Version 20).

RESULTS

During the present survey, all the eight wards were visited and a total of 320 small ruminants v*iz.* 160 sheep and 160 goats were randomly inspected for tick collection. Out of 320 animals 215/320×100 (67.2%) were found to be infested with one or more of tick species. From the sampled animals 134/160×100 (83.8%) and 81/160×100 (50.6%) sheep and goats respectively were found positive for tick infestation. The differences in tick infestation in species (χ^2= 7.89, df= 1, P< 0.05), in age (χ^2= 3.83, df= 1, P< 0.05),and in body conditioned scored (BCS) (χ^2= 12.82, df= 1, P< 0.05)were statistically significant. However, the difference in sex (χ^2= 2.35, df= 1, P> 0.05), was not significant (Table 1).

Overall, a total of 933 *ixodidae* ticks were collected from 160 sheep and 160 goats. In general, four *Ixodidae* tick genera (Table 2) and five species (Table 3) were identified from the study area. From the identified tick species male ticks outnumber female ticks (Table 4).

Table 1: Prevalence of Ticks' Infestation Based on Rick Factors.

Variable	Category	No. of animals examined	No. of animals infested (%)	Significance
Species	Sheep	160	134(83.8)	χ^2= 7.89
	Goats	160	81(50.6)	P= 0.005
Sex	Female	160	122(76.3)	χ^2= 2.35
	Male	160	93(58.1)	P= 0.126
Age	Young	160	89(55.6)	χ^2= 3.83
	Adult	160	126(78.8)	P= 0.050
Bcs	Poor	149	134(89.9)	χ^2= 12.82
	Good	171	81(47.4)	P= 0.000

Table 2: Prevalence of Tick Burden at Genera Level in the Study Area.

Tick species	Sheep (Prevalence in %)	Goats (Prevalence in %)
Amblyomma	216 (37.44)	236 (66.29)
Rhipicephalus	319 (55.29)	60 (16.85)
Boophilus	42 (7.28)	28 (7.87)

Tick species	Sheep (Prevalence in %)	Goats (Prevalence in %)
Hyalomma	0 (0.00)	32 (8.99)
Total	**577 (100)**	**356 (100)**

Table 3: Tick Species-Level Prevalence on Small Ruminants in the Study Area.

Tick species	Sheep (n=160) Prevalence (%)	Goat (n=160) Prevalence (%)	General score of all ruminants Prevalence (%)
R. evertsievertsi	63 (39.4)	7 (4.4)	70/320 × 100 (21.9)
A. variegatum	49 (30.6)	10 (6.3)	59/320 × 100(18.4)
B. decoloratus	32 (20.0)	8 (5.0)	40/320 × 100 (12.5)
H. anatolicumexcavatum	0 (0.00)	36 (22.5)	36/320 × 100(11.3)
R. pulchellus	0 (0.00)	26 (16.3)	26/320 × 100 (8.1)

Table 4: Total Adult Tick Species and Sex Ratio in Small Ruminants.

Tick species	Female tick Count	Male tick Count	Female: Male Ratio
Amblyommavariegatum	200	252	0.8: 1
Rhipicephaluspulchellus	0	24	0: 1
Rhipicephalusevertsievertsi	200	155	1.3: 1
Boophilusdecoloratus	24	46	0.5: 1
Hyalommaanatolicumexcavatum	32	0	1: 0

DISCUSSION

The study revealed the overall prevalence of tick infestation 67.2%. The result recorded in this study is higher than 16.7% prevalence of ecto-parasites in sheep and goats reported inNorth Eastern, Nigeria by(1), but this result is slightly lower than 68.1%in South Eastern Nigeria reported by (8). The higher proportion of ticks' infestation in sheep (83.8%) as compared to goats (50.6%) could be due to the marshy habitat and soft skin of sheep as compared to drier habitat and hardy skin of goats. This result is in consistence with the previous work of (10) who reported higher prevalence in sheep (47.0%), in goats (19.0%). The difference in the prevalence might be due to the geographical difference, season of the study period, management conditions as well as ticks control strategies in the study area.

The difference in the prevalence rate was found to be statistically significant between the two species of the small ruminants' production. This result was in agreement to the study undertaken by another author on ecto-parasites in Gombe State, South Eastern Nigeria (1). However, this report is parallel to the findings of (4) who reported that male animals are more susceptible to ticks.

The proportion of tick infestation was higher in adult animals as compared to young animals. However, there was no statistical significant association (P> 0.05) and the greater prevalence rate could be due to the long distance movement of the adult animals in search of food and water in comparison to the young animals; this maximized the chance of exposure to ticks. This finding is in line with the report ofecto-parasites by(17) who statedsimilar observation for a higher proportion of adult animals being studied.

The higher prevalence of tick infestation found in this report was not statistically significant between bodies conditioned scored. This observation could be attributed to the fact that good body conditioned scored animals were well fed and this make them to developed resistance to different types of diseases to which they were exposed whilst grazing in the field or were maintained in their sheds in comparison to poor body conditioned scored

animals who lack body potentials to build resistance as a result of poor nutrition especially during the dry season, thus make them to be more susceptible to ticks. This report of higher prevalence in poor body conditioned scored animals is in accord with that of (13).

The higher prevalence of single infestations to double infestations recorded in this report agreed with that of (3) who reported a single infestation, three double infestations and one triple infestation. The effects of tick infestations are more noticeable when infestation is heavy and combined. Thus, more single infestation recorded in this report means that the effect of tick infestations was not so noticeable on the animals.

In all cases, except *Rhipicephalusevertsievertsi*and *Hyalommaanatolicumexcavatum*, males ticks out number females ticks, this is due to the fact that the females engorged on much blood, its expanded greatly then detached and convert the blood to eggs drop off the body of the host to the ground to lay eggs, and finally dies after this single laying, while the males ticks takes repeated small meal of blood and attempt to mate repeatedly whilst on the same host (16).

CONCLUSION AND RECOMMENDATION

The present study revealed a high prevalence of tick infestation on small ruminants in the study area and difference determinants such as species, sex, age and body conditioned scored are the risk factors for ticks' distribution. Therefore, based on this finding further studies is recommended on the epidemiology of tick infestation, tick borne diseases as well as tick related risk factors on small ruminants production; as these may provide a benchmark to design appropriate prophylactic and control measures of tick infestation in the study area.

ACKNOWLEDGEMENT

The authors are thankful to the farmer communities of the study area and field staff of veterinary section of Paikoro Local Government Area of Niger State, Nigeria for their support during tick collection.

ABSTRACT
Serological study was conducted to determine the prevalence of brucellosis in some settled cattle farms in Bauchi Local Government Area, Bauchi State, Nigeria. A total of 500 cattle sera from 6 farms were collected and examined for antibodies against *Brucella* species using Rose Bengal plate test (RBPT). Information about the sex, age, and breeds of cattle were collected using structured questionnaire. Association between prevalence of the disease and age, sex and breeds of cattle were determined using Chi-square test. The results obtained revealed overall prevalence of 35 (7%).The highest prevalence observedin cattle aged between 4-6 years old was 18 (3.6%) while the least prevalence of 1 (0.2%) was recorded in cattle aged above 9 years. Based on sex, the infection was higher in females 22 (4.4%)than males 13 (2.6%). There was a significant association between the prevalence of brucellosis and the sex of cattle at $P \leq 0.05$. However, there is no significant association between prevalence of the disease and the age and breeds of cattle examined.The study confirmed the presence of brucellosis in the study area and infected cattle in the screened farms are likely to transmit the disease to humans and other susceptible animals. It is recommended that allinfected animals should be immediately culled to avoid further spread of the infection, susceptible animals should be vaccinated and public should be enlightened about the zoonotic nature of the disease.
Key words: Brucellosis, Cattle,Prevalence, RBPT

INTRODUCTION

Brucellosis is an infectious and contagious disease primarily of livestock caused by a number of host-adapted species of Gram-negative intracellular bacteria of the genus *Brucella*. The disease is one of the most widespread zoonoses in the world (Munir*et al.*, 2010). It is one of the most devastating trans-boundary animal diseases and also a major trade barrier and economically very important as a major cause of losses in the livestock industry (Gul and Khan, 2007). Brucellosis infection is widespread globally and is endemic in many developing countries including Nigeria and it has been reported in various parts of the country and in various animal species and in humans (Cadmus *et al*., 2006;Mai *et al*., 2012; Kudi*et al*., 2015; Saleh *et al*., 2016;Mai *et al.*, 2018).In a large seroprevalence survey of brucellosis in cattle herds under diverse production systems in northern Nigeria,Mai *et al*. (2012) reported a significantly higher seroprevalence of brucellosis in cattle with overall level of 37% using RBPT and 26.3% after confirmation with c-ELISA. Many cases have been reported in various literatures (Adamu*et al*., 2016; Saleh *etal*., 2016; Agada*et al*., 2017).

The disease is well known for its effects on decreasing productivity of infected livestock by causing abortions, reduced fertility and decreased milk yield, resulting in substantial economic losses (Nicoletti, 1980). Other clinical signs that characterised the disease include; sterility, still birth, retained placenta, orchitis, hygroma and epididymitis (Adams, 2002). However, the rare clinical signs like mastitis, repeat breeding and joint ill were also reported (Chakravarty *et al.*, 2007). There is an occupational risk to veterinarians, abattoir workers and farmers who handle infected animals/carcasses and aborted fetuses or placentas. Brucellosis is also one of the most easily acquired laboratory infections (OIE, 2006).

Yagupsky and Baron (2005) reported that *Brucella* infection is readily transmissible to humans, causing acute febrile illness – undulant fever – which may progress to a more chronic form and can also produce serious complications affecting the musculo–skeletal, cardiovascular, and central nervous systems. Infection is often due to occupational exposure and is essentially acquired by the oral, respiratory, or conjunctival routes, but ingestion of dairy products constitutes the main risk to the general public. The incidence of the disease in human is thus closely tied to the prevalence of the infection in sheep, goat and cattle and to practices that allow exposure to humans, to potentially infected animals or their products (Carrera *et al.*, 2006).

MATERIALS AND METHODS

To have an insight in to the role of cattle in the epidemiology of brucellosis, we conducted a study to determine the prevalence of brucellosis in some settled cattle farms in Bauchi Local Government Area, Bauchi State, Nigeria.A total of 500 serum samples were collected from six settledcattle farms and tested for the presence of *Brucella* antibodies using Rose Bengal Plate Test (RBPT) as described by Alton *et al.* (1975).Information about individual animal and farms were collected using structured questionnaire (Thrusfield, 2005).

RESULTSAND DISCUSSION

The overall prevalence of brucellosis observed in all the six farms combined was 35 (7%). This is in line with the result of the investigation carried out on cattle by Adamu *et al*. (2016) in three senatorial zones of Bauchi State which revealed the prevalence of (5.4%) using RBPT. Similarly, Farouk *et al*. (2011) also reported much lower overall herds' prevalence of (4.04%) using RBPT from Jigawa State.

The prevalence among the age groups showed that cattle aged between 3-6 years had a prevalence of 18 (3.6%) followed by those between the ages of 7-9 years 11 (2.2%), 0-3 years 5 (1%), and those aged above 9 years 1 (0.2%). This supported the result of investigation conducted in Bauchi State by Adamu *et al*. (2016), who reported the seroprevalence of 6.3% in cattle aged 4-5 years, followed by 5.5% in cattle aged<4 years thencattle with the age range of 5-7 years showed the prevalence of 4.6%, whereas cattle aged above 7years showed the least seroprevalence of 4.0%.Our result revealed no statistically significant association at $p \leq 0.05$ among all the age groups tested. This is also in consonance with the report by Adamu *et al*. (2016).

Based on sex, the result revealed the highest prevalence in females than in males with 22 (4.4%) and 13 (2.6%) respectively using RBPT. Statistically, this showed significant association between the sex of the cattle and the prevalence of the disease ($P \leq 0.05$). This is because female cows remain the locale of the infection, which helps to spread the disease from one animal to another, either through lactation or during mating. Pregnancy and lactation were reported to enhance susceptibility to infection. The growth of virulent strains of *Brucella* organism was reported to be stimulated more in females because of the presence of higher volume of D-erythritol normally found in fetal tissue than in testes and seminal vesicles (Bayemi*et al*., 2009). These thoughts provide proofs as to the different extend of prevalence of bovine brucellosis in relation to sex of animals concern.In addition, this finding agreed with earlier reports byJunaidu*et al*. (2011) who stated that the foci of *Brucella* infection remain in females, which spread the infection from one animal to another. Also, Adamu *et al*. (2016) reported similar result of higher prevalence in females (7.6%) than males (5.8%).

Based on the breeds of cattle examined, the highest infection was found in Bunaji with prevalence of 18 (3.6%), followed by Friesian with 8 (1.6%), Cross breeds 5 (1%), Wadara 3 (0.6%), Bokoloji 1 (0.2%) and Red Bororo 0 (0%). There was no statistically significant association between the breeds of cattle examined and prevalence of brucellosis ($p \leq 0.05$). This agrees with the report by Saleh *et al*. (2016) who indicated that brucellosis is more prevalent in Bunaji cattle slaughtered in three municipal abattoirs of Gombe state. Cadmus *et al*. (2006) also reported the highest prevalence of brucellosis in Bunaji cattle over Red Bororo, Bokoloji and Cross breeds.

CONCLUSIONS AND RECOMMENDATIONS

This study showed that brucellosis is found in the study area. Cattle of all ages and both sexes are carrying the disease andinfected cattle in the herds examined are likely to transmit the disease to humans and other susceptible animals. It is recommended thatinfected animals should be isolated and culled immediately to enable the total eradication of the disease. Food products derived from animals should be properly cooked to protect the consumers from *Brucella* infection andintegrating vaccination against brucellosis into the annual vaccination program of livestock are highly recommended.

[3]Department of Zoology,ModibboAdama University, Yola

ABSTRACT
This study was conducted to determine the clinical manifestations of brucellosis in cattle under differentmanagement systems in northern Nigeria. Using multi-stage sampling, serum samples of 4,745 cattle from 271 herds were tested using the Rose-Bengal plate-agglutination test (RBPT) and positives were confirmed using a competitive enzyme-linked immunosorbent assay (c-ELISA). The results indicated the seroprevalence of 37% with RBPT and 26.3% following confirmation with c-ELISA. The infection level was greater amongst pastoral herds than agro-pastoral herds and in herds with hygromas.

INTRODUCTION
Brucellosis is an infectious and contagiouszoonotic disease primarily of livestockthat has significant animal health and devastating national and international trade consequences.It is an endemic, emerging and neglected diseasein Nigeria.

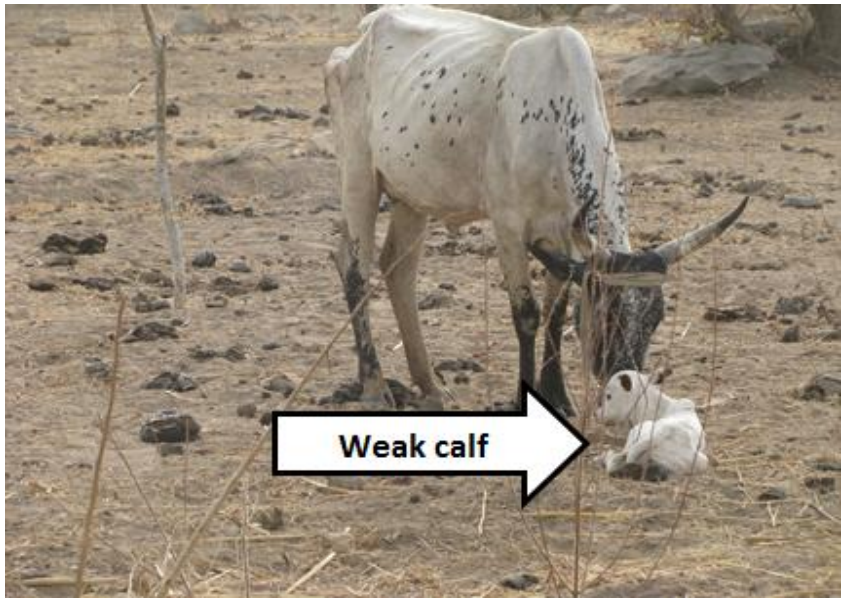
The disease is caused bya number of host-adaptedbacteria species of the genus *Brucella*.The genus consists of small non-motile, non-spore forming, non-encapsulated, intracellular,Gram-negativeaerobic cocci, coccobacilli or bacillary organisms of 0.5-0.7 x 0.6-1.5 µm dimension, usually arranged singly, but they may be in pairs or small groups.

*Brucella*species are poorly staining and are seen mostly as single cells and appearing like “fine sand”**.** Colonies are smooth, round, small, translucent and pale honey colour. Later they became, larger and browner but remain clear.

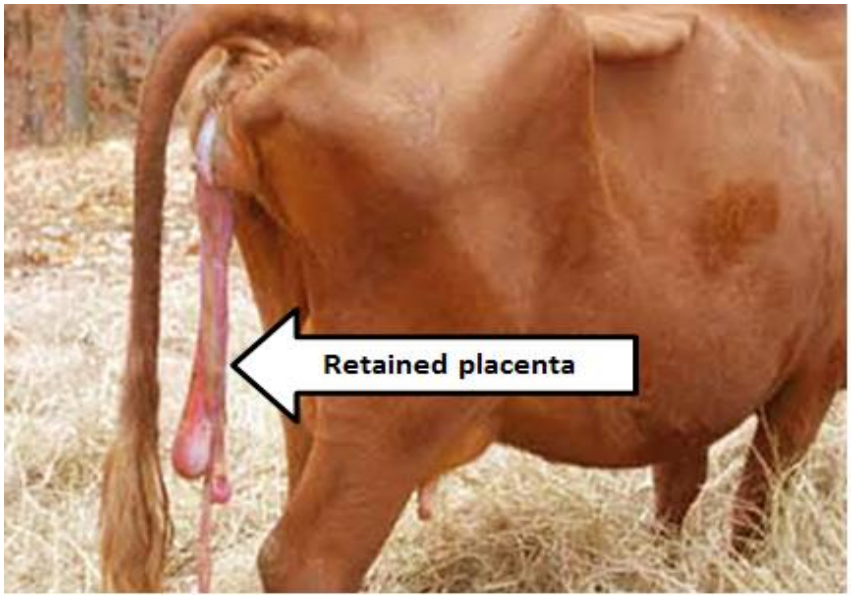
Objectives
The study was aimed at determining the clinical manifestations of brucellosis in cattle from different management systems over a wide geographic area of northern Nigeria using accurate tests.

MATERIAL AND METHODS
This study was carried in cattle under various management systems in Adamawa, Kaduna and Kano states, northern Nigeria. Using multi-stage sampling, serum samples of 4,745 cattle from 271 herds were tested using the Rose-Bengal plate-agglutination test (RBPT) and positives were confirmed using a competitive enzyme-linked immunosorbent assay (c-ELISA).

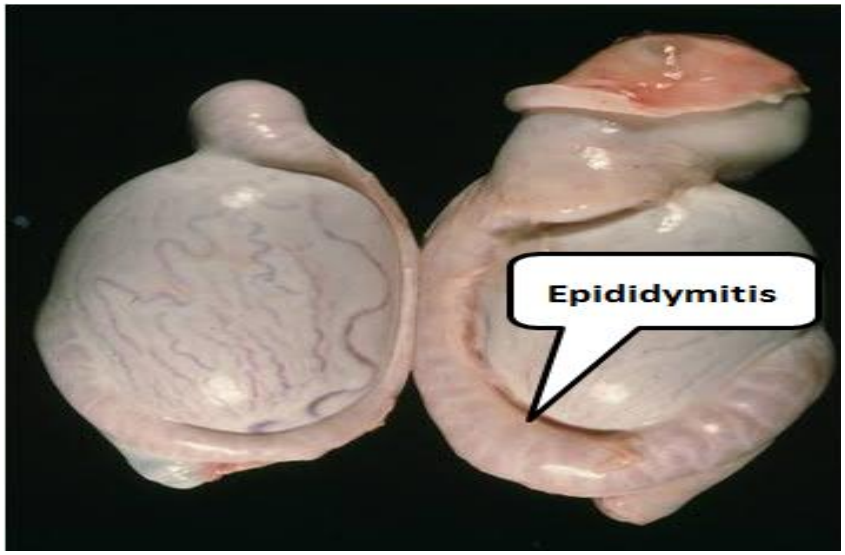
Clinical signs of brucellosis observed in cattle during the study period and laboratory pictures of the two tests results



The signs of brucellosis in cattleincluded: abortion, still birth, retained placenta, birth of weak calves, hygroma, orchitis and epididymitis. However, other symptoms like mastitis, repeat breeding and joint ill were seen.



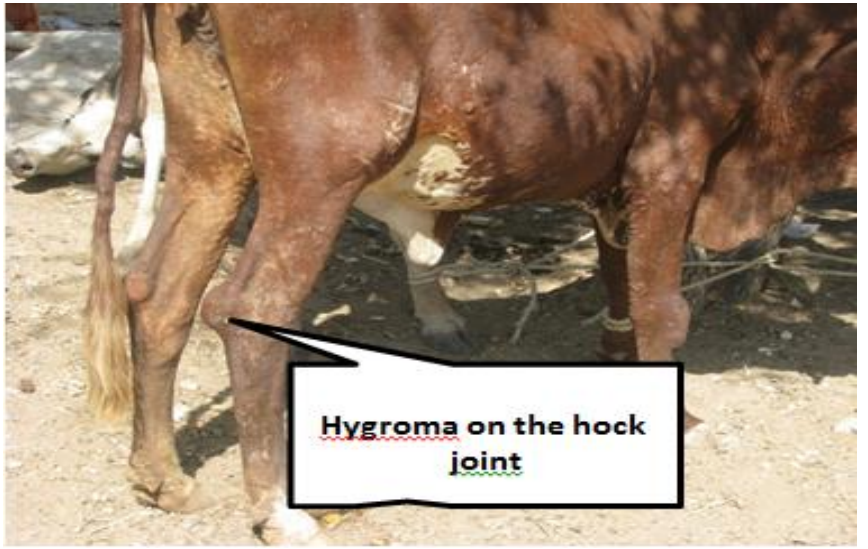
I. Effects of brucellosis onreproductive system



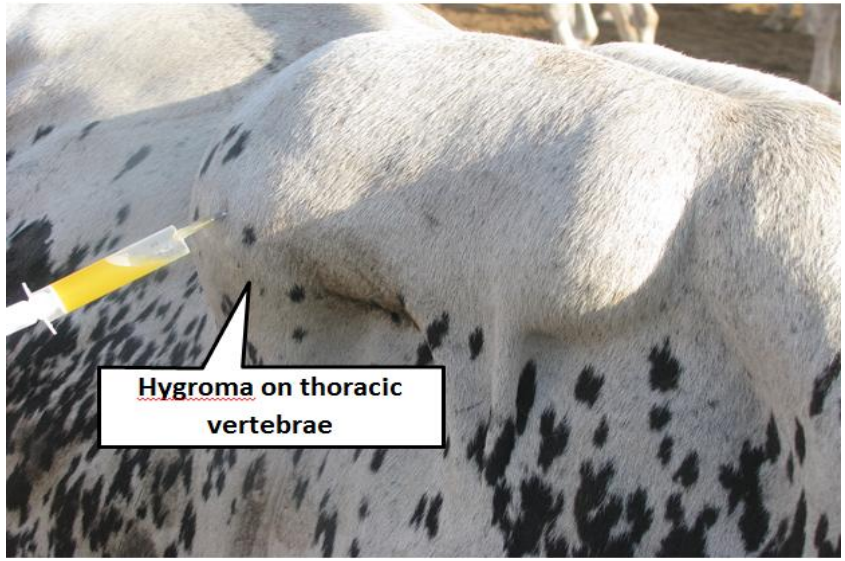
Stillbirth calf

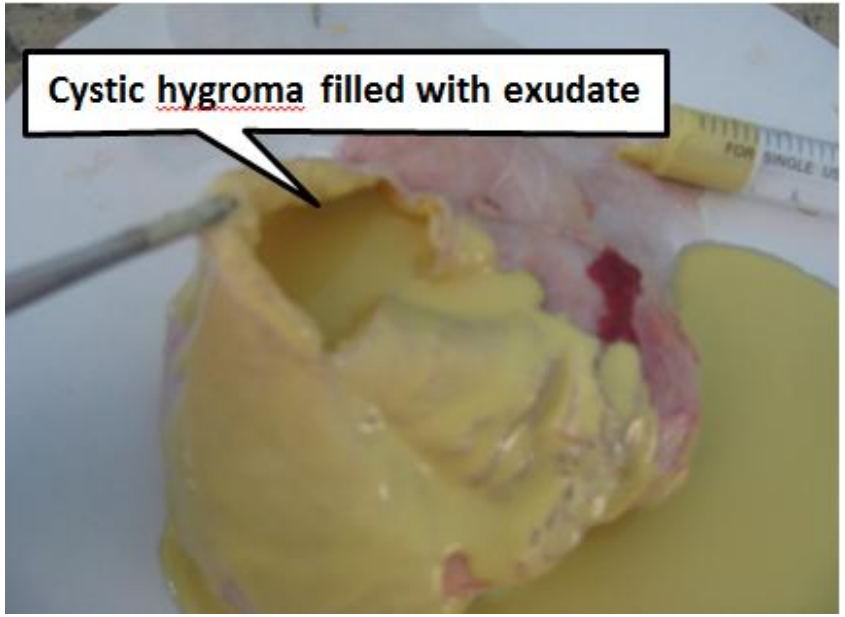
Weak calf

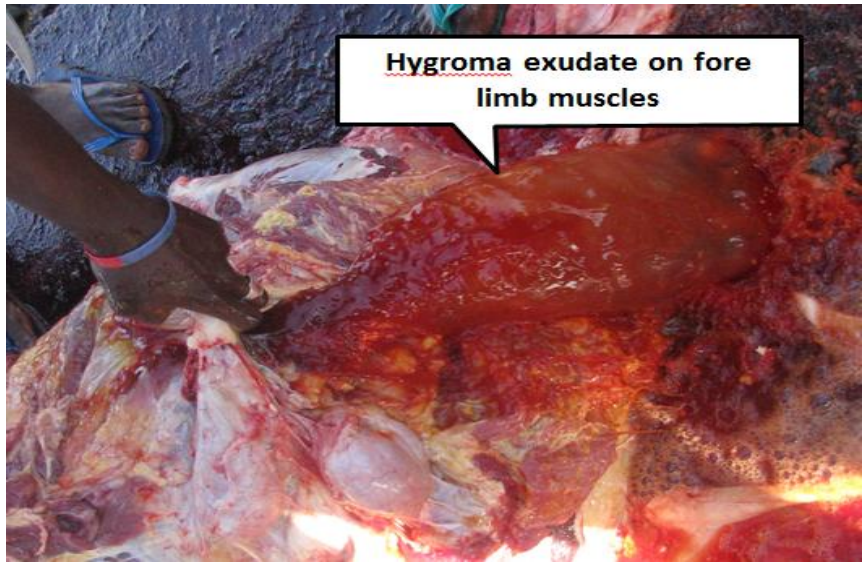
Retained placenta



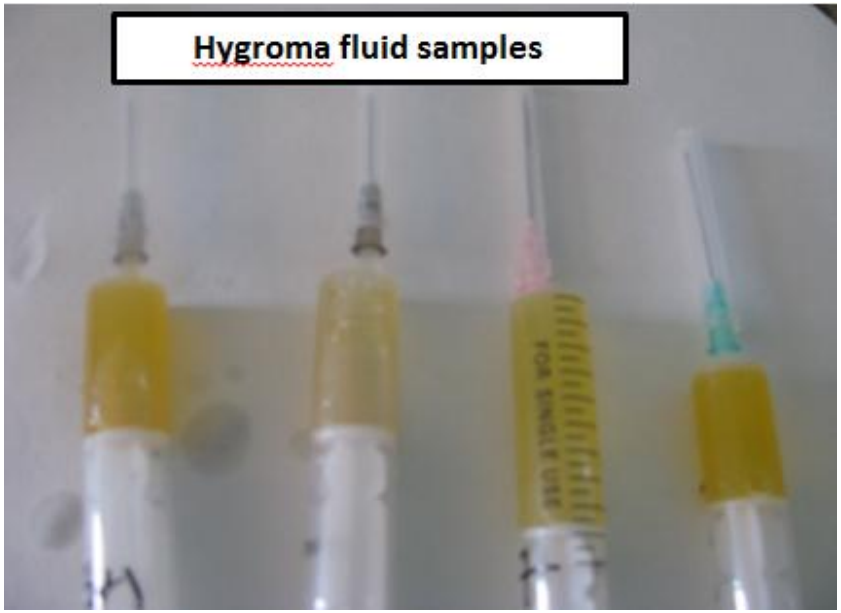
Mastitis

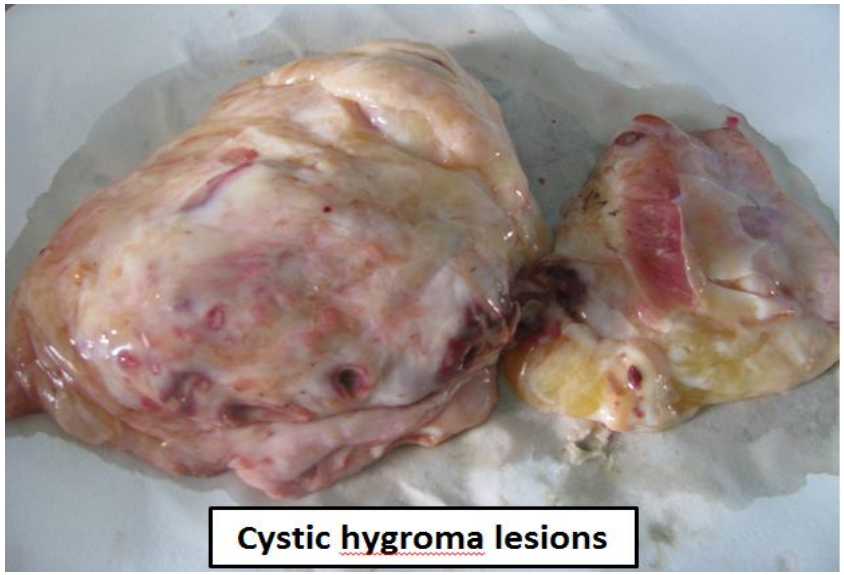




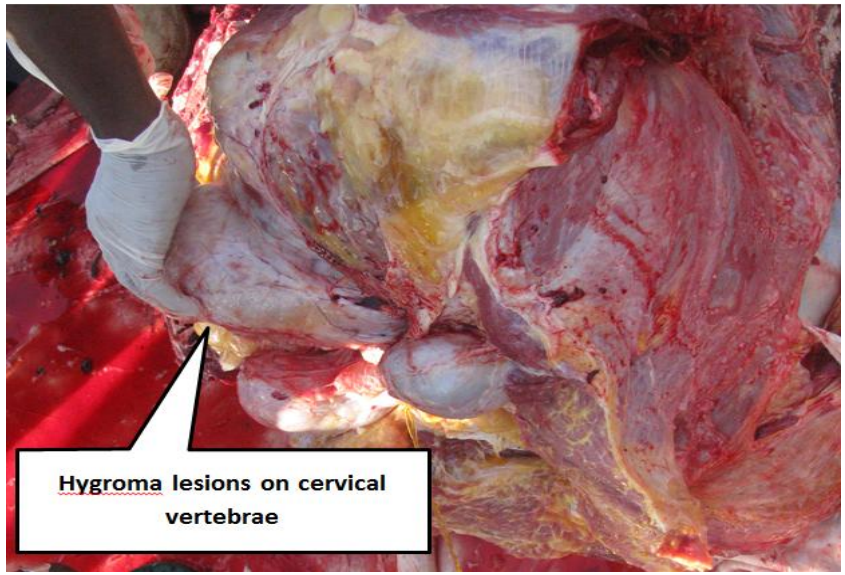


II. Effects of brucellosis on joints/muscles& nature of the fluid

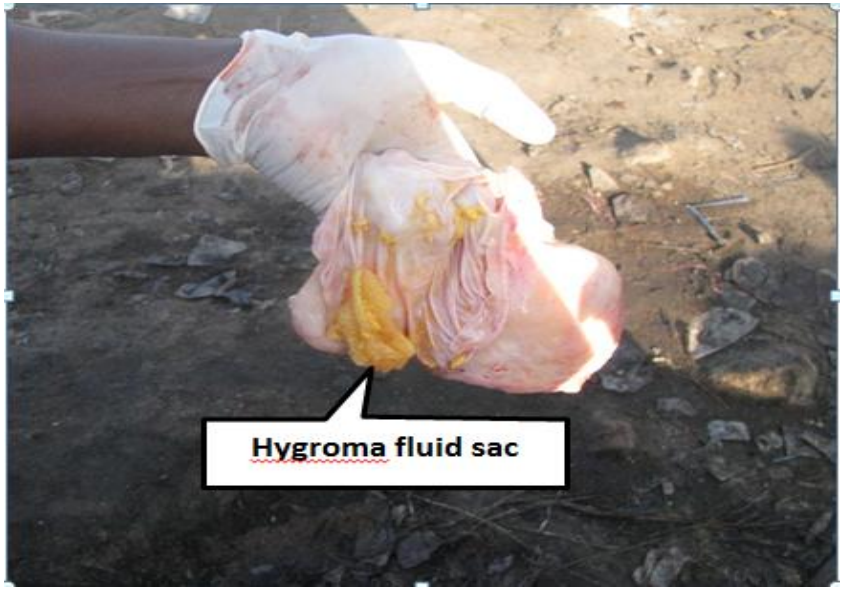




Hygroma on thoracic vertebrae



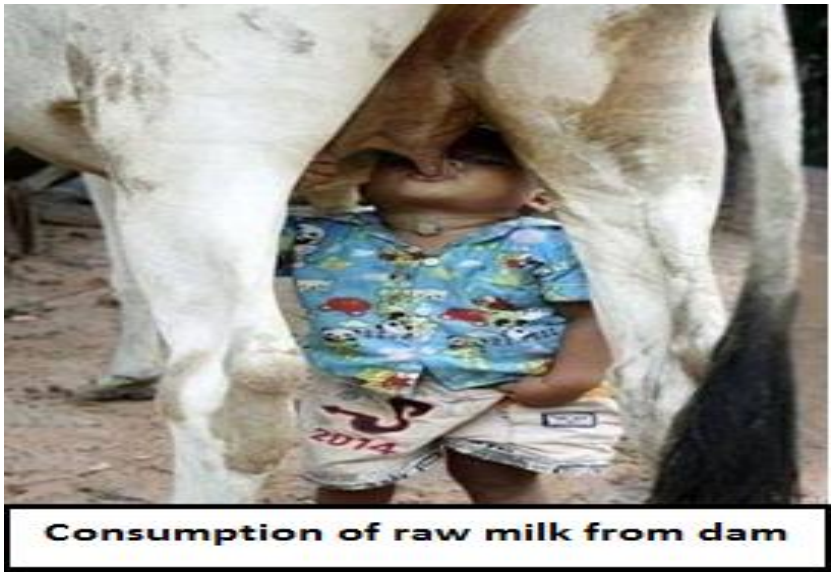
Cystic hygroma filled with exudate



Hygroma exudate on fore limb muscles

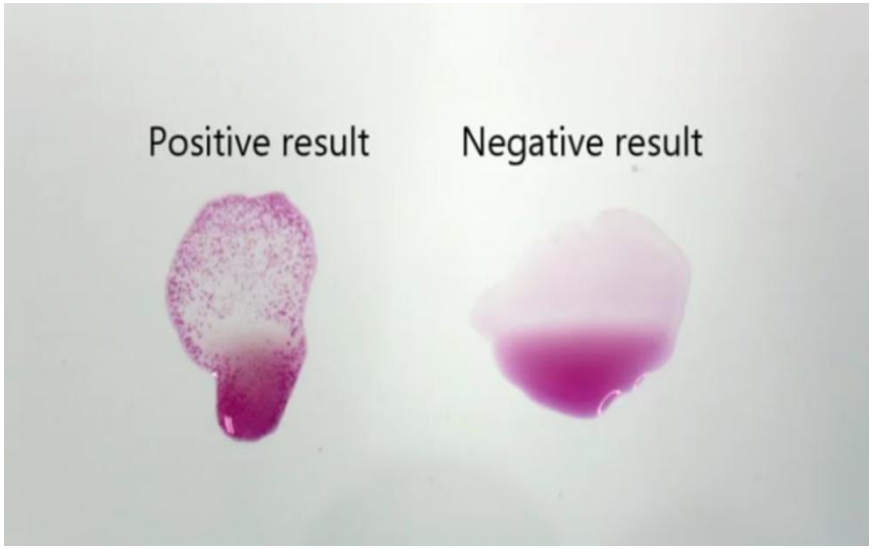
Hygroma fluid samples

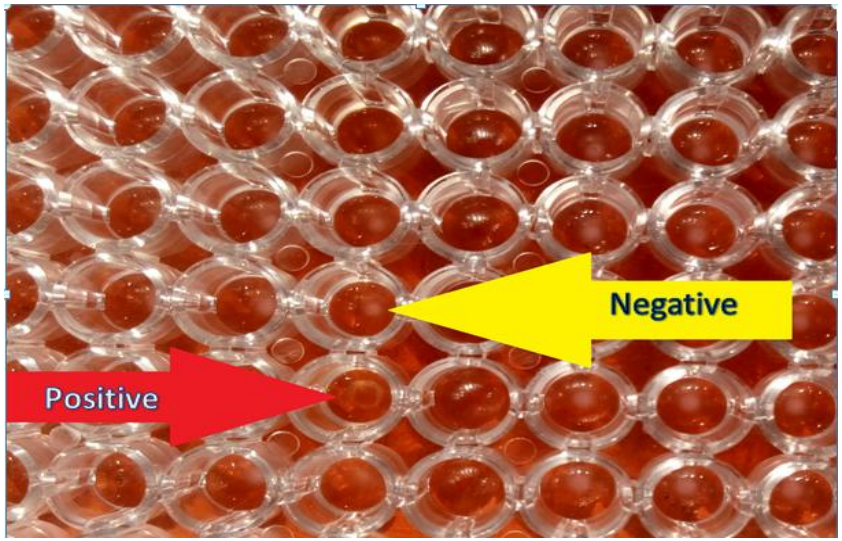
Cystic hygroma lesions



Hygroma lesion on hind limb

III. Transmission of brucellosis incattle and humansand the traditional practice for treatment of hygroma





IV. Laboratory pictures of the two tests results

Brucellosis positive and negative samples using (RBPT)

Brucellosis positive and negative results on micro plate using c-ELIS

RESULTS AND DISCUSSION

Data from the 4,745 samples from 271 herds used in the study showed 37% of all animals were RBPT positive, and after confirmation with c-ELISA the overall animal-level seroprevalence was 26.3%. Based on herds examined, there were 225 herds (84.9%) with at least one animal testing positive based on RBPT and 210 herds (77.5%) based on c-ELISA. The herd-level seroprevalence of brucellosis in the three states combined, adjusted for the sampling weights, was estimated to be 77.5%.Interstate movement and trade in cattle across the country, as well as the nomadic nature of the pastoral Fulanis may have contributed to the high infection of brucellosis.

Twenty three per cent of all herds sampled and 30% of the infected herds had animals with hygromas. Of the 63 herds in which hygromas were present, 54 (64.3%) were from Adamawa, 7 (13.7%) from Kano and 2 (2.7%) from Kaduna states. Only one herd with cattle with hygromas (1.6%) was negative for brucellosis. Other clinical manifestations of brucellosis on the reproductive system, joints, muscles etc. were also observedwith varying nature of fluids and cysts. Furthermore, transmission in cattle and humans were noted.

The odds of brucellosis seropositivity were 3.5 times greater amongst pastoral herds than agro-pastoral herds in this study. The high seroprevalence of brucellosis in a pastoral management system may partly be attributed to long distance movement of cattle in search of pasture and water and co-mingling in communal grazing areas and at watering points, particularly during the dry season having adverse weather conditions and famine. During such times animals become concentrated on scarce pastures and around watering points, which may become contaminated with aborted foetal materials or fluids from infected normal calvings.

CONCLUSIONS

It is evident from this study that brucellosis is endemic in northern Nigeria with high seroprevalence. Various clinical manifestations were observed in cattle in the study areas, affecting differentbody systems. Increased education and farmer extension, particularly amongst the nomadic Fulani, regarding the zoonotic risk associated with milk consumption and contact with aborted materials, and implementation of appropriate control measures are recommended.

ABSTRACT

The study was conducted to determine the prevalence of fasciolosis in nomadic pastoralist's cattle herds in Oyo state, Nigeria.Faecal samples were collected from 750 apparently healthy cattle. An overall infestation of 399 (53.2%)were recorded. The prevalence from three selected geographical zones in the state were82.0%, 34.8% and 42.8% for Ibarapa, Ogbomoso and Oke-ogun zones respectively. Thebreeds based prevalencerecorded were Bunaji168 (50.9%), Bukoloji 125(50.8%) and Rahaji 106(60.9%).Based on sex,the result revealed higher prevalence in females 266(56.7%) than males 133(50.4%). In relation toage,higher prevalence was recorded in adultswith 249 (56.1%) and the least inyoung with 150(49.0%).Seasonal distribution of the diseaserecorded were 36.9%,57.4%,73.4% and 44.9% for early dry, late dry, early wet and late wet seasons respectively.There was significant association between the prevalence of fasciolosis and location and season at $P<0.01$. However, no significantassociation was observed between the prevalence of the disease and the sex, age and breeds of cattle ($P<0.05$). The result of the study showed the presence of fasciolosis in the study area. It is recommended that periodic medication of affected animals and public enlightenment of the nomads on the mode of transmission of fasciolosis should be employed. Control of snails intermediate host is also essential for the control of the disease.

Key Words: Cattle,Fasciolosis, Nomadic, Pastoralists, Prevalence

INTRODUCTION

Fasciolosisalso known as fascioliasis is an important disease caused by trematodes of the genus *Fasciola*. *Fasciolagigantica*and *Fasciola hepatica* species are responsible for the disease in tropical and temperate regions respectively (Damwesh and Ardo, 2012). Fasciolosis caused by *Fasciolagigantica*is responsible for heavy economic losses to farmers due to reduced weight gain, poor carcass quality, reduced milk yield, cost of treatment and control, mortality and condemnation of affected livers at abattoirs and slaughtered slabs in Nigeria (OdigeandOdigie, 2013; Yahaya and Tyav, 2014).

Walker *et al.* (2008) indicated that the life cycle of *Fasciola* worms involved snail as an intermediate host. The species of snails involved in their life–cycles vary according to geographical distribution and climatic differences. The *Lymnaenatalensis* is the snail for *Fasciolagigantica* and *Lymnaetrucatula*is the intermediate host for *Fasciola hepatica* (Bhatia *et al.*, 2014). The life cycles of *Fasciola*involves five larval stages commencing with eggs which hatches into Meracidium, Sporocyst, Radia, Cercaria and Metacercariae (Anawat*et al.*,2015).

Fasciolosis is transmitted by ingestion of metacercaria-infested forage or drinking water containing floating metacercariae (Arjona*et al.*, 1995).Among many parasitic problems of farm animals,fasciolosisis a major disease which imposes direct and indirect economic impact on livestock production particularly of cattle and sheep (Keyyu *et al*., 2006). Fasciolosis is enzootic in Nigeria and is of great economic importance especially in the northern part where stagnant water and fadamas are used as watering and grazing sites during the dry season (Biu*et al.*, 2006).

The pathological manifestations depend mainly on the number of metacercariae of *Fasciola*ingested;these may results in acute, sub-acute or chronic fasciolosis(Bhatia *et al.*, 2014;Walker *et al*., 2008).

According to Suhardono*et al*. (2006) the form of the *Fasiolosis*thatoccurs will depend on the numbers of infective metacercariae ingested and the period of time over which they are ingested. Acute fasciolosisin ruminant is often a syndrome of death without apparent clinical abnormalities (Kelly, 1999). In Sub-acute fasciolosis the infected liver is seen covered with migratory tracts, infiltration of white cells is more in evidence and early fibrosis maybe seen. While in chronic fasciolosisthere will be loss of weight, sub-mandibular edema and pale mucous membrane.Over a period of weeks shedding of wool or hair may occur in sheep and cattle, also in cattle there will be reduction in milk and chronic diarrhea (Bhatia *et al.*, 2014).

MATERIALS AND METHODS

Faecal samples were collected from 750 nomadic pastoralist cattle from thethree selectedgeographical zones of Oyo State and examined for the presence of fasciolosis using standard sedimentation technique as described by Hanson and Perry (1994). Structured questionnaires were administered in collection of data on the location, sex, age and breeds of cattle.

RESULTS AND DISCUSSION

The study revealed the overall prevalence of392(52.3%). This corresponds with 52.1% reported by Olusegun-Joseph*et al*. (2000)from Zaria and 54.0% prevalence observedin Gwagwalada abattoir Abuja by Idris *et al*. (2004).In addition, a higher prevalence of 94.8% was reported by Yohanna*et al*. (2012) in Jos.However, lower prevalence of 46.6% and 2.37% were reported by Hassan and Anwo (2010) and Oladele-Bukala and Odetokun (2014) respectively.

Based on locations,the result showedthe highestinfectionof 82.0% in Ibarapafollowed by 42.8% in Oke-Ogunand 34.8% inOgbomoso zones. The high prevalence in Ibarapa zone mightbe due to more favourable environmental conditions of the area such as presence of flooded natural pastures, water shed areas, ponds and rivers which favour the development ofsnail intermediate hosts.It may also be associated with the fact that the zone is neighbouring Ogun State which is characterized by lots of swampy areas and lagoons that may favour the growth of greener pastures that may attract nomadsmigration during the dry season resulting in congregation of the cattle which will enhance the spread of fasciolosis than in other zones. There was significant association between the prevalence of fasciolosis and location at $P<0.01$ in this study.

Breed based prevalence indicated 60.9% in Rahaji, 50.9% in Bunaji and 50.8% in Bokoloji. In relation to sex, the result revealed the highest prevalence in female (56.1%) than male (50.4%).The lower margingrecorded between the prevalence in males and females may be associated with close cohabitation of the animalsas nomadic pastoralist keep both females and malestogether and grazed them onsame pasture and move in search of food and water together which could expose them to similar risks of infection.

The prevalence among the age groups showed that older cattle aged>3 years had higher prevalence of (56.1%) than younger once aged <3 years with (49.0%). This agrees with the report of Iboyi*et al*. (2017) who indicated that fasciolosis prevalence is higher in adult than young cattle.However, the resultsof this study showed no significant association between prevalence of fasciolosis and breed, sex and age of cattle at $p<0.05$. This is in line with the finding of Magaji*et al*. (2014) and Adang*et al*. (2015).

Regarding seasons, the distribution of the disease indicated highest infestation in early wet season with 138 (73.4%) followed by late dry season 108 (57.4%), late wet season 84 (44.9%) and early dry season 69 (36.9%). This corresponds with the report ofDamwesh and Ardo (2012) who also observed that the prevalence of fasciolosis was high before and during the onset of rainy season in Adamawa State, Nigeria. Similar resultswere reported by various researchers (Qureshi *et al*., 2012; Shahzad*et al*., 2014).There was significant association betweenprevalence fasciolosis and seasons at$p<0.01$.

CONCLUSIONS AND RECOMMENDATIONS

The results of the study showed that fasciolosis is enzootic in the study area which may affect the performance of the cattle resulting in hugeeconomic losses. It is recommended that all animals in the study area should be dewormedwith broad spectrum anthelminthic in the beginning and end of each rainy season, indiscriminate used of flukicide should be avoided as it could lead to the development of drug resistance and nomads should be educated on methods of prevention and control of the disease.

ABSTRACT
A retrospective study was conducted on prevalence of *Pests-des-PetitsRuminantum* (PPR)and helminthosisfromKundila veterinary hospital and Gwale veterinary clinic, Kano state, Nigeriabetween2012 and 2016. The investigation revealed the presence of the diseases in the study area. The results recorded showed the highest prevalence of PPR during early rainy season(34.98%), whereashelminthosis was observed to be higherduring the late rainy season (40.00%).Based on species, PPR tended to be higher in goats than sheep; 76.88% and 23.12% respectively. On the other hand, sheep were more susceptible to helminthosis(65.49%) than goats (44.71%). Regarding sex of the small ruminants, both the diseases were more prevalent in females than males:PPR;females (60.31%),males (39.68%) and helminthosis;females (54.26%)males (45.74%). ThePPR and helminthosis are important diseases of small ruminants which may affect their productivity. The results indicated that the diseases occurred throughout the study period and all year round with varying intensities. The occurrenceofthe diseases in both species were statistically significant ($P<0.05$) in relation to sex, season, species and annual distribution. It is recommended that farmers should be enlightened on the effects of the diseases, routine management and seeking prompt veterinary attention in cases of outbreaks.Annual vaccination against PPR isemphasized.

INTRODUCTION
Nigeria has an estimated populationof 490 million Sheep and 483 millionGoats. The contribution of livestock to the overall food output in developing countries is increasing faster than that of cereals. In 1990, meat production increased from 69million tones to about 105million tones by the year 2000 (FAO, 2003).Small ruminants constitute an important source of animal protein to Nigerians. A lot of socio-economic importance is therefore attached to ownership of these animals. In some cases, it may be the only reliable wealth of a rural household. This economic importance is primarily associated with their small size, as it favours low investment, small risk of loss and their high reproductive efficiency (Omoike, 2006). Sheep and goats are major sources of food and fiber and play very significant social and economic roles in developing countries. Sheep and goats' secondary functions include the production of milk, wool, skin and manure (Tefera *et al*., 2009).

Pests-des-PetitsRuminantum (PPR)is endemic in various parts of the world including Nigeria(Peacock, 1998;ILCA, 1991). The PPR was first described in sheep and goats in 1956 in Ivory Coast (Cote D'voire) and the Republic of Benin. Small ruminants in all climatic zones of Nigeria are affected by the disease (Peacock, 1998). It has been among the most devastating diseases of small ruminant production in Nigeria. PPR is Rinderpest-like in manifestation and still has a great influence on animal protein supply in many countries (ILCA, 1996).

Helminthosis is a disease or group of diseases which affects animal hosts caused by parasitic worms known as *helminiths*. The infestation is prevalent and constitutes a serious economic problem in livestock. Helminthosis is also a serious risk to humans and companion animals such as dogs, cats and other pets (WIPO, 1994). The rate of development of the parasites tends to increase with rise in temperature and moisture which are factors known to be common in Nigeria, particularly in the northern part. The parasites develop rapidly to the infective stage (Williamson, 1989), and are controlled using various forms of anthelminthic (Peacock, 1998).

RESULTS AND DISCUSSION
The results obtained revealed the variation in the clinical prevalence of both PPR and helminthosis in sheep and goats in the study area. Goats appeared to be more susceptible to PPR than sheep with 3,927 (76.88%) and 1,181 (23.12%) respectively. This is in line with the report of Tail (1984) which

stated thatGoats are often affected by the acute form of the disease while sheep usually suffer from the sub-acute or chronic form. Also, according to Obi (1992) sheep are found to be less affected with PPR than goats.

On the contrary to the findings on PPR above,helminthosisis found to be higher in sheep than goats with 3,422 (65.49%) and 1,803 (34.51%) respectively. This is in line with the results of Downie (1990) who recorded higher prevalence of helminthosis in sheep than in goats.

Based on sex, female sheep and goats showed higher frequency for all the diseases than their male counterparts.This trend is similar with the report of Egwurube and Ofukwo (2002) who indicated higher cases of helminthosis and PPR in females than males small ruminants.

The seasonal distribution of PPR and helminthosis in sheep and goats seem to occur all year round with varying prevalence. In the case of PPR, the highest infestation of 1,784 (34.98%) occurred during the early rainy season followed by the early dry season1,736 (33.99%), then late dry1,073 (21.01%) with least prevalence during the late rainy season 512 (10.02%).The rise in the prevalenceduring the early rainy season and the fact that the disease is mostly encountered all year round is in agreement with the findings of Obi (1990) and Tamburawa (1997) from southern Nigeria.

In case of helminthosis, the highest number of cases was encountered during the late rainy season 2,090 (40.00%). This is in consonance with the findings of Smyth (1996) who stated that these parasites require a period of development outside the host before becoming infective and that the rate of their development and survival are influenced by climatic and environmental factors such as a rise in temperature and moisture. Also, eggs of some trematodes such as *Fasciolahepatica* and *Fasciolamagna* are found to be wide spread in wet, swampy or sub-irrigatedareas which support the emergence of substantial population of their intermediate hosts(snails).

Annually, thedistribution of the disease revealedthe total of 5,108 cases of PPR in both sheep and goats within the study period (2012 – 2016). The highest prevalence of 1,403 (27.47%) were recorded in the year 2016 while the lowest prevalence of 612 (11.98%) was observed in 2014. Thisresultcorresponds with that of Taylor *et al*. (1990), who reported that the disease follows a cyclic pattern with significant increase in prevalence every 3 – 4 years.

For helminths, 5,225 cases were recorded with the highest of 1,501 (28.73%) in 2016. The lowest number of cases of 682 (12.02%) was obtained in 2013. The trend of the disease showed an increasing pattern. Thisis in agreement with the suggestionof Peacock (1996) that the probable increase in animal population and inadequateknowledge of the disease by farmers and poormanagement practices such as lack of regular deworming lead toincrease of the disease.Theresult of the study indicated that occurrence ofthe diseases in both species were statistically significant ($P<0.05$) in relation to sex, season, species and annual distribution.

CONCLUSIONS AND RECOMMENDATIONS

The investigation revealed that thediseasesareendemic in the study area with an increased in prevalence in both species.Theoccurrence of the diseases was affected byspecies, sex, season and annual distribution.Farmers should be enlightened on the effects of these diseases, need to seek for prompt veterinary attention and improved management practices such as good hygiene and annual vaccination against infectious diseases especially PPR.

ABSTRACT
This retrospective study was aimed at determining the prevalence of tuberculosis in cattle slaughtered in Jos abattoir from 2010 to 2016. A total of 41,607 cattle were slaughtered during the periodwith an overall prevalence of 3.3%. The result showed highest number 876 (8.6%) of tuberculosis lesions in 2010 and the lowest 7 (0.1%) was observed in 2014. There was seasonal trend of tuberculosis lesions with peak prevalence in early rainy season. In terms of months, May showed the highest and December the lowest prevalence. The study showed that bovine tuberculosis is prevalent in Plateau state. Government at all levels should organize public enlightenment campaigns aimed at highlighting the zoonotic importance of bovine tuberculosis among butchers, livestock owners, veterinarians and meat handlers who are at high risk of acquiring the disease. Proper meat inspection at the abattoirs should also be employed.
Key words: Bovine, prevalence, retrospective, tuberculosis,

INTRODUCTION
Tuberculosis (TB) is an infectious, chronic and debilitating disease caused by acidfast, rod-shaped bacillus *Mycobacterium tuberculosis* which typically affects the lungs but can affect other organs (WHO, 2001).Bovine tuberculosis results from infection with *Mycobacterium bovis* that occasionally affects other species of mammals butcattle are the primary host (Abubakar *et al*., 2005). It is a zoonotic disease that can spread to humans typically by the inhalation of aerosols, ingestion of unpasteurised milk or through breaks in the skin. Raw or undercooked beef can be a source of infection (Ameen *et al*.,2008).In most cases, *M. bovis* is transmitted between cattle in aerosols during close contact. Drinking raw milk is the primary route of *M. bovis* infection in humans; hence human tuberculosis caused by *M. bovis* is mostly extra pulmonary, particularly in cervical lymphadenitis (Ameni and Erkihun, 2007).
Although bovine tuberculosis was once found worldwide, control programs have eliminated or nearly eliminated the disease from domesticated animals in countries like Denmark and Sweden(Ashford *et al.*, 2001; Ameni and Erkihun, 2007). Bovine tuberculosis is still widespread in Africa, parts of Asia and some Middle Eastern countries (Assaged*et al*., 2000).According to WHO Report (2011), tuberculosis continues to be a global priority. In 2010, an estimated 8.5–9.2 million tuberculosis cases were reported globally along with 1.2–1.5 million deaths (including deaths from TBamong people living with HIV). Asia and Africa are disproportionately affected with 57% and 26% of the disease burden, respectively (WHO, 2011).

MATERIALS AND METHODS
Surveillance records of slaughtered cattle and suggestive tuberculosis lesions examined at postmortemfrom 2010-2016 in Jos abattoirPlateau State was used.Characteristics TB lesions on organs were diagnosed by veterinary officers andsimple percentages were used in analyzing the result.

RESULTS AND *DISCUSSION*
Records on annual slaughtered cattle and suggestive TB lesion cases at Jos abattoir, Plateau State, Nigeria showed that a total of 41,607 cattle were slaughtered from 2010-2016, out of which 1,373

(3.3%) were found with lesions of tuberculosis at post mortem. The record reviewed revealed that, the highest number 876 (8.6%) of tuberculosis lesions in cattle were recorded in 2010 followed by *275 (5.6%) in 2011.* However, the lowest prevalence of (0.1%) was recorded in 2014, then (0.2%) prevalence in 2015 and 2016 consecutively. The low prevalence observed in this study may be due to under reporting and reduced activities at the abattoir as a result of extensive religious and ethnic crisis experienced in the study area.

Information on bovine tuberculosis in Plateau State is limited, though TB was the most common pathology encountered at abattoir*(*Lilian *et al*., 2016).*Below arethe annual results (Figure 1) and monthly distribution of suggestive tuberculosis lesions (Figure 2).*

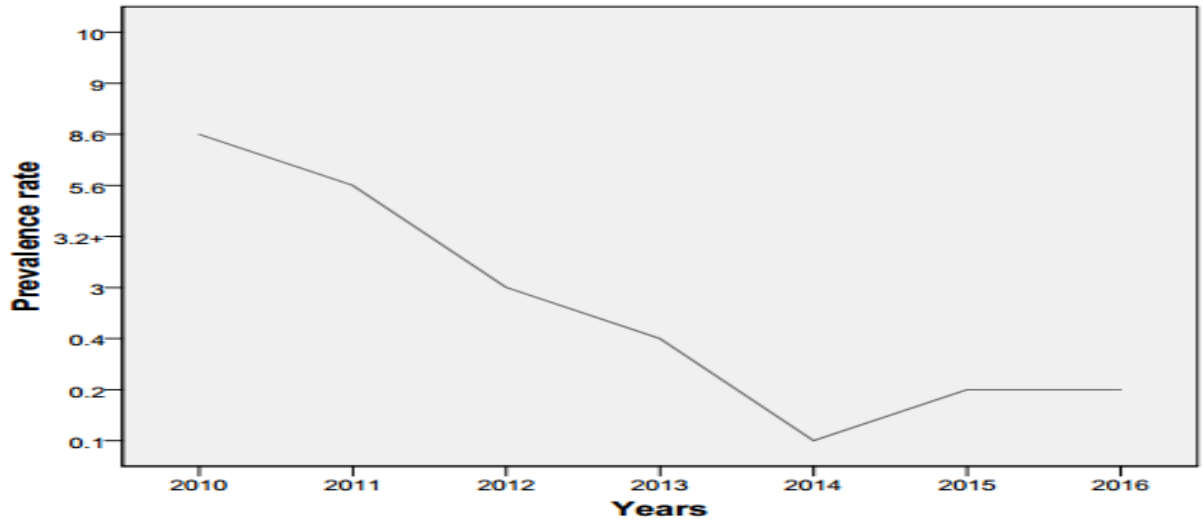

Figure 1:*Overall prevalence of TB lesions in cattle from 2010-2016.*

The finding of this study showed that TB is more prevalent during the months of May(most critical) and least in December (Figure 2). This supports the report of Perry *et al*. (2002) who stated that the detection of tuberculosis lesions was influenced by season and it was higher during stressful periods such as inter-season and peak-season periods and also when slaughtering was elevated. In addition, similar observation was reported by Bikom (2005) in Cross River State abattoir indicating strong association between the occurrence of tuberculosis lesions and seasonal distribution.

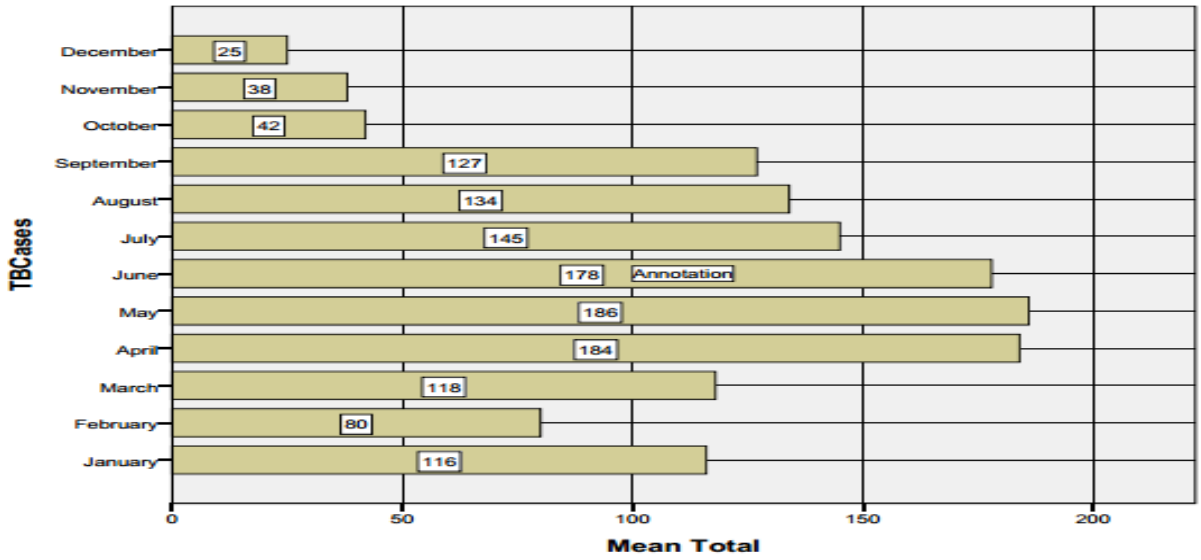

Figure 2: *The number per month of suggestive tuberculosis lesions from slaughtered cattle at Jos South abattoir, Plateau State*
Nigeria 2010-2016.

The reasons responsible for the wide fluctuation in annual distribution of the TBduring the entire period of the study were not clear. However, inadequacies in capacity building and lack of thoroughness of the veterinary staff carrying out meat inspection could have played major roles. These agree with Perry *et al*. (2002) who reported that postmortem surveillances for detection of bovine TB lesions in particular depend on the work load, time and diligence of the inspectors conducting the examinations.It was also common that when veterinary staff inspect carcasses, condemn and seize infected meat and meat products for disposal, some pathological cases may be missed completely due to lack of adequate personnel in the abattoirs couple with rough behaviors of butchers and meat traders. In addition, with repeated meat inspections, butchers acquire ample knowledge about the nature of pathologies that can lead to condemnation of carcassesand therefore avoid condemnation of their products by the veterinary staff. Furthermore, unruly butchers could obstruct inspection of their carcasses or hide lesions from meat inspectors.

CONCLUSIONSAND RECOMMENDATIONS

The study showed that tuberculosis is present in the study area and adds to the existing evidence depicting lack of adequate knowledge on the effect of tuberculosis.Public awareness is essential to avoid theconsumption of improperly cooked meat especially lungs and the zoonotic nature of TB. Condemnedmeat should bediscarded, burnt or buried and owners of such should beadequatelycompensated. Proper surveillance/ambulatory servicesshould be carried out within the state and its environs, for diagnosis and treatment of infected animals.This information can serve as critical input for health programmesaiming at tackling the cases of tuberculosis in bothanimals and humans.

ABSTRACT
The study was conducted at Area Veterinary Clinic Ran Road Bauchito investigate the prevalence of turkey pox in turkeys from 2010 to 2017. A total of14,596 turkeys were presented, out of which 1,822cases of turkey pox were recorded within the study period. The highest prevalence of 28.3% was observedin 2010and the least (6.4%) in 2013. turkey pox overall monthly prevalence was higher in the month of September and August with 15.4% and 13.4% respectively and the lowestprevalence was recorded in November with 4.8%. In addition,turkey pox overall prevalence was higher in poults/hens than chicks/tomswith 58.9% and 41.1% respectively. Similarly, the overall prevalence was higher in poults/chicksthan hens/tomswith 72% and 28% respectively. Out of the total number of cases recorded during the study period, late rainy season accounted for the highest prevalence of 39.2%, followed by late dry season 26.7%, early dry season 17.3% and early rainy season 16.9%. However, season and sexhave nostatistically significant difference on disease occurrence whereas ageis significant ($p<0.01$). The findings of this study indicate that, turkey pox is an important avian disease affecting turkeys which may decrease their productivity. Therefore, it is recommended thatturkey farmers should be enlightened on methods of prevention and control whichshould include vaccination and use of netted cages/houses to control vectors of the disease.
Key words: Poults, Prevalence,Retrospective,Toms,Turkeypox.

INTRODUCTION
The production and consumption of eggs and poultry meat is increasing worldwide. Over the last quarter of a century, the consumption of eggs has doubled and chicken meat tripled (Jordan and Pattisons, 2001). Poultry production forms an important component of Nigeria's livestock sector as a provider of employment and income. Over 70% of those who keep livestock are reported to keep poultry birds for the production of day old chicks, meat, eggs, and poultry manure for rural, urban and semi-urban populations (Amar-Klemesu and Maxwell, 2000; Eduvie, 2002). Poultry sector is next to ruminants as a source of animal protein supply in Nigeria and accounts for about 25% of local meat production (Ajala and Alli-Balogun, 2004).
There are many underrated, but highly promising poultry species such as turkeys, quails and guinea fowls. Turkey (*Meleagrisgallopavo*) is a type of poultry species with numerous attributes; turkey thrives better under arid conditions, tolerates heat better and has higher quality meat (Yakubu*et al.,* 2013). Currently, turkey production is an aspect of poultry industry whose potentials have not been fully utilized and is one of the most suitable alternative sources of animal protein supply in Nigeria considering the cost of production (Ibe, 1990; Peters *et al.*, 1997).Smith (1990) reported that carcasses of turkeys contained a higher percentage of protein than the carcasses of chickens.
Diseases have been the major constraint in rearing domestic poultry especially in developing countries (Van-Riper and Forrester, 2001). Turkeypoxis one of the most commondiseases in the wild turkey population(Wright *et al.*, 2005). It is caused by turkeypox virus of the genus *Avipoxvirus* under the family *Poxviridae*(Timoney, 1988). Like all avipoxviruses, is transmitted either through skin contact or by arthropods (typically mosquitos) acting as mechanical vectors(Wobeser, 1997).*Avipoxvirus* infections have been reported in over 232 bird species in 23 orders of birds, but most of our knowledge comes from the study of *fowlpox* virus and *canarypox* virus as they are the only species with full genome sequences available (Weli and Tryland, 2011).

Turkey Pox is a worldwide, slow-spreading disease characterized by formation of progressively increasing nodular lesions in part of the unfeathered skin such as head, upper neck and eyelids (cutaneous form) that progresses to thick scab or fibrin necrotic and proliferative lesions in the mucous membrane of the upper respiratory tract, mouth, and oesophagus (diphtheritic form) (Jordan and Gordon, 1982; Docherty *et al*., 1991). A concurrent systemic infection may also occur (Abdu and Musa, 2014).

MATERIALS AND METHODS

Recorded data on cases of turkey pox for eight years (2010-2017) presented to the veterinary clinic Ran Road Bauchi, Bauchi State were considered. The disease was diagnosed based on flock history, clinical signs and post mortem findings. The distribution of the disease based on sex, age, seasons and months of the year were obtained during the study.

RESULTS AND DISCUSSIONS

A total of14,596 turkeys were presented to the veterinary clinic, out of which 1,822cases of turkey pox were recorded within the study period. This gives an average of about 228 cases annually. The year 2010 recorded the highest number of cases 515(28.3%), while the lowest prevalence of 117(6.4%) were recorded in 2013 (Table 1). The results confirmed the high prevalence of turkey pox in the study area. The disease may be exacerbated by other pathogens such as viruses of Newcastle disease, infectious bronchitis and fowlpox, and also *Haemophilusparagallinarum* and *Mycoplasma gallisepticum*. Deficiency of Vitamin A and excess ammonia in the atmosphere may also predispose to severe turkey pox infection (Jordan and Patherson, 1999).

Table 1: Yearly distribution of positive cases of turkey pox in Bauchi metropolis during the eight year period (2010 – 2017)

Year	Number positive	Percentage +ive
2010	515	28.3
2011	222	12.2
2012	181	9.9
2013	117	6.4
2014	153	8.4
2015	194	10.6
2016	214	11.7
2017	226	12.4
Total	**1,822**	**100**

In relation to sex, poults/hens are found to be more infected than chicks/toms with 1074(58.9%) and 748(41.1%) prevalence respectively. This may not be unconnected to the fact that, farmers usually keep high number of poults/hens than chicks/toms in the study area.

Based on age, a total of 1,310 cases were recordedin poults/chickswhich account for (72%) prevalence whereas512(28%)prevalence were recorded in hens/toms.This corresponds to the report of Odoya*et al.* (2006) which reported higher outbreak in young turkeys in VomPlateau State, Nigeria. The high prevalence in young ones could also be associated with the under developed immune system of the young ones which make them more susceptible to the infection than adults.

In relation to the season, the overall prevalence revealed the highest infection in late rainy season with 713 (39.2%), followed by late dry season 487 (26.7%) and early dry season 314(17.3%). The least prevalence was recorded in the early rainy season 308 (16.9%).The monthly distribution of the disease indicates a steady rise from July through Augustand the peak in September. This represents the rainy season when there is high presence of the disease vectors (mosquitoes) responsible for transmitting the disease causing organism to the susceptible hosts (turkeys).This agrees with the findings of Anon (1991) whostated that when mosquitoes are plentiful, transmission within the flock may be rapid. Furthermore, in another study,Odoya*et al*. (2006) reported the outbreak of the turkey

pox inVom, Plateau State, Nigeria in the month of June which also indicated the highoccurrence of the disease in the rainy season.In this study,there was no significant difference observed between the prevalenceof turkey poxwith sex but with ageat $p<0.01$.

CONCLUSIONS AND RECOMMENDATIONS

The study showed that turkey pox is a major constraint affecting turkey production in Bauchi metropolis causing economic losses by reducing productivity, predisposing affected birds to secondary infections; attract treatment cost thereby increasing cost of production.Birds of all sexes and ages are susceptible to the infection. It is recommended that control measuresagainst mosquitoes should be adapted as the potential preventivemeasure.Fowl pox vaccine is the most common vaccine used against the infection in Nigeria. However, development of turkey pox vaccine from turkey pox virusis strongly recommended for effective prevention of the disease.

ABSTRACT

In order to ensure sustainable pig production in most tropical countries, alternative flooring systems need to be investigated and adopted. A five-week experiment was carried out to investigate the growth performance and skin lesion score of 36 weaned pigs, separated into four treatments with three replicates each, in a completely randomized design. The treatments include three different heights of Guinea Grass Straw (GGS): T1 (without GGS): concrete floor, T2: 0.1m high GGS, T3: 0.2m high GGS and T4:0.3m high GGS. Data were collected on growth performance: final weight, weight gain, feed intake and feed conversion ratio (FCR) and skin lesion (front, middle and rear). All data obtained were subjected to analysis of variance (ANOVA). Weight gain 4.75kg (T3) was higher ($P<0.05$) when compared with 4.28kg (T2), 3.94kg (T4) and 3.34kg (T1). Final weight followed similar trend with pigs in T3 (9.94kg) having the highest weight compared with T2 (9.40kg), T4 (9.22kg) and T1 (8.55kg). Higher ($P<0.05$) FCR was recorded for T1 (4.72) while the least was in T3 (3.39). The result for skin lesion for the different parts observed, revealed the least lesion in pigs on T3 and higher occurrence in pigs on T1 (without beddings). Generally, skin lesions occur most at the front legs and heads. It can be concluded that the use of guinea grass straw at the depth of 0.1m and 0.2m can improve the performance of weaned piglets, while guinea grass straw of 0.3m high reduced skin lesions score.

Keywords: Beddings, depths, environmental enrichment, guinea grass, weaned pigs

INTRODUCTION

The value of enrichment materials for pigs could be higher if the materials are complex and compound (Jensen and Pedersen, 2007) and include one or more attractive food components (Olsen *et al.,* 2000). Studnitz *et al*. (2007) concluded that exploratory behaviour of pigs is best stimulated by materials that are complex, changeable, destructible, manipulable and contain sparsely distributed edible parts. Experts on pig welfare assign considerable importance to the availability of a substrate such as straw in their welfare assessments of housing systems (Spoolder *et al*., 2003). Enrichment and flooring are important factors affecting the incidence of injuries and stomach ulcers in pigs. Ariane *et al.* (2005) evaluated the impact of housing systems on the health and welfare of grower and finisher pigs. Evaluation of pig behaviours associated with health and welfare were assessed through indicators including presence of lesions on the snout, ears, shoulders, legs and tail. Ramis *et al.* (2005) found that the prevalence of limb lesions was much greater in barren-housed pigs (24% of observations) compared to pigs housed in sawdust-bedded barns (1% of observations). Guinea Grass (*Panicum maximum*) which is indigenous to Africa and widely distributed in West Africa, grows naturally in many parts of Nigeria, this could therefore help in boosting welfare-friendly pig production systems in Nigeria. Hence, this study was conducted to investigate the growth performance and skin lesion score of weaned pigs reared on guinea grass bedded pigsties.

MATERIALS AND METHOD

The experiment was carried out at the Piggery Unit of the Teaching and Research Farm, University of Ibadan, Ibadan, Oyo State.Thirty-Six (36) (Land race X Large white) weanling pigs were used for the study. The animals were kept and monitored for one week for acclimatization and proper adaptability before the commencement of the experiment. Animals were fed with commercial feed and water was provided *ad libitum*. The treatments were the control (without straw) and three different heights of Guinea Grass Straw (GGS): T1: concrete floor (without GGS), T2: Guinea Grass Straw (0.1m high), T3: Guinea Grass Straw (0.2m high), T4: Guinea Grass Straw (0.3m high). Growth performance data were collected on initial weight, feed intake, weight gain, final weight and feed conversion ratio (FCR).For the purpose of skin lesion assessment, the body of the pigs was divided into three parts. Each part received a score based on the number of lesions on it. The parts of the body assessed were: (1) front (head, neck, shoulders and front legs), (2) middle (flanks and back) and (3) rear (rump, hind legs and tail). To keep the scores consistent throughout the experiment, direct observation of the skin

following the checklist of Björklund (2005) was used. All data obtained were subjected to analysis of variance (ANOVA) using SAS 9.2 (2012) Software. Means were separated using Duncan's Multiple Range Test (DMRT) of the same statistical software.

RESULTS

PERFORMANCE CHARACTERISTICS

The effect of different height of guinea grass straw beddings on performance characteristics of weaned pigs was as shown in Table 1. The average initial weights ranged from 5.12kg to 5.28kg. There was no significant effect (P>0.05) of the different straw height on the feed intake, however, pigs in T1 consumed the highest feed (15.73kg) while the least was 15.56 in pigs on T3 and T4. There was significant (P<0.05) difference in weight gain, final weight and FCR. Weight gain in T3 (4.75kg) was higher compared to 4.28kg (T2), 3.94kg (T4) and 3.34kg (T1). Final weight followed the same trend with pigs in T3 (9.94kg) having the highest weight compared to T2 (9.40kg), T4 (9.22kg) and T1 (8.55kg). Highest FCR was recorded in T1 (4.72) while the least was in T3 (3.39).

Table 1: Effect of different height of guinea grass straw beddings on performance characteristics of weaned pigs

Depth(m)	Initial weight(kg)	Feed intake(kg)	Weight gain(kg)	Final weight(kg)	FCR
T1	5.21	15.73	3.34^{b}	8.55^{c}	4.72^{a}
T2	5.12	15.60	4.28^{ab}	9.40^{ab}	3.68^{b}
T3	5.19	15.56	4.75^{a}	9.94^{a}	3.39^{b}
T4	5.28	15.56	3.94^{ab}	9.22^{bc}	3.98^{ab}
SEM	0.22	0.05	0.17	0.11	0.13

^{a,b,c} means on the same column with different superscripts are statistically significant (P<0.05)

SEM: Standard error of means; T1: Concrete, T2: Guinea grass staw at 0.1m high, T3: Guinea grass straw at 0.2m high, T4: Guinea grass straw at 0.3m high, FCR: Feed conversion ratio

SKIN LESION OBSERVATIONS

The mean skin lesion score on the front body part among the treatments is reported in Figure 1. It was observed that the control treatment (T1) had lesions at the various parts (front legs (1), shoulder (1), neck (1)) and recorded the highest score (2) for head among the treatments. The least lesion was recorded in GG 0.3 where lesion was observed only in the front leg (1). Figure 2 illustrates the mean skin lesion score on the middle body part of the pigs among the treatments. T2 and T4 had no record of lesions. However, the control (T1) and T3 recorded a lesion score of 1 each on the flank. Figure 3 shows the mean skin lesion score on the rear body part of the pigs among the treatments. There was no record of lesion on pigs in T3 and T4. However, the control (T1) had lesion records for hind leg (1) and tail (1) while T2 had a lesion record for hind leg (1).

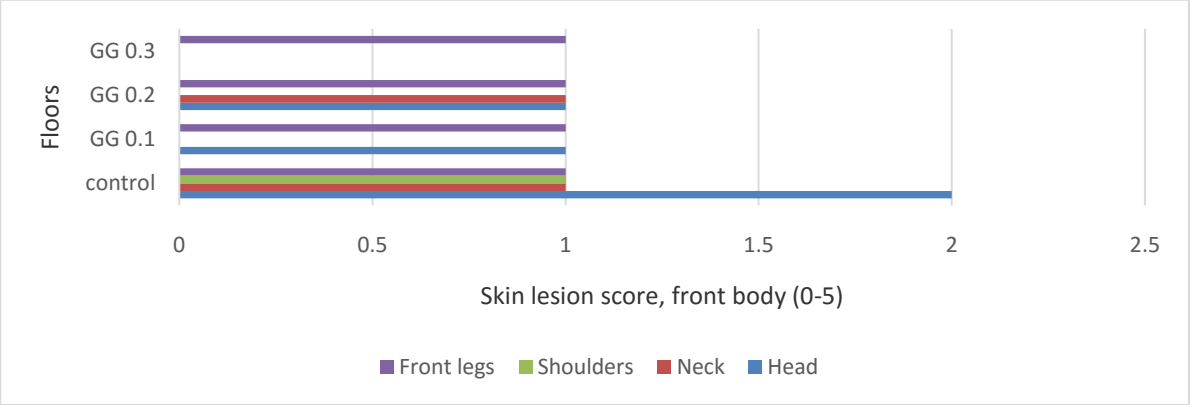

Figure 1: Mean skin lesion score on the front body part of the pigs among the treatments
Control: Concrete at 0metres high; GG 0.1: Guinea grass bedding at 0.1metres high; GG 0.2: Guinea grass bedding at 0.2metres high; GG 0.3: Guinea grass bedding at 0.3metres high.

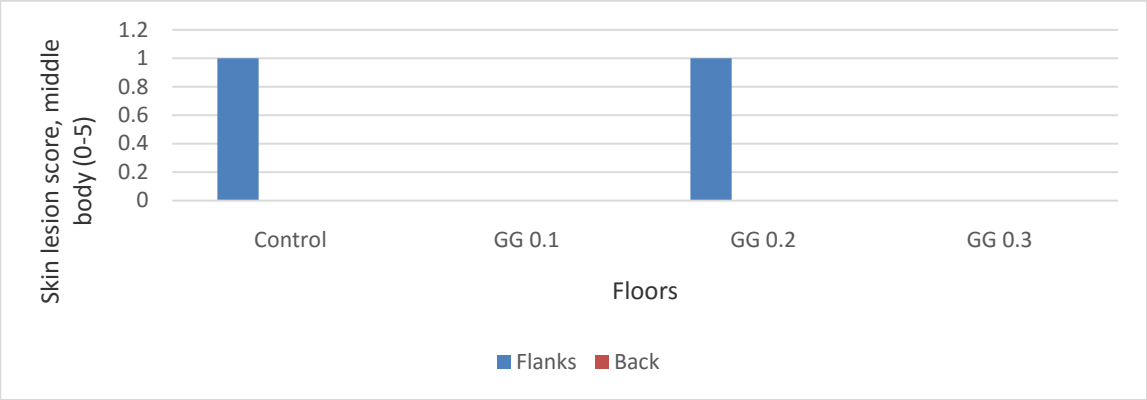

Figure 2: Mean skin lesion score on the middle body part of the pigs among the treatments
Control: Concrete at 0metres high; GG 0.1: Guinea grass bedding at 0.1metres high; GG 0.2: Guinea grass bedding at 0.2metres high; GG 0.3: Guinea grass bedding at 0.3metres high

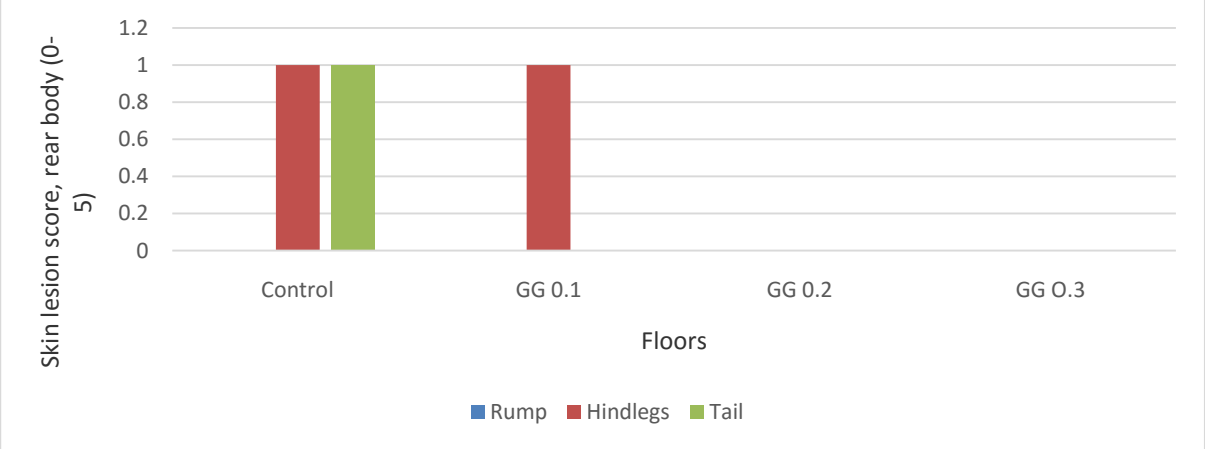

Figure 3: Mean skin lesion score on the rear body part of the pigs among the treatments
Control: Concrete at 0metres high; GG 0.1: Guinea grass bedding at 0.1metres high; GG 0.2: Guinea grass bedding at 0.2metres high; GG 0.3: Guinea grass bedding at 0.3metres high.

DISCUSSION

Environmental enrichment is crucial for pig production as it reflects in their performance and welfare. In this study it was observed that treatments with beddings had higher values for final weight and weight gain. This corroborate the findings of Vanheukelom *et al*. (2011) that reported an increase in post weaning weight gain for pigs housed in an enriched environment. In the study of Van de Weerd *et al.*, (2006) using different enrichment substrates, it was reported that pigs housed in straw-bedded pens had higher daily weight gain than their counterparts. Conversely, Jordan (2013) reported that straw and hay did not influence growth rates of pigs. It was also observed in this study that the FCR across the treatments were lower in treatments with beddings when compared to the concrete floor. This was in agreement with the report of Beattie *et al.* (2000) that observed a similar trend in pigs reared on wood shavings as against concrete floor.

The provision of guinea grass bedding in this study was beneficial to the pigs as most of the lesions recorded were from pigs housed in concrete floor. This agreed with the findings of Ramis *et al*. (2005) on prevalence of limb lesions in barren-housed pigs (24% of observation) compared with pigs housed in sawdust-bedded barns (1% of observations).Specifically, Peterson *et al*. (1995) reported that pigs housed in pens enriched with straw, logs, and branches spent more time rooting, biting, and chewing the provided materials, whereas pigs housed in barren environments spent more time rooting, biting, and chewing the floors and walls of their pen. These findings suggest that any environmental enrichment that promotes exploration and is an outlet for oral activities may be the most effective means of redirecting oral vices away from pen fittings and penmates in order to improve animal well-being. This might explain the reason why in this study, tail lesion was only recorded in the control (without guinea grass straw) since there was absence of explorative materials that could help divert the attention of the weaner pigs. On the contrary, Scott *et al.* (2006) reported that adding enrichment objects to straw-bedded pens had no influence on skin injuries.

CONCLUSION

It is therefore, concluded that guinea grass height of 0.1m and 0.2m are preferred for the enhancement of the conventional concrete floor in consideration for growth performance, while height of0.3m is excellent enhancement of concrete floor in terms of skin lesion occurrence.

ABSTRACT

This study was conducted to investigate the effect of stocking densities on the temperature and humidity of broiler pens during the wet season. Ninety day-old chicks of Arbor acre breed were used for the experiment which lasted 8 weeks. The birds were randomly assigned to three treatments of stocking densities 5, 10 and 15 birds/m^2 with three replicates per treatment in a deep litter house. Data on daily ambient Temperature and Relative Humidity within the pen were obtained using the Maxims thermocron i-button Temperature and Humidity sensors, which were programmed to measure at 10 minutes sampling interval. Virtually no significance observed between the stocking densities in weekly mean temperature and relative humidity in the broiler chicken pens throughout the period of the study. Therefore, it is concluded that stocking density does not influence broiler chicken's ambient temperature and humidity.

Key words: Broilers pens, stocking density, temperature, humidity

INTRODUCTION

The commercial production of broiler chickens under intensive management is commonly at stocking densities higher than optimum stocking density of 5 birds per m^2 (Asaniyan and Agbede, 2012). This may influence the ambient condition of the birds. The impact of the ambient condition may be beneficial or detrimental, depending on the extent of weather elements variations. The impact of weather elements may be expressed singly or in combinations; for instance, Bianca (1976) reported that low ambient temperature plus high air movement (cold) or high ambient temperature and high relative humidity plus solar radiation (heat) exert various effects on animal well-being, demonstrated in neuroendocrine, cardiorespiratory and behavioural responses. The concern for weather elements in recent years is due to the fact that they are not constant, but change continuously. Such changes affect the internal environment of birds, including the blood through the nervous and endocrine systems (Oladele *et al*., 2003). In the tropical environment, weather elements exert significant influence on domestic birds. Direct weather elements affecting birds include, especially, high ambient temperature and high relative humidity, resulting in severe heat stress (Ayo *et al*., 2011). The report of Egbunike (1979) suggests that the effect of a hot environment on the body of birds depends not only on the nature of the microclimatic factors involved, but also on their intensity. Heat stress is very common and on the increase in the tropical and subtropical production of poultry chickens. It inflicts heavy economic losses on poultry production as a result of stunted growth (Sahin *et al.,* 2001). In Nigeria, the combination of high ambient temperature and high relative humidity, reaching climax at the onset of the rainy season, constitutes extreme heat stress, which depresses the production of broiler and layer birds. Conversely, the low ambient temperature and low relative humidity, prevailing from November to February during the Harmattan season, especially in the morning and evening hours of the day, enhance egg and broiler production (Bannor and Ogunsan, 1987). Heat stress depresses growth rate and production as a result of a down-turn in voluntary feed intake in broilers (Sahin *et al.,* 2001). Heat stress is a deterrent to successful and profitable poultry production (McNabb and King, 1993). The optimum ambient temperature range for poultry is 12–26◦C (Plyaschenko and Sidorov, 1987). However, the ideal temperature for broilers is 10-22˚C to get optimum body weight and 15-27˚C for feed efficiency (Rama Rao *et al*., 2011). A temperature above 30˚C represents a heat-stressed condition for birds and is one of the most common stressors that affect the production criteria in poultry (Rama Rao *et al*., 2011). Broiler heat loss is comprised of two components; latent heat loss and sensible heat. Latent heat loss is usually expressed as the amount of water evaporated from the

broiler, referred to as "moisture production". Evaporation uses broiler heat to change water state from liquid to vapor. The evaporation takes place inside the broiler as water passes over the wet surfaces of its respiratory system. Sensible heat loss refers to heat dissipated through heat transfer from the broiler to the surrounding air. If the air is cooler than the broiler's surface temperature, heat flows from the broiler to the surroundings. If the air is warmer than the broiler's surface temperature, broilers will not be able to dissipate heat and heat stress will occur. Stress is of major concern for poultry industry because it exerts deleterious effects on different parameters like feed intake, feed conversion ratio, weight gain and so on (Pawan *et al*., 2012). Therefore, this study tends to investigate whether stocking densities influence ambient temperature and relative humidity within the broiler chicken pens.

MATERIALS AND METHOD

This study was carried out on the Poultry Unit of the Teaching and Research Farm, Joseph Ayo Babalola University, Ikeji Arakeji, Osun State, Nigeria; located at latitude 07° 51' N and longitude 4° 88' E.Prior to the start of the experiment all chicks were individually weighed and randomly assigned to three groups of different stocking densities. Each pen was 1m^2. In each treatment, the chicks were kept in tagged pens under deep litter management system in a ventilated house. Ninety (90) day-old chicks of Arbor acre breed were used as experimental unit in the experimental trial that lasted eight (8) weeks. The birds were randomly assigned to three treatments of stocking densities S5, S10 and S15 of 5, 10 and 15 birds/m^2 respectively with three replicates per treatments. The birds were raised in deep litter system bedded with wood-shaving litter.

The meteorological data (Temperature and Relative humidity) within the pen were obtained using the Maxims thermocron i-button Temperature and Humidity sensors, which were programmed to measure at 10 minutes sampling interval. Each of the sensors were shielded and well positioned in each pen. Data on the daily ambient temperature and relative humidity were collected throughout the eight weeks duration of the study. The data obtained from the experiment were subjected to Analysis of Variance and the means were separated by Duncan Multiple Range Test (SAS Institute, 1987).

RESULTS AND DISCUSSION

The weekly mean values of weather parameters observed in the broiler chicken pens under the three stocking densities (5, 10 and 15 birds/m^2 tagged S5, S10 and S15 respectively) are presented in Table 1.

Table 1: Weather parameters of poultry pens at three different stocking densities from week 1 to 8

Week	Temperature			Relative Humidity		
	S5	S10	S15	S5	S10	S15
1	27.15±0.193	27.15±0.198	27.22±0.196	79.5±0.801	79.4±0.826	79.3±0.814

Mean± SEM S5 = 5 birds/m^2; S10 = 10 birds/m^2; S15 = 15 birds/m^2Means with different superscripts in the same row are significantly different (P<0.05).

The overview of the responses revealed no significant (P>0.05) influence of the stocking densities on weekly mean temperature and relative humidity of the poultry pens throughout the period of study except in week 8 for the relative humidity.The mean temperatures of the broiler chicken pens showed similar increasing trends from the first week to the third week with the peaks at 31.43±0.353^{o}C for treatments S5 (5birds/m^2), 29.84±0.266^{o}C for S10 (10birds/m^2) and 31.79±0.360^{o}C for S15 (15birds/m^2), and decreased thereafter. The increasing temperatures that got to their peak at week three for the different treatments was probably as a result of increasing body sizes of the broiler chicks that enhance increasing metabolic activities with the corresponding heat loss through the skin and breathing. However, the temperature that peaked on week three and decreased thereafter confirmed the fact that broiler chickens had limited physiological capacity to control body temperature at the early age (1-4 weeks) as reported by Maarten *et al*. (2015). Also, the differently peaked temperatures for the treatments could be attributed to the different stocking densities; showing that stocking densities is directly proportional to the temperature within the broiler pens. Therefore, increasing stocking densities could bring about increased ambient temperature according to the findings of Dawkins *et al*. (2004). However, recorded mean temperatures were not too far from the 30°C crucial temperature for poultry, beyond which feed and energy intake declines to such an extent that birds are no longer able to compensate for it, thereby suffer rapid production decline and increase rate of mortality (Daghir, 2009).This tends to show that the birds experienced similar ambient atmospheric condition throughout the period irrespective of the different stocking densities. The significant (P<0.05) influence of the stocking density on the relative humidity among the treatments at the eighth week could be jointly associated with the relative differences in temperature at week 8 and the age related increase in metabolic activities that yielded more respiratory and faecal moistures that contributed into atmospheric moisture within the pens. Fortunately, mortality was not recorded throughout the duration of this study. This could be an indication that the weather conditions within and outside the broiler house during rainy season (between late May and early July) when the study

was conducted had contributed favourably (good ventilation) to the inability of the stocking densities to influence the weather situation within the broiler pens significantly to the detriment of the broilers' welfare. This corroborated the report of Dawkins *et al*. (2004) that high environmental quality is far more important than density per se in maintaining good health, performance and welfare of broiler chickens. Therefore, irrespective of stocking density levels, adequate ventilation has the mediating potential against the fatality of weather modification in the broiler pens.

CONCLUSION

There was virtually no significant influence of the stocking densities on weekly mean temperature and relative humidity in the broiler chicken pens during the rainy season.

Recommendation

Irrespective of stocking density levels, rearing environment of broiler chickens should not compromise adequate ventilation.

ABSTRACT
This study was conducted to determine the effect of age on the Incubation weight loss, fertility and hatching characteristics of Japanese quail eggs. One hundred and fifty (150) Japanese quails comprising of one hundred (100) females and fifty (50) males were selected from 5 weeks old quail flock on the farm. Eggs were collected from the birds in triplicate for incubation at different ages i.e. the 9th, 13th and 17th weeks of age of the birds. Data were collected on incubation weight loss, fertility, hatching traits and subjected to One-way Analysis of variance. Age of Japanese quail did not significantly (P>0.05) affect fertility. Hatchability was better at 13(74.64%) and 17(70.09%) weeks of age. The highest (P<0.05) embryonic mortality was recorded at the 9th week of age and chick weight varied consistently with egg weight. Based on the result obtained in this study, it could be concluded that age did not influence incubation weight loss, fertility and hatch weight. Hence, eggs for hatching should be selected after four weeks in lay.
Keywords: Fertility, Hatchability, Incubation and Embryonic mortality, Age

INTRODUCTION
One of the important factors such sex ratio, period and condition of egg storage, breeding system and the parental life weight that will have effect on fertility and hatchability of eggs is the age of the laying quails (Narahari *et al.*, 1988). Researchers reported that the fertility (Kling and Soares 1982 and Narahari *et al*., 1988) and hatchability of incubated eggs reduced depending on the older the age of the laying quail (Narahari *et al*., 1988 and Elibol *et al*., 2002) and also embryonic mortality increased in eggs of older laying birds compared to younger ones (Novo *et al.*, 1997). Sahan and Ipek (2000) considered eggs obtained from very young and very old laying quails inappropriate for incubation. Hence, this study sought to investigate the effect of age of laying quail on the laying performance, fertility, hatchability, incubation weight loss and the embryonic mortality in early and late periods.

MATERIALS AND METHODS
Experimental Site: The rearing of the birds was carried out at the poultry unit of the University Farms, Federal University of Agriculture, Abeokuta while egg incubation took place at Obasanjo Hatchery, Owiwi, Abeokuta.
Source and Management of Experimental Birds: One hundred and fifty (150) Japanese quails comprising of one hundred (100) females and fifty (50) males were selected from 5 weeks old quail flock on the University farm and raised in cages. The male to female ratio was 1:2 i.e. 50 females to 25 males. Birds were fed diet containing 20.2% crude protein and 2976.48Kcal/kg Metabolisable Energy. Eggs were picked twice daily (morning and evening).
Experimental Design: Eggs were collected from the birds for incubation at different ages i.e. the 9th, 13th and 17th week of age of the birds. Eggs for incubation were collected within 3days of stipulated weeks and stored in refrigerator (7°C) in order to get sufficient number of eggs. The eggs (180) collected per each week in lay was in triplicate i.e was randomly grouped into three (3) replicates (60 eggs each).
Egg Management: Potassium tetraoxomanganate VII ($KMnO_4$) and formaldehyde (HCHO) at ratio 1:2 was used as fumigant for the eggs. The treatment lasted for 20 minute in a closed chamber. The eggs were set in egg trays with broad end upward to prevent rupture of air cell. Each egg tray was labelled according to the replicate and individual eggs were numbered prior to setting to facilitate data collection. Eggs were set in Petersime incubator (B-9870 model). Temperature (37.5°C) and humidity were automatically regulated. Egg turning was automatic on hourly basis.

Data Collection
Determination of Incubation Weight Loss: The eggs were weighed before setting and on the 15th day. Incubation weight loss was determined using the formula below;
Weight loss (g) = Initial weight – Final weight Weight loss (%) = $\frac{Weight\ Loss\ (g)}{Initial\ \ Weight\ (g)}\ X\ 100$

Percent Fertility: This was determined using the formula stated below;

$$\text{Fertility (\%)} = \frac{Number\ \ of\ fertile\ \ eggs}{Total\ \ number\ \ of\ eggs\ set\ in\ the\ incubator}\ X\ 100$$

Percent Hatchability: This was determined using the formula stated below;

$$\text{Hatchability (\%)} = \frac{Number\ \ of\ chicks\ \ hatched}{Total\ \ number\ \ of\ \ fertile\ \ eggs}\ X\ 100$$

Percent Embryonic Mortality: This was determined using the formula stated below;

$$\text{Embryonic mortality (\%)} = \frac{Number\ \ of\ unhatched\ fertile\ \ eggs}{Total\ \ number\ \ of\ \ fertile\ \ eggs}\ X\ 100$$

Hatch Weight: This was determined using the formula below;

$$\text{Hatch weight} = \frac{Total\ \ Weight\ of\ chicks\ \ hatched}{Total\ \ number\ \ of\ chicks\ \ hatched}$$

Statistical Analysis: Data collected were subjected to One-way Analysis of variance using SAS (1999) while significant means was compared using Duncan's Multiple Range Test (Duncan, 1995) in the package.

RESULTS

Effect of Age on Incubation Weight Loss an hatching Characteristics of Japanese Quail eggs

The incubation egg weight loss and hatching traits of Japanese quails at different ages is shown in Table 1. Percent egg weight loss were similar (P>0.05) at the 9th and 17th week of age, but higher at the 13th week (14.98%) of age. The fertility percentage of the eggs was similar (P>0.05) at all stages of lay considered. Percentage hatchability of eggs collected at the 9th week (58.23%) of age was significantly (P<0.05) lower while the hatchability was similar (P>0.05) at the 13th week (74.64%) and 17th week (70.09%) of age. The total embryonic mortality was highest (p<0.05) in eggs collected at the 9th week (41.77%) of age but was similar (P>0.05) at the 13th (25.36%) and 17th (29.91%) week of age.

DISCUSSION

The observed significance in incubation weight loss across the ages in this study did not give a clear picture of effect of age as there was no definite trend. According to Romanoff (1967), most of the water of the egg is initially in the albumen which declines continuously during incubation as a result of water loss to the ambient air and movement to the compartments.

The result of fertility is in consonance with Islam *et al.* (2002) who reported that age did not influence percent fertility and hatchability but rather by factors such as genetic, physiology, social and environmental factors. However, the result is at variance with Elibol (2002) who reported that fertility decreases as parental age increases. Similarity in fertility among the eggs selected for incubation at various week of age could be as a result of short interval between weeks of collection.

The percent hatchability obtained in this study is in agreement with Insco *et al.* (1971), who stated that a gradual increase was noted regarding the hatchability of incubated eggs of the Japanese quails up to the age of 12-14 weeks then a gradual decrease occurred in the age period of 15-19 weeks. The percent hatchability obtained in this study is also in correlation with the report of Sahan and Ipek (2000) who reported that eggs obtained from very young and very old laying quails are not considered as appropriate for the hatching activities. However, similarity observed between 13th and 17th week of age might be due to short interval (4 weeks interval) between the ages.

Table 1: Effect of Age on Incubation Weight Loss and Hatching Traits of Japanese Quails

	Age of quail hens (Weeks)		
Parameters	9	13	17
Egg weight loss			
Initial egg weight (g)	$9.48^{c} \pm 0.03$	$10.02^{a} \pm 0.60$	$9.67^{b} \pm 0.04$
Final egg weight (g)	$8.22^{c} \pm 0.10$	$8.57^{a} \pm 0.05$	$8.41^{b} \pm 0.05$
Weight loss (g)	$1.26^{b} \pm 0.07$	$1.45^{a} \pm 0.06$	$1.26^{b} \pm 0.10$
Weightloss (%)	$13.29^{b} \pm 0.40$	$14.98^{a} \pm 0.20$	$13.03^{b} \pm 0.38$
Hatching traits	$9.48^{c} \pm 0.03$	$10.02^{a} \pm 0.60$	$9.67^{b} \pm 0.04$
Fertility (%)	96.34 ± 0.42	96.34 ± 2.04	94.34 ± 1.36
Hatchability (%)	$58.23^{b} \pm 3.18$	$74.64^{a} \pm 1.15$	$70.09^{a} \pm 1.78$
Embryonic mortality (%)	$41.77^{a} \pm 3.18$	$25.36^{b} \pm 1.15$	$29.91^{b} \pm 1.78$
Hatch weight (g)	$5.69^{c} \pm 0.06$	$6.54^{a} \pm 0.19$	$5.99^{b} \pm 0.02$

^{abc} means with different superscript differs significantly ($p<0.05$)

Highest total embryo mortality observed at 9th week of age support the result of Ritsareva (1991), who noted that hatching of first laid quail eggs was not satisfactorily successful. Similarity observed between the 13th and 17th week of age is in agreement with Othman *et al*. (2014), who concluded that there was no significant difference between the effects of age of hens on embryo mortality rate of eggs. Variation in chick weight observed in this study could not be attributed to differences in age but due to differences in the weight of eggs incubated as variation were consistent between both. A positive correlation was observed between the egg weight and the chick weight in a related study by Farooq *et al.* (2001).

CONCLUSION

This study concludes that fertility was not influenced by age of quail, however hatchability of eggs collected at the 9th week of age was poorest. Variation in hatch weight of chicks was a result of concomitant variation in egg weight and not the age of quail hens.

RECOMMENDATION

It is recommended that quail eggs for hatching should be selected after 4 weeks in lay for better hatchabillty.

CHEMICAL COMPOSITION AND ORGANOLEPTIC EVALUATION OF MINCED MEAT *(DAMBUN NAMA)* OF SOME POULTRY SPECIES

***Ambore C.B., Mancha Y.P., D.J.U Kalla., U.D. Doma**

Department of Animal Production Abubakar Tafawa Balewa University Bauchi, Bauchi State Nigeria

**Corresponding author: brucecharles95@gmail.com mobile No: 07064328014*

ABSTRACT

The study examined chemical composition, sensory evaluation and microbial loads of minced meat product of poultry species within Bauchi metropolis. Five different minced meat products from guinea fowl, Noiler, Indigenous chicken, Broiler and duck were subjected into sensory evaluation. These products were given to a taste panel which comprises of staffs and student using a 9 – point hedonic scale. The different meat products were subjected to chemical and microbial load analysis. The result showed that in proximate composition of protein ranges from 59.13 – 56.93%, dry matter 83.61 – 81.61%, ether extract 11.29 – 10.19% and Ash 2.03 – 1.83% respectively. The minerals of different minced meat product varied in terms of calcium, from 0.21 – 0.17%, phosphorus 0.20 – 0.15%, sodium 0.06 – 0.04% and likewise potassium 0.003 – 0.001% differ from each other. The microbial counts revealed the total bacteria load of the products varied significantly ($P<0.001$) with indigenous chicken 272.67 x 10^6cfu/g tends to have highest bacteria load while 109.33 x 10^6cfu/g the least load of bacteria was in broiler minced meat. Total fungal count was also significant statistically ($P<0.001$) in various product however, indigenous chicken, 121.10 x 10^6cfu/g differ among the products, statistically and broiler 68.67 x 10^6cfu/g was the lowest. However sensory evaluation of different minced meat product were significant ($P<0.001$) in terms, of flavour, aroma, acceptability while juiciness, palatability were also significant at ($P<0.001$) and colour tends to be significant ($P<0.05$), tenderness not significant among all products. Guinea fowl and Noiler tends to have higher flavour as compared with the rest of the products though all are similar, aroma is high in Noiler (8.33 x 10^6cfu/g) followed by guinea fowl (8.30 x 10^6cfu/g) and low in duck (6.63 x 10^6cfu/g). Juiciness is high in Noiler (8.17x 10^6cfu/g) low in duck (6.67x 10^6cfu/g) respectively. In conclusion Noiler and broiler, meat were most preferred by the taste penalists as well as having the least microbial load. It is safer for short time storage particular for travellers.

Keywords: poultry, Minced meat

INTRODUCTION

Today the world faces the problem of shortage of food supply, which makes malnutrition and its consequences in developing countries a major problem (Sadler *et al.,* 2004). Food of livestock origin such as meat and meat products contain important nutrients like amino acids, vitamins, minerals and fatty acids which are essential for growth and development (World Population Data Sheet, 2010). Further processing of meat offers the opportunity to add value, improve food safety and extend shelf life, resulting in increased household income and improve nutrition. Moreover, a significant number of the world population are deficient in key vitamins and minerals, particularly vitamin A, iodine, iron and zinc. Highly nutritious foods such as meat are required by women, children and HIV AIDS infected people. Bala (2014) showed that meat preservation is more difficult than other forms of food preservation as it may lead to oxidative rancidity, mouldiness, sliminess, discolouration and off flavour. It has been shown that processing of meat produced enhanced handling, packing, distribution and marketing of the products (Omojola *et al.*, 2004). An average Nigerian for instance, consumes only about 10g *per* day of the minimum daily intake of 35g recommended by food and agricultural organization (FAO, 1992). The processing of meat in different forms to avoid spoilage can close the gap of protein shortage (Ani and Okorie 2004). However, in Nigeria there are different types of meat products, specifically dambun nama, as a major contributor of quality nutrients for normal growth and reproduction, less importance is attached to possible effects on health due to product contaminants. Over the last years, there has been a growing interest in meat from different animal species such as duck, guinea fowl, broiler chicken, Noiler chicken, indigenous chicken, rabbit etc (Horbanczuk, 2003). Therefore the objectives of this research was to evaluate the proximate and mineral composition, microbial load and sensory properties of minced meat from duck, guinea fowl, Noiler chicken, broiler chicken and indigenous chicken meat.

MATERIALS AND METHODS

The study was conducted within Bauchi metropolis. Live broiler chicken, duck fowl, guinea fowl, Noiler chicken, indigenous chicken were bought from various locations within Bauchi metropolis. They were taken to Bauchi abattoir for dressing into carcass and immediately transported for processing into minced meat (Dambun nama) and analyzed so as to determine dry matter, crude protein, ether extract, crude fibre and ash following the procedures of AOAC (1995).

Processing of Dambun Nama

(Minced meat) duck, guinea fowl, Noiler, broiler meat (chicken), and indigenous chicken meat were processed to produce various dambun nama. Dambun nama (minced meat was prepared from meat of these livestock using the procedures of Farouk (1995) and Kalla *et al*. (2005). Fresh meat of good grade was cut into pieces of about 4cm by 2.5cm dimension and washed thoroughly with clean water, mixed with spices and ingredients (seasoning, salt, curry, ginger and thyme) boiled for about 90 minutes and pounded into shreds using a mortar and pestle. This was then shallow fried using groundnut oil in stainless steel frying pan to obtain dambun nama, which is usually brownish in colour.

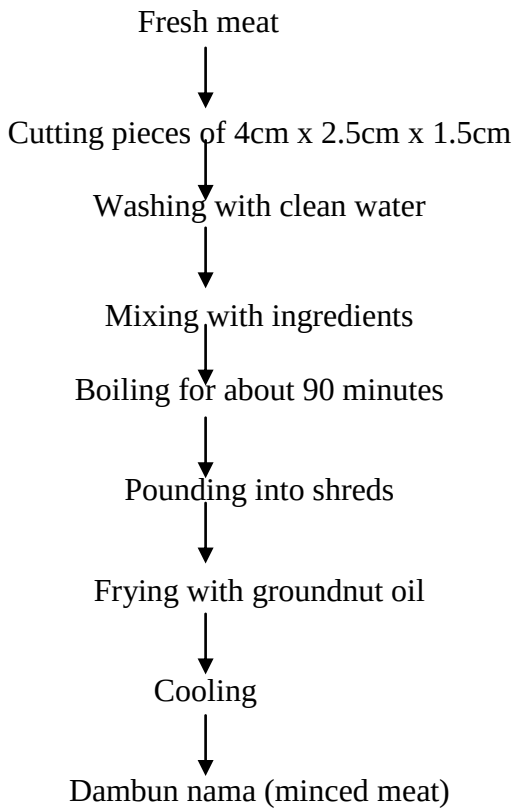

Fig 1: Preparations of Dambun nama: (Bube, 2003)

Data collection

The data for the study were collected through the sixty (60) questionnaires using Hedonic scale. The questionnaires were distributed among university staff and students. Five different samples were given to each individual. All the questionnaires distributed were later collected from different respondents.

Data analysis

Data from the study were subjected to analyses of variance (SAS, 2002). The means with significant differences were separated using Duncan's Multiple Range Test (DMRT).

RESULTS AND DISCUSSION

Table 1: Proximate Composition (%) of Minced Meat (Dambun Nama) of Some Poultry Species

	Meat types					
Parameters (%)	**Guinea fowl**	**Noiler**	**Local chicken**	**Broiler**	**Duck**	**Overall mean**
Dry matter	83.61	82.31	82.94	81.61	82.50	82.59
Protein	58.13	59.13	56.93	57.64	57.59	57.88
Ether extract	10.74	10.19	10.23	11.29	10.45	10.58
Ash	1.83	2.03	2.10	1.92	1.86	1.95

The proximate composition of minced meat (Dambun nama) in relation to dry matter, crude protein, ether extract, ash content are shown in Table 1. The values reported were in line with Bube (2003) who reported dry matter contents of 93.8 to 95.9% using monogastric and ruminants dambun nama. This research finding on chemical composition of dambun nama processed from guinea fowl, Noiler, local chicken, broiler chicken meat and duck meat varies among these poultry species. The dry matter was high in guinea fowl followed by local chicken. The trend is in conjunction with the investigation of Bube (2003). Similarly, the protein content of dambun nama was high in Noiler followed by guinea fowl and differ among the others and was in accordance with reports of Bube (2003) and Kalla *et al.* (2005), though parameters such as ether extract and ash tends to followed same trends according to the work of Muhammad *et al.* (2010) who uses local meat products. Ether extract was high in broiler chicken and low in Noiler, ash was high in local chicken and lower on guinea fowl. These could be based on genetic makeup and mode of management in relation to the differences in parameter observed.

The result for mineral composition of minced meat is shown in Table 2. The calcium and phosphorus content is in agreement with the finding of Bube (2003), Kalla *et al.* (2005). Calcium content was high in Noiler, low in local chicken whereas phosphorus was high in Noiler with the least in duck followed by sodium which was high in guinea fowl minced meat and low in broiler minced meat and then potassium was more in local chicken.

Table 2: Mineral composition (%) of minced meat (Dambun nama) of some poultry species

	Meat types					
Parameters (%)	**Guinea fowl**	**Noiler**	**Local chicken**	**Broiler**	**Duck**	**Overall mean**

Acceptability	7.83^{a}	8.53^{a}	7.90^{a}	7.80^{a}	6.97^{b}	***

abc means within row having different superscripts differ significantly at (* =p<0.05, **p<0.01, ***p<0.001, NS = not significant)

Table 3 shows the results for sensory evaluation of minced meat of some poultry species. The most superior flavour was obtained from guinea fowl and Noiler chicken which were closely followed by broiler chicken. Noiler chicken was observed to give the best aroma, guinea fowl Noiler chicken and local chiken were the juiciest while Noiler chicken was the most palatable. All the meat was observed to be tender as there was no significant difference among them. Noiler chicken was observed to posses the best colour. Acceptability is an important quality of meat and from the result it was

deduced that duck meat was the least acceptable while guinea fowl, Noiler chicken, local chicken and broiler chicken were the most acceptable.

Table 4 shows the microbial load of minced meat of some poultry species stored for seven days. The bacterial load of various meat products were significant (P<0.001). Local chicken has the highest bacteria count (272.67 x 10^6cfu/g) followed by the least bacterial count in broiler chicken (109.33 x 10^6cfu/g) which is the most preferred to consumers as reported by Rouger *et al.* (2017) Therefore, ensuring the microbial safety of poultry meat products is an important factor in the context of increasing consumption and production.

Among the products, it was observed that broiler chicken has the lowest fungal load (68.67 x 10^6cfu/g) while local chicken possessed the highest fungal load (121.00 x 10^6cfu/g) which deter its consumption as compared to the broiler which seems to be the most preferred in terms of quality to consumers.

Table 4: Microbial loads of minced meat *(Dambun Nama)* of some poultry species stored for seven days

	Meat types					
Parameters	**Guinea Fowl**	**Noiler Chicken**	**Local Chicken**	**Broiler**	**Duck**	**LOS**
Bacterial Load(2.2 X10^6 cfu/g)	212.00^b	175.67^d	272.67^a	109.33^e	181.33^c	***
Fungal Load(1.08X10^6 cfu/g)	108.33^b	87.00^d	121.00^a	68.67^e	91.67^c***	

abcde mean different superscripts with the row differ significantly (*=p<0.001)**

CONCLUSION

It was concluded that Noiler and broiler birds were most preferred by consumers. Processing poultry meat into minced meat (*Dambun Nama*) significantly increased shelf life and acceptability of the product by the consumers. It is therefore recommended that standard method of processing and production of minced meat be enforced so as to reduce the level of microbial load and increase shelf life.

ABSTRACT
The objectives of this study were to determine the profitability of beef cattle production, A multi-stage sampling procedure was employed in the selection of a sample size of 72 beef cattle butchers used in the study. The study made use of primary data which were obtained through the use of computer-aided personal interview software. Descriptive statistics and Net income analysis was used for the data analyses. The results of the profitability of beef cattle butchery activities shows that the total cost incurred in beef cattle butchery was ₦4,093.77 per 10 slaughtered cattle, the total revenue was ₦33,185.15, resulting in a net revenue or profitability of ₦29,091.38 per 10 slaughtered cattle. The results of the constraints confronting the beef cattle butchering activities showed that most (95.5%) of the abattoirs lack facilities. It can be concluded that beef cattle butchery activities was a profitable agribusiness activity. Lack of facilities in the abattoirs was one of the major constraints encountered by majority of the butchers in the study area as such it was recommended that private sector should participate in the provision of better slaughtering facilities such as modern abattoirs.
Key Words: Profitability, butchers, net income, Abattoirs.

INTRODUCTION
Beef cattle production is a crop-livestock economic production activity in the core cattle producing states of Nigeria because they are used for farm operations and subsequently fattened and sold off (Okaiyeto *et al.,* 2006). However, beef cattle production has been shown to be inefficient across nomads, agro-pastoralists and ranchers indicating that there is still much opportunity for increased efficiency given the present state of technology (Nwigwe *et al.,* 2016). Butchery in the beef production includes stunning, exsanguinations, skinning, and evisceration, splitting and selling of the beef and its products to the consumers. Economically butchery activities provide an important source of empowerment and income generation in Nigeria and it has an important socio-cultural position in the rural areas (Oyediran *et al.,* 2018). Empirical evidence on cost and returns of butchery activities in the study area is limited in the study area.
Therefore, the main objectives of this study were to**:**

i. determine the costs and returns of beef cattle butchers in the study area
ii. identify the constraints limiting beef cattle butchers in the study area

METHODOLOGY
Study area
The study was conducted in Kano, Kaduna and Katsina States of north-west zone, Nigeria. The north-west comprises of Jigawa, Kano, Katsina, and Kaduna, Zamfara, Sokoto and Kebbi States. According to the 2006 population census, the total population of the zone was estimated at 35.7 million with an average density of 103 persons per square kilometer (NPC, 2006). The projected population of the zone in 2016 was about 47.5 million, based on an annual growth rate of 3.2%. The north-west zone is known for livestock production activities such as cattle, goat, sheep, and poultry etc.
Sampling and data collection
Multi-stage sampling technique was employed in the selection of the respondents. First, six Local Government Areas (LGAs) Rimin Gado, Gwarzo, Kubau, Soba, Faskari and Kafur were purposively selected (two from each State) based on their prominence in beef cattle production (agro-pastoralist). One abattoir in each of the 6 LGAs was randomly selected to give a sample of 6 abattoirs and 10 butchers per abattoir to give a sample of 66 butchers derived from a registered list of cattle butchers association.

The study made use of primary data. The data were obtained through the use of computer-aided personal interview (CAPI) version of survey instrument rather than paper-based questionnaire. The survey was administered using trained enumerators under the supervision of the first author.

Analytical Technique

Descriptive statistics

Descriptive statistics such as percentages was used to identify the constraints limiting beef cattle butchery activities in the study area.

Net income analysis

Net income analysis was used to determine the cost and returns of beef cattle butchery. It is expressed as:

π = Net income or Profit (₦)

TR = Total revenue (unit price x quantity) (₦)

TC = Total cost (Total variable cost + Total fixed cost) (₦)

The unit of profit for beef cattle butchery was Naira per 10 slaughtered cattle. Variable costs for butchers includeD cost of beef cattle/beef purchase, feeds, water, labour, marketing costs such as costs of transportation, packaging, beef refrigeration, market charges, brokers charges, costs of processing items etc. Fixed costs included depreciation on equipment and tools as well as land/shop rent. The depreciation was estimated by the straight line method:

$$D = \frac{P-S}{N} \quad \ldots\ldots 3.3$$

Where,

D = Depreciation (₦)

P= Purchase value of each asset (₦)

S= Salvage value, which is the price of the asset after its expected years of usage (₦)

N = Life span of the asset measured in years.

Following Bennett *el al.* (2019) a value added model was used to gain further insights on the value created by the actors in the beef cattle value chain and it is expressed as follows:

$$VA = TR - IC \quad \ldots\ldots 3.4$$

Where,

VA = Value added (₦)

TR = Total revenue (unit price x quantity) (₦)

IC = Intermediate consumption (cost of raw materials used up in the value addition activity) (₦)

Profitability of beef cattle butchery

The costs and returns in beef cattle butchery enterprise was estimated per 10 slaughtered cattle**.** The results presented in Table 4.1 showed that a total cost of ₦4,093.77 was incurred while total revenue of ₦33, 185.15 was generated by the beef cattle butchers resulting in a profitability of ₦29,091.38 per 10 slaughtered cattle. This showed that beef cattle butchery was profitable in the study area. The profit per naira invested in beef cattle butchery was 7.11 which indicated that a naira invested in beef cattle butchery gave a profit of ₦ 7.11. This high returns supported the income generation and youth empowerment opportunities in butchery activities as reported by Oyediran *et al.* (2018). Also, the results revealed that value addition by beef cattle butchery in the study area was ₦30,460.31. The average number of cattle slaughtered by the butchers in a month was 38. Based on the average number of cattle slaughtered in a month, an annual income of ₦1,326,566.92 was generated which was far above the minimum wage of ₦216,000 per year (₦18,000 per month). Therefore the income generated from beef cattle value chain by the butchers corresponded to 614.2% of the annual national minimum wage which was in agreement with the findings of Oyediran *et al.* (2018) on the potentials of butchery activity for income generation. In terms of the cost components of butchery activity, the costs of processing items (₦2,167.41 per 10 slaughtered cattle) constituted the highest variable cost incurred in beef cattle butchery activities in the study area and the least was the cost of water (₦557.43) as shown in table 1.

Table 1: Costs, returns, profitability and value addition of beef cattle value chain actors

Items	Butchers
Average costs	
Water	557.43
Marketing charges/tax/levy	1,152.60
Processing items (ingredients, firewood, kerosene etc.)	2,167.41
Total variable cost (TVC)	3,877.44
Depreciation	216.33
Total fixed cost (TFC)	216.33
Total cost (TC)	4,093.77
Average revenue	
Revenue per 10 cattle slaughtered	33,185.15
Total revenue (TR)	33,185.15
Net income (NI) = TR-TC	29,091.38
Profit per naira invested (NI/TC)	7.11
Intermediary consumption (IC)	2,724.84
Value added = TR-IC	30,460.31

Note: Average number of cattle slaughtered by butchers per month is 38

Constraints faced by butchers in beef cattle value chain

Lack of facilities in abattoirs indicated by 95.5% of the butchers ranked as the first constraint faced by the butchers as shown in Table 2. The poor and unhygienic conditions of abattoirs was not only common to the study area but appears to be a common challenge in most abattoirs across the country as reported by Iyiola, and Oni-Ojo (2013). This adversely affects the effective operation of butchery activities in the abattoirs. Lack of access to credit as indicated by 75.0% of the butchers ranked as the second constraint faced by butchers in the study area. This is in line with the findings of Oyediran *et al.* (2018) who reported that poor infrastructure in the abattoir and limited access to credit as well as poor financial support from formal financial institutions were some of the constraints faced by youths involved in butchery activities in the Abattoirs of Ogun State, Nigeria. Other constraints faced by butchers in the study area were high cost of butchery inputs, inadequate organization of butchers, lack of training opportunities, high charges, low bargaining power/difficulty in setting price and lack of health inspection of animals before slaughter.

Table 2: Constraints faced by butchers (n=66)

Constraints	*Frequency	Percentage	Ranking
Lack of facilities in abattoir	63	95.5	1st
Lack of access to credit facilities	58	87.8	2nd
High cost of butchery inputs	46	69.6	3rd
Butchers are not well organized	46	69.6	3rd
High charges	35	53.0	4th
Lack of training opportunities	24	36.3	5th
Low bargaining power/difficulty in setting price	22	33.3	6th
Lack of health inspection of animals before slaughter	8	12.1	7th

*NB: Multiple responses allowed

CONCLUSION AND RECOMMENDATION

It can be concluded that beef cattle butchery activities was a profitable agribusiness activity. Lack of facilities in the abattoirs was one of the major constraints encountered by majority of the butchers in the study area. Therefore, it was recommended that private sector participation in the provision of better slaughtering facilities such as modern abattoirs and proper drainage systems, amongst others were necessary to create good enabling environment to improve beef butchery activities.

Extended Abstract

INTRODUCTION

Peste des petits ruminants (PPR) has been identified as one of the major diseases that pose a serious challenge to successful small ruminant farming. It is acute, highly contagious, trans-boundary viral disease of sheep and goats that poses a threat to livestock production in many developing countries and produces variable rates of morbidity and mortality that can reach 100% and 90%, respectively (El-Yuguda *et al.,* 2009). The economic loss due to PPR outbreaks in Nigeria was estimated to be 6.8 billions of Naira (NGN) (Fadiga *et al.*, 2013). Close contact between susceptible animals is important for the transmission of PPR virus (the aetiologic agent) to occur as discharges from the eyes, nose, mouth, as well as the loose faeces contain large amounts of this virus. Fine infective droplets are released into the air from these secretions and excretions, particularly when affected animals cough and sneeze (Ezeibe *et al*., 2008). There is no specific treatment for PPR. The most effective control measures among others is mass vaccination of small ruminants with the homologous PPR vaccine (OIE, 2012). The homologous PPR vaccine has been widely used to protect small ruminants against PPR virus, but outbreak of the disease is still being reported and thus the continuous spread of PPR infection (Albina, *et al.,* 2013). This study was conducted to find out the level of PPR vaccination awareness and consultation of veterinary service amongst small ruminant farmers in South East Nigeria.

MATERIALS AND METHODS

Three states: Anambra, Ebonyi and Enugu(latitudes 7°07′N and 3°90′N and longitudes 6°51′E and 8°30′E) in South East Nigeria were randomly selected for the study.Scheduled structured interviews were conducted on sheep and goat farmers/traders and veterinary doctors. Information elicited includes: the most encountered disease symptoms among their flock, farmer's awareness of PPR vaccination and consultation of veterinary services and also the availability of PPR vaccine in Veterinary establishments. The pretested structured interview used for the study was validated by an epidemiologist in the Department of Veterinary Public health and Preventive Medicine, Faculty of Veterinary Medicine, University of Nigeria, Nsukka. Data obtained were subjected to descriptive statistics.

RESULTS

Seventy-eight (52%) of the 150 farmer respondents indicated they used herbal medicine in the treatment of their ruminants while 57 (38%) and fifteen (10%) employed orthodox and both herbal and orthodox medicine in small ruminants, respectively. Forty (55.5%) of those that practise orthodox medicine usually consult the services of a veterinarian while 32 (44.4%) purchase their drugs from local drug stores on the drug seller's prescription. None of the respondents has ever vaccinated his/her flock against PPR. Among the symptoms listed, diarrhoea caused the biggest problem (92%) in their flock. This is followed by catarrh (85%), cough (64%) and the least abortion (10%). Out of the 100 practising Veterinary doctors that were interviewed, none had homologous PPR vaccine available at their establishments at the time of the study. Nearly all (90%) of the practicing Veterinary doctors never had the vaccine in their establishments, while 10% had the vaccine at a time.Also 97% of the

practicing Veterinarians said there was no demand of the homologous PPR vaccine by their clients (farmers/small ruminant keepers).

DISCUSSIONS

The small ruminant rearers/raisers were engaged in indiscriminate use of antimicrobial without prescription. The rearers resort to selling their sick animals when they are seriously sick and weren't responding to their medications. This correlated with the low demand for veterinary services for small ruminants recorded in the study area compared to veterinary services for dogs and poultry. This corresponds with the report of Obua (1992) in his study in Southern Nigeria. Sheep and goat rearers tend to consult butchers or sell off their ill animals instead of veterinary doctors. The self-medication practiced by small ruminant farmer/traders offers room for the development of antimicrobial resistance due to misuse and overuse of antibiotics. Sales of animals on medication and before the withdrawal period for human consumption leads to the development of antibiotics resistance in human. Inappropriate prescription practices and the use of antimicrobials in animal production has been reported to lead or cause the development of antibiotics resistance (Ayukekbong *et al*., 2017). Taking ill animals to the market for sales equally serves as a source of spread of the disease to other animals from different households and communities. Animals not sold or those bought are taken home to other flock. This practice encourages outbreaks of the disease. The non-availability of homologous PPR vaccine at the time of visit in the veterinary establishments/outlets in the studied States was another major finding. Lack of demand and inadequate power to preserve the vaccine (maintenance of cold chain), expiration of stored vaccines were the chief complaint recorded from veterinary doctors. Thus, lack of awareness of PPR vaccination amongst small ruminant farmers, lack or limited use of veterinary services by sheep and goat rearers, non-availability of vaccine at veterinary establishments in the sampled States are potential risk factors of PPR prevalence in South East Nigeria. Poor consultation of veterinarians by farmers will lead to poor management of the disease and delayed or lack of treatment, will in-turn create room for further contamination of the environment and spread of the disease. Based on our findings, there is need for extension program on the importance and benefits of PPR vaccination and the use of veterinary services with stakeholders and farmers. This will serve as a tool for effective planning of nationwide vaccination campaign for improved control of PPR in South East Nigeria and the country at large.

EFFECT OF COLD WATER NEEM (*Azadirachta indica)* LEAVES EXTRACT ON MEAT QUALITY OF BROILER CHICKENS

Egbeyale, L. T*., Ojetunji, O. C., Adeleye, O.O., Ayo-Ajasa, O. Y. & Adewole, F. A.

ABSTRACT
This study was conducted to determine the effect of cold water neem leaf extract on meat quality of broiler chicken. One hundred and sixty broiler chicks (Cobb) were randomly divided into four groups of 40 birds per treatment. Each group was sub-divided into four replicates of 10 birds. The birds in group 1 served as control and antibiotics were administered to them while 0.1, 0.2 and 0.3% concentration of neem leaf extract were administered to bird on groups 2, 3 and 4, respectively. The period of experiment was six weeks. The birds were fed ad libitum. One bird close to average final weight was selected randomly in each replicate and was slaughter at 42nd day of the experiment. Meat samples from breast muscle of the bird were subjected to cooking weight loss, refrigeration weight loss and sensory evaluation. The data obtained were subjected to one-way Analysis of Variance in a completely randomized design (RCD). The cooking loss increased ($P<0.05$) with higher concentration of the extract while refrigeration weight loss percentages were similar ($P>0.05$) across the treatments. The result on Sensory evaluation showed that only colour, tenderness and overall flavour were significantly ($P<0.05$) influenced. The study concluded that aqueous Neem (Azadirachta indica) leaf extract (ANLE) administration in drinking water of broiler chicken as alternative to antibiotics did not pose any adverse threat on the meat quality.
Keywords: neem extract, refrigeration and cooking losses, sensory evaluation, broiler chicken

INTRODUCTION
Medicinal plants extracts were developed and proposed for use in food as natural antimicrobials (Hsieh and Mau, 2001). Beneficial effects of herbal extracts or active substances in animal nutrition includes the stimulation of appetite and feed intake, the improvement of endogenous digestive enzyme secretion, activation of immune response and antibacterial, anti-viral, antioxidant and anthelminthic actions. Generally, plant extracts have no problem of antimicrobial resistance (Tipu *et al*., 2006) and broilers fed on herbal feed additives were accepted well by consumers (Hernandez *et al.*, 2004).
Aqueous extract of Neem leaves has a good therapeutic potential as anti-hyperglycemic agent, antibacterial agent and could be used for controlling airborne bacterial contamination in the residential premise (Mishra *et al.,* 2013). It was shown that Neem leaves extract acts as a growth promoter (Landy *et al.,* 2011), improves performance and hematological parameters (Nayaka *et al.*, 2013) and immune response (Jawad *et al*., 2013) in broilers. Due to paucity of information on the effect of neem leaf extract on meat quality, this study was designed to investigated the effect of cold water extraction of neem leaves on eat quality of broiler chickens.

MATERIALS AND METHODS
Experimental site: The rearing of birds took place at the Poultry Units of the Teaching and Research Farm, while the meat quality section was carried out at the Meat Processing Laboratory, Department of Animal Production and Health, College of Animal Science and livestock Production, of Federal University of Agriculture Abeokuta (FUNAAB).
Source and preparation of the extract: Fresh neem (*Azadirachta indica*) leaves were harvested, rinsed thoroughly with water to remove all the dirt from it then pounded in a mortar with pestle to increase the surface area for better extraction. The pounded leaves were weighed on the sensitive scale at 1, 2 and 3g, which were needed for the experiment. The weighed freshly pounded neem leaves were added to clean cold water (at room temperature) at 1g of neem leaves to 1 litre of water, 2g of neem leaves to 1 litre of water, and 3g of neem leaves to 1 litre of water and thereafter was left for 12 hours at room temperature and was sieve before it was offered to the birds.
Experimental Design: A Completely Randomized Design (CRD) was adopted for this experiment. The one hundred and sixty 7 days old broiler chicks of Cobb strain were allocated into four treatments

with each treatment contains 40 birds. Each treatment was further sub-divided into four replicates of ten birds each. The period of the experiment lasted for six weeks. The treatment groups are; Treatment 1 (Control) was administered antibiotics (Enrofloxacin at the manufacture's recommendation), Treatment 2 (0.1%) of neem extract in drinking water, Treatment 3 (0.2%) of neem extract in drinking water and Treatment 4 (0.3%) of neem extract in drinking water. Starter broiler diet of 23% CP and 11.47 MJ/Kg was supplied *ad libitum* for the first three weeks while finisher broiler diet of 20.10%CP and 11.62 MJ/Kg was supplied during the last three weeks of the experiment.

Data Collection: At the 42nd day of the experiment, one broiler chicken close to average final weight was selected randomly from each replicate and was slaughtered. After dressing, breast meat sample of 54.13-54.80g from each broiler chicken was cooked separately at 70°C for 15 minutes in a water bath (Egbeyale *et al*., 2012). The difference between the weights before and after cooking gave the cooking weight loss of the meat samples. Meat samples of another set of 51.20-54.50g were cut from the breast muscles of the slaughtered broiler chicken. Each sample was weighed and labeled according to the treatment before being stored in a refrigerator at about 10°C for 24 hours (Egbeyale *et al*., 2012).

Sensory evaluation: For sensory evaluation, a uniform size of cooked chicken breast meat was sliced into cubes and the cooked chicken breast meat was labeled according to each treatment and samples were allowed to cool before serving the panel. Eight educated panelists were isolated from each other, so as to prevent communication and each panelist was asked to rinse his/her mouth with ordinary water after each sample testing to avoid any carry over effects. The panelist evaluated the meat colour, flavour, juiciness, aroma, texture, saltiness and overall acceptability. The evaluators were asked to score the sample on nine points scale according to Egbeyale *et al*. (2012)

Statistical analysis: Data collected were subjected to one-way Analysis of Variance (ANOVA) and differences in means were separated using Duncan Multiple Range Test (SAS 2012) at 5% significance level.

RESULTS

The effect of aqueous neem leaf extract (ANLE) on cooking and refrigeration weight losses of broiler chicken is present in Table 1. Cooking weight loss (CWL) was significantly ($p<0.05$) influenced. The CWL of meat from birds on 0.3%ANLE were significantly higher than the control. However, the meat from birds that drank water containing 0.1 and 0.2% ANLE recorded values similar to both control and 0.3%ANLE group. The refrigeration weight loss and percentage refrigeration loss did not show any significant ($p>0.05$) different among the treatments.

Table 1: Effect of cold water neem (A*zadirachta indica*) leave extract on cooking and refrigeration loss of broiler chicken

	Inclusion level of NLE (%)			
Parameters	0	0.1	0.2	0.3
Cooking				
Weight before cooking (g)	54.80±0.47	54.13±0.78	55.33±1.36	54.30±1.11
Weight after cooking (g)	49. 15±0.37	47. 13±0.95	48. 90±1.26	46.98±1.36
Cooking weight loss (g)	5.65±0.37^{b}	7.00±0.61^{ab}	6.43±0.18^{ab}	7.33±0.55^{a}
Percentage weight loss (%)	10.30±0.61^{b}	12.94±1.12^{ab}	11.62±0.27^{ab}	13.52±1.11^{a}
Refrigeration				
Weight before refrigeration (g)	53.80±1.35	51.20±0.58	54.08±0.91	54.50±0.55

$^{a,b;}$ Means on the same row with different superscripts are significantly ($p<0.05$) different

DISCUSSION

The cooking loss values reported in this study are lower than the values reported by Gohar *et al*. (2012) who compared cooking loss in broiler and layer meat and reported that cooking loss in broiler meat was in the range of 15.55 to 36.00%. The increase in the cooking weight losses with increasing levels of ANLE obtained in this study is in accordance with the results of the work of Ncube *et al*. (2018) who studied the effect of *Acacia angustissima* leaf meal on yield of carcass components and meat quality of broilers and reported that increasing levels of the leaf meal resulted in drier meat. High cooking loss also implies the less ability of the meat to hold water during processing and storage (Abu *et al*., 2015). According to Michalczuk *et al*. (2014), high meat cooking loss has an adverse effect on sensory perception as it reduces juiciness. The influence of ANLE on tenderness and overall flavour is consistent with results published by Jang *et al.* (2008) on the enhancement of flavour after feeding a mixture of herbal tree extracts to broilers. Similarly, the result agrees with Aderinola *et al.* (2013) who reported enhanced flavour of meat from *Moringa oleifera*-fed broilers. These similarities in juiciness and meaty flavour are in agreement with findings of Bonsu *et al*. (2012) who studied the medicinal response of broiler chickens to diets containing neem (*Azadirachta indica*) leaf meal. Egbeyale *et al*. (2012) in their study of meat qualities characteristics of broiler chicken fed varying levels of *Ocimum gratissimum* reported that parameters such as juiciness, saltiness and overall acceptability were not significantly influenced. However, the authors reported that overall flavour were significantly influenced which is in accordance with the results of this study.

CONCLUSION AND RECOMMENDATION

Aqueous extracts of neem (*Azadirachta indica*) leaf at 0.3% could be administered in the drinking water of broiler since it does not compromise the quality of meat.

ABSTRACT
In March 2018, the Nigerian Society for Animal Production (NSAP) held its 43rd Annual Conference at Owerri, southeast Nigeria, with the theme "Exploring Science and Technology Innovations for Sustainable Livestock Development" and produced a book of proceedings as its major conference output. This paper analyzed the 440 papers contributed to the book of proceedings, in order to highlight the current research priorities and sources of animal agriculture research (AAR) in Nigeria. Overall, 387(87.95%) oral and 53(12.05%) poster papers were contributed. AAR in Nigeria focused more on monogastric animal nutrition (MON) (18.68%, n=82) and animal physiology, reproduction and welfare (APRW) (17.27%, n=76) than other disciplines such as agricultural economics and extension (2.27%, n=10) and aquaculture (2.50%, n=11). The most popular animal model used in these studies was the domestic chicken, which accounted for 36.00%, (n=158) of overall papers and 34.81% (n=55) and 25.95% (n=41) of papers contributed under MON and APRW respectively. Papers were contributed from all the six geographical zones of the country, with the southeast (34.00%, n=149) and southwest (27.00%, n=116), recording the highest contributions and northeast the lowest (3,6%, n=17). The participants came from 83 institutions; however, more institutions were based in northcentral (24.12%, n=20) and southwest (21.62%, n=18) Nigeria. Most of the principal authors were affiliated to universities (59.00%, n=49), while only 4.00% (n=3) were affiliated to research institutions. AAR activities need to be resuscitated in these research institutes, while agricultural social scientist, aqua-culturist and pasture management experts should be encouraged to participate more in future conferences.
Keywords: Animal production, chicken, livestock, Nigeria

INTRODUCTION
The livestock industry in Nigeria represents a very important national resource that contributes substantially to the national wealth and also supplies the populace with the important animal proteins which are required for healthy living (Achonwa, 2017). For the past 43 years, the Nigerian Society for Animal Production (NSAP) has organized an annual conference, with the overall objective of linking the science of animal agriculture with the broader stakeholders in a knowledge sharing environment in order to engender innovative products development and practices. During these events, experts working across the different disciplines in animal agriculture research (AAR) gather to learn, share, innovate and foster new collaborations. Papers that highlight the current research focus and priorities of the national AAR community are routinely presented and produced as an annual conference book of proceedings.

In March 2018, the Society held its 43rd Annual Conference at the Federal University of Technology Owerri (FUTO) in southeast Nigeria, with the theme "Exploring Science and Technology Innovations for Sustainable Livestock Development". A conference book of proceedings containing 440 paper contributions was produced as the major output from the event. In this paper, we present our analysis of this book of proceedings, with the main objective of determining the current research priorities and affiliations of animal agriculture research scientists in Nigeria.

MATERIALS AND METHODS

The 2018 Annual Conference of the Nigerian Society for Animal Production (NSAP) was held from 18 – 22 March 2018 at the Federal University of Technology Owerri (FUTO), Imo State, Nigeria. The FUTO campus is located at Ihiagwa in Owerri West Local Government Area (LGA) of Imo state, South East Nigeria. The state lies between latitudes 05° 30" and 05° 56" north of the equator and between longitudes 05° 37" and 07° 26" east of the Greenwich meridian and occupies a land area of 13, 032 square kilometers. The climate falls under type AW in the Kopper-Geiger classification of wet and dry climate and zone B of the Nigerian eco-climatologically zones (Ofomata, 1975). Given the close relationship between climate and vegetation, the location of the conference coincides with the rain-forest belt. It receives an annual rainfall range of 2000 to 2484 mm, with an average daily temperature of 26°C.

The event generated a conference book of proceedings containing 440 presentations made-up of 387oral and 53 poster papers. With the aid of frequency counts and percentages, we analyzed the information on the paper contributed by authors to the book of proceedings, in order to determine their disciplinary, inter-disciplinary, regional and researcher affiliation diversity. In all cases, researcher affiliation was based on the given address of the principal author. Data generated were presented in graph formats.

RESULTS AND DISCUSSION

Figure I shows that out of the 440 papers presented at the conference, 18.64% (n = 82) and 17.27% (n = 76) were on monogastric animal nutrition (MON) and animal physiology, reproduction and welfare (APRW) respectively, constituting the major subject areas of focus by the researchers. Papers dealing with Animal production, economics and extension (APE), aquaculture and fishery management (AFM) and pasture and range management (PRM) were particularly few.

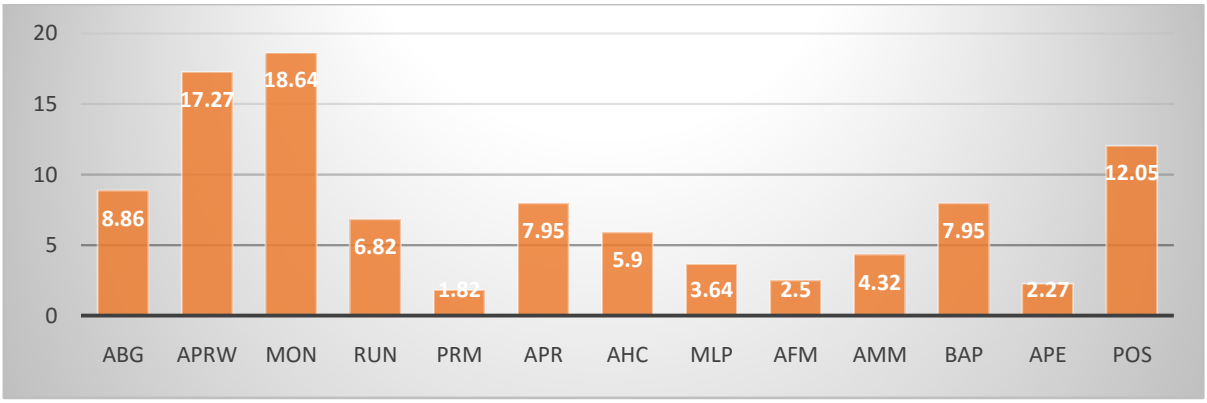

Fig. I: Percentage distribution of papers contributed across different subject areas during the conference (n = 440). Legend:ABG = Animal breeding and genetics; APRW = Animal physiology, reproduction and welfare; MON = Monogastric nutrition; RUN = Ruminant nutrition; PRM = Pasture and range management; APR = Animal products and processing; AHC = Animal health and disease control; MLP = Microlivestock production; AFM = Aquaculture and Fishery Management; AMM = Animal Management and Modelling; BAP = Biochemistry and Biotechnology Applications; APE = Animal production economics and extension; POS = Poster presentations

Figure II shows the percentage distribution of paper contributions across different animal species highlighted the fact that the domestic chicken was the major species (35.91%, n = 158) used as animal model by the researchers. Of these papers dealing with domestic chicken research, 34.81% (n = 55) and 25.95% (n = 41) were presented under MON and APRW subject areas respectively (Figure III). The results in figure IV also show that across the two popular research areas, MON and APRW, chicken research again constituted 67.07% (n = 55) and 55.26% (n = 42) of the papers presented. The use of chicken as animal model for researching alternative feedstuffs is popular in Nigeria and is driven by the urgent need to sustain the recent growth in the industry through identification of cheaper and locally available feed ingredients (Esonu, 2009; Ifeduba, 2018).

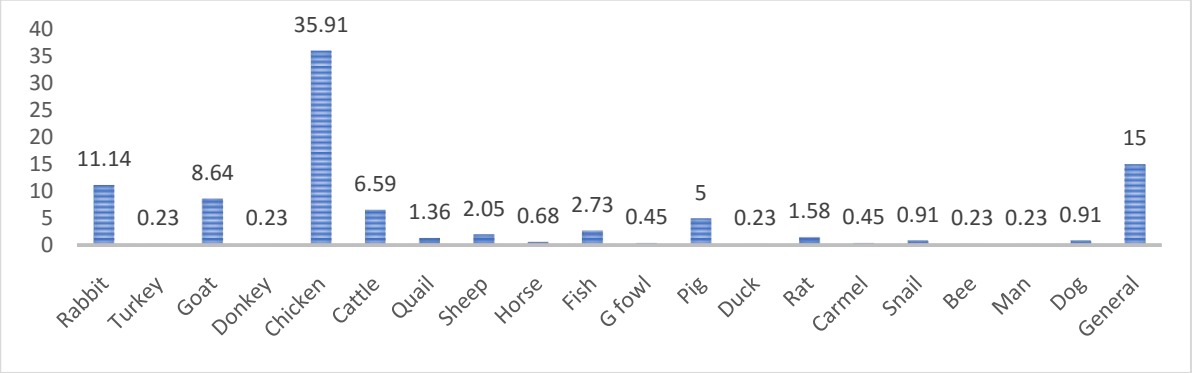

Fig. II: Percentage distribution of paper contributed across different animal species (n = 440)

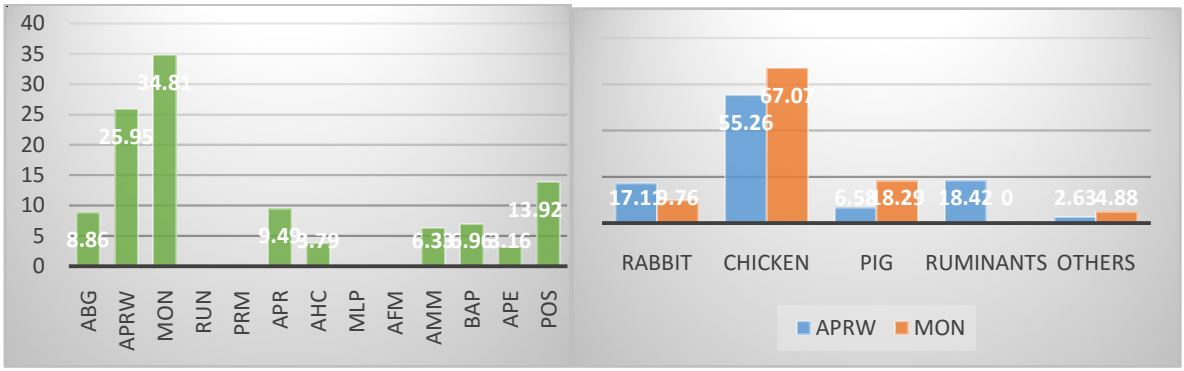

Fig. III: Percentage distribution of papers dealing with chicken research across different subject areas (n = 440). Legend: As in Figure I

Fig IV: Percentage distribution of animal species used in animal physiology and monogastric nutrition research (n = 76 for APRW and 82 for MON). Legend: As in Figure I

Figure V shows the percentage distribution of papers across the six geographical zones of Nigeria, namely South west (SW), South east (SE), South-south (SS), North central (NC), North west (NW) and North east (NE) zones. It is interesting to note that all the six zones were represented, however, about 34.00% (n = 149) of the papers were understandably contributed by researchers affiliated to institutions based in the SE zone, which was the location of the conference venue.

Fig. V: Percentage distribution of papers across the different geographical zones during the conference (n = 440). Legend: SW = South west; SE = South east; SS = South-south; NC = North central; NW = North west; NE = North east.

Fig. VI: Percentage distribution of institutional affiliations of first authors of papers (n = 83)

Figure VI showed that the papers were actually contributed by researchers working in 83 institutions spread across the different zones of the country, with NC (24.12, n = 20) and SW (21.69, n = 18) hosting the highest number of institutions. It is therefore interesting to note that even though 15.00% of the conference papers were contributed by researchers based in NC Nigeria, its institutional

representation was higher than those of other zone. Figure VII showed the percentage distribution of papers according to types of authorship. Generally, most of the papers were written by more than one author, with the trend being multiple authorship.

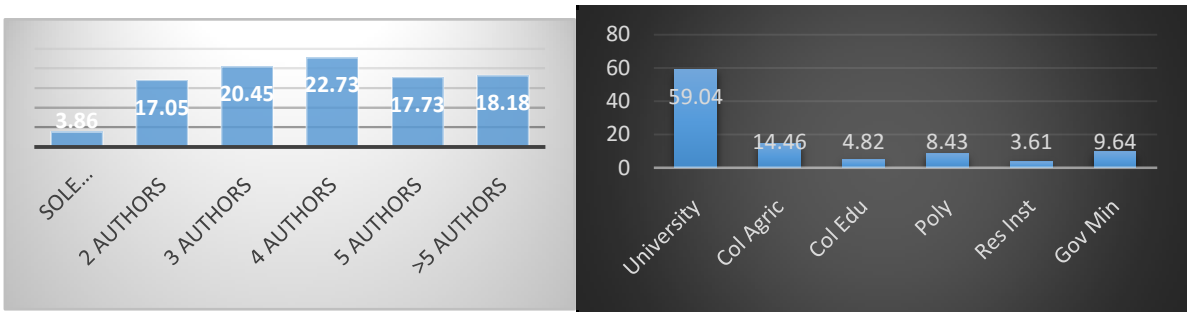

Fig. VII: Percentage distribution of papers according to type of authorship (n = 440)

Fig: VIII: Percentage distribution of papers according to type of institutions affiliated to the first authors (n = 440). Legend: Col Agric = College of Agriculture; Col Edu = College of education; Poly = Polytechnic; Res Inst = Research Institute; Gov Min = Government Ministry

Figure VIII presented the percentage distribution of papers according to institutional affiliation of the principal authors of the papers. The results show that 59.00% (n = 49) of the institutions affiliated to the principal authors were university, while 14.00% (n = 12) were affiliated to colleges of agriculture. The lowly 4.00% (n=3) recorded for research institutes was strange and may reflect serious challenges to research in these institutions, probably due to poor funding by government.

CONCLUSION

This study has shown that animal agriculture research in Nigeria is currently focused majorly on monogastric animal nutrition and animal physiology, reproduction and welfare and that the most popular animal model for these studies is the domestic chicken. These papers were contributed by researchers from all the six zones of the country, but especially from the SE and SW, mostly affiliated to the university system. The very low research output from the country's research institutes might be reflecting serious challenges to research in these institutions. There is the need to attract more papers from economics and extension, aquaculture and pasture management researchers to future conferences, since they were poorly represented.

ABSTRACT
A total of thirty (30) grower pigs were used to determine the effect of sole and combined herbal leaf meal as feed additives in-feed antibiotics on carcass characteristics and meat quality of growing pigs. The pigs were grouped on weight equalization into 5 treatments (T1: pigs fed diet without antibiotics, T2: pigs fed diet containing synthetic antibiotics, T3: pigs fed diet containing moringa leaf meals, T4: pigs fed diet containing Neem leaf meals, T5: pigs fed diet containing mixture of Moringa and Neem leaf meals). Each treatment consisting of 6 pigs was further subdivided into 3 replicates. Each replicate consisted of 2 pigs. On the last day of the study, 2 pigs from each treatment were slaughtered for carcass analysis and meat quality. Data generated were subjected to Analysis of Variance in a Completely Randomized Design. Results revealed head was significantly ($p<0.05$) highest (11.40%) in T4 and lowest (9.27%) in T1. Tail was significantly ($p<0.05$) highest (0.38%) T4 while lowest values (0.21 and 0.22%) were recorded in T1 and T2, respectively. Values (0.43, 0.42, 0.45 and 0.37%) recorded for heart were statistically similar in T1, T2, T3, and T5, respectively which were significantly ($p<0.05$) lower than 0.56% recorded in T4. Cooking loss and thermal shortening were significantly ($p<0.05$) highest (22.73 and 38.40%) in T4 and lowest (15.06 and 26.46%) in T5. Chilling loss was significantly ($p<0.05$) highest (2.30%) in T2 and lowest (1.05%) in T5. Therefore, feeding pigs diet containing Neem leaf meal improved cut parts (head and tail), organs (heart) and meat quality.
Keywords: herbal leaf meal, carcass, meat quality, pigs

INTRODUCTION
The use of antibiotics in feed of livestock has not only been linked to the emergence of antibiotic resistant zoonotic bacterial pathogens but the presence of antibiotic residue contamination of animal products (Gong *et al*., 2014). Thus, a great number of consumers are concerned about the type and quality of their food. These consumers are rejecting the use of synthetic chemicals, such as antibiotics because their use is associated with animal and human health risks (Hao *et al*., 2014). This has led to the prohibition of the use of antibiotic for livestock production in many countries and the thorough search for alternatives to antibiotics (Valenzuela-Grijalva *et al*., 2017). One of such alternative sources is moringa and Neem (*Azadirachta indica*). Moringa (*Moringa oleifera*) is known as a miracle tree because of its numerious nutritional properties. Neem is an indigenous plant known for its useful medicinal properties like antibacterial, antifungal, antiprotozoal, hepato-protective and various others without showing any adverse effects (Esonu 2006). This study therefore aimed to determine the effect of sole and combined herbal leaf meal as alternatives antibiotics on carcass characteristics and meat quality of growing pigs.

MATERIALS AND METHODS
Experimental Site
The study was carried out at the Piggery Unit of the Directorate of Universities farm, Federal University of Agriculture, Abeokuta while analysis of meat was carried out at the Animal Product and Processing Laboratory of the Department of Animal Production and Health, Federal University of Agriculture, Abeokuta.
Preparation of Herbal leaf meals
Neem (*Azadiracta indica*) and Moringa (*Moringa oleifera*) leaves were procured within Odeda Local Government Area, Ogun State. The leaves were air dried for 3-5 days until they became crispy while retaining their greenish coloration. The leaves were afterwards milled and incorporated into experimental diets.

Experimental pigs and management

A total of thirty (30) grower pigs were purchased from a reputable farm in Abeokuta, Ogun State. The pigs were grouped on weight equalization into 5 treatments (T1: pigs fed diet without antibiotics, T2: pigs fed diet containing synthetic antibiotics, T3: pigs fed diet containing moringa leaf meals, T4: pigs fed diet containing Neem leaf meals, T5: pigs fed diet containing mixture of Moringa and Neem leaf meals). Each treatment consisting of 6 pigs was further subdivided into 3 replicates. Each replicate consisted of 2 pigs. Feed and water were provided *ad libitum* throughout the experimental period that lasted for 12 weeks.

Data Collection

Carcass Characteristics

On the last day of the study, 2 pigs from each treatment were selected, weighed, fasted overnight, stunned using percussion method and slaughtered by severing the jugular vein. The carcass weights as well as weights of cut-parts and offals were recorded and expressed as percentages of the live weights.

Meat Quality

The following meat quality parameters were determine;

- Cooking loss (%) = $\frac{(\text{Weight of meat before cooking} - \text{weight of meat after cooking})}{\text{Weight of meat before cooking}} \times 100$
- Chilling Loss (%) = $\frac{\text{Weight before refrigeration} - \text{Weight after refrigeration}}{\text{Weight before refrigeration}} \times 100$
- Thermal Shortening = $\frac{\text{Length before cooking} - \text{length after cooking}}{\text{Length before cooking}} \times 100$
- Cold Shortening = $\frac{\text{Length before refrigeration} - \text{length after refrigeration}}{\text{Length before refrigeration}} \times 100$

Statistical Analysis

Data generated were subjected to Analysis of Variance in a Completely Randomized Design using SAS (2003). Significantly ($p<0.05$) different means were separated using Duncan Multiple Range Test as contained in the same statistical Package.

RESULT AND DISCUSSION

The effect of sole and combined herbal leaf meal as alternative feed additives antibiotics on carcass characteristics of growing pigs is presented in Table 1.Values recorded for head was significantly ($p<0.05$) highest (11.40%) in T4 and lowest (9.27%) in T1. Tail was significantly ($p<0.05$) highest (0.38%) on T4 while lowest values (0.21 and 0.22%) were recorded in T1 and T2, respectively. Similar means (14.30, 14.65 and 14.39%) were recorded for GIT in T1, T3 and T4, respectively which were significantly ($p<0.05$) lower than 17.75% recorded in T5. Values (0.43, 0.42, 0.45 and 0.37%) recorded for heart were statistically similar in T1, T2, T3, and T5, respectively were significantly ($p<0.05$) lower than 0.56% recorded in T4. Full stomach was significantly ($p<0.05$) highest (2.45%) in T5 and lowest (1.38%) in T3. In terms of these characteristics, literature is limited on the use of herbal leaf meal in pig production. However, few studies with phytochemicals that assessed carcass characteristics in poultry revealed improvement in parameters, including carcass weight, breast weight, and carcass dressing percentage and reduced abdominal fat and relative abdominal fat (Hong *et al*., 2012; Kanduri *et al*., 2013).

Table 1: Effect of sole and combined herbal leaf meal as alternative feed antibiotics on carcass characteristics of growing pigs

Parameters	T1	T2	T3	T4	T5
Live weight (kg)	57.25±10.18	52.50±4.84	50.75±0.85	53.75±3.57	51.50±2.63
Hot carcass weight(Kg)	35.35±6.55	33.00±3.70	34.00±0.82	33.00±3.51	33.75±3.68

[a, b, c,] means values with different superscripts within row are significantly different ($p<0.05$)
[1, 2,] values are expressed as percentages of the live weight

In Table 2, the effect of sole and combined herbal leaf meal as alternative feed antibiotics on meat quality of growing pigs is shown. Values for cooking loss was significantly ($p<0.05$) highest (22.73%) in T4 and lowest (15.06%) in T5. Chilling loss was significantly ($p<0.05$) highest (2.30%) in T2 and lowest (1.05%) in T5. Cold shortening values were significantly ($p<0.05$) higher (11.38 and 11.30%) in T1 and T3 and lowest (7.24, 5.52 and 7.52%) in T2, T3 and T5, respectively. Thermal shortening was significantly ($p<0.05$) highest (38.40%) in T4 and lowest (26.46%) in T5. Although, there are few studies on the effect of herbal leaf meal on meat quality of pigs, the present study contradicted the findings of Liu *et al.* (2016) who reported no effect of *S. baicalensis* and *Lonicera japonica* extract mixture supplementation on cooking loss and drip loss of meat from finisher pigs. Lei *et al.* (2018) also reported negligible results for drip loss and cooking in pigs fed natural and fermented herbs. This contradiction may be due to the kinds of herbs used and the age of the animal.

Table 2: Effect of sole and combined herbal leaf meal as alternative feed additives antibiotics on meat quality of growing pigs

Parameters (%)	T1	T2	T3	T4	T5
Cooking loss	20.55±0.73^{b}	21.24±0.20^{ab}	19.77±0.44^{b}	22.73±0.74^{a}	15.06±0.86^{c}
Chilling loss	1.60±0.18^{bc}	2.30±0.22^{a}	1.57±0.18^{bc}	1.85±0.38^{ab}	1.05±0.08^{c}
Cold Shortening	11.38±1.89^{a}	7.24±0.67^{b}	5.52±0.80^{b}	11.30±1.56^{a}	7.57±0.95^{b}
Thermal shortening	34.69±1.80^{ab}	32.38±1.63^{b}	36.12±1.42^{ab}	38.40±1.45^{a}	26.46±1.16^{c}

[a,b,c,] means values with different superscripts within row are significantly different ($p<0.05$)

CONCLUSION AND RECOMMENDATION

From this study, it was concluded that feeding pigs diet containing Neem leaf meal improved cut parts (head and tail), organs (heart) and meat quality while feeding pigs diet containing moringa and moringa and neem leaf meal improved dressing percentage and reduced cooking loss.

ABSTRACT
Sheep and goats enterprise has been found to sustain economic growth and alleviate poverty among the farmers but inadequate feedstuff has posed a threat to their production beyond subsistence level. Therefore, this study investigated the agro-industrial by-products used by households and farmers in Osun State. Information on socio-economic background and utilisation of agro-industrial by-products for sheep and goats production was collected from 160 respondents using interview schedule. It was observed that more of the respondents were married (57.5%), had secondary education (46.9%) and majority (85.6%) earned about ₦49,000:00 monthly. Maize stover (57.5%) and cut grass (45.6%) were often used in feeding sheep and goats in the study area. Among the agro-industrial by-products used in sheep and goats feeding were from maize, sorghum, cowpea, rice, groundnut and millet production.
Keywords: Alternative feed resources, ruminant production, rural households

INTRODUCTION
Essentially, sheep and goats contribute immensely to rural development in many parts of Nigeria yet; the output is not enough to meet the animal protein requirements of the populace. For instance, in Nigeria it has been estimated that there are about 22.1 million sheep and 34.5 million goats (FDLPCS, 1992) and about 70% of these were reared by smallholder farmers under semi-intensive and extensive systems. This has been attributed to farmers lack of interest in rearing sheep and goats as well as inadequate feedstuff with poor nutritional quality and low forage productivity (Amole and Ayantunde 2015; FAO, 2012; Olorunnisomo, 2011). To ameliorate these constraints, a coping mechanism whereby alternative feed resources are utilised in sheep and goats feeding has been suggested (Haile *et al*., 2017; Garg *et al*. 2013; Ugwu, 2007). Hence, this study was aimed at investigating the utilisation of available and unconventional feedstuff in sheep and goats production in Osun State.

MATERIALS AND METHODS
Study location
Osun State has 30 local government areas with three senatorial zones: Osun East, Osun West and Osun Central and it is situated in the tropical rain forest zone of Nigeria with abundant mineral resources and presence of rivers. It covers an area of approximately 1,487,500 hectares and lies between latitude 7° 30′ 0″ North and longitude 4° 30′ 0″ East with 3,423,535 people (NPC 2006). It has cultivatable land area of 1,190,000 hectares, with only 761,600 hectares cultivated with arable crops and 178,500 hectares cultivated with tree crops (Osun MTSS, 2019-2021). The state is estimated to have about 256,000 farm families. As an agrarian state, there is availability of both food and cash crops as well as animals like cattle, sheep, goats, poultry, rabbits and swine, hence the high economic activities in the state.
Sampling technique, data collection and analysis
Simple random sampling approach was used to obtain information from sheep and goat rearers in the three Agricultural Development Program (ADP) zones: Ife/Ijesa, Iwo and Oshogbo in Osun State. This was further subdivided into 16 sub-zones proportionate to the sizes of the ADPs (4 sub-zones each in Iwo and Osogbo and 8 in Ife/Ijesa) for reliable data collection. Ten sheep and goat rearers were randomly selected in each area to respond to interview schedule that had 30 close-ended questions. Information were gathered on personal and socio-economic characteristics and utilisation of agro-industrial by-products for sheep and goats feeding and were analysed using simple descriptive statistics according to Adesoye (2004).

RESULTS AND DISCUSSION

The personal socio-economic characrteristics of the respondents presented in Table 1 showed that more married people (57.5%) were involved in sheep and goats production, while 18.8% widow/widower were also involved. Among the respondents, 16.3% had primary education, 46.9% and 10.0% had secondary and tertiary education, respectively. A total of 26.9% did not have formal education. Respondents were mostly Christians (57.5%), followed by Muslims (39.4%) while 3.1% practiced traditional religion. These observations corroborated the report of Fakoya and Oloruntoba (2009) that more married people with a level of education across the main religious groups in Osun State, are involved in small ruminant production. Though the respondents were basically farmers (40.6%) and traders (35.0%), majority of them (85.6%) earned about ₦49,000:00 only. One of the respondents (0.6%) earned about ₦200,000 monthly. Though an insignificant proportion, it suggests that sheep and goats rearing could be a veritable source of livelihood especially among the rural dwellers. This seemingly lent more credence to the assertions by many people, that sheep and goat rearing contributes immensely to household's income particularly, as source of cash to meet instant household financial obligations (Amole and Ayantunde, 2015; Legesse *et al*., 2008; MoFA, 2006; Dibissa, 2000). Therefore, sheep and goats rearing should be encouraged to enhance the well-being of households in particular and the gross domestic product at large.

Table 1: Distribution of respondents by their personal and socio-economic characteristics

Variables	Categories	Frequency	Percentage
Marital status	Single	13	8.1
	Married	92	57.5

Source: Field survey (2018)

Table 2 shows the agro-industrial by-products used by sheep and goats rearers in Osun State. Maize stover (57.5%) and cut grass (45.6%) were often used in feeding sheep and goats, compared to sorghum stover, sorghum grain residue, maize grain residue and cowpea haulm that were reported to be rarely used by 63.1%, 55.0%, 53.1% and 47.5% of respondents, respectively. Interestingly, it was observed that millet grain (81.3%), rice straw (74.4%) and rice grain (68.8%) were never used in feeding sheep and goats among the respondents. This could be possibly due to lack of awareness of the potentials of the feed resources and may also be due to unavailability of those resources. Also, it could be largely due to feedstuff selective behaviour of sheep and goats even in confinement that made *in situ* grazing still a better feeding option for sheep and goats (Oppong-Anane, 2013; Ugwu, 2007). Meanwhile, Haile *et al*. (2017) stated that pastures and stubbles are inadequate to meet the nutritional requirements of sheep and goats due to overgrazing and climate change adversities. Hence, the need for utilisation of agro-industrial by-products as a coping measure to boost animal protein availability in Osun State in particular and Nigeria at large.

Table 2: Agro-industrial by-products utilisation in sheep and goats production in Osun State

Agro-industrial by-products	Never	Rarely	Often	Very often
Maize stover	2 (1.3)	17 (10.6)	92 (57.5)	49 (30.6)
Sorghum stover	13 (8.1)	101 (63.1)	41 (25.6)	5 (3.2)
Cowpea haulm	54 (33.8)	76 (47.5)	29 (18.1)	1 (0.6)
Rice straw	119 (74.4)	37 (23.1)	4 (2.5)	0 (0.0)
Groundnut haulm	128 (80.0)	31 (19.4)	0 (0.0)	1 (0.6)
Cut grass	37 (23.1)	43 (26.9)	73 (45.6)	7 (4.4)
Maize grain/residue	25 (15.6)	85 (53.1)	45 (28.1)	5 (3.1)
Sorghum grain/residue	58 (36.2)	88 (55.0)	12 (7.5)	2 (1.3)
Rice grain/residue	110 (68.7)	44 (27.5)	4 (2.5)	2 (1.3)
Millet grain/residue	130 (81.3)	24 (15)	6 (3.8)	0 (0.0)

Source: Field survey (2018). Values in parentheses are the corresponding percentages (%)

CONCLUSION AND RECOMMENDATION

Myriads of agro-industrial by-products like those from maize, sorghum, cowpea, rice, groundnut and millet appeared to be available in Osun State but maize stover and cut grass were more utilised. However, all the identified agro-industrial by-products could be utilised in sheep and goats production to enhance the well-being of households. Consequently, awareness on the possible utilisation of these by-products in sheep and goats feeding becomes imperative.

ACKNOWLEDGEMENT

The authors sincerely appreciate all the members of Staff of Osun State Agricultural Development Program, for their valuable contributions to the success of this study.

ABSTRACT

The anti-trypanosomal effects of dry leaf meals of *Moringa oleifera*and *Azadirachta indica* for serum total protein were investigated using grower rabbits. Forty rabbits were randomized into eight groups (1, 2, 3, 4, 5, 6, 7 and 8) of five animals each with mean live weights of 1.2 Kg. Groups 5, 6, 7 and 8 were Inoculated subcutaneously with normal saline diluted blood containing $3.98\times10^{6}ml^{-1}$ of *Trypanosoma brucei brucei* , while groups 1, 2, 3 and 4 were not inoculated . The rabbits were fed on four diets. Diet (D) 1 had no leaf meal (basal) and was fed to groups 1and 5 (controls). D 2 was fortified with 1% Moringa Leaf Meal (MLM) and was fed to groups 2 and 6. D 3 had 1% Neem Leaf Meal (NLM) and was fed to groups 3 and 7. D 4 had both MLM and NLM at 1% each and was fed to groups 4 and 8. Data were subjected to statistical analysis using SPSS ANOVA and Duncans new multiple range test at 95% confidence limit. The results of total blood proteins gl^{-1} was significantly ($P<0.05$) higher for rabbits inoculated with *T. brucei brucei* than for non inoculated rabbits except group 6 ($P>0.05$). The findings in this study reveals that the serum total protein of rabbits in group 6 inoculated with *T. brucei brucei* which was not significant ($P>0.05$) from group 2 (non inoculated rabbits) supports the hepato protective capability of MLM over NLM.

Keywords: Anti-trypanosomal, serum total protein

INTRODUCTION

The disease Animal African Trypanosomosis (AAT) affects most domestic animals. It is caused by extracellular haemoprotozoan parasites belonging to the genus *Trypanosoma* (Zawua *et al*., 2015). The most important species of trypanosomes affecting livestock in Nigeria are *T. vivax, T. brucei brucei, T. congolense, T. evansi* and *T. simiae*. Trypanosomes are mainly transmittedcyclically by tsetse fly, a vector belonging to the genus *Glossina*. Trypanosomosis is considered to be among the most important constraint to livestockproductivity in sub Saharan Africa (Wellburn *et al*., 2001). Losses include a decrease in productive potential such as diseased growth rate, poor milk yield, weight loss in young growing animals and death(Kaewthamasorn and Wongsamee, 2006). Several ethno medicinal plants have been researched on to find alternative treatments for trypanosomosis as against the three major salts of Diminazene, Homidium and Isomethamidium chloride produced in 1950s and still used as trypanocides to treat AAT (Nok *et al*., 1993; Geerts *et al*., 2001 and Atawodi, 2005).

The shrub *Moringa oleifera* is a pan-tropical species that is reputed to possessing nutritional and medicinal properties (Gafar and Itodo, 2011). It belongs to the family moringaceae. It is widely cultivated in Asia, Africa and other tropical parts of the world (Makker and Becker, 1997). Anti-trypanosomal trial of moringa leaves prolonged the lifespan of rats and was reported to be non toxic (Olugbemi *et al*., 2010).

The neem tree scientifically called *Azadirachta indica* has been highly valued in India for over 4,000 years and is referred to as miraculous healing plant (Gunguli, 2002). It belongs to the mahogany family meliceae and can reach a height of 15-20 meters. Reports had been made on the trypanocidal potentials of *Azadirachta indica* leaves extract (Nok *et al*., 1993). Domestic rabbits (*Oryctolagus cuniculus*) were used as model laboratory animals to represent animals naturally infected by trypanosomosis.The aim of this study was to investigate the antitrypanosomal effect of serum total protein in prophylactic treatment of moringa and neem leaf meals against *T. brucei brucei*experimentally infected rabbits.

MATERIALS AND METHODS

Experimental Site

This study was conducted at the Nigerian Institute for Trypanosomiasis Research (NITR) -Vom in Plateau State, Nigeria.

Preparation of Moringa and Neem Leaf Meals

Fresh moringa and neem leaves were harvested from residential houses in hudco quarters north bank, makurdi, Benue state. The leaves were air dried on clean surfaces in the laboratory indoors until crisp. The dried leaves were then pulverized and stored in sealed polythene bags until they were used in feed preparation.

Experimental Animals and their Management

Forty weaner rabbits were purchased from Dagwom farm in Vom. They were vaccinated against Coccidiosis using Coccinor, treated with long acting Oxytetracycline and Ivermectin following manufacturer's directives against mange and gastro-intestinal parasites. The animal house, hutches and all handling equipments were washed with detergent and disinfected with 3.5% Sodium Hypochlorite before arrival of the rabbits. Each rabbit were housed individually in wire mesh cages. An acclimatization period of three weeks was observed. The animals were maintained according to the CIOMS guidelines (1985).

Proximate Composition and Energy Content of Leaf Meals

The proximate composition and energy value of *Moringa oleifera* Leaf Meal (MLM) and Neem Leaf Meal were determined according to AOAC (2002) at the Biochemistry Department of the National Veterinary Research Institute (NVRI) Vom.

Experimental Diets, Animal Groups and Inoculation with Trypanosomes

Four types of diet and eight groups ofrabbits fed with diet 1 which contained no leaf meal (basal diet) served as control. The second diet (D 2) contained 1% Moringa Leaf Meal (MLM). The third diet (D 3) had 1% Neem Leaf Meal (NLM). The fourth diet (Diet 4) had approximately 1% each of MLM and NLM.Diet 1 was fed to groups 1 and 5, diet 2 was fed to groups 2 and 6, diet 3 was fed to groups 3 and 7 and diet 4 was fed to groups 4 and 8 respectively.

The *T. brucei brucei* (Federe Strain)used was obtained from the parasitology division of Nigerian Institute for Trypanosomiasis Research (NITR) Vom, Plateau State, Nigeria. The parasites were maintained by serial passage in albino rats bred in NITR-Vom. Blood was obtained from the serial passage rats by tail bleeding into normal saline and the parasitaemia adjusted to 3.98×10^6 trypanosomes per milliliter (ml) by the method of Herbert and Lumsden (1974). Each infected rabbit received 0.5ml of saline containing *T. brucei brucei.* The infection was by intraperitoneal injection. The duration of the experiment was 12 weeks (3 weeks pre-infection and 9 weeks post-infection periods).

Collection of blood samples

Trypanosomes were monitored daily and detected using a rapid approximation method (Herbert and Lumsden, 1974). At the end of the experiment, 5ml of blood was collected from the heart of three rabbits each per group and euthanized, for serum total protein test into blood sample tubes.

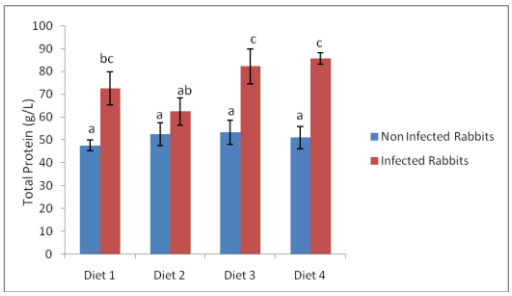
Biochemical technique

The total plasma protein was estimated using the Golgberg refractometer method as described by Kohn and Allen (1995).

Statistical analysis

The data collected were subjected to statistical analyses by Analysis Of Variance (ANOVA) and Duncans New Multiple Range Test (DMRT) at 95 % confidence limit using SPSS 24 (2016). Data are presented as Mean ± standard error ba

RESULTS AND DISCUSSION



The results of proximate composition of neem and moringa leaf meals are presented in Table 1. The moringa leaf meal had higher moisture, crude protein, ether extract, ash, Nitrogen Free Extract (NFE) and metabolizable energy than the neem leaf meal.

Table 1: Proximate composition of Neem and Moringa leaf meals.
Weight per 100grams of sample.

Neem Leaves		Moringa Leaves
Proximate analysis	**Result (g/100g)**	
Moisture	10.4	15.0
Crude Protein	16.2	25.4
Ether Extract	4.1	6.3
Crude Fibre	14.5	8.6
Ash	7.4	8.8
NFE	47.3	35.9
Metabolizable Energy Kcal/Kg	2596.1	2694.5

M.E was calculated using the method of Pauzenga, 1985. M.E (Kcal/Kg) = 37 x % CP + 81.8 x % EE + 35 x % NFE.

The results on serum total protein effects of moringa leaf and neem leaf meals are presented in figure 1. It revealed significantly ($p<0.05$) higher total protein for the rabbits inoculated with *Trypanosoma brucei* than the non inoculated rabbits for groups fed on diets 1, 3 and 4 except for diet 2 which had no significant difference ($p>0.05$) between the non inoculated and the *T. brucei* inoculated rabbits that fed on the diet containing the 1% moringa leaf meal. The significantly higher ($P<0.05$) serum total protein of the infected rabbits in this study agrees with the report of Takeet and Fagbemi (2009) who also had increase in serum total protein of rabbits infected with trypanosomes. This strongly suggests an increase in some forms of the serum protein reacting to the presence and activities of the trypanosomes in the body system of animals.

Different a, b and c means are considered significant at $p<0.05$, I error bar.
Figure 1. Effects of diets 1(basal), 2 (basal and 1% Moringa Leaf Meal MLM), 3 (basal and 1% Neem Leaf Meal NLM) and 4 (basal, 1% MLM and 1% NLM) on serum total protein of rabbits after 9 weeks post inoculation (pi) with *Trypanosoma brucei brucei*.

CONCLUSION AND RECOMMENDATION

The findings in this study reveal the superior hepato protective capabilities of MLM over NLM in *T. brucei brucei* infection constraint. In conclusion, the serum total protein revealed greater potentials of moringa over neem in trypanosmosis infection of rabbits. It is recommended that MLM should be selected to ameliorate trypanosomosis disease over NLM.

ABSTRACT

A feeding trial was conducted for 28 days to evaluate the nutrient digestibility and productive performance of wistar albino rats fed processed sickle pod (*Senna obtusifolia*) leaf meal (SOLM) –based diets. Five experimental diets were compounded to contain 0 and 20% each of the sun-dried, boiled, fermented fresh and boiled and fermented SOLM designated as T_1, T_2, T_3, T_4 and T_5, respectively. A total of 90 growing albino rats with an initial average weight of 13.52 – 14.48 g were randomly allocated to the dietary treatments in a completely randomized design replicated 3 times with 6 rats each. The apparent nutrient digestibility indicated significant ($P<0.05$) variation except the nitrogen-free extract and energy. The apparent nutrient digestibility in the rats fed the processed SOLM based-diets indicated similar trend.The dry matter, crude protein and crude fibre digestibility in rats fed the processed SOLM-based diets range from 66.75 to 68.15%, 64.45 to 66.71% and 30.22 to 34.61%. The productive performance was not significantly ($P>0.05$) different except for the feed intake which indicated significant ($P<0.05$) variation. The highest total feed intake was recorded in albino rats fed the control diet 0% SOLM (365.40 g) and 20% boiled and fermented SOLM (334.32 g). The overall weight gain among the albino rats fed the processed SOLM-based diets were not significantly ($P>0.05$) different. It was concluded that, the different processed SOLM-based diets were better digested and had enhanced the productive performance of the albino rats. However, the boiled and fermented SOLM-based diet indicated better nutrient digestibility and growth performanceand is therefore the most recommended for feeding albino rats.

Key words: Nutrient digestibility, productive performance, *Senna obtusifolia*.

INTRODUCTION

The use of alternative feed ingredients to augment the conventional feed resources has become very paramount in the Nigerian livestock industry. This will go a long way to make available affordable protein to many Nigerians especially the North-eastern part of Nigeria were insecurity challenges had consequently led to protein malnutrition. Ardo *et al.* (2019) and Shaahu *et al.* (2010) advocated the use of alternative feed resources to be integrated into sustainable livestock feeding systems.

It was documented that green vegetables are the most abundant and cheapest source of protein which is due to their ability to synthesize amino acids from wide range of primary sources (Fasuyi, 2016). *Senna obtusiolia* leaves have good protein content (20.40%) but also contain some anti-nutritional factors such as tannins which necessitates some forms of processing before incorporation into livestock feed. It is in view of the above that this study was conducted to evaluate the effects of feeding differently processed *Senna obtusifolia* leaf meal-based diets on nutrient digestibility and productive performance of wistar albino rats.

MATERIALS AND METHODS

Location of the study area

The study was conducted at the Animal House of the Department of Biological Sciences, Adamawa State University, Mubi. The area is located between latitudes 9° 30' and 11° north of the equator and longitudes 13° and 9° 45' east of Greenwich meridian (Adebayo, 2004).

Experimental diets and treatments

Five experimental diets were compounded to contain 0% and 20% each of the sun-dried, boiled, fresh fermented and boiled and fermented *Senna obtusifolia* leaf meal designated as T_1, T_2, T_3, T_4, and T_5, respectively as presented in Table 1.

Table 1: Ingredient Composition and Calculated Analysis of the Experimental Diets

Experimental animals and their management

A total of 90 young albino rats with initial average weight of 13.52 to 14.48 g were managed inside constructed metal cages. The rats were acclimatized to the cages and the experimental diets for one week. Thereafter they were fed with measured quantity of feed which was supplied at *ad libitum*. Clean drinking water was regularly supplied. The rats were managed using standard management practice of handling experimental animals as described by Ochei and Kolhatkar (2007) and also in accordance with the Animal Care and Ethics Committee of the Adamawa State University, Mubi. The experiment lasted for 28 days.

Parameters measured

The feed intake was determined by the difference between daily feed offered and feed leftover. Total fed intake was obtained by cumulative addition of the daily feed intake.

Weight gain: The rats were weighed at the commencement of the experiment and the initial weight was recorded. Final weights of the rats were recorded at the end of the experiment and overall weight gain was obtained by subtracting the initial weight from the final weight.

Feed conversion ratio: This was determined by dividing the weight gain by feed intake.

Mortality: The mortality was recorded as they occur.

Determination of nutrient digestibility

At the end of the experiment, 4 rats were randomly selected from each treatment and placed in small cages with perforations underneath. A metal tray was placed beneath each cage for feacal collection.Faecal samples were collected and feed intake was also measured. The feacal samples were bulk, properly oven-dried and analysed for their proximate composition. Nutrient digestibility (ND) was computed using the formula

$$ND = \frac{\text{(nutrient in diet x feed intake)} - \text{(nutrient in faeces x feacal output)}}{\text{Nutrient in diet x feed intake}}$$

RESULTS AND DISCUSSION

The result of apparent nutrient digestibility of wistar albino rats fed processed SOLM-based diets is presented in Table 1.Theresult revealed significant ($P<0.05$) variation among the treatment groups except digestibility for nitrogen-free extracts and energy. The nutrient digestibility among the rats fed the process SOLM-based diets indicated similar digestibility trend. This is an indication that all the processing methods were effective in reducing the levels of the anti-nutritional factors and fibre content thereby enhancing digestibility and utilization of nutrients. This finding corroborates the report of Ardo *et al.* (2019) who reported similar findings for albino rats fed processed *Senna obtusifolia* seed meal-based diets. Sun-drying was reported to be effective in reducing anti-nutritional factors of leafy vegetables thereby enhancing their utilization (Udofia and Obizoba, 2005; Patricia *et al.* 2015). Tuleum *et al.* (2011) reported that boiling and fermentation are effective in neutralizing anti-nutritional factors in feedstuffs.

The albino rats fed the control diet (0% SOLM) indicated higher feed intake followed by those fed the boiled and fermented SOLM-based diet. This observed effects might be due to the flavour of the processed SOLM in the diet which is in line with the report of Takashi *et al*. (2013) who reported that, flavour have sedative effect, decrease the motivation to eat feed, feed intake and weight gain

abc = means in the same raw with different superscript are significantly different; SEM = standard error of means; SOLM = *Senna obtusifolia* leaf meal; SDSOLM = Sun-dried *Senna obtusifolia* leaf meal; BSOLM = Boiled *Senna obtusifolia* leaf meal; FFSOLM = Fresh fermented *Senna obtusifolia* leaf meal; BFSOLM = Boiled and fermented *Senna obtusifolia* leaf meal; NFE = Nitrogen-free extract

CONCLUSION

It was concluded from this study that the different processing methods (sun-drying, boiling and fermentation) were effective in detoxifying *Senna obtusifolia* leaves which positively enhances nutrient digestibility and productive performance.

ACKNOWLEDGMENTS

The authors are grateful to the Tertiary Education Trustfund (TETFUND) and the Management of Adamawa State University, Mubi for providing the funds used to conduct this study. The authors sincerely thank the Head of Department of Zoology and his staff for allowing the researchers to have access to their Animal House and the facilities therein.

ABSTRACT
One hundred and twenty (120) freshly laid eggs by 36 weeks old Isa brown layers kept at the Poultry Unit, Teaching and Research Farm, Ondo State University of Science and Technology, Okitipupa were randomly collected and stored at room temperature for 21 days. At week 0, week1, week 2 and week 3 of storage, 30 eggs were broken for egg quality analysis. Data collected were subjected to statistical analysis. Duration of storage had significant effect ($p<0.05$) on all the internal and external parameters except shell index and shell thickness. The overall egg weight, egg length, egg width, shell index, shell weight, shell ratio and shell thickness were 56.82, 5.69, 4.43, 78.02, 7.45, 13.11 and 0.28 respectively, while yolk height, albumen height, yolk weight, albumen weight, albumen ratio, yolk ratio and Haugh unit were 13.55, 4.97, 16.32, 33.06, 58.11, 28.82 and 67.50 respectively. Most of the traits declined in values as the storage duration increased except yolk weight and ratio which increased as the egg aged. Duration of storage of egg had effect on the egg quality that determines acceptability by consumers.
Keywords: Eggs; Isa brown; storage duration; shell index; yolk ratio

INTRODUCTION
The egg is a complex structure distinguished by having four different parts; the egg shell, shell membrane, albumen and yolk. When eggs are for human consumption, it is important that they are suitable for this purpose (Kabir *et al.,* 2014). This is determined by both the internal and external quality (Smith, 1990). Egg quality is composed of characteristics that affect its acceptability to consumers such as cleanliness, freshness, weight, shell quality, yolk index, albumen index, Haugh unit and chemical composition (Song *et al.*, 2000). Unlike external quality, internal egg quality begins to decline as soon as the egg is laid. Variability in the quality and nutritional values of eggs have significant impact on consumers' health and welfare. Some factors affect egg quality. They include the breed and strain of layers (Kucukyilmaz *et al*., 2012), dietary composition (Goldberg *et al*., 2012), birds' health, environmental conditions and storage, processing and handling and age (Ryu *et al*., 2011 and Kabir *et al.,* 2014). The objective of this study is to determine the effect of duration of storage on the internal and external quality of eggs kept at room temperature.

MATERIALS AND METHODS
One hundred and twenty (120) freshly laid eggs were randomly collected in a batch from 36 weeks old exotic chickens (Isa Brown) kept at the Poultry Unit, Teaching and Research Farm, Ondo State University of Science and Technology, Okitipupa, 30 of the eggs were analysed for internal and external quality within 24 hours of laying. The remaining were stored at room temperature on the laboratory desk and at weekly interval 30 eggs were randomly selected till 21 days and similarly analysed.The external quality parameters included egg weight (EWt), egg length (EL), egg shell weight (ESWt), egg width (EWdt), shell index (SIdx), shell ratio (SRatio) and egg shell thickness (EST). The internal egg quality traits included albumen weight (AlbWt), albumen height (AlbHt), albumen ratio (AlbRatio), yolk weight (YlkWt), yolk height (YlkHt), yolk ratio (YlkRatio), Haugh unit (Hu).Data collected were subjected to one-way analysis of variance procedure of SAS (2003). Significant means were separated using Duncan Multiple Range Test, (Duncan, 1955). The following statistical model was employed:

$Yij = \mu + Di + eij$

Where: Yij= Individual observation, μ= Overall mean, Di= Effect of the ith duration (i= 1, 2, 3, 4) and eij= Random error.

Results

Table 1 shows the summary statistics of egg quality traits. The external quality traits - egg weight, length, width and shell index, weight, ratio and thickness were 56.82 g, 5.69 mm,

4.43mm, 78.02 %, 7.45 g, 13.11 %, 0.28 mm respectively, for external traits. The internal quality - yolk height, albumen height, yolk weight, albumen weight, albumen ratio, yolk ratio and Haugh unit were 13.55 mm, 4.97 mm, 16.32 g, 33.06 g, 58.11 %, 28.82 % and 67.50 respectively.

Table 1. Summary Statistics for egg quality traits

Variables	Means	N	Minimum	Maximum	CV
Egg weight (g)	56.82 ± 0.40	109	47.3	67.96	7.37
Egg length (mm)	5.69 ± 0.03	109	5.06	6.62	6.39
Egg width (mm)	4.43 ± 0.02	109	4.06	5.28	6.12
Shell index	78.02 ± 0.50	109	64.23	92.63	6.70
Shell weight (g)	7.45 ± 0.07	109	5.60	9.14	9.39
Shell ratio	13.11 ± 0.10	109	10.91	15.52	7.58
Shell thickness (mm)	0.28 ± 0.02	109	0.01	0.49	59.40
Yolk height (mm)	13.55 ± 0.23	85	7.09	16.90	15.84
Albumen height (mm)	4.97 ± 0.15	107	2.36	10.23	30.76
Yolk weight (mm)	16.32 ± 0.19	89	12.50	22.90	10.92
Albumen weight (g)	33.06 ± 0.40	89	24.10	41.87	11.41
Albumen ratio	58.11 ± 0.37	89	46.35	65.20	6.02
Yolk ratio	28.82 ± 0.34	89	21.22	40.00	10.98
Haugh unit	67.50 ± 1.21	107	40.15	100.00	18.58

Table 2 shows the effect of duration of storage on the external traits. Significant difference ($P<0.05$) was observed in all the traits considered except shell index. In egg weight, no significant difference was observed from week 0 to 2. Egg weight reduced with age. Egg lengths across weeks were 5.72, 5.87, 5.63 and 5.49 mm. No significant difference was observed from week 0 to 2. Similar trends were observed in egg width and shell ratio. The values for shell weight were 7.72, 7.38, 7.19 and 7.43 for the weeks respectively. Table 3 shows the effect of storage duration on the internal quality traits. Significant difference ($P<0.05$) was observed in all the traits considered. For yolk height, significant difference was observed from week 0 to 3. Hence, yolk height reduced as the egg age. The values for albumen height were 6.80, 4.32, 4.30 and 3.86. Similar trend was observed for albumen ratio and Haugh unit. Albumen ratio reduced as the egg age, but yolk ratio increased with age.

Table 2: Effect of storage duration on external quality of egg

Variable	0-week	1-week	2-week	3-week	SEM
Egg weight (g)	58.48[a]	57.38[a]	56.29[a]	53.94[b]	0.40

Means with different superscript in a row are significantly different ($p<0.05$)

DISCUSSION

The significant effect of duration of storage observed on virtually all egg quality traits observed in this study is in agreement with the works of earlier researchers (Akyurek and Okur, 2009; Silversides and Scott, 2001; Sekeroglu *et al.*, 2008; Sung and Kyung, 2014). The decrease in egg weight observed in this study as egg aged could be attributed to evaporation of water through the shell pores. This is in line with the observation of Sung and Kyung (2014). This could also be responsible for decrease in

Haugh unit, albumin weight, yolk height, albumen height with age. However, yolk weight increased as the duration of egg storage increased,Khan *et al*. (2013) postulated the movement of water from albumen to the yolk as the possible explanation of the increased yolk weight with storage duration. This also accounted for decrease in albumen weight.During aging there is carbodioxide and oxygen exchange and water evaporates through the shell increasing the air chamber and reducing albumen height. The Haugh unit of 61.6 at the seventh day of storage is lower to 66.2 reported by Sung and Kyung, 2014 at room temperature. The discrepancies could be attributed to differences in age and breed of the layers used. The non-significant effect of storage duration on shell thickness and shell index is similar to the observation of Sung and Kyung, 2014 while the significant effect observed in shell weight is contrary to the report of the researchers. It could be concluded that storage reduces the acceptability of egg by consumers as quality is grossly affected.

PREDICTION OF BODY WEIGHT OF TWO STRAINS OF LAYERPULLETS USING MORPHOMETRIC TRAITS

Sabo M.N., j., Sani and R. A. Hamzat
Department of Animal Science, Federal University Dutsin-Ma, Katsina State.

ABSTRACT
A total of 200-day old layer chicks comprising of 100 chicks each of Nera Black and Lohmann Brown Classic were used to determine prediction models for body weight from morphometric parameters. Data were collected on body weight and morphometric trait; breast girth, body length, wing length, shank length and thigh length. All the morphometric traits measured in chick were significantly ($P<0.05$) correlated with body weight. The breast girth has better correlation with body weight than other morphometric trait in Nera Black (0.763) and for the two strains combined (0.788). However, body length had the highest correlation with body weight in Lohmann Brown Classic chicks. Breast girth showed the highest coefficient of determination (R^2 value) of 0582 in Nera Black while body length had the highest R value of 0.715 and 0.610 for Lohmann Brown Classic and the two strains combined respectively. This study showed that morphometric trait like body length and breast girth can be used in estimation of body weight.
Keywords: Trait, prediction, correlation, regression, body weight

INTRODUCTION
Morphometric traits also called linear body measurements or conformation traits are important parameters in predicting body weight and this has been observed by commercial breeders and producers. Breeders, therefore, breed desirable sizes of chickens which also have the desirable production traits particularly body weight (Ojedapo *et al.*, 2010). Apart from body weight, a number of conformation traits are also known to be good indicators of good growth (Ibe, 1989). Such conformation traits include shank length, breast width, knee length, wing span, chicken height, body length, and head circumference (Ojo *et al.*, 2010). Linear body measurements have been used to predict live weights in poultry (Okon *et al.*, 1997), Prediction of body weight with morphometric traits in layers is therefore important.The easiest way to assess an animal's body mass is to weigh the animal. However, under some situations scale may not be available and prediction of body weight from body measurements could be preferred practically (Latshaw and Bishop, 2001). The objective of this study therefore to determine the morphometric parameters of egg strain chicks, their correlation between with body weight and develop a prediction equation for body weight from those parameters of egg strain chicks

MATERIAL AND METHODS
The experiment was conducted in the Department of Animal Science Teaching and Research Farm, Federal University Dutsin-ma. It lies within latitude 11° 7' and 13° 22' N and longitude 6° 52' and 9° 2' E (Abaje *et al.*, 2014).
A total of 200 day-old- layer chicks purchased from a reputable hatchery in Nigeria were used in the experiment.Routine management practices were carried out on the layer chicks. The chicks were fed *ad-libitum*. The data of prediction of body weight in egg layer strain chicks using morphometric traits were collected.Birds in each replicate were weighed at the beginning of the experiment and subsequently on weekly basis. Feed intakes were recorded weekly and were determined by the weigh-back technique. Feed conversion ratio was determined. The Linear Body Measurements were taken at week 10. The body parameters were taken in centimetres with the use of tape. Morphometric parameters measured include:thigh weight, shank length, breast girth, wing length and body length. SPSS (2008) Package was used to obtain estimate of correlation and regression between body weight and each of the morphometric trait. The significance of the correlation regression coefficient was determined at P-value of less than 0.05

RESULT AND DISCUSSION

Table 1 shows the comparison of means of body weight and linear body measurements of Nera Black and Lohmann Brown Classic layer strain chicks. Body weight, breast girth, wing length and thigh length were not significantly different between the strains. However, body length was significantly different with Nera Black having longer body length (23.55cm) than Lohmann Brown Classic (22.71cm).

Table 1: Comparison of means of body weight (g) and morphometric traits (cm) of Nera Black and Lohmann brown classic layer strain chicks at 10 week of age.

Trait	Near black	Lohmann brown classic	SEM
Body weight	552.24	531.68	13.55
Body length	23.55[a]	22.71[b]	0.22
Breast girth	19.87	19.73	0.27
Wing length	15.56	15.33	0.13
Shank length	6.88	6.57	0.11
Thigh length	7.25	6.99`	0.11

[a, b] Values with different superscripts differ significantly, SEM= Standard error of mean

Table 2 shows the correlation of the body weight and Morphometric traits of combined layer strain at week 10. Body weight is highly correlated to all the morphometric traits with Breast girth having the highest correlation (0.788).

Table 2: Combined correlation of body weight and morphometric traits of Nera Black and Lohmann Brown classic layer strains chicks at 10 week of age

	BW	BL	BG	WL	SL	TL

BWT-body weight; BG-Breast girth; BL-Body length; WL-Wing length; SL-Shank length; TL-Thigh Length; SEM= Standard error of mean

Table 3 shows prediction equations relating the body weight and morphometric traits in combined layer strain at week 10. The R^2 values of range from 0.351 to 0.610 with Body length have the highest R^2 value of 0.610. This implies that body length could be the best predictor of body weight of layer strains.

DISCUSSION

The high correlation between body weight and morphometric measurements in this study agrees with the earlier report of Yahaya *et al.* (2012) who obtained high correlation coefficients between body weight and morphometric traits in Hubbard and Arbor Acre broiler strains. The estimates contained in their reports were generally higher than the values obtained in the present study. The observed close relationship between body weight and breast girth in both Nera black and Lohmam brown classic agrees with the earlier findings of Adebambo *et al*. (2006) who reported that breast girth is a good indicator of predicting body weight in most poultry species.

The regression result shows that breast girth and body length could be the best predictors of the body weight of layer strain chicks. This result agreed with Udeh and Ogbu (2011) who reported that Arbor Acre strain with R^2 of 96% in breast girth and 92% in body length were the best predictors of the body weight of broiler strains. All other linear body parameters in all studied reported R^2 values above 50% which implies any of linear body parameter could also be used to predict body weight of the layer strain chicks. The result of regression coefficients of the two strains combined agrees with the observation Ubani *et al* (2011) who reported that breast girth and body length recorded the highest R^2 value among Nu-breed, Arbor, Acre and Marshall Strains between 3-5 weeks of age. The body length and breast girth are best for predicting body weight in layer chicks (Nera Black and Lohmann Brown Classic).

The result obtained from this research shows that prediction of body weight is possible from various linear body parameters. Generally breast girth and body length were found to be the best and most reliable parameter in estimates body weight. In terms of hierarchy, breast girth was significantly highest followed by body length in Nera Black and Lohmann Brown Classic at week 10. Application of linear model to all parameters at week 10 was found to be highly significant (P<0.05). All linear body parameter whose R^2 values were above 50% could be used to predict body weight of the layer strain, although the accuracy of prediction increased with an increase in the R^2 value.

CONCLUSION AND RECOMMENDATION

The present study showed that there exists strong correlation between body weight and most of the morphometric indices like body length, breast girth, wing length, shank length and thigh length of Nera Black and Lohmann brown Classic. Prediction of body weight is possible from various linear body parameters. Generally breast girth and body length were found to be the best and most reliable parameter in estimates body weight. It is therefore recommended that body length and breast girth be used in predicting body weight.

ABSTRACT

A total of nine hundred (900) goats comprising of three hundred Sahel goats from Borno state, three hundred Red Sokoto goats from Sokoto state and three hundred West African Dwarf goats from Ogun state were used for the study. Each breed consisted of three hundred goats each, made up of fifty males and fifty females distributed in the following age groups <1, 1-2 and 2-3 years. These were evaluated for morphometric characteristics. The pairs of permanent incisors in the dentition of the goat were used to determine age. The effects of age, breed, and sex on linear measurement were estimated using the GLM procedure of the statistics analysis software package. These were computed on the basis of interaction with age groups. Means were separated within age groups using Duncan multiple range test. The result of this study indicated that the Sahelian breed was superior to other breeds across all age groups in body weight, while the red Sokoto was intermediate followed by the West African Dwarf.

INTRODUCTION

Goats are the largest in number among ruminant livestock in Nigeria totaling about 58.3 million (FAOSTAT, 2008). Goats, predominantly are kept by the rural household and ownership is spread across all human age groups and sexes (Akpa,1999).The importance of goat stem from its ability to convert forages and household by-product into high quality human food and their role as locally available source of food, fibre, power and other products to suit local community needs. The indigenous breeds found in Nigeria are, Red Sokoto, Sahel, and West African Dwarf (WAD) goat (Adu and Ngere, 1979). These differ considerably in size, coat colour, horn length, etc. Their broad genetic variability enables them to survive under stressful environmental condition including high disease incidence, poor nutrition which may increase animal susceptibility to disease, high temperature, and traditional husbandry system.

MATERIALS AND METHODS

The study was carried out in Borno, Sokoto and Ogun States. These states were selected because they are locations having close to pure breeds of the goats. Animals used for this study were sampled in the abattoir, of Borno, Sokoto and Ogun states when brought for slaughter either by the owner or by the slaughter man. It is believed that all animals find their way into the abattoir from villages and local markets, where they are kept in small numbers by local farmers; they are raised under the extensive system of management. A total of nine hundred (900) goats comprising of three hundred Sahel goats from Borno state, three hundred Red Sokoto goats from Sokoto state and three hundred West African Dwarf goats from Ogun state were used for the study. Each breed consisted of three hundred goats each, made up of fifty males and fifty females distributed in the following age groups <1, 1-2 and 2-3 years. These were evaluated for morphometric characteristics. The pairs of permanent incisors in the dentition of the goat were used to determine age.

The following metric characters were measured on each animal: Body Weight (BW), Age, Horn Length (HL), Ear length (EL), Shoulder width (SW), Neck circumference (NC), body length (BL), Withers Height (WH), Heart Girth (HG), Pouch Girth (PG), Tail Length (TL) and Scrotal

circumference (SC). Weights of the animals were taken using a spring balance and Walk-in weighing scale. Flexible measuring tape was used to take the body measurement. During body measurement, animals were made to stand upright and restrained by two assistants in such a way that their heads, necks, and chest were stretched almost in a straight line. Each measurement was taken at least three times and the mean recorded to the nearest centimeter or kilogram. Reference marks used for body measurement according to the method of and Salako and Ngere (2002).

Data analysis

The effects of age, breed, and sex on linear measurement were estimated using the GLM procedure of the statistics analysis software (SAS, 1990) package. These were computed on the basis of interaction with age groups. Means were separated within age groups using Duncan multiple range test.

RESULTS AND DISCUSSIONS

Mean body weight in Red Sokoto, Sahel and West African Dwarf goats less than one year are presented in Table 1. The Sahel breed is superior to the other breeds with a body weight of 13.56±0.56Kg and 14.94±0.52Kg in does and bucks respectively. Within the Red Sokoto population, body weight in doe and buck was 13.73±0.51Kg and 12.86±0.42Kg respectively while in West African Dwarf, 10.44Kg±0.22 and 10.62±0.21Kg for does and bucks. Coefficient of variation ranges between 13.98% and 29.40% suggesting the influence of major genes on this trait.

Summarized in Table 2 are Sahel goats had a mean weight of 17.13±0.43Kg and 16.86±0.49Kg followed by West African Dwarf goats with 15.45Kg±0.54 and 17.65±0.44Kg for does and bucks respectively. Red Sokoto goats weighed 13.60±0.46Kg (does) and 13.51±0.43Kg (bucks).

Live weight is important for assessing the condition of the animal and represents a criterion of selection. Mean live weight of 13.73 Kg, 13.56 Kg, 10.44 Kg and 12.86 Kg, 14.94 Kg and 10.44 Kg for does and bucks for the three breeds respectively for age less than one year are within the range of 12-18 Kg reported by Katongole *et al*. (1996) for indigenous goats in Kenya. Mean live weight of 13.60 Kg, 17.13 Kg, 15.45 Kg and 13.51 Kg, 16.84 Kg and 17.65 Kg for does and bucks between the age one through two years are lower than values of 20-40kg reported by several authors (Akpa *et al*., 1998, Otoikhan *et al*., 2008 and Salako *et al*., 2006) in different breeds of goat. Mean live weight of 18.95 Kg, 23.60 Kg, 19.13 Kg and 19.21, 25.12 Kg and 19.35 Kg for does and bucks above two years are closer to the range reported by several authors (Akpa *et al*., 1998, Osuhor *et al*., 2002 and Otoikhan *et al*., 2008), with Sahel breed fell within the specified range of 20-40 Kg. The average body weight at different ages fell within the range of 16-30 Kg specified by Hassan and Ciroma (1990) for both does and bucks from age 1-5 years in different breeds of goats.

CONCLUSION

Present results showed that age has strong influence, as there were consistent increases in all the traits studied as the animals aged. The scenario is however not surprising since the size and shape of the animal is expected to increase as the animal is growing with age. There was wide variability as the age of the animals increased most particularly in the bodyweight. This was in consonance with the report of Orheruata and Olutogun, (1984) in cattle.

ABSTRACT
The study investigated the effects of breed, season, sex and age on body weight, packed cell volume, Haemoglobin concentration and Faecal egg count of some indigenous breeds of sheep in Gombe State between March and October, 2017. Stratified random sampling was applied to collect the 300 samples comprising of 130 Yankasa, and 73 Balami 97 Uda sheep. Faecal egg count was measured using the modified McMaster technique for faecal samples found positive forgastro intestinal parasite eggs. Packed cell volume (PCV) was determined by micro-haematocrit technique. Faecal egg count (FEC) significantly (P<0.001) differed among the breeds with highest value of 1271.65epg recorded in Uda. Balami and Uda had higher values of body weight than Yankasa. There were no breed effects on PCV and HBC recorded in this study. Seasonal effects on BWT, PCV, HbC and FEC was observed with the wet season recording higher values of 32.32kg,36.04%, 11.99g/dl and 1140.95epg.This could be attributed to the fact that wet season is the period of lush pasture which has positive influence on BWT, PCV, and HbC. Furthermore, the wet season is a suitable period for the development of the infective stages of the Gastro intestinal parasites and hence higher burden. Age of sheep affected the values of BWT, PCV, HbC and FEC significantly. The values of 45.02kg,32.43%,10.82g/dl and 725.34epg forBWT, PCV, HbC and FEC respectively were significantly higher in adult than the younger sheep. This could be attributed to the fact that these parameters normally increase with age and physiological changes.

Key note: Season, Sex, breed, Packed cell volume, Haemogolobin Concentration, Faecal egg count.

INTRODUCTION
Nigerian sheep population is estimated at 44.3 million and over 70% is found in the Savanna regions where three of the four breeds of sheep (Balami, Yankasa and Ouda) predominate. Sheep thrive in a wide variety of environments in the tropics and sub tropics and requires less capital as they can be completely maintained on pastures, browse and agricultural waste products (FAO, 2007).Gastro-intestinal infections among other variables are significant constraints to livestock production (Badran*et al*. 2012). The major factor that influences gastrointestinal parasites infection in small ruminants, especially sheep is exposure to faecal contamination of grazing land (Pathak, 2011).Greer (2008) stated that the degree of disease infection varies with the host immune response. Males are generally more susceptible than females due to the production of androgen hormone which lowers immune response (Asif*et al*., 2008). Heavy animals also show more resistance due to sufficient body fat reserves that aids immune responses (Bilbo and Nelson, 2001). During rainfall the number of infective larval stages increase and animal are also more susceptible to infection (Kantzoura*et al*., 2012). Blood properties are indices of the physiological and pathological changes in animals (Cambell, 2007). Haemotological tests have been widely used for the diagnosis of disease and nutritional status of animals. Information gained from blood parameters substantiates physical examination and together with medical history provide the basis for judgment and decision making (Schalm *et al*., 1975). Several researches were conducted on the effects of breed, season, sex and age on PCV, HbC and FEC on sheep in Nigeria particularly the northern part however; there was scant information on that in Gombe state. This study was carried out to bridge the gap in information, provide useful information for further research and to make recommendations.

MATERIALS AND METHODS
Area of the Study
The research covered the three senatorial zones of Gombe State comprising North, Central and South. Gombe State. It is situated in North East region of Nigeria and occupies a total land area of about

20,265 Km^2. The state is located between latitude 9^0 30' and $12^0$30'N and longitude $8^0$45' and $11^0$45'E of the Greenwich Meridian (Abubakar, 1974).

Experimental Animals

Three indigenous breeds of sheep namely Yankasa, Balami and Uda commonly reared by peri urban and urban households in Gombe state were used for this study.

Study Design.

Faecal and blood samples were collected randomly from 300 sheep for laboratory analysis. Stratified random sampling was applied to collect the 300 samples comprising of 130 Yankasa, 73 Balami and 97 Uda sheep. The total sample size was calculated according to Thrusfield (2005) using 95% confidence and expected prevalence of 89.1% from previous study of James (2014) and desired precision of 5% as follows:

$n = 1.96^2 P_{exp} (1- P_{exp}) / d^2$

Where n = sample size

$P_{exp=}$expected prevalence (89.1% of James, 2014)

d = desired absolute precision of 5% (0.05).

$n = 1.96^2$ x 0.891 (1-0.891)/ $(0.05)^2$

n = 3.8416 x 0.891(0.109)/ 0.0025

n = 0.3731/ 0.0025

n = 150 samples approximately

The value of 150 was multiplied by 2 to avoid sampling error in accordance with (Jatau*et al*., 2011).

Faecal sample collection and analysis

Fresh faecal sample (5g) was collected using hand gloves, directly from the rectum of the sheep into clean universal containers, labeled and stored. The samples were subsequently processed for gastro-intestinal parasite presence and identification.Samples found positive were counted using the modified Mcmaster technique according to Soulsby (1986).

Blood sample collection and analysis

Blood samples (5 ml per animal) were obtained from the jugular vein using a10 ml syringeattached to 21gauge x ½ inch needle. Air was first cleared from the syringe before puncturing at 20^0 angle (Pratt, 1985) and the syringe was aspirated to confirm insertion and collection of blood. The blood sample collected was then placed in labeled tubes coated with ethylene-diamine tetra-acetic acid (EDTA) as anticoagulant. Packed cell volume (PCV) was determined at Gombe State Specialist Hospital laboratoryusing the micro-haematocrit technique (Pratt, 1985) and classified into low, normal and high.Haemoglobin concentration wasdeterminedby dividing PCV values by 3 according to (Addass, 2010) and also classified as low, normaland high whilehaemoglobin type was identified through electrophoresis (Wintrobe, 1967).

Data Analysis

Data collected were analyzed using descriptive statistics and were further subjected to analysis of variance (ANOVA) using the general linear model (GLM) procedure of SPSS, version 22 (Allen *et al.,* 2013) as in the following model. Significantly different means were separated using the Duncan multiple range test (DMRT).

$Y_{ijk} = \mu + B_i + E_j + e_{ijk}$

Where;

Y_{ijk}= Observations on dependent variables

μ = common mean

B_i = effect of ith breed

E_j= effects of all other factors, but taken individually; number and types (of factor) varied with the dependent variable.

e_{ijk}= random error term.

The relationships among PCV, HbC, Bwt and FEC were determined using the Pearson's product moment correlation coefficient.

	45.02	0.80	32.43	0.59	2.28		63.60	

*** =P<0.001), * =P<0.05, ** =P<0.01, NS =Not significant, PCV =Packed cell volume inpercentage, HbC =Haemoglobin concentration in gramme per decilitre (g/dl), FEC = Feacal egg count, X = Mean, SD = Standard deviation, Bwt (Body weight, in kilogramme) and values in a column within a subset with different superscripts are significantly different.

Table 2: Effects of Faecal egg count on PCV, HbC and BWT

Category	PCV	HbC	Bwt
LS	NS	NS	**
Low	1060.13	1023.97	1023.30[a]
Normal	890.42	894.43	578.93[b]
High	1126.67	1080.00	955.74[a]

LS = Level of significance, PCV = Packed cell volume (percent), HbC = Haemoglobin concentration (gramme per decilitre), Bwt= Body weight (Kilogramme), NS = Non-significant. Values in a column with different superscripts are significantly different.

RESULTS AND DISCUSSIONS

The means and standard deviations of BWT, PCV, HbC and FEC by breed, season, sex and age are presented in Table 1. The overall values of BWT, PCV, HbC and FEC were 35.67Kg, 34.25%, 11.42g/dl and 1083.45 epg.Faecal egg count (FEC) significantly (P<0.001) differed among the breeds with highest value of 1271.65epg recorded in Uda. This finding is similar to observations reported byFantu*et al*. (2012) and Hassan *et al*. (2013) but disagrees with Mbap and Chiroma (1998) who found that Yankasa breed had higher FEC values than the others. The body weights recorded in this study were similar for Balami and Uda but differed significantly from value obtained for Yankasa.Balami and Uda had higher values than Yankasa, this report corroborates with earlier findings of Mason (1997).There were no breed effects on PCV and HbC recorded in this study, similar observations was reported by Kasali*et al*. (1988). The lower FEC in Yankasa in this study could probably be due to breed difference. Significant (P<0.001) seasonal effects on BWT, PCV, HbC and FEC was observed with the wet recording higher values, and this concur with earlier reports of Kasali*et al*. (1988) and Fantu*et al*. (2012). The wet season is the period of lush pasture which has positive influence on BWT, PCV, and HbC (Pathak and Pal, 2008). Furthermore, the wet season is a suitable period for the development of the infective stages of the Gastro intestinal parasites and hence higher burden. Sex had no influence on the parameters assessed in this study, this contradicts earlier reports by (Dangnachew*et al*., 2011; Hassan *et al.*, 2013), the authors reported significant sex variation on faecal egg count. Male sheep are generally more susceptible than females due to the production of androgen which lowers immune response. Oestrogen in females increases resistance to worm burden. However, female sheep become prone to parasitism due to hormonal changes during pregnancy; especially in the later stages (Asif*et al*., 2008). Age of sheep affected the values of BWT, PCV, HbC and FEC significantly; this is in agreement with earlier report of James (2014). Body weight, packed cell volume, haemoglobinand faecal egg count are usually higher in adult than the young because these parameters normally increase with age due to physiological changes (Fantu*et al*., 2012). This is however, contrary to reports of Winkler (1982), Mbap and Chiroma (1998). The authors reported higher FEC in the younger sheep and attributed it to low innate immunity and so-called self-cure phenomenon and/or high acquired immunity which increasewith age. Table 2 shows the influence of PCV, HbC and Bwt on worm burden. There was significant influence of Bwt (P<0.01) on FEC. The value of 578.93 epg, for the medium weight category was lower than 1023.30 and 955.74 epg for the lower and higher respectively. The PCV and HbC however had no significant influence on FEC.The PCV, HbC and Bwt are all indicators of body condition and thus are related to the physical, physiological and health status of animals.

CONCLUSIONS AND RECOMMENDATIONS

In conclusion, the study revealed that three indigenous breeds of sheep studied harbors gastrointestinal parasite however, the level of infection is more in Uda. Balami and Uda had higher body weights and worm burden. However, breed had non-significant effect on PCV and HbC. Body weight differed among breeds with Balami and Uda recording higher values than Yankasa. Furthermore, Balami and Uda had higher FEC than Yankasa. Season had significant influence on Bwt, PCV, HbC and FEC with the wet season recording higher values. Sex had no influence on the parameters assessed but, there were significant age differences in BWT, FEC, PCV and HbC .Proactive measures are required to sensitize farmers on the need to ensure routine deworming exercise and adherence to good husbandry practicesall year round. Further study should be conducted using molecular marker to determine the genetic distance between the sheep breeds in terms of resistance to gastrointestinal parasite infection.

ABSTRACT
The study was conducted to determine the characteristic and economic value of exotic breeds of pigeon in Bauchi Metropolis. Purposive sampling was employed to select farmers of exotic breeds of pigeon in Bauchi metropolis and a total of 60 respondents were used. The study revealed that 100% of the respondents were males and 50% aged between 26-35 years, followed by 16-25 years (25%) while the least (10%) aged between 5-15 years. Majority (51.67%) of the respondents had secondary school certificate while 48.33% attained tertiary education level. Majority (58.33%) of the farmers practiced inbreeding only. However, 41.67% of the respondents practiced both inbreeding and out-breeding. Furthermore this study revealed that 28 different exotic breeds of pigeon with unique features were available in Bauchi metropolis. Majority (66.7%) of the exotic breeds of pigeon with good flying ability were small size while the least (11.1%) was recorded among large ones. However, the large breed recorded highest poor flying ability (60%) followed by (40%) among average size, none of small size breed had poor flying ability. Most (75%) of them had average resistance to prevalence diseases when compared with the local breed. Female farmers should be encouraged to rear exotic breeds of pigeon. Cross breeding of exotic and local breeds of pigeon should be employed to complement each other.
Keywords: Exotic, Breed, Pigeon

INTRODUCTION
The domestic pigeon (*Columba livia domestica*) belongs to class: Aves, order: Columbiformes and family: Columbidae. Pigeons have made contributions of considerable importance to humanity especially in times of war (Levi, 1997). In war the homing ability of pigeons has been put to use by making them messengers. The homing pigeon is a variety of domestic pigeon derived from the rock pigeon, selectively bred to find its way home over extremely long distance (Levi, 1997). Members of this breed of pigeon are still being used in the sport of pigeon racing and the white release-dove ceremony at weddings, anniversaries and funerals. The wild rock pigeons have an innate homing ability (Blechman, 2007) meaning that they will generally return to their nest and mate.

Pigeon can also be reared as a meat. Young pigeons bred for meat are known as squabs. Rearing pigeons for meat is an accepted industry in overseas countries, particularly Europe and the United States (Bolla, 2007). In Kano state, the domestic pigeon (*Columba livia domestica*) is reared for meat production by some household, thereby contributing significantly to the protein need of the local populace (Rabiu and Arzai, 2012). However this aspect is yet to be optimally exploited in Nigeria as a whole. Breeding for fancy pigeon is an overwhelming aspect in pigeon production with a lot of economic and tourist potentials. There has been an insignificant development in the Nigerian fancy pigeon industry since its introduction from overseas some years ago. Most of exotic breeds of fancy pigeon have been proven to be adaptive to our local environment. Those who love bird life can find unlimited pleasure in the breeding of pigeons and besides, as they become more proficient in the art of breeding can earn a nice little income from their birds (Hazard, 1922). Pigeon can be bred for purposes which include: breeding for utility, breeding for fancy, breeding for homing and breeding for racing and show. All these provide wider areas of specialization for breeders and researchers in pigeon production. However, there is limited information today on the characteristic and availability of exotic breeds of pigeon in Nigeria. Their potentials and production are yet to be efficiently exploited in Nigeria. Therefore, this study aimed to determine the phenotypic characteristic and breeding method exotic breed of pigeon in Bauchi metropolis.

MATERIALS AND METHOD

Description of Study Location

The study was carried out from January to August 2019 in Bauchi metropolis. Bauchi state is located in the northern guinea savannah agro-ecological zone of Nigeria. The state is located geographically at approximately 10°17'N, 9°49'E and 690.3m above sea level (Kowal and Knabe, 1972).

Sampling Procedure

The Research-sampling design that was used to select the sample was non-probability purposive sampling. A total of 60 exotic breeds of pigeon farmers were used.

METHODS OF DATA COLLECTION

Data for this study were collected using both primary and secondary sources. The primary data (Type, size, flying ability, and relative disease resistance,) were collected through farm visitation and physical examination of the pigeons. Secondary data (breeding methods) were collected by using a questionnaire.

Statistical Analysis

The data collected were subjected to simple descriptive statistic and χ^2 test for association using SPSS version 17

RESULTS

The socio-Economic characteristic of the exotic breeds of pigeon farmers in Bauchi metropolis were presented in Table 1. The results revealed that 100% of the respondents were male and (50%) were within the age bracket of 26-35 years, followed by 16-25 years (25%) and 36-45 years (25%) while the least (10%) were within 5-15 years old, non-of the farmers was above 45 years.Majority (51.67%) of the respondents had secondary school certificate, 48.33 % were able to attained tertiary education while none of the respondent had non-formal or primary education as highest level of education. The results also showed that (50%) of the respondents were new in the pigeon farming with 0-5 years of experience followed, by 31.7% with 6-10 years of experience while the least (18.3%) had above 10 years of experience.

Table 2 presented the distribution of some phenotypic characteristics of exotic breeds of pigeon in Bauchi metropolis. The results showed that most (78.6%) of the exotic breeds of pigeon in Bauchi metropolis were fancy type while the least 21.4% were utility.With respect to size 39.3% of the breeds were medium, followed by large (35.7%) while 25% were small in size. Majority (53.6%) of the breeds had poor flying ability, 32.1% were good, while 10.7% had average flying ability. Most (75%) of the breeds had average resistance to diseases while 25% were susceptible to prevalence diseases.

Table 1: Socio-Economic Characteristics of the Exotic Pigeon Farmers in Bauchi Metropolis.

Variables	N (%)

Table 3 presented the association between the body size and flying ability of exotic breeds of pigeon in Bauchi metropolis. Significant ($P > 0.01$) association between body size and flying ability of exotic breeds of pigeon in Bauchi metropolis was detected. Majority (66.7%) of the exotic breeds of pigeon with good flying ability were small size while the least (11.1%) was recorded among large ones. However, the large breed recorded highest poor flying ability (60%) followed by (40%) among average size, none of small size breed had poor flying ability.

Table 4 presented breeding methods employed by exotic breed of pigeon farmers in Bauchi metropolis. The results revealed that (55%) of the respondents practice only inbreeding, followed by 45% practice both inbreeding and out-breeding, while none practice only out-breeding. Out of 45% of the respondents that practice out-breeding, only few (3.33%) performed a planned cross-breeding while majority (41.67%) performed unplanned cross-breeding without targeting any trait.

Table 3. Association between Body Size and Flying Ability of Exotic Breeds of Pigeon

Body Size	Flying Ability			χ^2	LOS
	Good	Average	Poor	17.4	**
Small	6 (66.7%)	1 (25%)	0 (0.0%)

DISCUSSION

The result obtained from this study that only males embarked on exotic breeds of pigeon farming in Bauchi metropolis is in line with the findings of Bakoji *et al.* (2012) and Suleiman *et al.* (2017) they reported more males participation than females in poultry farming in Bauchi and Kaduna states respectively. The (50%) of exotic breeds of pigeon farmers in Bauchi metropolis were within the age bracket of 26-35 years is similar to findings of Bakoji *et al.* (2012), who reported (48.89%) of quail birds' farmers in Bauchi Local Government were within the age bracket of 31-40 years. . The age distribution might have been influenced by the nature of the business which required highly energetic and independent youths for effective farming and marketing. The high literacy level of the respondents in this study is in line with the findings of Nurudeen (2012) that the majority of the poultry farmers had tertiary education. Bukunmi and Yusuf (2015) reported that level of education had a positive coefficient which could be because education helps the farmers to understand better the innovation introduced to them. Experience in poultry production usually determines the effectiveness of farmers' decision with respect to inputs combinations or resource allocation (Umar, 2012). The(50%) of respondents were still new in the business with 0-5 years of experience. This implied that the business was still at young stage and therefore, more studies were still needed to be done in the exotic pigeon farming for better improvement.

The majority (78.6%) of the exotic breeds of pigeon in Bauchi metropolis were fancy type. Fancy pigeon breeds are kept for their gorgeous colour, form and texture. The higher availability of fancy breeds could be an indication that exotic breed of pigeon production in Nigeria was mostly targeted for pet. Most of these exotic breeds of pigeon had average resistance to diseases when compared with the local breeds is in accordance with the findings Bunza *et al.* (2008) reported zero infestation of tick on local breed of pigeon at Sokoto central market.

The significant association observed between body size and the flying ability of exotic breeds of pigeon. Sudik (2007) reported high and positive correlations between live weight and body size in chickens. Pigeons with larger body size will likely have higher body weight which will make them have poor flying ability. Pigeon with small body size has the tendency of lower body weight and good flying ability. This might serve as vital guide line to future breeders. While selecting for racing pigeon breeding, the size of the pigeon should be considered.

Majority (58.33%) of the respondent practice only inbreeding was to maintain the breed purity and to prevent any limitation on the required features.

CONCLUSION AND RECOMMENDATION

It can be concluded that most of the farmers practice inbreeding. Therefore, Cross breeding of exotic and local breeds of pigeon should be employed to complement each other.

ABSTRACT
Proper knowledge of variations and diversities between, among and within the populations of animals helps in classifying animals into their various genetic groups, which helps in identification and conservation of important alleles. A total of seven hundred (700) donkeys consisting of (280) adult, (210) young and (210) weaner donkeys were sampled from Jigawa, Kaduna, Kano, Katsina, Kebbi, Sokoto and Zamfara States of Nigeria using a random sampling techniques. Biometric traits measured among sampled donkeys were body weight, head length, head width, ear length, neck length, neck circumference, shoulder width, height at withers, heart girth, body length and tail length. Data obtained were subjected to statistical analysis to determine the genetic distance estimate across the strains. The classification of Black (Duni), White (Fari), Brown (Idabari), Red (Auraki) and Brown-white (Idabari-fari) donkeys (by using Euclidean as the distance measurement, Single Linkage, Average Linkage, and Complete Linkage were applied, and the obtained results were compared. The simple discriminant analysis procedure was used to classify the strains using the R 2.13.0 (R Development Core Team) package. Homogeneous genetic distance was observed for head width (16, 16) and shoulder width (21, 21) in male red donkeys. Female donkeys showed similar and closed genetic distances for ear length in red (26, 21), black (21, 26) and brown (26, 21) and male Red (26,22), Black (22, 25), White (26, 22) and Brown (22, 25) across the strains. Heart girth, body length and height at wither showedhigh level of genetic variability among the strains. Heaviest body weight was recorded in male red (141.90kg) donkey strain with a distance of 6.75cm compared to other strains of donkeys. Further classification of donkeys into various genetic groups should employ heart girth, body length and height at wither.
Keywords: Donkey, genetic distance, classification, strain, Nigeria.

INTRODUCTION
Knowledge of morphometric characteristics marks the first step in classification of Farm animal genetic resources (FAnGR) (Delgado *et al*., 2001). Genetic distance is a measure of the genetic divergence between species or between populations within a species, whether the distance measures time from common ancestor or degree of differentiation (Nei, 1987). Populations with many similar alleles have small genetic distances. This indicates that they are closely related and have a recent common ancestor. Genetic distance is useful for reconstructing the history of populations. For example, evidence from genetic distance suggests that Sub-Saharan Africa and Eurasian people diverged about 100,000 years ago (Nei, 1974). Genetic distance is also used for understanding the origin of biodiversity. For example, the genetic distances between different breeds of domesticated animals are often investigated in order to determine which breeds should be protected to maintain genetic diversity (Ruane, 1999). Since donkey population has suffered substantial decline in its size, it is expected that the levels of inbreeding and risk of extinction may be high which necessitates a genetic study to assess variability among donkey populations for their conservation along with their breed assignment, better utilization, production and management practices. This study aimed at determining the genetic clustering, extent of genetic diversity and classification of donkeys into various genetic groups using biometric traits.

MATERIALS AND METHODS
Seven hundred donkeys (700) donkeys comprising 280 adults, 210 young and 210 weaner donkeys were used. The study was carried out in the North West of Nigeria. The States where donkeys were sampled were Jigawa, Kaduna, Kano, Katsina, Kebbi, Sokoto and Zamfara States of Nigeria using random sampling techniques. These States in North West Nigeria were selected for this study because of existence of high population of donkeys. The age of the donkeys was determine using teeth count in combination with the information provided by donkey owners. Biometric traits measured were

body weight, head length, head width, ear length, neck length, neck circumference, shoulder width, height at withers, heart girth, body length and tail length using a flexible tailor's tape. The classification of Black (Duni), White (Fari), Brown (Idabari), Red (Auraki) and Brown-White (Idabari-fari) donkeys (by using Euclidean as the distance measurement; Single Linkage, Average Linkage, and Complete Linkage were applied, and the obtained results were compared. The cluster analysis procedure was used to classify the strains using the R 2.13.0 (R Development Core Team, 2015) package. DISCRIM procedure was used to calculate the probabilities of including an animal in determining the strain, taking into account the error made in classification of the strain. Stepwise discriminant procedure (STEPDISC) was applied to determine, which performance traits were used in the final clustering analysis.

RESULTS AND DISCUSSION

The classification by the application of Euclidean to measure distance among biometric traits of male and female donkeys are shown in Table 1. In male black donkey, homogeneous genetic relationships were observed for head width (16, 16), between cluster 1 and 2, and shoulder width (21, 21) in male red donkey. Similar genetic relationships were observed between cluster 1 and 2 for ear length in male red (26, 22), Black (22, 25), White (26, 22), and Brown (22, 25). In female donkeys, the genetic distance between cluster 1 and 2 for ear length in Red (26, 21), Black (21, 26), Brown (26, 21) and Brown-white were similar for neck length (38, 36) and head length (38, 35). Closer and similar genetic distances were also observed for head width in female Black (11, 14) and White (11, 14). Heart girth, body length and height at wither showedhigh level of genetic variability across the strains. Similar report was observed in the findings of Nei, 1987 who reported genetic divergence among animal populations with many similar alleles having small genetic distances. This indicates that they are closely related and have a common ancestor.

The classification by the application of single, average and complete linkage are shown in Table 2. The heaviest body weight was recorded in male red (141.90kg) donkey strain with a distance of 6.75cm compared to other strains of donkeys. Male donkey with the smallest body weight was recorded in white (123.55kg) with a distance of 12.01cm.

Female donkey with the heaviest body weight was recorded in brown donkey strains (123.07kg) with a distance of 16.78cm while the female donkey with the smallest body weight was recorded in brown-white (52.25kg). The high level of genetic variability observed among strains of donkeys signifies that the higher the genetic distance estimates among the strains, the further the genetic distances and the more or better the chances for selection in the population. The result of this study is similar with the findings of John *et al*. (2017) who reported similar and closed genetic distance estimates in the qualitative traits of donkeys.
