Male	HWD(cm)	16	12	Female	SW(cm)	15	19	Male	HWD(cm)	13	11	Male	SW(cm)	13	23				
Female	HWD(cm)	15	11	Female	HWD(cm)	11	14	Female	HWD(cm)	11	14	Male	HWD(cm)	11	15				

HL: Head length; HWD: Head width; EL: Ear length; NL: Neck length; NC: Neck circumference; SW: Shoulder width; HW: Height at withers; HG: Heart girth; BL: Body length; TL: Tail length. The values for each of the five groups wereranked; the first level of ranking was cluster 1 while the second level was cluster 2.

Table 2. Classification by the application of single, average and complete linkage

Sex	Strain	Body weight (kg)	Distance
Male	Brown	130.29	16.64
	Red	141.90	6.75
	Black	137.87	9.32
	White	123.55	12.01
Female	Brown	123.07	16.78
	Red	115.90	10.91
	Black	109.60	11.40
	White	113.45	12.09
	Brown-white	52.25	0.00

CONCLUSION AND RECOMMENDATION

High level of genetic distance estimates were recorded for heart girth, body length and height at wither among donkey strains in the studied populations. Further classification of donkeys into various genetic groups should employ heart girth, body length and height at wither.

ABSTRACT
The aim of this study was to validate and hence evaluate the effects of different concentrations of hydrogen peroxide on the healing of excision wounds in rats. Following wound creation, the animals in their respective groups were treated as follows; group A-0.9% normal saline (control), group B-1% hydrogen peroxide, group C-3% hydrogen peroxide and group D-5% hydrogen peroxide. Post-wounding, rate of wound contraction and re-epithelialisation time were used to assess the wound healing rate. Group C animals achieved 100% wound contraction on day 21 while 68.75%, 79.33% and 79.00% were obtained on the same day in groups A, B and D respectively. The result of this study has validated 3% hydrogen peroxide as the optimum concentration necessary for wound dressing since it provided the environment necessary for faster rate of wound contraction and healing with no visible side effect in this study.
Keywords: excision wounds, hydrogen peroxide, rat, re-epithelialisation, contraction

INTRODUCTION
A wound is a disruption in the normal continuity of tissues and metabolic function of body structures (Alam*et al*., 2011). Wound healing is the restoration of the disrupted anatomical stability and functional status of damaged tissues (Room and Ukrainsky, 2005). The process of wound healing according to Drouso*et al*. (2003) begins with wound cleansing. This has been made possible clinically by employing various methods and agents that promote healing (Drouso*et al*., 2003). The agents popularly used in wound cleansing since the nineteenth century is antiseptics. Commonly used antiseptics include povidone iodine, chlorhexidine, methylated spirit, chlorine compounds, silver compounds, hydrogen peroxide and a host of others (Zhu *et al*., 2017).
Hydrogen peroxide according to Bruno and Raynard (1994) is the most widely used among all the commercially prepared antiseptics. Zhu *et al*. (2017) proposed that hydrogen peroxide is a typical antiseptic which kills pathogens through oxidative burst and local oxygen production. In recent times, there have been arrears of controversy on the use of hydrogen peroxide as an antiseptic (Drosou*et al*., 2003). Kwakman*et al*. (2011) reported that since hydrogen peroxide is dangerous to new cells, it should not be recommended to clean every wound. Kwakman*et al*. (2011) stated that hydrogen peroxide damages cells that are needed for the wound to heal and hinder them from getting to the areas where the healing needs to take place. Hydrogen peroxide at various concentrations has been claimed by some authors to have both antibacterial and good wound healing effect. A cream containing 1% hydrogen peroxide has been reported by (Neithammer*et al*., 2009) to be effective and safe topical treatment of human *Impetigo contagiosa*caused by*staphyloccusaureus.* Thereport also said that 1% hydrogen peroxide cream showed excellent antibacterial effect and eliminated most of the bacteria from the skin. No side effect such as skin irritation or allergic reaction in human patients was noted with use of 1% hydrogen peroxide cream. A cream containing hydrogen peroxide at 1.5-3% concentration has been reported to increase circulation in ischemic ulcer and surrounding skin in a guinea pig model (Tandara and Mustoe, 2004).
Animal and human studies have also shown hydrogen peroxide to have a negative effect on wound healing at 3% concentration. Hydrogen peroxide was reported not to retard re-epithlialization in a rat model after irrigation but showed minimal bactericidal effect in-vitro (Tidhar*et al*.,2017). Kwakman*et al*. (2011) also found acceleration of re-epthlializationin wounds of rat treated with 3% hydrogen peroxide. In view of the above reports, and with the use of hydrogen peroxide as the most popular antiseptics in wound management, surprisingly few experimental studies have been conducted to examine its efficacy on wound healing process and as a wound antiseptic.
Additionally, we have observed that use of commercially available hydrogen peroxide (6 % concentration) on open wounds without dilution causing severe charring. In view of the above reports, the benefits and demerits of low and high concentrations of hydrogen peroxide on wound healing

needs to be fully investigated. The basic objective of this study was to ascertain the appropriate concentration of hydrogen peroxide which when used on open wounds will facilitate wound proliferation thereby enhance wound healing.

ANIMALS

Adult wistar rats (n=32) weighing between 170-184 g were used for this study. They were fed on commercial growers mash (Vital feeds®) and water was provided *ad libitum*. These rats were acclimatized for 2 weeks in the animal house at the Department of Veterinary Surgery, University of Nigeria, Nsukka.

WOUND HEALING STUDIES

Thirty two rats were anaesthetized by injecting intramuscularly 10 and 50 mg/kg bw of xylazine hydrochloride (Xylazine 20®, Kepro Holland) and ketamine Hydrochloride (Mark pharmaceuticals® Nigeria) respectively. Under general anaesthesia, dorsum of the rats were shaved and with mild antiseptic solution (0.5% chlorhexidine). Full thickness circular excision wound of 2cm in diameter was made on the scrubbed area of each rat and carefully dissected out. The animals were left untreated for 24 hours to allow for bacterial contamination of the wounds. Post wounding, the rats were randomly assigned into 3 groups of 8 animals per group and treated as follows: group A was treated with normal saline while groups B, C and D were treated with 1%, 3% and 5% hydrogen peroxide respectively. The animals were housed individually in clean and dust-free cages in the Department of Veterinary Surgery, University of Nigeria, Nsukka to avoid wound biting and/or licking and treated daily with their respective extract concentrations or drug until complete healing occurred.

ASSESSMENT OF WOUND HEALING

Wound healing was assessed using the percentage wound contraction rate as described by Chah*et al.* (2006) while wound re-epithelialisation was studied as described by Okoli*et al.* (2009).

RESULTS

Rate of wound contraction

Assessment of the effect of the different concentrations of H_2O_2 on the rate of wound contraction showed that increase in the percentage wound contraction was first noticed on day 4 post surgery in groups B and C rats. Day 7 post surgery, group C animals significantly ($P<0.05$) had a higher rate of wound contraction (21.50 %) than those in groups A (8.40%), B (9.33%) and D (5.00%).By day 21, 100% wound contraction was recorded in group C animals while 68.75%, 79.33%, 79.00% and were obtained in groups A, B and D animals respectively. The rate of wound contraction of group C animals remained significantly higher ($P<0.05$) when compared with those of groups A, B and D (Table 1).

Table 1: Percentage rate of wound contraction in rats post wounding.

	Groups			
Days	A(N/saline)	B (1% H_2O_2)	C (3% H_2O_2)	D (5% H_2O_2)
1	-6.86 ± 1.32^{ab}	-5.25 ± 1.93^{ab}	-4.13 ± 0.79^{a}	-7.63 ± 1.35^{b}
4	-3.00 ± 0.79^{b}	1.75 ± 3.22^{ab}	5.13 ± 1.14^{a}	-2.13 ± 0.64^{b}
7	8.40 ± 1.81^{b}	9.33 ± 4.85^{b}	21.50 ± 4.19^{a}	5.00 ± 1.21^{b}
14	48.00 ± 6.55^{b}	57.67 ± 0.67^{b}	71.50 ± 3.23^{a}	55.75 ± 2.25^{b}
21	68.75 ± 4.59^{c}	79.33 ± 2.6^{b}	100.00 ± 0.00^{a}	79.00 ± 2.35^{a}

Different superscripts[a, b,c] in a row indicate significant difference between mean at $P<0.05$

Wound Epithelialization

In this study, group C animals treated with 3% concentration of H_2O_2 had higher rate of wound epithelialization followed by groups A, D and B animals. Wound epithelialization occurred on days 45, 28, 19 and 32 in groups A, B. C and D animals respectively.

Table 2: Wound epithelialization time of rats post wounding.

Groups	**A (n/saline)**	**B (1%)**	**C (3%)**	**D (5%)**
Days of wound epithelialization	44.75 ± 3.20^{b}	28.60 ± 0.29^{ab}	19.00 ± 0.71^{a}	32.00 ± 2.04^{b}

Different superscripts in a ^{a,b} row indicate significant difference between mean at $P<0.05$.

DISCUSSION

The effects of different concentrations of hydrogen peroxide on healing of excision wound were evaluated in this study. Grossly, the effect on contraction and rate of wound epithelialization were studied. Wound contraction and epithelialization play a significant role in healing of excision wounds. According to Eichler*et al*. (2006) contraction of wound begins approximately a week after wounding when fibroblasts have differentiated into myofibroblasts. Wound contraction as documented by Sussman*et al*. (2005) peaks at 5-15 days post wounding. In this study a progressive decrease in wound size was observed on day 7 in all the groups and this finding was in agreement with the works of other researchers as documented above.

The fastest rate of wound contraction observed in 3% H_2O_2 treated group could be attributed to its content of antimicrobial properties. It kills microbes by interrupting cellular respiration of the microbes and as well prevents wound contamination by microorganisms with minimal tissue damage around the wound (Edward and Harding, 2004).

In conclusion, the result of this study validates 3% H_2O_2 as the optimum concentration of hydrogen peroxide necessary for wound dressing as it provides faster rate of wound healing with no visible side effects while 5% concentration should not be used in wound dressing due to its damaging effects on the tissue and blood vessels thus delaying wound healing. Also, 1% hydrogen peroxide and normal saline should not be used as wound dressing agents for excision wounds probably due to their poor antimicrobial property.

ABSTRACT
In spite of numerous advantages of guinea fowl over chicken, rearing of guinea fowl is believed to be uneconomical due to high information of PUFA that instigates poor semen quality. However, the study was designed to evaluate effect of vitamin E at different levels on semen quality and body weight of guinea cocks. Twenty-four guinea cocks were equally and randomly distributed into T1, T2, T3 and T4 of 0mg, 125mg, 250mg and 350mg vitamin E per kg diet respectively in a completely randomized design. Initial and final body weights were determined and semen samples were collected twice a week. Best values of semen volume, sperm concentration, sperm progressive motility, percentage live and dead sperm cells were obtained from cocks in T2. Reduction ($P<0.05$) in values of semen volume, sperm concentration, sperm progressive motility and percentage live were observed from cocks in T3 and T4 indicating that 250mg and 350mg vitamin E inclusion were in excess and had adverse effect on semen parameters of guinea cocks. Cocks in T2 had highest ($P<0.05$) gains in body weight than the control while cocks in T3 and T4 expressed significant ($P<0.05$) body weight lost. These results therefore prove that semen quality and body weight of guinea cocks were negatively influenced by 250mg and 375mg vitamin E inclusion while 125mg vitamin E inclusion had an improved semen quality at better body weight which is recommendable.

INTRODUCTION
Increase in Nigerian population has not been marched by growth in agricultural productivity especially in the area of animal production. This has caused low intake of animal protein intake in Nigeria as reported by FAO(1989). To correct this shortfall, there is need to improve on indigenous farm animals like guinea fowl (*Numidameleagris*) which is predominantly reared in northern part of Nigeria. Guinea fowl has many advantages over chicken which include low production cost, premium quality meat, greater capacity to scavenge for insects and grains, better ability to protect itself against predators and better resistance to common poultry parasites and diseases (Microlivestock, 1991). Guinea fowl products also have numerous nutritive and socio-cultural values. In spite of these, rearing of guinea fowl is believed to be uneconomical due to their monogamous and seasonal reproductive behavours.
The use of Artificial Insemination (AI) has not been properly explored as better alternative to break the inbreeding and monogamous behaviours of guinea fowl(Aire*et al*., 1983). Rengaraj and Hong (2015) reported thatavians are rich in PUFA which instigate oxidative damages that causes infertility. These damages may be controlled by given certain minerals and vitamins to act as antioxidants which vitamin E is a well unknown one.Vitamin E is a fat soluble vitamin that accumulates in tissues like testes and other reproductive organs (Rengaraj and Hong, 2015). This trace element is necessary for effective functioning of hormonal regulation and the reproductive system (Herrera and Barbas, 2001). This element is to increase the value semen parameters like sperm concentration, sperm livability and semen volume (Danikowski*et al*., 2002).However, excessive inclusion of vitamin E has also been reported to decrease semen quality (Arscot *et al*., 1995) and body weight (Aburto and Britton, 1998)ofguinea cocks.
Information on reproductive responses of chicken, turkey and quail given different levels of vitamin E has been investigated by many authors like Kling *et al*. (1987), Danikowiki *et al*. (2002), Lin*et al*. (2005), Hooda*et al*. (2007) and Biswas*et al*.(2009). Yet, no work has been done on effect of vitamin E inclusion on semenparameters and body weight of guinea cocks reared in humid tropics. Therefore, this work is designed to establish the level of vitamin E inclusion that will improve semen quality recommendable for natural and AI breeding management in guinea cocks with sustainable body fitness.

MATERIALS AND METHODS
Location and duration of the study: This study was conducted in the Poultry Unit of the Teaching and Research Farm of the Department of Animal Science, University of Nigeria Nsukka, Enugu State. Nsukka lies in the derived savannah region, and is located on longitude $6^{o}\,25^{1}$ N and latitude $07^{o}\,24^{1}$ E,

at an altitude of 430m above sea level (Ofomata, 1975). The climate is a typical humid tropical type with a relative humidity range of 56.01% - 103% (Energy Centre UNN, 2008). Average diurnal minimum temperature ranges from 22.0^{o}C–25.2^{o}C while the average diurnal maximum temperature ranges between 33^{0}C-37^{0}C (Energy Centre UNN, 2008). Annual rainfall ranges from 1567.05mm to 1846.98 mm (Energy Centre UNN, 2008). The study lasted 18weeks in which two weeks were used to acclimatize the birds.

Procurement, distribution and management of experimental guinea cocks: A total of twenty-four mature guinea cocks of 35-37 weeks old were procured from dealers in Abuja and acclimatized to the farm environment. The cocks were randomly allotted into four treatments: T1, T2, T3 and T4 of six cocks per treatment at different levels of vitamin E: 0mg, 125mg, 250mg and 375mg inclusion respectively. Initial and final body weights of the cocks were also determined. Diet containing metabolizable energy and crude protein of 2650Kcal/kg and 16.5% respectively was formulated which met the dietary recommendation for guinea fowl breeders under tropical conditions as recommended by NRC (NRC 1994) and served at 110g/day/cock as prescribed by Embury (2001). Water was given *ad libitum*.Other procedures carried out in this study were complied with the provisions of theUniversity of Nigeria, Nsukka Ethical Committee on the use of animals for biomedical research (2005).

Collection of semen samples: The guinea cocks were trained on semen collection within the period used for acclimatizing the birds. Semen samples were obtained by massage technique as described by Burrows and Quinn (1935). Semen samples were collected twice per week i.e. Saturdays and Wednesdays and were evaluated considering the processes described by Ugwu and Oleforu (2008).

Experimental design and statistical analysis: The experimental design that was used is a completely randomized design (CRD): $\mathbf{X_{ij} = \mu + T_i + E_{ij}}$**;** where$\mathbf{X_{ij}}$= individual observations of (ith) guinea cock fed with (jth) different level of vitamin E; **μ**= overall mean of the experiment; **T**i= effect of vitamin E on (ith) individual guinea cock;$\mathbf{E_{ij}}$= experimental error associated with observations of guinea cock fed with (jth) different level of vitamin E. The data were subjected to analysis of variance based on a Completely Randomized Design (CRD) using Statistical Package for Social Sciences (SPSS) computer package (SPSS, 2001). Significant means were separated using the Duncan option of SPSS.

RESULTS AND DISCUSSION

Results in Table 1 showed that there were significant differences (P<0.05) among the cocks in semen volume, progressive motility, sperm concentration, percentage dead sperm cells, percentage live sperm cells and total sperm cells with best mean values obtained for cocks fed with 125mg vitamin E (T2).The mean values of semen volume, live sperm cells and total sperm cells obtained for cocks in T3andT4 were significantly lower (P<0.05) than number of dead sperm cells whencomparedwith the control.Semen of cocks in T3 and T4 had slightdecrease (P<0.05) in progressive motility and sperm concentration values when compared with control treatment. These resultstherefore indicate that inclusion of125mg vitamin E

Table 1: Physical semen characters of the guinea cocks fed with different dietary levels of vitamin E

Semen Characters	T1 (control) (0mg vit. E)	T2 (125mg vit. E)	T3 (250mg vit. E)	T4 (375mg vit. E)
Semen volume (ml)	0.038[a] ±0.01	0.044[a]±0.02	0.022[b]±0.03	0.020[b]±0.02
Progressive motility (%	45.43 [b]±3.25	65.22[a]±4.05	40.40[b]±4.15	40.40 [b]±4.15
Sperm Concentration (x10^6/ml)	2.35[b] ±0.09	4.35[a]±1.13	2.20[b]±0.21	2.00[b]±0.16
Live sperm cells (%)	90.12[a]±3.34	92.56[a]±3.40	82.28[b]±2.28	81.53[b]±2.21
Dead sperm cells (%)	10.34[b] ±0.04	8.29[a]±0.22	18.77[c]±1.58	19.56[c]±1.50
Total sperm cells (10^9/ ejaculate)	0.83[a] ±0.018	0.91[a]±0.025	0.51[b]±0.017	0.41[b] ±0.010

[a, b, c]Means with different superscripts in a row are different (P<0.05).

perkg diet improved semen quality of guinea cocks.Further increase of vitamin E to 250mg and 375mg may progressively reduce values thesesemen parameters. These values were in accordancewith those of Arscot*et al*. (1995) and Danikowski*et al*. (2002) who reported that semen parameters of cocks may be negatively affected when they are given high level of 250mg vitamin E in diet.

Table 2: Daily live-weight gain of guinea cocks fed with different dietary levels of vitamin E

Body weight	T1 control (0mg vit. E)	T2 (125mg vit.E)	T3 (250mgvit. E)	T4 (375mgvit. E)
Initial weight(kg)	0.65±0.075	0.64±0.080	0.63±0.067	0.65±0.082
Final weight(kg)	0.78[b]±0.063	0.82[a]±0.403	0.56[c]±0.055	0.56[c]±0,057
Total weight gain (kg)	0.13[b]±0.021	0.18[a]±0.028	-0.07[c]±0.019	-0.09[c]±0.023
Daily Live-weight gain(g)	3.09[b]±0.19	4.28[a]±0.24	-1.67[c]±0.15	- 2.01[c]±0.07

[a, b, c]Means with different superscripts in a row are different (P<0.05)

Results in Table 2 showed that cocks in T2 had highest (P<0.05) daily live-weight gains (4.28[a]±0.24) while cocks in T3 and T4 had negative values (P<0.05) live-weight gains of -0.71g±0.15 and -0.92g±0.07 respectively indicating a reduction in body weights when compared to 3.98g±0.19 daily live-weight gain for the birds in control treatment. Also, similar trends were observed in final weight and individual weight gain of cocks given the different dietary levels of vitamin E (Table 2). These results agreed with the reports of Yates *et al*. (2009) that body, liver and heart weights of rats given dietary vitamin E were better at lower levels (42 IU and 242 IU) than (2042 IU and 20,042 IU). Similarly, Aburto and Britton (1998) observed that the body weights and bone ash of broilers were reduced significantly at high levels of vitamin E supplementation when compared with increased body weights and bone ash obtained forbroilers fed with lower levels of vitamin E. Dju*et al*. (1950) observed that fowls fed with excess vitamin E for a prolong period eliminate more than 75% of ingested feed through faeces. This may cause great loss of metabolizable nutrients including the energy required for production of quality semen and body development among others. In contrast, Pudelkiewics *et al.* (1960) reported that chicken receiving diet supplemented with 35g of vitamin E/kg diet defecate only 23% of ingested feed. This proves that more nutrients will be stored and utilized for production of semen of good quality and sustaining better body development among the chickens.

CONCLUSION AND RECOMMENDATIONS

These results suggest that guinea cocks required reduced amounts of vitamin E for body growth, gamete production and subsequent fertility. Deficiency or long-term omission of vitamin E in the diets of breeding guinea cocks may not significantly affect semen production, fertility and body weight gains while excessive inclusion of 250mg to 375mg of vitamin E per kg impair semen quality with significant loss of body weight which may further cause emaciation. These results showed that 125mg of vitamin E per kg diets reduces the oxidative damages of PUFA and therefore improves the semen parameters recommendable for natural and AI operations with better body fitness essential for optimum guinea fowl production.

ABSTRACT

The experiment evaluated the influence of strain on haematological values, blood chemistry and carcass characteristics of three strains (black, brown and spotted) of Noiler chicken. The experiment was conducted at the poultry section of the Bauchi State Agricultural Development Programme (BSADP) in Bauchi. A total of one hundred and thirty-six (136) eight weeks old Noiler birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system. They were randomly distributed into 3 treatment groups based on strain using a Completely Randomized Design(CRD). The experiment lasted for a period of three months from the first day of lay. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum. At 34 weeks, seventy-two (72) birds were randomly selected from three different strains (24 birds per strain) for haematology and biochemical analysis while at the end of the experiment, a total of fifty-seven (57) birds were randomly selected from different strains (19 per strain) for gut and carcass analysis.The Haemoglobin (Hb) result indicated that all the treatments were within the normal range (10.2 – 15.1g/dl), the packed cell volume (PCV) were within the normal recommended values.The result for lymphocytes fell within the normal value of 40 – 70% indicating that the birds were normal. The lymphocytes, neutrophils, Basophils, Eosinophils and monocytes were all within the normal range. The result showed that strain ($p<0.05$) significantly affected albumin glucose cholesterol and calcium. Dressing percentage, liver, large intestine pancreas and abdominal fat were also influenced by strain. This study therefore concludes that strain affected the haematological values, blood chemistry and carcass characteristics of Noiler chicken.

Keywords: Strain, Noiler, Haematological, Carcass, Blood Chemistry

INTRODUCTION

Chickens are regarded as the most important and widely spread avian species among poultry birds (Dutta*et al.,* 2013).Poultry production is an important agricultural activity of almost all rural communities in Africa and provides scarce animal protein in the form of meat and eggs, and is a reliable source of petty cash, they are said to be one of the important animal genetic resources used as a weapon for fighting poverty and malnutrition, especially in rural areas of most developing countries, which results in the growing interest on the use of chicken as a tool for poverty alleviation in villages throughout the world (Dunya *et al.,* 2015). However, chicken growth and development is a complicated life process and is subject to a significant amount of control by genetic and non-genetic factors (Pourtorabi *et al.,* 2017; Zhenqiang *et al.,* 2013).Poultry production is fast growing in Nigeria as it significantly contribute to animal protein source of the Nigeria population, Most farmers keep broilers for meat and pullets are kept for egg production. With the increasing population, there is need for a low cost feed input breed with increased output of meat and egg production.To achieve this, a dual purpose chicken breed like Noiler is unavoidable. Noiler is a dual purpose breed of chicken developed in Nigeria by a noble hatchery with the sole aim of addressing the challenges of animal food insecurity and also to solve problems of financial challenges especially of rural communities and small holder farmers as Noiler production is highly profitable and can easily substitute local chicken. The haematological profile, both in human and animals is an important index of the physiological state of the individual, the ability to interpret the state of blood profile in normal and diseased conditions is among its primary tasks (khan *et al,* 1987). Hematological indices are an index and a reflection of the status and condition of the blood available for an animal to meet its physiological, biochemical, and metabolic necessities (Euola *et al*,2004). Therefore the objectives of this study was to establish the haematological and serum biochemical values of the three strains of Noiler chicken and to determine the effects of strain on carcass yield and gut characteristics of Noiler chickens.

MATERIALS AND METHODS

The experiment was conducted at the poultry section of the Bauchi State Agricultural Development Programme (BSADP) along Yelwan Makaranta Dass Road, Bauchi State. A total of one hundred and thirty-six (136) eight weeks old Noiler birds were purchased from the Bauchi State Agricultural Development Programme (BSADP). The birds were raised on deep litter system until the age of 18weeks before they were transferred to battery cage housing system where they were randomly distributed into 3 treatment groups based on strain using a Completely Randomized Design(CRD). The experiment lasted for three months from the first day of lay. The birds were fed uniformly with a standard commercial diet and water was supplied ad-libitum.

Data Collection and Analysis

At 34 weeks, seventy-two (72) birds were randomly selected from three different strains (24 birds per strain) for haematology and biochemical analysis. 3ml of blood samples were collected from the basillic vein of the birds into a well labelled sterile bottle containing Anticoagulants. These were used to determine packed cell volume, haemoglobin (hb), white blood cell count (WBC), and the differential counts which are Neutrophils, lymphocites, monocites, Eosinophil and Basophils. Another 3ml sample of blood was collected into sterile labelled bottles without anticoagulants to determine the serum biochemical metabolites as follows: total protein, cholesterol, Glucose, Albumin, calcium, phosphorus, uric acid.

Hematological technique

Total red blood cell count and Total white blood cell count were determined by a manual method using hematocytometer (Campbell,1995). Differential counts were made on monolayer blood films, fixed and stained with leishman – stain. Packed cell volume was measured by a standard manual technique using micro hematocrit capillary tubes and hematocrit reader. Haemoglobin concentration was measured by cyanhemoglobin method (Ritche *et al*.,1994).

Biochemical technique

Total protein, glucose, calcium, phosphorus, cholesterol, and uric acid, were determined by automatic analyzer.

Gut and Carcass Analysis

At the end of the experiment, a total of fifty-seven (57) birds were randomly selected from different strains (19 per strain). They were deprived of feed for twelve hours but provided with drinking water. The chickens were weighed and slaughtered. Slaughtered birds were scalded in hot water (about 50^0c) for 1 minute and plucked manually, offal were then eviscerated for carcass yield and organ weight determination. The carcass yield and organ weight were calculated as percentage of the live weight. Dressing percentage was calculated using the relationships: -

$$\text{Dressing percentage} = \frac{\text{carcass weight}}{\text{live weight}} \text{ x } 100$$

Statistical Analysis

Analysis of variance was carried out on data collected using the general linear model of SPSS 20.0 (2011). Where means differed, Duncan multiple range test (DMRT) was used to separate them (Duncan, 1955).

RESULTS AND DISCUSSION

The result for haematological analysis of three strains of Noiler chicken is presented in Table 1. The result showed ($p<0.05$) significant difference among some of the parameters measured. Haemoglobin (Hb) values were similar among the treatments. The Hb result indicated that all the treatments were within the normal range (10.2 – 15.1g/dl) which is in agreement with the finding of Petra *et al*, (2014). The packed cell volume (PCV) were within the normal recommended values for healthy birds in all the treatments (30 – 49%) as outlined by Petra et al, (2014). The result for white blood cell count (WBC) revealed that all the treatments were within the recommended range ($3 – 11 \times 10^9$). The result for lymphocytes fell within the normal value of 40 – 70% indicating that the birds were in a normal health status. The neutrophils, Basophils, Eosinophils and monocytes are all within the normal range for healthy birds as outlined by Petra et al.

Table 1: Haematological values of three strains of Noiler Chicken

Parameters	Black strain	Sported strain	Brown strain	LS
Hemoglobin (g/dl)	11.13	10.33	11.54	0.3882 7 NS
Packed cell volume%	33.33	30.13	34.13	1.1785 1 NS
Whiteblood cell(x10)	5.41	3.65	3.75	0.5375 8 NS
neutrophil%	39.50	40.25	36.45	0.7578 5 NS
Lymph%	55.45a	51.79b	56.33a	0.8653 4 *
Mono%	3.92a	2.29b	3.45a	0.1738 2*
Basophils	0.02	0.01	0.01	0.0000 0 NS
Eosinophils	0.42a	0.00b	0.00b	0.0603 4 *

Ls= level of significant,NS/=Not significant, a and b= means with different superscript on the same row varies significantly.

Table 2: Blood Chemistry of three strains of Noiler Chicken

Parameters	**Blac k strain**	**Sporte d strain**	**Brown strain**	**SEM**
Total protein (gl)	57.62	60.24	56.67	1.19269 NS
Albumin (mmol/l)	21.62 $_{b}$	22.00$_{b}$	26.19^{a}	0.46649*
Glucose (mmol/l)	1.35^{b}	2.95^{a}	1.65^{b}	0.23103*
Cholesterol (mmol/l)	4.91^{b}	3.45^{c}	6.05^{a}	0.22020*
Calcium (mmol/l)	2.26^{b}	3.00^{a}	2.40^{b}	0.07510*
Phosphorus (mmol/l)	2.42	2.11	2.30	0.13478 NS

NS= not significant ($p<0.05$), SEM= standard error of mean, a, b and c= means with different superscripts on the same row varies significantly, *= significant.

The result for blood chemistry of the three strains of Noiler is shown in Table 2**.** The result showed that strain has effect on most of the serum biochemical parameters measured. The total protein was not significantly different among the three strains, but albumin values were similar in two of the treatments (Black and spotted) but differs significantly ($p<0.05$) with the brown. The result for glucose showed a similar value for the black and brown strain but differs significantly ($p<0.05$) with the spotted. All the treatments were within the normal glucose range for birds. Cholesterol levels were within the normal range but vary significantly ($p<0.05$) among the treatments. Brown strain records higher value for cholesterol compared to the Black and Spotted. Calcium and phosphorus levels were

within the normal range indicating proper metabolism of the calcium and phosphorus and also a proper functioning of the parathyroid gland.

Table 3: Carcass characteristics of three strains Noiler chicken

Parameters	Black strain	Sported strain	Brown strain	SEM
Live weight (g)	2738.5	2853.8	2638.5	0.10608
Pluck weight (g)	2509.2	2500.0	2411.5	0.10449
Eviscerated weight (g)	2249.2	2223.1	2169.2	0.10292
Carcass weight (g)	2107.7	1901.5	1960.0	0.09828
Dressingpercentage (%)	74.92[a]	66.74.[b]	72.76[a]	1.24794*
Head (%)	8.8	7.5	8.9	1.247NS
Leg (%)	8.5	7.5	7.8	4.928NS
Gizzard (%)	3.9a	3.5b	3.9a	2.617NS
Liver (%)	4.9[a]	3.4[b]	3.13[b]	9.400*
Kidney (%)	0.3	0.33	0.33	0.522NS
Small intestine(cm)	8.9	8.6	8.2	4.395NS
Large intestine(cm)	0.8[b]	0.83[b]	0.96[a]	0.220*
Pancreas (%)	0.3[b]	0.31[b]	0.38[a]	0.125*
Abdominal fat (%)	8.26[b]	8.60[a]	8.21[b]	9.85*
Spleen (%)	0.18	0.19	0.19	0.50NS
Caecum (%)	1.78	1.72	1.76	2.73NS
Lungs (%)	1.24	1.08	1.06	0.470NS
Hearts (%)	1.23	1.06	1.21	0.44NS
Testes (%)	0.71	0.73	0.78	2.211NS

SEM= standard error of mean, a and b= means with different superscript on the same row varies significantly. NS- not significant.

The result for carcass characteristics of three strains of Noiler chicken is shown in Table 3. The result showed that there were no significant difference on parameters like liver, plucked, eviscerated and carcass weight. The similarity may be as a result of uniformity in feed, environment and their genetic potentials for growth. The result for organ and gut expressed as percentage of body weight showed no significant difference in kidney, heart, testes, lungs, ceacum, spleen, gizzard, and small intestines. However, significant ($p<0.05$) difference was recorded for liver with the black strain recording the

highest (42.62). Other parameters measured include pancreas, large intestine, abdominal fat which varied significantly ($P<0.05$) among the treatments.

CONCLUSION

In conclusion, strain affected the haematological values, blood chemistry and carcass characteristics of Noiler chicken.

ABSTRACT

The aim of this study is to seek the effect of dietary energy and protein on the egg qualities. A total of four hundred and eighty day old un-sexed Japanese quails of about the same weight (26.56±0.02) were studied over a period of 12 weeks. After hatching, chicks were raised together during one week and fed with starting diet then divided into four dietary treatments (T1, T2, T3 and T4) with 30 quails in each replicate. Each treatment was replicated four times. T1: Control (Standard diet)SD; T2: High Energy Low Protein diet (HELP) ; T3 : High Energy High Protein diet (HEHP) andT4 : Low Energy High Protein diet (LEHP) in a completely randomized design. After 12 weeks of laying, eggs were collected from each treatment for both the external and internal egg characteristics. Data obtained were analyzed using ANOVA at $\alpha_{0.05.}$

Egg weight was higher (P<0.001) in the HEHP diet, egg height was also higher (P<0.05) in HEHP diet as well. Internal egg qualities, albumin height and albumen length had a significant influence (P< 0.05) in the HEHP diet.The albumen volume and the Yolk weight had the highest level of significance (P<0.001) in the HEHP diet. The shell weight was significant (P<0.001) with the HEHP diet having the highest values. There was also significance (P< 0.001) in the shell membrane and shell percent (P< 0.01) in the LEHP diet. The haugh unit are not significant in all the diets (P>0.05) but HEHP had the highest % of haugh unit.The results indicate that high energy and high protein (HEHP) diets is suitable for optimum performance of Japanese quail in terms of weight gain and egg quality.

INTRODUCTION

Increased poultry production has been advocated as one of the fastest means of providing quality animal protein at minimum cost (Nwachuckwu, 2015). The quail production story is more recent and also has the same characteristics that occurred in the broiler and laying hen production.

The establishment of quail production assumed importance worldwide in the last decade, not only for being a laboratory animal for poultry and biomedical research, but also because it is commercially exploited for production of meat and eggs.

Japanese quails mature in about 6 weeks and are usually in full egg production by 50 days of age. With proper care, hens should lay 200 eggs in their first year of lay. Life expectancy is only 2 to 2½ years (Randall, 2008).Quails produce up to five generations per annum (Saidu, 2014).

The optimum performance of livestock depends largely on the quality and quantity of their dietary nutrients (El-katcha, 2014). Precise nutrient supply reduces feed cost, wastage of nutrients, environmental pollution, and bad aroma in poultry house, and thus improves animal welfare (Kaur, 2015). Nutrition is by far the most important single factor under the environment in which poultry birds are reared, since it accounts for 60-75% of the inputs in poultry industry.

The aim of this study is to seek the effect of dietary energy and protein on the egg qualities.

MATERIALS AND METHODS

Location:

The experiment was carried out in the Poultry Division of the National Veterinary Research Institute Vom which is located in Plateau state ,central Nigeria in Jos South Local Government .Its geographical coordinates are on Latitude 09^0 44' 0'' North ,08^0 4' East .The trial was carried out from September to November 2018 (Maplandia.com).

Animals and management:

A total of four hundred and eighty day old un-sexed Japanese quails of about the same weight (26.56±0.02) were studied over a period of 12 weeks . The birds were sourced and raised in the Poultry Division of the National Veterinary Research Institute Vom in Plateau state. After hatching, chicks were raised together during one week and fed with starting diet then divided into four groups of 30 chicks each.

Experimental diets:

Diets were composed with local available feedstuff such as corn, soya bean cake and offered as mash (Table 1) and were randomly assigned to each treatment. The experiment included 4 dietary treatments (T1 , T2 ,T3 ,and T4) with 30 quails in each replicate. Each treatment was replicated four times.

The experiment consisted of 4 treatments designated as:

T1 : Control (Standard diet)(SD)

T2 : High Energy Low Protein diet (HELP)

T3 : High Energy High Protein diet (HEHP) and

T4 : Low Energy High Protein diet (LEHP)

Egg collections

After 12 weeks of laying ,eggs were collected from each treatment for both the external and internal egg characteristics.

Data collected

External characteristics

Internal characteristics

Statistical analysis

Data collected were analyzed using General linear model of SAS (SAS 2010). Statistical variations were observed and means were separated using Duncan's multiple range test.

RESULTS

The effect of the diets on egg quality is presented on Table 1. The Egg width and Egg shape index were similar for all the groups (P>0.05). Egg weight was higher (P<0.001) in the HEHP diet, Egg height was also higher (P<0.05) in HEHP diet as well. For the internal egg qualities, the Albumin height and the Albumen length had a significant influence (P< 0.05) in the HEHP diet .The Albumen weight was significant (P<0.01) in the LEHP diet .The Albumen volume and the Yolk weight had the highest level of significance (P<0.001) in the HEHP diet. The yolk volume was significant (P<0.01) with the HELP diet having the highest value.

The shell quality showed no significant difference (P>0.05) in the shell thickness, values in all the diets ranged between 0.10mm to 0.15mm. However, the shell weight had values ranging from 1.38g to 1.74g ,and it was significant (P<0.001) with the HEHP diet having the highest values. There was also significance (P< 0.001) in the shell membrane and shell percent (P< 0.01) in the LEHP diet.The Albumen width ,Haugh unit ,Albumen index ,Yolk percent ,Yolk height ,Yolk width ,Yolk length , Yolk colour ,Yolk index ,Yolk /Albumen ratio , were all not significant in all the diets (P>0.05).

Shell percent(%)	13.51^{b}	14.18^{b}	14.49^{ab}	15.47^{a}	0.19**
Shell Thickness(mm)	0.12	0.15	0.1	0.13	0.01^{NS}

[a, b] means with different superscripts within the same row differ significantly ($p<0.05$)., SEM means standard error of mean

SD= Control (Standard diet); HELP= High Energy Low Protein diet; HEHP= High Energy High Protein diet

LEHP= Low Energy High Protein diet

This present result was in line with Muhammad (2016), who indicated that the protein levels had no significant effect on albumin weight, yolk height, yolk width, yolk weight, yolk index, yolk colour and Haugh unit ($P>0.05$). In this study all that were indicated were not significant except Albumin weight which was significant ($P<0.01$). It was concluded in his study that increasing dietary protein level of 25% will increase the egg production performance of Japanese quails. Similar results was obtained with the report of Lotfi (2018) who reported that the groups of quails that were fed more energetic feeds, significantly higher egg weights were achieved. Gunawardana (2008) reported that dietary energy had no influence on egg weight. Wu *et al.* (2005), and Sohail (2003), who reported that egg weights of hens with high protein diets were greater than of those hens with low protein diets, which is a consequence of the increase in albumen and yolk weights was in line with the results obtained in this study. This study is also in agreement with Lotfi (2018) who reported that the increase of albumen weight might be partially attributed to the improved nutrient (protein, total sulfur amino acids, or lysine) utilization with increased dietary energy. On the other hand, Novak *et al.* (2006) reported that shell quality was affected by protein and its ratio in diet, which could potentially have serious consequences for commercial egg-laying operations which is in line with this study. The work of Lotfi (2018) which stated that the shell protein matrix is comprised of 70% protein ,and also, increasing the sulfate groups existing in the shell matrix significantly increases the Ca binding ability, which in turn may increase both shell percentage and specific gravity and overall shell quality.

CONCLUSION

The results indicate that high energy and high protein (HEHP) diets is suitable for optimum performance of Japanese quail in terms of weight gain and egg quality.

ABSTRACT
This study was conducted to estimate the variance components and heritability for birthweight and weaning weight, as well as the genetic and phenotypic correlations between these traits in N'dama and Muturu crosses at the University of Nigeria Nsukka (UNN) cattle herd. The study lasted for 6 months and the heritability and genetic correlation of the traits were estimated using Restricted Maximum Likelihood (REML) method of SAS mixed model. The direct heritability estimates obtained were 0.15±0.05 and 0.45±0.05 for birth weight and weaning weight respectively. The direct genetic correlation between the two traits was positive (0.53) between birth weights and weaning weights.
Keywords: Genetics, heritability, N'dama, Muturu and Correlation

INTRODUCTION
The beef cattle sub-sector plays important roles in the Nigerian economy, not only in terms of its contribution to the gross domestic products (GDP) but also contributes substantially to the supply of animal protein (FDLPCS, 2002 and Tewe, 2010). In the opinion of Grain de Sel (2010), Nigeria is by far the leading beef cattle producer in Central and West Africa with the cattle herds estimated at over 16 million heads, which is far ahead of Niger (8.7 million), Mali (8.2 million) and Chad (7 million).
However, Nigeria's rapidly growing population which is expected to reach 250+ million persons by 2030 (NLTP, 2019-2028), coupled with rising incomes and urbanization, are translating into increased demand for livestock products (FAO, 2018). Recent estimates suggest that, between 2010 and 2050, beef, poultry meat and milk consumption will increase by 117, 253 and 577 per cent, respectively (ASL2050 FAO, 2018). Hence, there is need to genetically upgrade the performance of our indigenous cattle species to raise the potential for higher meat yield.
Long (1980) opined that the genetic improvement of beef production systems is hinged primarily on two procedures which are; selection within breeds to enhance critical characters and selection among, and combination breeds to produce individuals that better fit production conditions and resources. N'dama and muturu which are predominant in the south eastern Nigeria produce minimally and are usually referred to as unimproved. However they have good adaptive traits that makes them hardy and resistance to certain environmental factors and diseases. Hence, they can be used in advanced beef cattle improvement programmes. Moreover, birth weight and weaning weight traits are recognized as important traits in determining economic efficiency of beef cattle (Oni et al 1988), and also an important selection criteria because of the ease with which they can be measured (Gregory 1965).
The effectiveness of breeding programmes depends on the accuracy of genetic and phenotypic parameter estimates, which include heritability and repeatability (Burrow, 2001). However, since the inception of breed improvement programmes in Nigeria, there has been no comprehensive analysis of the data generated either to obtain estimates of genetic parameters or to evaluate the genetic progress achieved in these populations. Such estimates are not only necessary for planning future breeding strategies but are also relevant for predicting response to selection and for evaluating genetic programmes. Although many genetic parameter estimates are now available in the literature from different breeds and production conditions, estimates of genetic and phenotypic parameters in pure breed indigenous cattle populations are scarce (Bosso et. al., 2002). Hence, the primary objective of this study is to estimate genetic parameters for birth weight and weaning weight of N'dama and Muturu crosses which will be used in subsequent genetic evaluation of the breed.
The objective of this study was to estimate the variance components and heritability for birthweight and weaning weight, as well as the genetic and phenotypic correlations between these traits in UNN cattle population.

MATERIALS AND METHODS

The study area

Data used in this study were obtained from the breeding and production records of beef cattle at the University of Nigeria Animal Science Farm, Nsukka. Nsukka lies within longitude 6˚45'E and 71E and latitude 7˚12.5'N (Ofomata, 1975) and on the altitude 447m above sea level. The climate of the study area is typically tropical, with relative humidity ranging from 65 – 80% and mean daily temperature of 26.8˚C (Agbagha et al., 2000). The rainy season is between April and October while dry season is between November and March with annual rainfall range of 1680 – 1700mm (Breinholt et al., 1981). The experiment lasted for three months.

Management of the herd

A total of 15 cows and 5 sires were used for the experiment. They were bred and managed properly through calving till weaning. Calving occurs all year round as no strict breeding season is enforced. Calves were weighed within 24 h of birth and thereafter weighed at bi-monthly intervals using a 100Kg capacity weighing scale. Calves were identified at birth and branded later, close to weaning. Calves were weaned at about 6 months of age. All animals were treated against ecto- and endoparasites and routine prophylaxis for trypanosomiasis and babesiosis was administered. The vegetation of the research station is described as guinea savannah type. The predominant grass species on UNN pasture are *Panicum maximum, Pennisetum purpureum* and *Cynodon dactylon* interspersed with legume species like *Centrosema pubesence, Mucuna sp., Mimosa sp.* and others.

Statistical analysis

Data were edited such that only animals with complete records on sire, dam and all fixed effects were used. The number of animals in the final data set were analysed by the MIXED model procedure of SAS (SAS University Edition 2019). The model used include the fixed effect of sex (male and female) and random effect of sire. Restricted maximum likelihood (REML) method of SAS mixed model was used to estimate the observable variance components due to sire (σ_s^2) and error (σ_w^2). Estimates of genetic correlations were obtained using varcomp procedure of Harveys computer program (Harvey, 1990). The programme also computed the genetic correlations and the appropriate standard errors of the estimated heritabilities.

$$h^2 = \frac{4\delta_s^2}{\delta_s^2 + \delta_w^2}$$

Where, h^2 is the sire heritability; δ_s^2 is the sire variance component and δ_w^2 is the error variance component.

$$rG = \frac{Cov\ (x\ y)}{\sqrt{\delta_s^2(x)\delta_s^2\ (y)}}$$

Where, *rG* is the genetic correlation; Cov (x y) is the genetic covariance of x and y components; δ_s^2 (x) is the sire variance of x component and δ_s^2 (y) is the sire variance of y component.

The detailed description of animals at UNN population is presented in Table 1 below.

Table 1: Descriptive statistics of the data

	Birth Weight	Weaning weight
No of records	15	15
No of sires	5	5
No of dams	23	23
Progeny per sire	3	3
Progeny per dam	1	1
Mean (kg)	10.77	58.29
Standard deviation	2.37	7.03
Coefficient of variation (%)	22	12.07

RESULTS AND DISCUSSION

Sex effect was not significant (P>0.05) for birthweight. However, there is significant difference (P<0.05) between male and female calf weight at weaning. Male calves weighed 6.87kg (11.8%) heavier. The result is in line with the work of Hopkins (1977), who observed an increased sex differences with increasing growth rate, signifying that male animalse are more responsive to improvement in the environment. The levels of weight advantage of male calves recorded in this study are comparable to what can be estimated from the values of Tawah et al. (1993) in Gudali but lower compared with values estimated by Tuah and Danso (1985) for WASH and Ndama in the humid forest zone of Ghana where favourable rainfall regime allowed greater quantities of high quality forage to be produced throughout the year, thus improving the nutritional environment for greater expression of male calves' responsiveness to improved environment.

Variance components and heritability in UNN cattle population

The variance and heritability estimates for birth and weaning weights are presented in Table 3 below.

Table 2: Variance covariance components and estimates for heritability (± SD) for birth and weaning weights

	Birth Weight		Weaning weight
Variance-covariance estimates			
Additive direct variance	0.8		16.37
Error variance	4.7		19.89
Phenotypic variance	5.5		36.26
Phenotypic correlation		0.05	
Genetic correlation *rG*		0.53	
Heritability estimates			
Direct heritability	0.15 ± 0.05		0.45 ± 0.05
Total heritability	0.15		0.45

Heritability

The variance, covariance and heritability estimates for birth and weaning weights are presented in Table 2. The estimates were low to medium but are in agreement with values reported by other researchers. The heritability value of 0.15 ± 0.05 for Birthweight in this study was close to 0.149 reported by Peters *et al.* (1998) for the same breed in a similar environment but lower than 0.37 reported by Johnson *et al.*(1992). Estimates of direct additive heritability (hi) for weaning weight (0.38 + 0.18) are in agreement with results of Mackinnon et al. (1991). The increase in heritability estimate with increase in age obtained in this study follows the same trend noted by Fogarty (1995).

Correlation

Phenotypic and additive direct genetic correlation coefficients between birth weight and weaning weight were 0.05 and 0.53 respectively. While the phenotypic correlation coefficient was slightly lower than those from other studies, the genetic correlation coefficient was similar to literature values. The unweighted and weighted means obtained from a review by Koots et al. (1994), of all published studies on correlations between birth and weaning weights were 0.36 and 0.46 for phenotypic correlations and 0.47 and 0.55 for genetic correlations, respectively. The lower phenotypic correlation relative to genetic correlation is in agreement with the trend reported in the reviews by Woldehawariat et al. (1977) Mohiud- din (1993) and Koots et al. (1994). The moderate genetic correlation between birth and weaning weights indicates that selection for one trait will result in a moderate positive correlated response in the other trait.

CONCLUSION

Estimates of heritability indicate that additive genetic variance exists for these traits. Selection for these traits, therefore, is likely to result in genetic gain for growth in UNN cattle population under tsetse infection pressure in south-eastern Nigeria and in the humid zone of Africa in general. The high genetic correlations between birth weight and weaning weight indicates that birth weight could be used as a cost effective means for selecting for cattle with high post weaning weight. The differences between male and female calves for weaning was highly significant hence, it is important for sex of calf to be correlated for in analysing preweaning calf data. Genetic improvement of indigenous West African cattle has been attempted in the past by crossbreeding with exotic breeds of cattle with little or no emphasis placed on selection. The estimates of genetic parameters obtained in this study indicate that if genetic improvement through selection for birth and/or weaning weight of indigenous cattle and their crosses is desired, there is high posibility for high genetic progress to be achieved.

ABSTRACT

The study was conducted at Federal College of Forestry, Jos. The objective of the study was to determine effects of age on egg number and egg weight in chickens. A total of 500 pullets were obtained from a reputable hatchery in Ilorin and received in Jos. They were brooded for six (6) weeks during which all recommended vaccines were and antibiotics were administered, they were further transferred to battery cage at fourteen weeks (14). Records were taken daily for total feed consumed per bird per day by weighing feed left over, mortality, egg lay, weight of egg (egg weight was measured using a digital scale) and clutch length. The experiment lasted for twenty (20) weeks from first day of lay. Birds were fed with predetermined weight of feed once a day. Commercial diet was used as the experimental diet. The result showed that a positive and strong significant ($P < 0.01$) correlation was observed between age of hen and weight of eggs ($r = 0.092$). Weak positive correlation ($P < 0.01$) was observed between age of hen and number of eggs ($r = 0.017$). From the finding of this study, it was concluded that, there was a positive relationship between age of birds and egg number. Positive relationship also exist between age of birds and egg weight. However it should also be noted that the correlation between age and egg weight was stronger than the correlation between age and egg number. Further research was recommended

INTRODUCTION

Poultry production is an important and diverse component of agriculture. Poultry are kept in most areas of the world and provide an acceptable form of protein to most people in the world. Many developed countries have adopted intensive poultry production system in order to meet protein demand for humans. Poultry are able to adapt to most areas of the world at relatively low price, they reproduce rapidly and have a high rate of productivity. Layer chicken hens are efficient egg producers.Breeds used for egg production are mostly based on leghorn and Rhode Island Red but selection and cross breeding have resulted in high productive laying hens (FAO, 1992). In Nigeria, poultry contributes about 15% of the total annual protein intake with approximately 1.3 kg of poultry products consumed per head per annum. In the past decades, there has been a recorded improvement in poultry production in Nigeria with its share of the Gross Domestic Product (GDP) increasing in absolute terms. The contribution of chicken egg and meat to the livestock share of the GDP increased from 26% in 1995 to 27% in 1999 with an increase in egg production alone accounting for about 13% during the period. In spite of the significance of the poultry industry to the national economy, poultry farms face challenges inimical to the growth of the industry. Poultry production in general is faced with low capital base, inefficient management, disease and parasite, housing and marketing problems, etc (Akintunde, *et al.,* 2015). Poultry production has become a fulltime job for many and is considered to be a commercially viable enterprise, contributing significantly to Gross National Product (GNP) (Nwagu *et al*, 2007b). Egg production is believed to have complex qualitative traits which are influenced by several factors such as breed, nutrition, age, weight of bird, management practices and environmental factors. Over the last decades, poultry management techniques in Nigeria have improved significantly, with rapidly increasing production. Under subtropical environments, growth rate as well as egg production are generally depressed by high ambient temperature (Bordas and Merat, 1984; Farooq*et al*, 2001). A significant interaction between environments and lines was found for laying traits, which indicated that the selected line was more sensitive to environmental changes than the control line for production level (Chen *et al.,* 2004). Poultry plays an important role in human nutrition, employment and income generation. Therefore the objective of the study was to determine the effects of Age on Egg number and Egg weight laying birds.

MATERIALS AND METHODS

The study was conducted at Federal College of Forestry, Jos. It is located in the central part of the Nigeria between latitude $8^{o}30^{|}$ and $10^{o}30$N and longitude $8^{o}20$ and $9^{0}30^{|}$E, with a surface area of about 9,400km^2. It has an average elevation of about 1,250 meters above sea level. A total of 500

pullets were obtained from a reputable hatchery in Ilorin and received in Jos. They were brooded for six(6) weeks during which all recommended vaccines were and antibiotics were administered, they were further transferred to battery cage at fourteen weeks (14). Records were taken daily for total feed consumed per bird per day by weighing feed left over, mortality, egg lay, weight of egg (egg weight was measured using a digital scale) and clutch length. The experiment lasted for 20 weeks from first day of lay. Birds were fed with predetermined weight of feed once a day. The experimental diet was of commercial origin.

RESULTS AND DISCUSSION

Table 1: Pearson Correlation Between Age and Weight of Eggs

		Age of birds (in weeks)	Weight of eggs
Age of birds (in weeks)	Pearson Correlation	1	
	Sig. (2-tailed)		
	N	4834	
Weight of eggs	Pearson Correlation	0.092**	1
	Sig. (2-tailed)	0.001	
	N	3975	3975

** Correlation is significant at the 0.01 level (2-tailed).

Pearson correlation between age and weight of eggs was presented in table 1. A positive and strong significant ($P < 0.01$) correlation was observed between age of hen and weight of eggs ($r = 0.092$). Also, Pearson correlation between age and number of eggs was presented in table 2. A weak positive correlation ($P < 0.01$) was observed between age of hen and number of eggs ($r = 0.017$). The finding of this study were in agreement with that of Anderle *et al*. (2014) and similar to Zanon *et al*. (2006).

Table 2: Pearson Correlation Between Age and Number of Eggs

		Age of birds (In weeks)	Number of eggs
Age of birds (in weeks)	Pearson Correlation	1	
	Sig. (2-tailed)		
	N	4834	
Number of eggs	Pearson Correlation	0.017**	1
	Sig. (2-tailed)	0.227	
	N	4831	4831

** Correlation is significant at the 0.01 level (2-tailed).

CONCLUSION AND RECOMMENDATION

From the finding of this study, it was concluded that, there was a positive relationship between age of birds and egg number. Positive relationship also exist between age of birds and egg weight. However it should also be noted that the correlation between age and egg weight was stronger than the correlation between age and egg number. Further research was recommended.

BETAINE HYDROCHLORIDE AMELIORATES THERMOREGULATORY RESPONSES OF BROILER CHICKENS UNDER DEXAMETHASONE INDUCED HEAT STRESS

[1]L.A. Ademu*, [2]O.M. Daudu, [3]G.T. Iyeghe-Erakpotobor, [3]P.P. Barje, [1]J.A. Olusiyi

ABSTRACT
A study was conducted to investigate the ameliorative effect of betaine hydrochloride under dexamethasone induced heat stress. A total of 300 day-old *Arbor acre* broiler chickens randomly assigned to five treatments in a completely randomized design were used in the study. The five treatments with three replicates (n= 20 birds/rep) made up of a treatment containing no dexamethasone and no betaine served as the control. Another treatment was fed 0.30% betaine only supplemented diets, with the other three treatments given daily dexamethasone concentrations at 1, 2 and 3 mg/L in water, respectively. All dexamethasone treated birds were fed 0.30% betaine HCl in their diets. Results indicated a decrease (P>0.05) in rectal temperature and respiratory rate with increasing dose of dexamethasone, especially with the betaine only group. Betaine HCl had a positive effect on thermoregulatory parameters of broiler chickens by ameliorating the negative effect of heat stress.
Keywords: Stress, Dexamethasone, Broilers, Betaine, Osomolyte

INTRODUCTION
Broiler chicken production under high ambient temperature and high relative humidityhas been shown to induce heat stress (Ali *et al*., 2010). Heat stress results in the excess production of reactive oxygen species (ROS) which cause oxidative damage (Zhang *et al*., 2014). Given its similarity to endogenous corticosteroids, dexamethasone's ability to reproduce the effects of high levels of corticosterone, thus mimicking stress associated signalling pathways has been demonstrated (Eid *et al*., 2006; Aengwanich, 2007; Ademu *et al.*, 2018) A. With stress a costly problem for the broiler industry, nutritional strategies to lessen its effects are being developed. Betaine supplementation to diets for livestock has increased during the last decade (Fernandez-Figares *et al.*, 2008). Betaine, the trimethyl derivative of the amino acid glycine, is a naturally occurring compound, which is widely distributed in many plants and animal tissues. Betaine exerts an osmo-regulatory role in cells, regulating water balance, which is beneficial for alleviating physical reactions to heat stress (Ratriyanto and Mosenthin, 2018). The aim of the study was to investigate the ameliorative effect of betaine hydrochloride on the thermoregulatory responses of broiler chickens under induced heat stress conditions.

MATERIALS AND METHODS
The experiment was conducted at the Teaching and Research farm of the Department of Animal Science, Ahmadu Bello University Samaru, Zaria. Three hundred day old *Arbor acre* broiler chicks were used in the experiment. They were randomly allotted to five experimental treatments in a completely randomized design. Each treatment was replicated three times with twenty birds per replicate.A maize/soybean based broiler starter and finisher diet was formulated according to NRC (1994) nutrient requirement for broiler chickens. Birds receiving 0 mg dexamethasone and without betaine supplementation served as the control. Birds administered 1, 2 and 3 mg dexamethasone in drinking water along with a betaine only group were given diets supplemented with Betaine HCl at 0.30%. Daily doses of dexamethasone (1, 2 and 3 mg) was administered by dissolving in a litre of water and supplied for twenty-eight days beginning from when the birds attained 14 days of age.

Thermoregulatory Measurements
Indoor temperature and relative humidity readings were recorded daily using an electronic digital thermo-hygrometer. Both readings were taken in the morning (8.00 am) and afternoon (3.00 pm) throughout the experimental period. Rectal temperatures and respiratory rates were measured by placing a digital thermometer in the rectum and counting of respiration (breath/minute) with the aid of

a stopwatch respectively. Temperature-humidity index (THI) was calculated using the formular of Tao and Xin (2003).

$$THI = 0.85\,T_{db} + 0.15\,T_{wb}$$

Where,
THI = temperature-humidity index in °C,
T_{db} = dry-bulb or ambient temperature in °C and
T_{wb} = wet-bulb temperature in °C.
Wet bulb temperature was determined from ambient temperature and relative humidity using the empirical expression functions by Stull (2011). Heat stress was classified as absence of heat stress (<27.8), moderate heat stress (27.8-28.8), severe heat stress (28.9-29.9) and very severe heat stress (>30.0).

Data Analysis

All data collected from the experiment was subjected to analysis of Variance (ANOVA) using the general linear model procedure of JMP (2012).Where the result of ANOVA was statistically significant, test for multiple comparisons was performed to compare means of all groups using Tukey (1949).

RESULTS AND DISCUSSION

The average temperature humidity index (THI) inside the poultry house during the experimental period for mornings and afternoons is shown in Figure 1. THI in the afternoons were 25.4% higher than in the mornings indicating the absence of heat stress in the morning and the presence of very severe heat stress in the afternoon. Tao and Zin (2003) also observed that the body temperature of broilers tends to rise at THI 30.0.

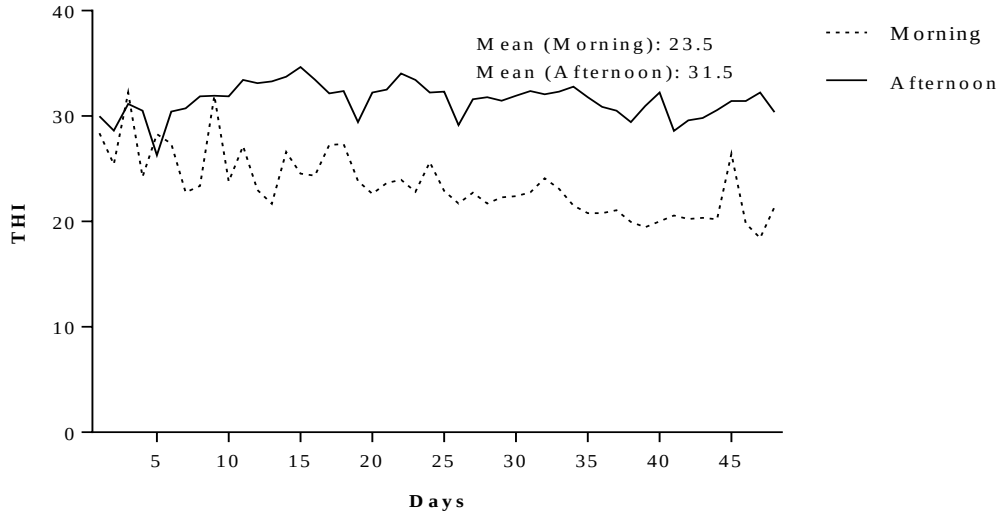

Figure 1: Daily Temperature-humidity index inside the poultry house during the experimental period

The effect of betaine HCl on rectal temperature of broiler chickens **under** dexamethasone **induced stress** is shown in Figure 2. A decrease in rectal temperature with increasing doses of dexamethasone was observed. Birds in the betaine only group had the lowest rectal temperature compared to other treatment groups. This result is supported by Hassan *et al*. (2011) and Nofal *et al*. (2015) who concluded that betaine supplementation in diets reduced rectal temperature. As an osmolyte, betaine may have a stabilizing function on cells subjected to osmotic stressors (Klasing *et al.*,(2002) by regulating the water balance, resulting in the stability of tissue metabolism especially in the gastrointestinal tract (Lipinski *et al.*, 2012), protecting them from heat shock.

The respiratory rate (Figure 3) across the treatment groups was not significant (P>0.05). However, a decrease in respiratory rate with increasing dose of dexamethasone was observed. Birds in the betaine only group had the lowest respiratory rate. One of the visible symptoms of a bird under heat stress is panting or increased respiratory rate (Etches *et al.*,2008)When the environmental temperature exceeds

the comfort limit, chickens suffer heat related stress resulting in physiological and metabolic changes (Borges *et al.,* (2007).

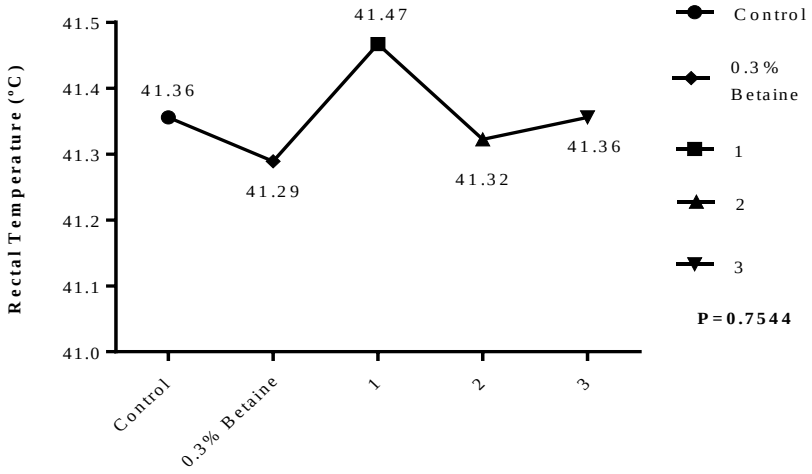

Figure 2: Effect of 0.30% Betaine HCl on Rectal Temperature of Dexamethasone Stress-induced Broiler Chickens

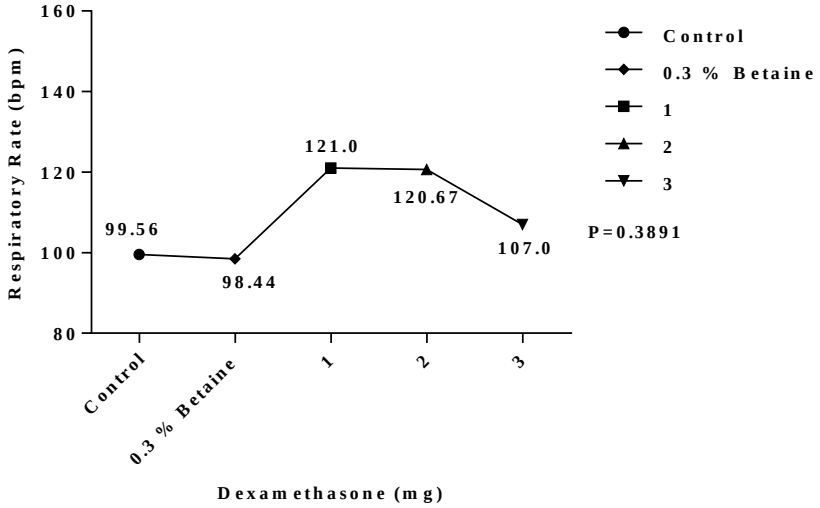

Figure 3: Effect of 0.30% Betaine HCl on Respiratory Rate of Dexamethasone Stress-induced Broiler Chickens

This study also agrees with Aengwanich (2007) who administered dexamethasone at 1-5 mg/kg to broiler chickens. Respiratory rate was found to be reduced even below that of the control group for the betaine only group indicating the ameliorative effect of betaine.

CONCLUSION

The supplementation of betaine HCl in broiler chicken diets had an ameliorative effect on thermoregulatory parameters of broiler chickens.

ABSTRACT

The physical properties of meat from broiler chickens fed diets based on four cassava peel products were investigated using ten-day old Ross 308 broiler chickens (n=455). The chicks were randomly allotted to 13 treatments of 35 broilers each. Each treatment was replicated five times and a replicate comprised seven chicks. Sundried cassava peel meal (SCPM), whole cassava peel mash (WCPM), fine cassava peel mash (FCPM) and coarse cassava peel mash (CCPM) each replaced dietary maize at 20, 40 and 60% level while the last diet was a maize-based diet. The chicks were fed the respective grower and finisher experimental diet for 10-24 and 24-26 days, respectively. Meat were harvested from the chicken and assessed for physical parameters. Results showed that cooking loss, water holding capacity, thermal shortening, colour, flavour, texture, tenderness, juiciness and overall acceptability were significantly influenced ($P<0.05$) by replacement of maize with the cassava peel products. The cooking loss, water holding capacity, thermal shortening were highest in 40% SCPM (22.00%), 20% FCPM (79.81%) and 40% CCPM (39.00%), respectively. Meat colour, flavour, texture, juiciness and overall acceptability in 60% CCPM (8.50), 40% CCPM (8.50), 20% FCPM (8.00), control (7.00) and 20% WCPM (8.50) were the highest. Meat from birds on control (7.50) and 20%WCPM (7.50) had the highest tenderness score. It was concluded that cassava peel products could be an attractive option in broiler feed, however, the choice and dietary inclusion levels of the products should be dependent on expectations in the meat physical attributes.

INTRODUCTION

There is a growing demand for poultry product due to the rapid growth in human population. Cakmak (2002) estimated that world population would have grown to 10 billion by the year 2050. Oloyede (2005) also observed that 41-54% of the minimum protein requirement of adult is expected to be sourced from animal protein. One of such source of protein is broiler meat. Production of broiler meat will put pressure on the already scarce and sometimes costlier maize. Maize is an important ingredient required in the formulation of high energy diet required by fast-growing broiler chicken meat production.

There is an increased search for alternatives that could partially or totally replace maize in broiler chicken feed and products. Cassava grit, acha, and cassava peel meal have been considered as suitable alternatives (Salami and Odunsi, 2003; Ogunwole *et al.,* 2016*;* Wumnokol *et al.,* 2019). Cassava peel, which is obtained from generous peeling of cassava tuber could, however, be a viable alternative to maize due to less competition for cassava peel by humans as food, relative to alternatives. The cyanide scare and challenges associated with usage of cassava peel in livestock has led to the deployment of processing methods such as sun-drying, soaking and fermentation (Udedibia *et al.,* 2004; Aniebo, 2012; Oladimeji *et al.,* 2019) with various degree of success.

Subjecting cassava peel to various physical treatment could ensure high quality product that is low in aflatoxin and could be used in poultry feed (Okike *et al.,* 2015; Oladimeji *et al.,* 2019). Though Oladimeji *et al.* (2019) reported on the carcass characteristics of the broiler chicken fed cassava peel products, however, there is also the need to determine the physical attributes of meat from broiler

chickens' when fed diets with varying inclusion levels of cassava (*Manihot esculenta* Crantz) peel meal, which is the aim of this study.

MATERIAL AND METHODS

Test materials

Cassava peel products used for the study were obtained from freshly peeled cassava tuber after which one part was sundried till constant weight was attained and named sundried cassava peel meal (SCPM). Other products, namely whole cassava peel mash (WCPM), fine cassava peel mash (FCPM) and coarse cassava peel mash (CCPM) were obtained using the method of Okike *et al.* (2015) as modified Oladimeji *et al.* (2019)

Experimental Animal

Ten-day old Ross 308 broiler chickens (n=455) were used for the study. They were obtained at 1-day old and raised on commercial feed for ten days after which they were randomly allotted to 13 dietary treatments. Each treatment was replicated five times. Each replicates comprised seven chicks. The chicks were offered feed and water *ad-libitum* throughout the period of the study.

Experimental Diets

Thirteen iso-caloric and iso-nitrogenous diets were formulated for the grower and finisher chickens. The cassava peel products SCPM, WCPM, FCPM and CCPM were used to replace 20, 40 and 60% dietary maize in the control diet. Details of the basal experimental formulation have been documented (Oladimeji *et al.*, 2019), the metabolizable energy and crude protein of the grower was 3050.5 Kcal/Kg and 20.9% while finisher was 3103.9 Kcal/Kg and 19.51% respectively. Grower diets were offered from day 10 to 24 and the finisher from day 24 to 46.

Meat analyses

At day 46 of the experiment, two chickens per replicate with body weights closest to the group average weight were selected, tagged and starved of feed over-night. The chickens were subsequently sacrificed by severing the jugular vein and allowed to bleed after which they were de-feathered and properly dissected. The breast meats were afterwards harvested for cooking loss **(**Omojola and Adesehinwa, 2007), water holding capacity (Hamm, 1986) and thermal shortening (Allen *et al.*, 1998)

Organoleptic Studies

Twenty semi-trained individuals aged between 24 to 30 years were used to assess four replicate of prepared meat sample from the birds fed the 13 different dietary treatments. The samples were evaluated using a nine-point hedonic scale for flavour, colour, juiciness, tenderness and overall acceptability according to the procedure of Cross *et al.* (1986). The evaluation of each meat samples was independent of each other. The poorest condition was scored 1 and the best 9.

Experimental Design

The experimental design was a 1+(4x3) augmented factorial arrangement in a completely randomized design. Data were subjected to analysis of variance using SAS (2002) while means were separated at $\alpha_{0.05}$.

RESULTS AND DISCUSSION

The effect of varying inclusion levels of cassava peel products on physical properties of meat of broiler chickens were presented in Tables 1 and 2. Results showed a significant effect of replacement of maize with all the test cassava peel products on the physical properties evaluated. Cooking loss is a measure of juiciness of meat sample (Bertram *et al.*, 2004). Broiler on 40% SCPM (22.00%) recorded the highest ($P<0.05$) cooking loss while those on 60% FCPM (7.00%) were least. The higher the cooking loss the more juicy the meat. Water holding capacity (WHC) is a measure of ability of meat to retain moisture, meat from broilers on 20% FCPM (79.81%) had the highest WHC ($P<0.05$) while those on 60% SCPM (60.03%) had the least. The thermal shortening of meat from birds on 40% CCPM (39.00%) was highest.

The meat colour of birds on 60% WCPM (8.50) was significantly higher ($P<0.05$). Kartika *et al.* (2016) submitted that meat colour is dependent on the myoglobin type, chemical and physical state of

component of meat. The meat of chickens on 40% SCPM had the highest flavour score (8.50) while those on 60% SCPM (4.50), 40% CCPM (4.00), 40% WCPM (4.50) and 40% FCPM were the least. The texture of the meat from broiler on 20% FCPM (8.00) had the highest score while those on 40% SCPM (4.50), 60% SCPM (5.00), 40% FCPM (5.00) and 60% FCPM (5.00) had the least score.

^{abc} Means with the same superscripts in the same column are not significantly different (P>0.05) SEM= Standard error of mean

Tenderness of meat from chickens on control diets (7.50), 20% WCPM (7.50) as well as the juiciness of those on the control (7.00), 20% WCPM (7.00) were the highest. Sensitivity of the mouth, texture of meat, meat water holding capacity and fat content could have contributed to the observed differences (P<0.05) in the tenderness and juiciness of the meat, as they play an important role to

lubrication when chewing (Juarez *et al.*, 2015). Cross *et al.* (1986) reported that meat is directly related to intramuscular lipid and moisture content which was corroborated by Omojola and Adesshinwa (2007) that the combination of water and melted lipids form broth which are retained in the meat and released when chewed. The overall acceptability of meat from birds on 20% WCPM (8.50) was highest and least in those on 40% CCPM (5.50). The fibrous nature of coarse cassava peel mash perhaps contributed to lower meat acceptability recorded by broiler on 40% CCPM.

CONCLUSION AND RECOMMENDATION

Cassava peel products could be a viable alternative to maize in broiler feed, however, choice of products and replacement level for inclusion should be based on the expected use of the meat.

ACKNOWLEDGEMENT

Authors appreciate the entire staff and management of International Livestock Research Institute, Ibadan for assisting the study with some cassava peel products.

EVALUATION OF CHEMICAL AND MICROBIOLOGICAL PROPERTIES OF *TSIRE* SOLD IN KANO METROPOLIS

Abba A. I. Inusa S.K., Abdullahi, M. H. & Adamu A.S.
Department of Animal Science, Faculty of Agriculture,
Bayero University, PMB 3011, Kano.
karkarna63@gmail.com

ABSTRACT
The study was conducted to evaluate the chemical and microbiological properties of *Tsire*, a ready-to-eat meat product snack sold in Kano metropolis northwest Nigeria. Samples for the study were purchased at four different locations, Gwarzo Road, Sabon Gari Market, Rimi Market and Zoo Road within the metropolis. At each location, samples were collected in triplicates and were subjected to proximate and microbiological analyses. The proximate analysis revealed that there were significant (P<0.05) differences in protein content of the samples. Zoo Road had the highest protein content (38.59%), while Rimi Market had the least (31.73%). The highest ether extract and ash contents were recorded in *Tsire* samples from Rimi market, whereas Zoo Road had the lowest. There was no significant (P<0.05) differences in moisture content across the samples. The indicator organisms were identified as *Staphylococcus aureus* and *Escherichia coli*. Higher counts *Staphylococcus aureus* was obtained from Rimi market and was significantly difference (P< 0.05) from counts at other locations. Also, there was significant difference in *Fecal coliform* where by Sabon Gari Market samples had the highest (23 MPN/g). *E. coli* was significantly (P< 0.05) lower than *S. aureus* at all the locations. This study shows the Tsire, harbors microorganism of public health importance in numbers that could likely cause health problems. Therefore, proper hygiene in the process-line and the processing environment of *Tsire* is recommended to prevent the likely detrimental health implications to consumers.

Key words: *Escherichia coli*, meat, public health, *Staphylococcus aureus*, *Tsire*.

INTRODUCTION

Meat plays an important role in human diet by contributing high quality protein and macro and micro nutrients that are required for growth and good health maintenance. The rate of increase in *per capita* consumption of meat was found to be very high in developed countries when compared with the developing nations (Anjaneyulu *et al.*, 2007). Meat is high in nutrients, especially proteins, minerals and vitamins. It is however prone to spoilage (Anna *et al.*, 2005). Meat is considered to be spoiled when it is unfit for human consumption. Meat is subjected to changes by its own enzyme, by microbial action and its fat may be oxidized chemically. Microorganisms grow on and meat cause visual, textural and organoleptic changes when they release metabolites (Jackson and Mcgowan, 2001).

Tsire is a consumer meat product fast food which is processed and sold along streets often under unhygienic conditions (Uzeh *et al.*, 2006). At sales location, *Tsire* is usually packaged with old newspapers, brown papers and other used paper materials. Also, processing the product, the materials used, the handlers and the environment where it is processed and sold can serve as sources of contamination (Uzeh *et al.*, 2006). It was reported by Omojola (2008) that the meat and some of the ingredients used for processing *Tsire* can also serve as the product contaminants, especially defatted groundnut cake powder.

The fact that *Tsire* is not consumed immediately after preparation but held at ambient temperature for more than 5 hours before serving has previously been reported (Edema *et al.*, 2008). This practice might create an avenue for microbial contamination. These micro-organisms are capable of endangering human lives by causing health problems.

This experiment was conducted to evaluate the chemical and microbiological properties of *Tsire* sold in Kano Metropolis.

MATERIALS AND METHODS

The experiment was conducted at Food and Science Laboratory, Kano State University of Science and Technology, Wudil, Kano State. Kano state lies between longitude $9^0 30^{'}$ and $12^0 30^{'}$ North and latitude $9^0 30'$ and $8^0 42^{'}$ East. The area is characterized by tropical wet and dry climate. The State occupies a land area of 20,400km^2 with a population of over 9,383,682 (NPC, 2006). Hausa-Fulani are the major ethnic groups in the area and Islam is the dominant religion.

Ready-to-eat *Tsire* samples were purchased at four different locations in Kano Metropolis. These places are Gwarzo Road, Sabon Gari market, Rimi Market, and Zoo Road. The sampling was triplicated at each of the designated locations. All the purchased samples were transported to the Laboratory in labeled sealed bags for analyses. All the *Tsire* samples were subjected to proximate analysis according to the procedures of AOAC (2007), while microbial analysis was conducted according to the procedures of APHA (2005).

Completely Randomized Design (CRD) was used for the experimental design. Data obtained were analyzed with SAS (2002), while the means were separated using the Least Significance Difference (LSD) method.

RESULTS AND DISCUSSION

Table 1 shows the proximate composition of *Tsire* sold at different locations in Kano Metropolis. The value obtained revealed significant (P<0.05) differences in protein content and ether extract across the locations where *Tsire* samples were collected. The highest and lowest protein contents (38.59% and 31.73%) of *Tsire* samples were recorded at Zoo road and Rimi Market. The ether extract was highest (2.10%) in *Tsire* samples obtained from Rimi Market. The percentage protein content of the samples agreed with 31.8% reported by Abdulahi *et al.* (2004). Also the values obtained (Abdulahi *et al.*, 2004) for fat and ash level which respectively were 23.7% and 2.4%, agreed closely with that obtained by Abdullah *et al.* (2004). There was no significant (P<0.05) differences in moisture content across all the locations. This closely agreed with the finding of Apata, et al. (2013). Rimi Market recorded the highest ash (5.13 %) while there were no significant differences among the others values.

Table 1: Proximate Composition results of *Tsire* sold in Kano Metropolis.

Nutrients	**Locations**				
	Gwarzo Road	**S/Gari Market**	**Rimi Market**	**Zoo Road**	**LSD**
Protein	33.90^c	35.74^b	31.73^d	38.59^a	0.972
Ether extract	23.96^b	20.57^c	25.37^a	18.31^d	1.111
Moisture	35.62	37.09	34.68	36.07	3.567
Ash	1.80^b	1.70^b	2.10^a	1.90^b	0.633

a, b, c and d means in the same row with different superscripts are significantly different (P<0.05)

Table 2 shows the microbial counts of *Staphylococcus aureus, Salmonella spp* (cfu/g) and fecal coliform MPN/g in the *Tsire* samples. There was significant (P<0.05) differences in *Staphylococcus aureus* and *Salmonella spp* (cfu/g) across the locations. Results obtained for highest *S. aureus* count of 2.26 x 10^4 cfu/g was slightly higher than the 1.97 x 10^4 reported previously (Edema *et al.*, 2008). Similar, high *S. aureus* values were reported by Yousuf *et al.* (2008) and Okonko *et al.* (2009). The reason for the high counts of these organisms in the *Tsire* could be environmental, handling

contamination issue and holding time. Rimi and Sabon Gari markets are situated closer to waste dumping sites and gutters more than the two other locations, hence contributing to the higher microbial counts. It showed that Rimi Market had the highest count (2.26×10^4) of *Staphylococcus aureus* while Gwarzo Road recorded the least *Staphylococcus aureus* (1.14×10^4). There was no *fecal coliform* MPN/g in *Tsire* samples obtained from Gwarzo Road while Sabon Gari with 23 MPN/g *Fecal coliform* had the highest count. No *Salmonella spp* were isolated from all the *Tsire* samples.

Table 2: Microbial counts of *Staphylococcus aureus, Salmonella spp* (cfu/g) and Fecal coliform MPN/g of *Tsire* samples

	Location			
Indicator organisms	**Gwarzo Road**	**S/Gari Market**	**Rimi Market**	**Zoo Road**
Staphylococcus (cfu/g)	1.14×10^4	2.13×10^4	2.26×10^4	1.73×10^3
Fecal coliform MPN/g	_	23	<3	4
Salmonella (cfu/g)	_	_	_	_

S/Gari market = Sabon Gari market

Table 3 shows the occurrence of indicator organisms. The results revealed that *Staphylococcus aureus* was the most predominant pathogen because it occurred in all the *Tsire* samples. This agrees with previous report by Clarence *et al*. (2009) who reported *S. aureus, E. coli, Klebsiella spp* and *Pseudomonas spp* in meat pie. *Escherichia coli* occurred in the *Tsire* samples obtained from Sabon Gari market and Zoo road, while *Salmonella spp* was not present in all the *Tsire* samples.

Table 3: Occurrence of Indicator Organisms in Experimental *Tsire* Samples.

	***Tsire* samples**											
Isolates	**GR 1**	**GR 2**	**GR 3**	**SBG 1**	**SBG2**	**SBG 3**	**RM 1**	**RM 2**	**RM 3**	**ZR 1**	**ZR 2**	**ZR 3**
Staphylococcus aureus (cfu/g)	+	+	+	+	+	+	+	+	+	+	+	+
Escherichia coli	_	_	_	+	_	_	_	_	_	+	_	_
Salmonella (cfu/g)	_	_	_	_	_	_	_	_	_	_	_	_

GR= Gwarzo Road, SBG = Sabon gari Market, RM = Rimi Market and ZR = Zoo Road.

CONCLUSION AND RECOMMENDATIONS

Some of the bacteria isolated and identified in Tsire are of public health importance and their presence can cause food poisoning and food borne diseases. There is need for proper handling and the establishment of legislation regarding the sale of *Tsire* and other meat products at strategic locations to reduce the level of contamination in such product

ABSTRACT
Mutton is an excellent source of biological value with its inherent low fat content, however, it has untapped market as a good potential for value added meat products. Therefore, it is necessary to appraise the nutrient composition of meat floss (MF) from different breeds of ram. Five kilogram of *Semitendonisus* muscle was harvested from carcasses of four breeds of rams consisting of West African Dwarf (WAD), Yankasa (YK), Uda (UD) and Balami (BA) intensively fattened for ninety days. Cooking loss (CL), water holding capacity (WHC), moisture contents (MC), crude protein (CP) and ether extract (EE) of mutton and freshly prepared meat floss (MF) were determined. Thiobarbituric Acid Reactive Substances (TBARmgMDA/100g) and microbiological counts (MC) (log 10^2cfu/g): Total Aerobic Counts (TAC), Total Coliform Counts (TCC) and Total Fungal Counts (TFC)) at the seventh day were determined. The CL (38.19%, 39.51%) of WAD and YK mutton were significantly higher ($P<0.05$) while their WHC (61.49%, 59.97%) were lower than UD and BA. The CP (23.16%) and EE (5.85%) of BAM were higher ($P<0.05$). The CP were (46.75%, 48.73%, 47.82%, 49.60%) and EE (25.69%, 25.46%, 25.88%, 27.35%) for WAD, YK, UD and BA, respectively. The TBAR ranged from 1.12-1.17 mgMDA/100g. The mean MC (log 10^2cfu/g) on the MF from WMF was 6.76cfu/g while YMF, UMFand BMF for TAC were 4.38, 3.96 and 3.58cfu/g, respectively. The keeping qualities value of the MF does not exceed the threshold values of stored meat products, therefore, it can be inferred that MF from mutton has a high nutrient and keeping qualities profile.

Keywords: Keeping quality, Mutton, Nutrient profile, *Semitendinosus*

INTRODUCTION
Sheep production is indispensable to meet protein and some domestic needs of people throughout the world as they are sources of income and raw materials (Mapiliyao *et al*., 2012). Mutton has a high biological value with its inherent low fat contents. However, it has received little attention in consumption pattern as compared with other sources of meat such as beef and chevon, therefore has an untapped market value as a good potential for value added meat products. MF is among the popular traditional foods that constitutes an important part of Nigerian meal. Considerable progress has been made in standardization of product profile and mechanization of traditional meat products. In Nigeria, particularly in rural communities and towns, processing of carcass usually takes place under very unhygienic conditions. This coupled with high ambient temperature, high humidity, shortage of portable water and poor handling practices exposes meat products like MF to microbial contamination and rapid deterioration. Therefore, the microbiological testing at various stages of food production is relevant to reveal and understand the characteristic trends in distribution of microbiological contamination (ICMSF, 2011). Information available on meat floss specifically is usually centred on other sources of meat while little or none is available on processed mutton. However, if such information is available, it might bring into limelight the nutritional quality inherent in mutton and also help in changing the consumption pattern of the meat. Therefore, this study aimed at assessing the nutritional and keeping qualities of meat floss prepared from mutton of different breeds of ram.

MATERIALS AND METHODS
Experimental design
The study was a completely randomized design and each treatment was replicated thrice.
Meat sample: source, collection and preparation
The *Semitendinosus* used for this study was harvested from the skinned mutton carcasses of four breeds of rams (BA, UD, YK and WAD breeds) intensively fattened for ninety days. They were cut into chunks with average weight of 100g. Thirty chunks were randomly selected to have three kilograms of fresh mutton for each breed.

PRODUCTION OF MEAT FLOSS

The steps involved in production of the meat floss were spice mixture preparation, meat preparation, cooking, shredding, frying and de-oiling following Kassim (2013). The meat chunks were cooked in a pot on an electirc hot plate (Pifco Japan Model number ECP 2002) with water added at the ratio of 1.5 litres to 1.0 kg of meat and the cooking recipe added at a ratio of 1 g to 100 g of meat. The cooking was done at an internal temperature of 72°C until the broth completely dried on the broiled mutton. The meat samples were removed from the pot and spread on a tray to equilibrate to room temperature. The cooled meat was shredded separately by pounding with a local mortar and pestle with shredding recipe at a ratio of 1.00g to 20.00g meat. The shredded meat was deep-fried in soya oil (pre-heated to 180°C) in the ratio of 1 litre to 500g of meat. The meat was fried at 70 strokes per minute for 20 minutes until they turned golden brown in colour. The products were emptied into a colander, pressure applied to drain oil and obtain a dry spongy product. Upon cooling the meat floss were separated into strands and immediately packed into an air tight container and left at room temperature.

PARAMETERS MEASURED

Meat Quality

Cooking loss (CL)

Cooking loss was determined (following the procedure of Honikel, 1987) in the *Semitendinosus* muscles of each breed and samples were taken in triplicates.

Thermal shortening

This was carried out according to the procedure described by Mahendraker *et al*. (1988). Cores of 0.5 cm in diameter were taken from the *semitendinosus* muscle of each breed. Each breed was replicated thrice and the average taken.

Water holding capacity (WHC)

WHC was evaluated using a method adapted from Hamm (1960), based on meat water loss when pressure is applied on it. This was determined by the press method described by Wierbicki and Deatherage (1958) as modified by Tsai and Ockerman (1981).

Product yield

The product yields of the meat floss were determined by measuring the weight of the MF for each treatment and were calculated as the ratio of cooked weight to raw weight expressed as percentage.

Microbial analysis

The microbial quality determination was carried out on the freshly prepared meat floss. The Total Aerobic Counts (TAC), Total Coliform Counts (TCC) and Total Fungi Counts (TFC) were carried out following the procedure of Garbutt (1997).

Statistical analysis

Data collected were analysed using Analysis of Variance (ANOVA) and significant means were separated using Duncan Multiple Range Test (DMRT) at 5% level of probability.

RESULTS AND DISCUSSION

The physical measured traits of mutton used in the production of meat floss are presented in Table (2). The CL ($P<0.05$) of *Semitendinosus* from YK (39.59%) and WAD (38.19%) were significantly different than 34.70% and 30.20% obtained for UD and BA, respectively. This same trend could be noticed in their TS with YK (34.67%) and WAD (33.34%) having the highest TS shrinkage than UD (29.62%) and BA (26.40%). WHC is one of the major quality characteristics of fresh meat, as it affects some major characteristics of cooked meat such as product yield, appearance and sensory properties. WHC obtained from *Semitendinosus* muscles of mutton used in this study were between 59.97 and 71.60%. BA and UD had the highest ($P<0.05$) value while WAD and YK had similar ($P>0.05$) values which were the least (Table2). The denaturation and aggregation of sarcomere could be responsible for the shrinkage observed in the thermal shortening of the mutton because the extent of sarcoplasmic and myofibrillar protein during cooking depends on the resistance of the muscle fibres to compression (Sheffler and Gerrard, 2007).

Table 2: Physical properties of raw *Semitendinosus* muscles from different breeds of rams used in meat floss production

Parameter (%)	WAD	YK	UD	BA	SEM
Cooking Loss	38.19^{a}	39.51^{a}	34.70^{b}	30.20^{c}	0.25
Thermal Shortening	34.67^{a}	33.34^{a}	29.62^{b}	26.40^{c}	0.18
Water Holding Capacity	61.49^{c}	59.97^{c}	65.60^{b}	71.76^{a}	0.14

[a, b, c] Means with different superscripts in the same row are significantly different ($P<0.05$)
WAD: West African Dwarf; YK: Yankasa; UD: Uda; BA:Balami

Chemical composition of raw *Semitendinosus* muscles from different breeds of rams used for the production of meat floss

The chemical compositions of the mutton used are displayed in Table 3. The moisture content of the muscles ranged from 69.57% to 69.86% while the crude protein contents, ash, ether extracts and cholesterol of the muscles differ significantly ($P<0.05$). It ranged from 22.58% to 23.16%; 1.13%-1.30%, 5.85%to 6.44% and 0.21% to 0.29% for crude protein, ash, ether extracts and cholesterol, respectively. The average chemical analysis values for the *Semitendonisus* muscle in the present study are in agreement with the reported values in food composition tables of National Food Institute, (2009 and Chuaynukool *et al*., 2007). The differences in fat content in the meat samples could be due to the differences in genetic and non-genetic factors as reported by Bogosavljevic-Boskovic *et al*. (2010). The low moisture contents of the meat floss as compared to its raw muscles could be attributed to the fact that MF preparation involves a high thermal processing method and most of the water contained in the meat would have been dried-off during the process. It was observed that MF from BA muscle had the highest nutrient profile especially in crude protein contents, ash and ether extracts. This could be attributed to the fact that it was the muscle that has the highest nutrient profile in the raw state. It could also be as a result of its high water holding capacity because nutrient composition of a muscle after thermal treatment depend on the ability of the muscle to hold on to its inherent water which

contain the nutrients of the muscle. During thermal treatment, water would be lost with some nutrients but a muscle with high water holding capacity would have a low cooking loss thereby retaining most of its nutrients. The high product yield of MF from the mutton could be attributed to the procedure because water holding capacity and cooking loss are inversely correlated (Nasiru *et al*., 2011). The lower product yield of meat floss from WAD muscle might be attributed to the excessive fat separation and water release during cooking (Pietrasik and Shand, 2003). The increase in the ash contents of the MF compared to the raw meat could have been contributed by the added ingredients used during production. Similar observations were reported by Ogunsola and Omojola (2008) who reported that the high ash contents of kilishi is due to individual mineral levels of the spices used to give accumulative mineral level during processing. Also, the average total ash values of MF in the present study is in agreement with the reported values in food composition tables of National Food Institute, (2011) for meat products. The increasing level of cholesterol in processed samples might be as a result of the conversion of other substances from food into cholesterol during thermal degradation (Chizzolini *et al*, 1999).

Table 3: Product yield and chemical composition of freshly prepared meat floss from four *Semitendinosus* muscles of different breeds of rams

Parameter (%)	WMF	YMF	UMF	BMF	SEM
Moisture Content	10.52^{a}	10.49^{ab}	10.63^{a}	10.20^{b}	0.05
Crude Protein	46.75^{d}	48.73^{b}	47.82^{c}	49.60^{a}	0.04
Ether Extract	25.69^{c}	25.46^{d}	25.88^{b}	27.35^{a}	0.03
Ash	7.28^{c}	7.31^{c}	7.96^{a}	7.75^{b}	0.03
Cholesterol mg/g	10.11^{ab}	8.33^{c}	11.33^{a}	9.00^{bc}	0.01

[a, b, c] Means with different superscripts in the same row are significantly different (P<0.05). WMF = West African Dwarf Meat floss; YMF = Yankasa Meat floss; UMF =Uda Meat floss

Microbial loads of mf produced from different breeds of ram

The microbiological counts (10^2cfu/g) and the TBARS (mg/kg) of the meat floss is displayed in Table (4). The result revealed that there were significant differences (P<0.05) in all the microbial assessment among the products. The total aerobic counts (TAC) were 1.13, 0.73, 0.66, 0.60; while the total coliforms counts (TCC) were 0.20, 0.20, 0.36, 0.23 and the total fungal counts were 1.03, 0.46, 0.29, 0.20 for WFM, YMF, UMF and BMF meat floss, respectively. Microbial assessment of food provide a general indication of the microbiological quality of the products. The microoganisms isolated in food could come from different sources such as processing, cooking and the environment. The high fat content also can acts as a medium for the growth of microorganisms (Kumar and Sharma, 2004). The microbial counts recorded for coliforms and fungi were well below the levels of $\log10^4$ cfu/g and $\log10^3$ cfu/g that could cause microbial spoilage (Jay, 1996). Lipid oxidation is a major cause of food deterioration as it decreases nutritional properties of foods and the generation of potentially toxic reaction products. TBARS values of MF samples were illustrated in Table 4, from which it is apparent that BMF samples exhibit 0.39 mg MDA/kg meat. However, the mean TBARS values of all the MF samples in this study were found to be lower than 2.0 mg MDA/kg, accepted as the critical value of lipid oxidation for meat and meat products (D'agata *et al*., 2010).

Table 4: Microbiological quality (log 10^2cfu/g) and Thiobarbituric reactive substances of meat floss prepared from *Semitendinosus* muscles of different breeds of rams

Parameter	WMF	YMF	UMF	BMF	SEM

Total Coliform Counts	0.20^{b}	0.20^{b}	0.36^{a}	0.23^{b}	0.24
Total Fungal Counts	1.03^{a}	0.46^{b}	0.29^{c}	0.20^{d}	0.06
TBARS(mg MDA/100g)	0.38	0.37	0.38	0.39	0.03

[a, b, c] Means with different superscripts in the same row are significantly different (P<0.05). WMF=West African Dwarf Meat floss; YMF = Yankasa Meat floss UMF = Uda Meat floss; BMF = Balami Meat floss

CONCLUSION

The nutritional and keeping qualities of meat floss as revealed in this study indicated that mutton is a meat with high biological value which is inversely proportional to its consumption pattern. It could be recommended that the spices should be subjected to treatment that would reduce the microbial load of the products to avoid introduction of pathogens that might bring about spoilage and contamination of the product.

ABSTRACT
A 72 – day feeding trial was conducted using 240, 35week-old Lohmann® brown layer chickens, to study the effect of supplementing diet with three types of leaf meal on the shelf life of chicken eggs. The birds were grouped into 16 replicates of similar live body weight, and 4 replicates were randomly allocated to each of four treatments using the Completely Randomized Design. Treatment 1 served as control, with no leaf meal added to the diet. Treatments 2, 3 and 4 were, respectively, supplemented with 5% of leaf meal mucuna (*Mucuna cochinchinensis*), Cassava (*Manihot esculenta*) or Neem (*Azadirachta indica*). Eggs from all treatments were gathered on the same day and kept in plastic egg crates place on a wooden table in the same room at room temperature. The eggs were sampled on the same day and weekly for six weeks and analysed for yolk colour, yolk index and Haugh unit score. There was Significantly difference ($P<0.05$) for yolk colour, yolk index and haugh unit for eggs from birds fed leaf meals, with cassava leaf meal giving the best results for up to six weeks of the experimental period.

Key words: Egg-quality, Feed-additive, Leaf -Meal, Egg-shelf-life.

INTRODUCTION
Majority of people, in the world, generally like to eat eggs and foods that contains eggs, because they are not only tasty and nutritious, they are also quick and easy to boiled or cooked. Eggs contain all the essential nutrients, like protein, mineral and vitamins, in the best proportions to promote growth and good health in humans (FAO, 2011).

Efforts to boost animal protein intake in human diets must involve increased production and productivity of animals, improvements in quality of animal products and better processing and preservation techniques. This will lower animal product prices and enhance affordability and, therefore, consumption.

All foods have limited shelf life, which varies depending on the type of food and storage conditions. The egg is a very perishable food product which loses quality rapidly during the period between being laid and consumption. Egg quality is negatively affected by length of storage, and the rate of deterioration depends on environmental conditions such as ambient temperature and humidity. Storage modifies some characteristics of the egg including water content and pH of the albumen (Decuypere *et al*., 2001). Shell life of egg in the shell is 3 to 4 weeks at a temperature of 28-31°C, and that of egg white is 3 to 4 days and egg yolk is 2 to 4 days.

A wide range of supplements are added to the feeds of commercial egg production flocks. According to Slattery *et al* (2000), these materials are included to promote properties such as appearance, flavour, shelf life and to suppress the population of harmful microorganisms. Consumers, however, are becoming increasingly cautious about foods which contain artificial additives. As a result, there is an increasing interest in additives of natural origin (Balyavin and Marangos, 1988). Ingredients and additives that would be good replacements for artificial ones must not be a staple item of human food, should be readily available and inexpensive to procure.

The aim of this study is to assess the effect of mucuna *(Mucuna cochinchinensis),* cassava *(Manihot esculenta)* and Neems*(Azadirachta indica*) leaf meals, when used as feed supplements, on the shelf life of chicken eggs.

MATERIALS AND METHODS

The leaves were harvested and dried in the shade, in order to avoid bleaching of the green colour, until they became crisp. The dried leaves were milled to produce leaf meals which were mixed with other feed ingredients to produce the experimental diets (Table 1).

Table1: Ingredient and calculated nutrient composition of experimental diets (%)

	Control	MLM	CLM	NLM
Ingredient				
Maize	39.77	36.29	37.88	34.97
Maize offal	10.00	10.00	10.00	10.00

Lysine	0.80	0.80	0.80	0.80
ME (kcal/kg)	2600	2600	2600	2600

Two hundred and forty (240) 35-weeks old Lohman® brown chicken hens were used for the experiment. They were kept on deep litter in a tropical type poultry house with dwarf walls and open sides which was covered with wire mesh. The house was orientated in the east-west direction. The birds were grouped into 16 replicates of similar mean live body weight, and 4 replicates were randomly allocated to each of four treatments using the Completely Randomized Design. Treatment 1 served as control, with no leaf meal added to the diet, while the diet of birds in Treatments 2, 3 and 4 were, respectively, supplemented with 5% of the leaf meal of mucuna (*Mucuna cochinchinensis*), Cassava (*Manihot esculenta*) or Neem (*Azadirachta indica*).

Eggs for shelf life assessment were collected from all replicates on the same day and stored in plastic egg crates placed on a wooden table under room temperature (28-31°C) in the same room. Samples were taken on the same day and weekly for six weeks and analysed for yolk colour, yolk index and Haugh unit score.

Data for yolk colour, yolk index and haugh unit were subjected to analysis of variance (ANOVA) using Minitab statistical software (2006). Sets of means that were significantly different from each other were separated using Duncan's Multiply Range test.

RESULTS AND DISCUSSION

The result of estimates of internal egg quality are presented in Tables 2, 3 and 4. Internal egg quality deteriorated each week over the six weeks storage period and this was especially pronounced during the first week.

Yolk index was unaffected by treatment during all stages of storage with the exception of 2 week old eggs where it appeared that the feeding of mucuna and neem leafmeals accelerated the deterioration of yolk index.

The beneficial effects of feeding leafmeals on yolk colour and Haugh unit score were significantly ($p<0.05$) apparent at all storage stages, and cassava leafmeal always gave the best results. For yolk colour, mucuna and neem leafmeals followed in that order, with the control treatment always bringing up the rear. For Haugh unit score, for 2 weeks the leafmeals conferred better scores, with cassava leafmeal being best, mucuna and neem leafmeals tied for second place and the control bringing up the rear. From the third week to the end of the study in the sixth week the pattern was simply that of eggs from hens fed cassava leafmeal having a superior score above the others.

Table 2: Effect of Duration of Storage on Egg Yolk Colour

Duration (Week)	T_1	T_2	T_3	T_4	P	SEM
Week 0	2.30^{d}	5.05^{b}	5.90^{a}	4.50^{c}	0.00	0.17*

Table 3: Effect of Duration of Storage on Egg Yolk Index

Duration (Week)	T_1	T_2	T_3	T_4	P	SEM
Week 0	0.39	0.39	0.40	0.40	0.69	0.02^{ns}
Week 1	0.39	0.39	0.40	0.40	0.68	0.02^{ns}
Week 2	0.33^{a}	0.30^{ab}	0.34^{a}	0.26^{b}	0.00	0.03*
Week 3	0.28	0.25	0.28	0.24	0.20	0.03^{ns}
Week 4	0.25	0.22	0.25	0.22	0.29	0.03^{ns}
Week 5	0.21	0.20	0.22	0.18	0.31	0.03^{ns}
Week 6	0.18	0.17	0.20	0.16	0.26	0.03^{ns}

^{a,b,c,} means in the same row bearing different superscripts are significantly different ($P<0.05$)

The higher yolk colour score for eggs from birds fed leaf meals is an indication of absorption and utilization of the pigmenting xanthophylls present in the leaf meal. This is similar to what was reported by Austic and Neisheim (1990), when they supplemented layers feed with sunflower leaf meal. Mcdowell *et al* (1990) and Bailey *et al* (1989) also found that adding aquatic plants to the diets increase yolk pigmentation. A detailed chemical analysis of the leafmeals will be necessary before the reasons for the superiority of cassava over the other leaf meals could be speculated upon.

CONCLUSION AND APPLICATION

The inclusion of leaf meals, especially cassava leaf meal, improved the quality and shelf life of eggs. It is recommended that egg producers should include 5% of either cassava, mucuna, or neem leaf meal, in that order of preference, as cost and availability dictates, in the diet of their laying hens. The improvement in shelf life conferred will enable them to keep their eggs longer during periods of glut or enable them transport their eggs further afield in search of better markets.

Table 4: Effect of Duration of storage on Egg Haugh Unit (HU)

Duration (Week)	T_1	T_2	T_3	T_4	P	SEM

TEACHING ANIMAL PRODUCTS IN NIGERIA: FROM MEAT SCIENCE TO TROPICAL ANIMAL PRODUCTS INDUSTRY

Sonaiya, E.B.
Department of Animal Sciences, Obafemi Awolowo University, Ile-Ife, Osun State.

ABSTRACT
At the introduction of courses in animal products (AP) in Nigeria, meat science was the main focus of the training. In response to graduate unemployment and the paradigm shift to entrepreneurship, self-employment and job creation for university graduates the curriculum was expanded to include topics in economics and marketing and to emphasize the business dimension of AP. For the curriculum review to be successful there was the need to generate greater passion on the part of the teacher and the student to teach and learn, respectively, all the technical, as well as the business aspects of courses in AP. One well-tested way to generate student interest is to make textbooks available online in Open Access format that can be downloaded onto the smart phone. An Open Access e-book on the tropical animal products industry in Nigeria developed in compliance with instructional design directives evoked a higher student performance.
Key words: Teaching, Products, Course, e-book, Open-access

INTRODUCTION
In the early 1970s and 1980s, the first lecturers in animal products in Nigeria were trained in meat science (mostly in the US); for example: Professors Okubanjo (UI), Igene (UniMaid and UniBen), Sonaiya (OAU) and Aduku (ABU). Typical textbooks used and recommended were: Judkins and Keener, 1961, *Milk Production and Processing*; Lawrie, 1966, *Meat Science;* Zottola, 1972, *Introduction to Meat Microbiology*; Kramlich, et.al., 1973, *Processed Meats;* Forrest et al., 1975, *Principles of Meat Science*; Mountney, 1976, *Poultry Products Technology*; Price and Schweigert, 1978, *The Science of Meat and Meat Products*; and Frazier and Westhoff, 1978, *Food Microbiology*. By the middle to late 1980s, efforts were made to produce original textbooks that would accommodate the peculiarities of handling animal products in Nigeria. Three such texts were: Sonaiya, 1984, *Animal Products*; Ikeme, 1990, *Meat Science and Technology – A comprehensive Approach*; and Aduku and Olukosi, 1991, *Animal Products - Processing & Handling in the Tropics*. It was clear that the curriculum needed to be expanded to include topics in economics and marketing of animal products. In the same period, Taylor and Kauffman (1983) reported that the challenges facing the teaching of animal science included increased need for computer integration, improved communication skills, integration of business and economics into the livestock management systems and the approaches that will motivate students to learn and think. In Nigeria, the value chain approach to AP opens up investment opportunities in the AP industry (Sonaiya, 1998).
A hypothesis of this paper is that making textbooks available online in an Open Access format with lots of illustrations and downloadable onto the smart phone will lead to improved student performance.

MATERIALS AND METHODS
The response to changing needs for course content and student orientation must be accompanied by textbooks / instructional materials that are available online as electronic books in an Open Access format that makes access via the Internet as easy for the student as Facebook. To prepare adequate AP instructional materials requires the author to be familiar with curriculum and instructional design. In curriculum design, a course like Animal Products, as a segment of a B.Sc. / B. Agric. Animal Science (which can be visualized thus: Programme ← Courses ← Modules ← Study Units ← Sections ← Sub-Sections), must contain at least 3 modules. A module is a number of logically and thematically related study units. A study unit is the smallest segment of a course material that treats a topic which should adequately engage a learner for 3–4 hours of study. Each study unit can be viewed as an individual lecture and, depending on the topic, can be up to 25 pages (Times Roman,13-point size, single spacing) or as brief as 7 pages. The content of a typical study unit (NOUN, 2012) is shown in Table 1.

Table 1. Content of a typical study unit.

Study Unit Title:
1.0 Introduction
2.0 Objectives
3.0 Main Content
- 3.1
- 3.2
  - 3.2.1
  - 3.2.2
  - 3.2.3

5.0 Summary
6.0 Tutor-Marked Assignment
7.0 References/Further Readings

Table 2. Content of "Tropical Animal Products Industry in Nigeria".

Module 1. Introduction to animal products, animal by-products and animal products industry
Units
1. Introduction to animal products and by-products
2. Introduction to the animal products industry
3. Products of captured, hunted and harvested free-living animals
4. Products of domesticated food animals
5. Products from other domesticated ruminants and herbivores
6. Products from insects and special animals
7. Animal fibres and inedible animal products

Module 2. Meat production and primary processing
8. Animal growth and development
9. Animal body composition
10. Primary processing systems
11. Slaughter and conversion of muscle to meat
12. Meat processing, preservation and storage

Module 3. Secondary processing, product hygiene and safety
13. Secondary processing of meat animal products
14. Processing of egg and milk
15. Animal products hygiene and inspection

Module 4. Technical and economic aspects of animal products industry
16. Distribution and sale of animals and animal products
17. Economic and social value of animal products
18. Animal products science &technology

The textbook author's role is to analyse the course description and break it into appropriate study units, write appropriate learning objectives for each unit, select relevant content to attain these objectives and design relevant questions / activities to assess learners' attainment of stated objectives. Course learning materials are to be self-instructional; i.e. to "replicate what the teacher does in the classroom". The materials must be interactive and must stimulate independent learning; should be self-explanatory, self-contained, self-directing, self-motivating and self-evaluating. Self-assessment exercises (SAE) use questions, exercises and activities to enable learners review what they have learnt and assess/evaluate themselves. Tutor-marked assignments (TMA) are needed at the end of every study unit and at the end of every module. These are short answer or essay questions, projects or practicals for students to carry out which can serve the purpose of continuous assessment (CA). Summative assessment (SA) is the end of semester examination. The content of "Tropical Animal Products Industry in Nigeria" (Sonaiya et. al. 2019), an Open Access e-book that was developed in line with instructional design directive, is shown in Table 2. The material was made available to the class via Google drive and class performance without (in the 2017/2018 session) and with the drive (in the 2018/2019 session) was recorded and charted.

RESULT

The class performance without and with The Tropical Animal Products Industry in Nigeria (TAPIN) drive is shown on Figures 1 and 2. With an enrolment of 43 students in Figure 1, 54% of the class scored less than 50% and only 2% scored 70% of the 50 marks obtainable. In Figure 2, enrolment was 51 and 0% of the class scored less than 50% while 23% scored 70% and above of the 72 marks obtainable.

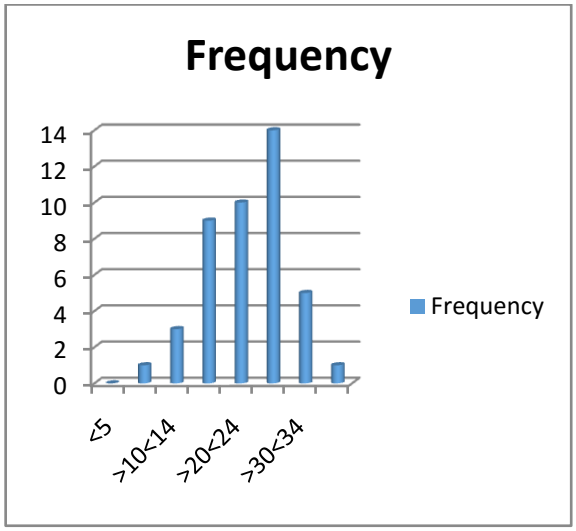

Figure 1. Class score without use of TAPIN

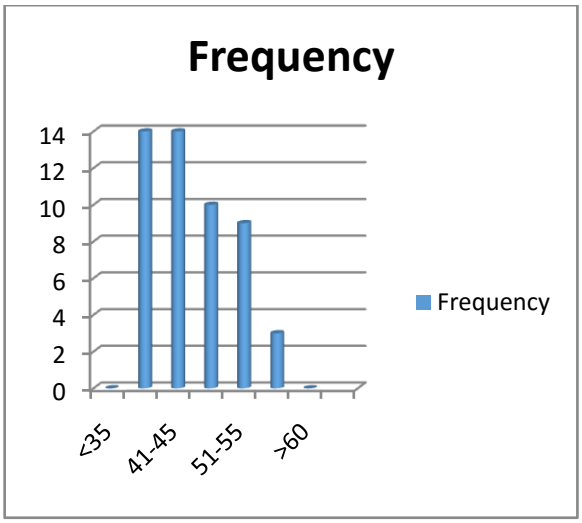

Figure 2. Class score with use of TAPIN

DISCUSSION

Animal products – meat, egg and milk – have great potential for balanced human nutrition, physical and mental development in the tropical countries of the third world. The next generation of Nigerians needs animal production scientists that are well trained and knowledgeable about the science, business, economics and politics of animal products and can leverage their knowledge to create viable businesses in "Animal Agriculture [which is] the goldmine of Nigeria's agro-revolution".

CONCLUSION AND RECOMMENDATION

In order to promote entrepreneurship in the AP industry, animal product scientists must apply the value chain approach in teaching about meat, milk and egg. To achieve this, Open Access e-books on the tropical animal products industry in Nigeria are needed. For the entire animal production science profession, a redesign of the curriculum is also recommended.

SURVEY OF CHEESE PRODUCERS IN OYO TOWN, OYO STATE, NIGERIA

***Okunlola, O. O. & Akindele W. O.**
Department of Agricultural Education, School of Vocational and Technical Education, The College of Education, Lanlate
Corresponding author:*greenfields2012@gmail.com

ABSTRACT
Cheese production in Oyo town is presently at a subsistence level and the producers are not well organized and employ mostly the traditional method of production of the snack. This study was aimed at collecting vital statistics that may help attract the attention of the concerned authorities to cheese producers, not only in Oyo town, but in Oyo state in general. Snowball sampling of the producers were employed and a total of twenty cheese producers were reached with interview schedule covering vital aspects like their bio data and cheese production activities. The results obtained show that all the respondents were female traders. Also, majority of them (75%) were within the age range of 20-39 years and married. All the respondents sourced their milk from cow while 45% and 35% of them used 20-29litres and 30-39litres of milk for production during the rainy and dry seasons respectively. Lack of capital to expand the business (40%) and inappropriate pricing of the product (25%) were major problems faced by the respondents. The study also revealed that all the respondents agreed that cheese production is profitable with majority of the making a profit ranging from 100-1000 naira and 1,100- 2000 naira during the dry and rainy seasons, respectively.
Key words: *cheese producers, Oyo town, production characteristics, production challenges, production finances*

INTRODUCTION
Cheese is a word derived from a Latin word *caseus* which translates, to ferment. It is also derived from the ancient English word *chese*, meaning "product derived from sour milk." Cheese is a hard consumable by-product of milk which is made by coagulating milk into solid form (Miaschi, 2017). Cheese is produced basically from milk, coagulant (animal or plant based enzyme) and salt.

About 20 million MT of natural cheeses was produced globally in 2011 and Cheese from cow´s milk accounts for above 80% of the global natural cheese production. Other sources of milk for cheese production include sheep, goat, and buffalo. Europe and Northern America produce more than 75% of the world cheese production (PM Food & Dairy Consulting, 2014). The North America and Europe are seen as major contributors to the global cheese production with their market share of not less than 75%. It was estimated that there were about 2000 varieties of cheese globally (OÃ¢Â Â™Connor, 1993, as cited by Orhevba and Taiwo, 2016). Cheese is mainly produced in Nigeria by the spouses of the Fulani nomads, which, apart from creating a variety into which milk is consumed, also serves the purpose of preserving excess milk produced due to poor storage facilities (Orhevba and Taiwo, 2016). It's been observed that culture greatly influences milk and milk products consumption in Africa (Ndambi *et al.*, 2007).

The study was carried out in Oyo town which has three Local Government Areas namely, Oyo East, Oyo West and Atiba. The town is the fourth largest in Oyo state and has an area of 1,757km2 and a population of 168,246 according to the 2006 census. The actual sampling was carried out in Akesan market, which was the largest and most cosmopolitan market, in terms of those who patronize it, in Oyo town. Snowball sampling technique was adopted in the study area. A total of 20 interview schedules were administered on the respondents. Information such as socio-economic characteristics, cheese production and cheese production finance were elicited from the respondents. Collected data were processed and subjected to descriptive analysis using frequency counts and percentages.

Result and discussion

Table 1: Bio data of cheese producers in the study area

Item	Criterion	No.	%
Gender	Female	20	100
Marital status	Single	02	10
	Married	15	75
	Separated	03	15
Age (years)	20-39	15	75
	40-59	05	25
Religion	Islam	12	60
	Christianity	06	30
	Traditional	01	05
	Atheist	01	05
Occupation	Trader	20	100
Household size	Below 5	09	45
	5-9	07	35
	10 above	04	20

Table 1 above shows the bio data of respondents in the study area. From the table, it was observed that all of the cheese producers were female traders. This signified that the business of cheese production was regarded as one for the womenfolk and that the producers engaged in cheese trading as a source of income. Also, majority of the respondents were between the age range of 20-39 years (75%), married (75%) and had household size below 5 (45%). The age range signified that the respondents were in their youthful age while the small household size was an indication that family labour was most probably not adopted in the production of cheese. Although, majority of the producers were Muslims (60%), the result obtained shows that other religions, including atheism were represented amongst the cheese producers. This was an indication that there was no religious discrimination against cheese production in the study area.

Table 2: Cheese Production in the study area

Item	Criterion	No.	%
Source of your milk	Cow	20	100
Volume (liters) of milk used in cheese production during dry season	10-29	13	65
	30-59	07	35
Volume (liters) of milk used in cheese production during raining season?	10-29	12	60
	30-59	08	40
Method of production	Traditional	20	100
Benefits of cheese production	Source of food	07	35
	Source of income	06	30
	Body development and freshness	06	30
	Source of strength	01	5
Challenges of cheese production	Lack of capital to improve the business	08	40
	Poor road network to transfer raw milk from farm	01	5
	Inappropriate market pricing	05	25
	No problem encountered	07	30
How do you feel the problem can be solved?	Provision of soft loan from government	06	30
	Membership of co-operative societies	12	60
	Good road infrastructure for transporting raw milk	08	40
Any assistance from government?	No	20	100

Table 2 above shows data on cheese production in the study area. Data from the table shows that the respondents' only source of milk was from cow and they all employed the traditional method of cheese production. Also, the average litre of milk used for production in the dry season was within the range 20-29 litres (45%), while the average used during the rainy season was within the range 30-39 (35%). Also, the average worth of cheese that a litre of milk could produce was ₦200 (55%) and majority (40%) of them claimed that capital was the major problem facing cheese production. Also, majority of the respondents claimed the problems facing them could be solved by making funds available for them. However, all the respondents claimed that cheese production was profitable during both dry and rainy seasons. The main benefits of production of cheese were income (30%) and food source (35%) and the average profit range during dry season was ₦600-1000 (70%), while the average profit during rainy season was within the range ₦1100-2000 (70%).

Table 3: Cheese production finance in the study area

Item	Criterion	No.	%
Is cheese production profitable?	Yes	20	100
Litre price of milk (₦) during dry season?	100	10	50
	150	9	45
	200	1	5
Litre price of milk (₦) during raining season?	100	8	40
	150	9	45
	200	3	15
On the average, how much worth (₦) of cheese can a litre of milk produce?	150	6	30
	200	11	55
	250	1	5
Profit (₦) per day from cheese during dry season?	100-1000	14	70
	1100-2000	4	20
	2100-3000	2	10
Profit (₦) per day from cheese during raining season?	100-1000	7	35
	1100-2000	13	65

Table 3 shows the financial implication of cheese production in the study area. From the table, all the respondents claimed that cheese production was profitable. It was also observed, from the table, that the average cost of a litre of milk was ₦100 (50%) and ₦150 during the rainy and dry seasons, respectively. The result from the table also shows that, on the average, a litre of milk produced ₦ 200 worth of cheese and the average profit range for the cheese producers per day were ₦100-1000 and ₦1,100-2,000 during the dry and rainy seasons respectively.

CONCLUSION AND RECOMMENDATIONS

The result from the study shows that young, married women were engaged in cheese production in the study area. It was also observed that there was no religious bias against the production of cheese in the study area as the various religious groups were represented amongst the producers. Also, cheese production was considered profitable by the producers and the major problems militating against the business were capital to expand their businesses and inappropriate pricing of their products by the retailers. It is therefore recommended that the appropriate authorities should make soft loans available to the producers in order to enhance their businesses. Also, the producers should organize themselves into cooperative units in order to easily access loans and work against the inappropriate pricing of their products by the retailers and unit buyers.

PRELIMINARY STUDY ON CHEESE CONSUMPTION PATTERN AMONGST RESIDENTS OF OYO TOWN, OYO STATE, NIGERIA

Okunlola, O. O.
Department of Agricultural Education, School of Vocational and Technical Education,
The College of Education, Lanlate
greenfields2012@gmail.com

ABSTRACT
Cheese is a popular snack that is eaten by many in Oyo town of Oyo state. However, the preferences of consumption in terms of quantity, benefits and disadvantages of consumption were different in the study area. A total of 100, respondents were randomly selected from whom information such as socio-economic characteristics and consumption pattern of cheese were elicited. Structured questionnaires were used to elicit information from the respondents. A multistage sampling was adopted with the study area divided into three in the first stage while 30 questionnaires were administered to respondents in Oyo East and Oyo West LGAs each and 40 in Atiba LGA. Collected data were processed and subjected to descriptive analysis using frequency counts and percentages. The results indicated that majority of the cheese consumers were male (58%) and within the age range of 40-59 (40%). Also, majority of the respondents were traders (46%) and with a household 6-10 (40%). The results also showed that majority (38%) of the respondents consumed cheese at least once per week. All the respondents also stated that cheese consumption had benefits which included good nutrition (96%) and good flavour (4%). Also, 10% of the respondents indicated that cheese consumption had some disadvantages which included, body hitching (40%) and cough (20%).
Key words: *cheese consumption, consumption benefits, consumption disadvantages, Oyo town*

INTRODUCTION
Milk, from which cheese is obtained, is the first natural food of all mammals as it contains vital nutrients for the sustainability especially at infancy, although adult humans consume processed milk in various forms (Adewumi et al., 2001). It is an important element of the pastoral civilizations in Africa, where it serves economic, social and cultural purposes (Mattiello *et al.*, 2018). A 2016 report by FAOSTAT showed that Africa produced 46,907,955 millions tonnes of milk which accounted for only 6% of world average production. The same report indicated that about 50% of total milk production in Africa were produced by six countries, Sudan (4,391,000 tonnes), Egypt (5,598, 477 tonnes), kenya (4,925,692 tonnes), Ethiopia (3,699,373 tonnes), South Africa (3,337,018 tonnes) and Algeria (4,241,414 tonnes). The report also put dairy cows as the highest milk suppliers with 74.05% of the world's total production, followed by goat (8.74%), buffalo (6.23%), camel (5.76%) and sheep (5.23%).
Cheese is a dairy product derived from milk that is produced in a wide range of flavours, textures and forms by coagulation of the milk protein casein (Encyclopedia Wikipedia, 2019). It is a major source of animal protein especially in rural communities (Akintunde *et al.*, 2010) and mostly processed by Fulani women, especially in this part of the world with the adoption of traditional method of production (Awoyele *et al.*, 2014). Cheese, commonly called *wara* or *warankasi* in Nigeria, is of soft type and so has poor shelf-life and mostly produced by the local Fulani women through the coagulation of milk induced by juice extract from the leaves of Sodom Apple plant (*Calotropis procera*) which contains enzyme calotropain (Iwuoha and Eke, 1996). Cheeses are mostly consumed by residents of the temperate countries with the first four highest consumers in terms of per capita consumption being Denmark (28.1 kg), Iceland (27.7 kg), Finland (27.3kg) and France (27.2kg) (Miaschi, 2017). The objective of the study was to determine the consumption pattern of cheese in Oyo town, Oyo state, Nigeria. Vital statistics considered were the biodata of respondents and cheese consumption in general.
The study was carried out in Oyo town which has three Local Government Areas (LGAs) namely, Oyo East, Oyo West and Atiba. It has an area of 1,757km2 and a population of 168,246 according to the 2006 census (FRN, 2009). Oyo town is highly cosmopolitan having people from various parts of the country living there. Also, it is a transit route from the south, to the north and vice versa making it have influx of people from time to time. Multistage sampling method was adopted. The study area was divided into three, on LGAs basis in the first stage while the second stage had 30 structured questionnaires purposively distributed to respondents in Oyo West and Oyo East LGAs and 40 in

Atiba LGA making a total of 100. Information such as socio-economic characteristics and consumption pattern of cheese were elicited from the respondents. Collected data were processed and subjected to descriptive analysis using frequency counts and percentages.

RESULTS AND DISCUSSION

Table 1: Bio Data of Cheese Consumers In The Study Area

Item	Criterion	No.	%
Sex	Male	58	58
	Female	42	42
Marital status	Single	50	50
	Married	40	40
	Separated	6	6
	Divorced	4	4
Age (years)	Below 20	28	28
	20-39	28	28
	40-59	40	40
	60 above	4	4
Religion	Islam	56	56
	Christianity	38	38
	Traditional	6	6
Occupation	Student	24	24
	Civil servant	8	8
	Trader	46	46
	Farmer	4	4
	Jobless	18	18
What is your household size?	Below 5	32	32
	5-9	40	40
	10 above	28	28

Table 1 above shows the bio data of respondents in the study area. From the table, it was observed that majority of the cheese consumers were male (58%), single (50%) and within the age range of 40-59 (40%). It can be deduced that the single males took cheese as a nutritious replacement for main menu, as some may find it difficult to cook. This result was in alignment with the results obtained by Adeosun (2018) who reported an age range of 21-30 for dairy products consumers in Iwajowa LGA of Oyo. Also, majority of the respondents were traders (46%) with household size that ranged between 5 and 9. Being traders, the respondents spent most of their daytime in the vicinity where cheeses were sold thereby making it easy for them to purchase. Regarding religious beliefs of the respondents, 56% of them were Muslims, 38% Christians and 6% traditionalists. This implies that there was no religious bias against cheese consumption in the study area.

Table 2: Cheese Consumption Pattern In The Study Area

Item	Criterion	No.	%
How often do you eat cheese?	Daily	20	20.00
	Weekly	38	38.00
	Monthly	08	08.00
	Once in while	34	34.00
What time of the day do you like to eat cheese?	Morning	36	36.00
	Afternoon	46	46.00
	Night	18	18.00
Reasons for afternoon purchases (n= 46)	Fresh	23	50.00
	Availability	20	43.48
	No reason	03	06.52
Any benefit of cheese consumption?	Yes	100	100.00
Benefits of cheese consumption	Good for health	96	96.00
	Good flavour	4	04.00
Any disadvantage of cheese consumption?	Yes	10	10.00
	No	90	90.00
Disadvantages of cheese consumption	Body itching	4	40.00
	Eye problem	2	20.00
	Cough	2	20.00
	Vomiting	2	20.00
Where do you buy your cheese?	Car parks	34	34.00
	Mobile retail seller	14	14.00
	Market	20	20.00
	By the road side	28	28.00

Table 2 shows the information about cheese consumption in the study area. Data obtained from the table show that majority of the respondents consumed cheese at least once per week (38%), purchased it at carparks (34%). All the respondents also concluded that cheese has health benefits although 10% of them also claimed that cheese consumption has side effects, which included allergies like body hitching (40%), cough (20%) and vomiting (20%). Benefits derivable from cheese consumption, according to the respondents, were good nutrition (96%) and good flavor (4%). Also, majority of the respondents liked to eat cheese in the afternoon (48%) and the reasons adduced for this were freshness (50%) and availability (43.48%).

CONCLUSION AND RECOMMENDATIONS

The study revealed that there was no religious bias against cheese consumption in the study area. Also, it was revealed that many of the residents of the study area consumed cheese that were worth between 200 to 290 naira weekly and mostly in the afternoon because of their desire for freshness of the product. Cheese consumption was considered to be of great benefits to health due to its nutritive values. However, some of the consumers of cheese reported allergies to the consumption which included, body hitching and vomiting. It is recommended that more awareness on the health benefits of cheese consumption be done by the concerned authorities so that the populace may live a more productive life.

ABSTRACT
The effect of frying time on proximate and organoleptic properties of beef fried with Shea butter oil was investigated. The meat type was purchased from Abattoir in Igboora 45 minutes after slaughtering, chilled and transported to the meat laboratory. The meat type was cut into 3 – 4 cm length, washed with distilled water, then boiled for 30 minutes with other ingredients and later fried with Shea butter oil at different frying time of 10 minutes, 15 minutes and 20 minutes in a completely randomized design. The fried meat was subjected to proximate and organoleptic analysis. Crude protein was significantly higher in 15 minutes frying time with least at 20 minutes frying time. Although, there was no significant different in ash, ether extract and crude fibre but 20 minutes frying time had the least values. 10 minutes frying time had the highest moisture content while 20 minutes frying time had the lowest. The highest colour, juiciness and texture was recorded in 20 minutes frying time while flavor, tenderness and overall acceptability was higher in 10 minutes frying time. In conclusion, in terms of proximate analysis, 15 minutes frying time was well favored while 10 minutes frying time was well favored in organoleptic evaluation.

Keywords: Beef , Bull, Shea butter oil, Organoleptic, Proximate, distilled water

INTRODUCTION
Beef is the culinary name for a meat from cattle. Beef can be harvested from bulls, cow, heifers, or steers is acceptability as a food source varies in different parts of the world. Beef Muscle meat can be cut into roasts, short ribs or steak (Field mignon sirlion steak, hanger steak e.t.c), some cuts are processed (corned beef or beef jerky) and trimmings, usually mixed with meat from older, learner cattle, or used in sausages. The beef can be boiled, grilled and fried. The oils can be used to fry beef such as olive oil, groundnut oils, soya oil and shea butter oil.

Shea butter is the fat extracted from the nut of the African Shea tree (*Vitellaria paradox*). It is usually yellow in color when raw, with unrefined, refined and ultra-refined Shea butter being ivory or white in color. Shea butter is a triglyceride (fat) derived mainly from stearic acid or oleic acid. It is widely used in cosmetics as a moisturizer, salva or lotion. Shea butter is edible and is used in food preparation in some African countries. Occasionally, the chocolate industry uses Shea butter mixed with other oils as a substitute for cocoa butter, although the taste is noticeably different.
The aim of this study is to assess the best frying time on proximate and organoleptic analysis of fried beef using shea butter oil.

MATERIALS AND METHODS
Experimental Site
The experiment was carried at the Department of Animal Production Technology of Oyo State College of Agricultural and Technology, Igboora, Oyo – State.

Materials and Equipment
Meat type (Beef), Onion, star anise, shea butter, distilled water, charcoal, salt, maggi, garlic, Ginger, and Black pepper.

Meat Preparation

Meat type (Beef) was purchase from Igboora Abattoir 45 minutes after slaughtering, chilled and transported to the meat laboratory at Oyo State College of Agriculture and Technology Igboora. All bones were removed and the fleshy part was washed and rinsed with distilled water. Meat type was washed and cut into chunks around 3 – 4cm and put in the pot, ingredients such as Maggi, garlic, ginger, coriander, star-anise, were added and cooked for about 30 minutes. Shea butter was melted to oil and the meat was fried with the oil at different frying time of 10 minutes, 15 minutes and 20 minutes in a completely randomized design.

Taste Panel Evaluation

A taste panel was set up consisting of 20 peoples to determine the organoleptic properties of the meat (beef) fried with shea butter oil using a nine point Hedonic scale. Parameters evaluated are:
Taste, Flavor, Colour, Juiciness, Texture, Acceptability

Statistical Analysis

Data obtained was subjected to analysis of variance and the mean value showing significant difference ($p<0.05$) was separated using Duncan's multiple range test (Duncan 1995)

RESULTS

Crude protein was significantly higher in 15 minutes frying time with least at 20 minutes frying time. Although, there was no significant different in ash, ether extract and crude fibre but 20 minutes frying time had the least values. 10 minutes frying time had the highest moisture content while 20 minutes frying time had the lowest.

Table 1: the proximate composition of fried meat at different time using shea butter oil

Parameters	10 minutes frying	15 minutes frying	20 minutes frying	SEM
Crude protein	60.34b	70.09a	56.18c	2.08
Ash	2.98	3.52	2.65	0.32
Ether extract	10.28	9.96	8.9	0.36
Crude fibre	0.02	0.01	0.02	0.00
Moisture content	15.92a	10.96b	14.88b	0.81

Figure 1 shows the Organoleptic Properties of Beef fried with Shea butter. The highest colour, juiciness and texture was recorded in 20 minutes frying time while flavor, tenderness and overall acceptability was higher in 10 minutes frying time. In conclusion, in terms of proximate 15 minutes frying time was well favored while 10 minutes frying time was well favored in organoleptic evaluation.

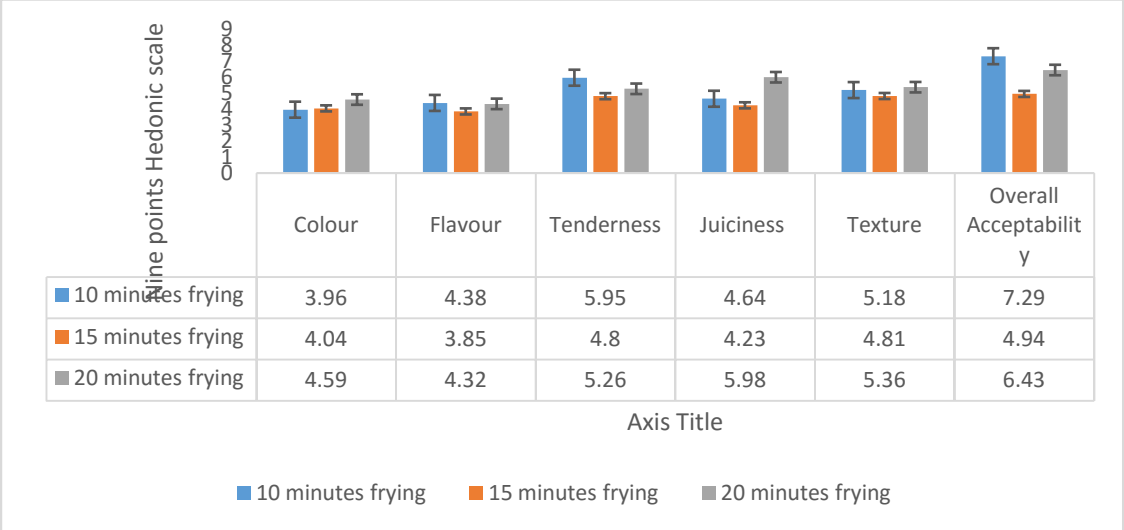

Figure 1: Sensory evaluation of fried meat at different time using shea butter oil

DISCUSSION

The Crude protein Content result obtained could be due to interaction of protein molecules (action and myosin) in meat to form actionomysin Complex and increases myofibrila Proteins which have been covered by denatured Sarcoplasmic protein. Although, there was no significant different in ash, ether extract and crude fibre but 20 minutes frying time had the least values. The result obtained for the moisture content could be as a result of frying time that affected the moisture retained in the meat (Kassama and Ngadi, 2004).

The Organoleptic Scores Showed that most of the parameters were not statistically different. The higher Colour was recorded in T_3. Swan (1993) revealed that colour intensity depends on the way the incident light is absorbed or Scattered and this is influenced by P^H. The highest juiciness score was recorded in Treatment 3. It is directly related to the intramuscular lipid and moisture intent of the meat (Cross *et al.*, 1986). Treatment 1 was more tender, tenderness is known to be the most important sensory attributes that affect meat acceptability (Quali, 1990). The highest flavour attribute was also recorded in Treatment 1 although the value was not significantly different from other treatments. Meat Flavour had taste and aroma as components (Warris, 2000).

CONCLUSION AND RECOMMENDATION

In conclusion, in terms of proximate, 15 minutes frying time was well favored while 10 minutes frying time was well favored in organoleptic evaluation. It is recommended that Shea butter oil can be used in frying meat. Further research should be carried out on the use of Shea butter oil in frying for preservation of meat.

ABSTRACT

A study was conducted to evaluate the influence of packaging materials and storage period on Storage stability (Thiobarbituric Reactive Substances), Appearance and ordor of *balangu* RTE-MP in a 3×4 factorial arrangement involving three packaging materials (aluminium foil, kraft paper and polyethylene film) and four storage length (0 , 24, 48 and 72 hrs) in a completely randomised design. Packaging materials and storage period had significant effect (P<0.05) on the Thiobarbituric Reactive Substances (TBARS), appearance (colour) and odour of *balangu* samples (Table 1). The TBARS value was significantly higher in samples packaged in polyethylene film than aluminium foil packaged samples, which was higher than samples packaged in paper. Appearance was scored significantly higher by paper packaged samples than aluminium foil packaged samples which did not differ significantly with paper and polyethylene film packaging, but higher than polyethylene film packaged samples. Similarly, samples packaged in paper had scored significantly higher than aluminium foil and polyethylene film which did not differ significantly. At storage, TBARS values, appearance and odor score increased from control with increase in storage period. There was also a significant interaction (P<0.01) between packaging materials and storage period on all the parameters measured after the storage period.The study concluded that the favourable combination of packaging material and storage length that could optimize storage stability, appearance and odor of *balangu* could be packaging in kraft paper or aluminium foil and utilized within up to 24 hrs of post-production.

INTRODUCTION

According to Adejumo and Ola (2008), in Nigeria there are diverse and numerous types of locally produced Ready-to-eat foods sold in public places for immediate consumption, and the packaging used for these foods is traditionally meant for take away, with little or no attention paid to the safety of the consumers and the shelf-life of the food. Furthermore, the hygienic state of the packaging materials and their appropriateness for the food products are not considered in their selection. Almost all the food products packaged by the local processors and vendors of Ready-to-eat meat products RTE-MPs in Nigeria are unlabeled. No indication is given of the names of the products, their sources, composition nor any information on appropriate storage conditions and instructions for use. Consequently, the role of packaging in the food industry, which includes protection, containments, transportation, preservation and advertisement are not achieved by most of the packaging materials and methods used by street food vendors in Nigeria. This in turn results in a huge loss of the food product not only during packaging processes but also during transportation and sales as a result of contamination by food spoilage microorganisms, dust and chemical contamination (Adejumo and Ola, 2008).

In Nigeria, RTE-MPs are widely produced and consumed with little or no due inspection. The highest regulatory body responsible for food safety, the National Agency for Food and Drugs Administration and Control (NAFDAC) is only concerned with pre-packaged foods in the registered companies. Little or no attention is paid to the control and or inspection of the local industries of RTE-MPs production where there is almost complete noncompliance with safety guidelines for the production of the RTE-MPs. This situation could place the consuming population at high risk of infection by foodborne pathogens which could be present in the RTE-MPs as a result of unhygienic processing,

handling, packaging and or storage. Abubakar *et al.* (2011) reported that appropriate and affordable technologies that are simple, cheap and effective in processing and preserving animal products must be sought and evaluated. Little or no attention is paid to the processing and packaging technics and there is scanty information concerning evaluating effectiveness of post-lethality packaging treatments that will allow products to be held for a shorter period of time without proliferation of bacteria. It is based on this that this research was designed, to conduct a study to compare packaging materials and storage period for physico-chemical, storage stability and sensory characteristics of balangu.

MATERIALS AND METHODS

The study was conducted in Kebbi and Sokoto States, North-West region of Nigeria. This study investigated the influence of packaging materials on storage stability, and sensory characteristics of *balangu*.

Experimental design

This study consisted of three packaging materials: Aluminum foil (ALF), kraft paper (KPA) and polyethylene film (PEF) with four storage times (0, 24, 48, and 72 hours). A total of twelve treatment combinations were obtained in a 3×4 factorial experiment involving three packaging materials and four storage periods in a completely randomized design.

Preparation of samples, packaging materials and packaging

The packaging materials used for the experiment were purchased from metropolitan supermarkets and processed according to required dimensions. A package consisted of a sheet of a material with the dimension of 25×25cm^2. *Balangu* was prepared from sliced beef in a portable drum kiln specifically designed to process the product under good hygienic condition. The sliced beef was placed on a brown craft paper sheet that has been spread over the wire mesh two feet above glowing fire from firewood. After two hours with regular turning interval of 15 minutes, *balangu* was produced. After gradual cooling for 30 minutes in the kiln, a clean knife was used to cut pieces of samples with dimension of 3×3cm^2. A total of 120 *balangu* samples were prepared and ten samples were randomly allotted to each of the already prepared packaging material, carefully wrapped and represented a packaging treatment according to the 12 treatment combinations. All 12 wrapped packages were then arranged in a flat platform at room temperature for their respective storage period. After each storage period, three samples were randomly taken from each treatment combination and evaluated for storage stability and seven samples were used for sensory evaluation.

Determination of storage stability (Lipid oxidation)

The oxidation of lipids was measured by determining the amount of the Thiobarbituric acid reactive substances (TBARS), expressed as mg malondialdehyde per kilogram (mgMDA/kg) of muscle or TBA units. Thiobarbituric acid reactive substances values were measured using the method of Witte *et al.* (1970).

Determination of sensory characteristics

Determination of sensory characteristics was subjectively conducted using the method of quantitative descriptive analysis (QDA) based on the principle of a panelist's ability to verbalize perceptions of a product. Hedonic scales according to Watts *et al.* (1989) were used to evaluate the colour appearance and odor of the product after each storage period using a panel of seven (7) judges.

Data Analysis

Data on sensory and storage stability were transformed and analyzed using non-parametric analysis to obtain means. The means were subjected to the GLM procedure to compare the effect of packaging and storage period on the RTE-MP. Significant means were separated using Tukey test at 5% level of significance.

RESULTS AND DISCUSSION

Storage stability (Thiobarbituric Reactive Substances)

Packaging materials and storage period had significant effect ($P<0.05$) on the Thiobarbituric Reactive Substances (TBARS), appearance (colour) and ordour of *balangu* samples (Table 1). The TBARS value was significantly higher in samples packaged in polyethylene film than aluminium foil packaged samples, which was higher than samples packaged in paper. Appearance was scored significantly higher by paper packaged samples than aluminium foil packaged samples which did not differ significantly with paper and polyethylene film packaging, but higher than polyethylene film

packaged samples. Similarly, samples packaged in paper had scored significantly higher than aluminium foil and polyethylene film which did not differ significantly. At storage, TBARS values, appearance and odour score increased from control with increase in storage period. There was also a significant interaction (P<0.01) between packaging materials and storage period on all the parameters tested after the storage period.

Table 1 Effects of packaging materials and storage period on the storage stability and sensory qualities of *balangu*

Treatments	Parameters		
	TBARS (mgMDA/kg)	Appearance (colour)	Odour
Packaging materials			
Aluminum foil	1.133[b]	4.071[ab]	2.321[b]
Paper	0.232[c]	4.429[a]	2.643[a]
Polyethylene film	2.133[a]	3.750[b]	2.286[b]
SE	0.049	0.134	0.104
Storage period (hours)			
0 (control)	0.058[a]	7.762[a]	4.238[a]
24	0.766[b]	4.762[b]	2.952[b]
48	1.843[c]	2.333[c]	1.476[c]
72	2.664[d]	1.476[d]	1.000[d]
SE	0.057	0.155	0.120
Interaction			
Packaging × Storage period	**	NS	**

a,b,c,d = means with different superscript along the same column within a subset differ (P<0.05)
** = P<0.001
NS= Not significant

In the current study, balangu packaged in polyethylene film and aluminum foil had developed higher TBARS (2.133 and 1.133g MDA/kg, respectively) than paper packaging (0.232g MDA/kg). This might be due to the fact that packaging *Balangu* which is an intermediate moisture meat product and hence, has relatively high moisture content with other concentrated nutrients like protein which could probably result in the production of free radicals (Min, 2008) or porosity of packaging materials (Ahn *et al*., 2000; Muhammad and Muhammad, 2007). TBARS values increased with increase in storage time. The storage period of 72 hours had higher value (2.664g MDA/kg) than 48 and 24 hours (1.843 and 0.766g MDA/kg, respectively). Controls had lower TBARS value (0.058g MDA/kg). The higher TBARS value could be as a result of extension of storage time leading to the production of free radicals (Kanatt *et al.* 2006). Several research findings (Kim *et al.*, 2014; Bağdatli and Kayaardi, 2015; Akinneye and Aringbagba, 2015) had reported similar trends of TBARS values in relation to storage time using different meat and other food products.

Appearance and Odour

In the current study, results of indicated that all packaging materials scored values that were below the desirable levels in the appearance scale after storage. However, paper had scored higher (4.429) than aluminum foil and polyethylene film packaging materials (4.071 and 3.750, respectively). At the storage length, samples in control (0 hrs) had shown better performance in color appearance (7.762) equivalent to extremely desirable. After 24 hours, the samples scored 4.762 equivalents to slightly desirable on the rating scale. This indicated that though balangu is produced for immediate consumption, yet, its colour appeal could extend up to 24 hrs stored at room temperature. At 48 and 72 hrs storage, the samples were rated extremely undesirable. It could be as a result of complete deterioration of the meat pigments and prolonged storage.

The current study shows that paper packaged balangu performed better (2.643) demonstrating that the samples have developed less off-odor than the aluminum foil and polyethylene film packaged balangu which scored 2.320 and 2.286, respectively and were categorized as having moderate odor development after storage. Apart from the control (0 hrs), other storage period indicated samples stored after 24 hrs had developed small odor (2.952) while those stored for 48 and 72 hrs had extreme odors scoring 1.476 and 1.000, respectively. The odors could be due to the production of low-molecular-weight volatile substances (Lamikanra and Dupuy, 1990).

ABSTRACT
A Comparative study of two traditional methods of milk preservation on microbiological safety was designed and conducted in two stages. The first stage was a survey which identified various methods of preservation of milk as well as the consumption pattern of traditional milk products in the study area. The second stage was a laboratory activity where two traditional preservatives (*Xylopia aethopica* (kimba) and charcoal) were used to preserve milk for 24 hours at six hours interval to investigate the microbiological safety of milk. Data from the survey were expressed in descriptive statistics while data on microbiological analysis was analyzed using ANOVA. The survey result shows that (70%) of the respondents were female and mostly used traditional methods (82.5%) in preserving milk. 77.5% do not add any substance to the milk for preservation, but (22.5%) of respondents add traditional substances to preserve milk. The main reason mentioned by the respondents was to add flavor (70 %) and extend the shelf-life of milk. Data on microbial load shows that except at zero hours, there was significant difference ($P < 0.05$) among all treatments. A trend was observed in that, for control samples, increase in preservation time lead to increase in microbial count, however, for the treated samples, a decrease in microbial count was observed with increase in preservation time, suggesting that the traditional preservatives had antimicrobial effect. *Staphylococcus, E.coli* and *Bacillus spp.* were the bacteria isolated from the milk. It was concluded that a decrease in microbial count was observed with increase in preservation time for treated samples with *xylopia aethopion* ('kimba') having lower bacterial count.

INTRODUCTION
Background of the Study
Milk is a nutrient rich, white liquid food produced by the mammary glands of mammals. It is the primary source of nutrient for infant mammals (including humans who are breast fed) before they are able to digest other types of food. Early lactation milk contains colostrum, which carries the mother's antibodies to its young and can reduce the risk of many diseases. It contains many other nutrients including protein and lactose (Pehrson, *et al.*, 2000). As an Agricultural product, milk also called dairy milks, is extracted from farm animals during or soon after pregnancy.

Milk consumption occurs in two distinct overall types, a natural source of nutrition for all infant mammals and a food product obtained from other mammals for consumption by humans of all ages. Many food products are perishable by nature and require protection from spoilage during their preparation, storage and distribution to give them desired shelf life. Since milk is often sold in areas of the world for distance from the production sites, the also extended safe shelf life for milk has also expand (Rassoli, 2007). Milk has a complex biochemical composition and its high water activity and nutritional value serves as an excellent medium for growth and multiplication of many kind of micro-organisms when suitable condition exist (Parekh and subhash, 2008). Because of the hand milking system pastoralists, it's not easy to avoid contamination of milk with micro-organisms therefore the microbial content of milk is a major feature in determining it equipment, feed, soil, cow faeces, and grass (Khan *et al.*, 2008).

Thus, although milk and milk products are minor constituent in most diets but contaminated milk is responsible for up to 90% of all dairy related disease of humans (Shirima, *et al.*, 2003). The risk of infection by milk borne zoonotic disease such as tuberculosis and brucellosis among other disease is one of the reasons for public health regulations, which discourage the informal milk markets and consumption of raw or unpasteurized milk (Shirima, et al., 2003).

Traditional milk processing methods, the pastoral are the most important sources of domestic milk in Nigeria. The wives of pastoralist usually process fresh milk into various traditional milk products.

These include nono (sour milk), kindirmo (sour yoghurt), manshanu (local butter), cuku (Fulani cheese) and wara (Yoruba cheese).these product are usually hawked around the local area by women or are sold in a specific location (CBN, 1999).

In rural settings particularly in several pastoralist communities, use of medicinal plants is the commonly used technique for different food preservation including milk. Several plants, herbs and spice extracts have been reported to possess antimicrobial activity against a range of bacteria, yeast and molds (Burt, 2004). Charcoal from *Oleaeuropea, lagenariasiceria* and *Olea Africana* were documented to be used to coat the inside of milk storage gourds to add flavor/ aroma and also to protect the milk against spoilage micro-organisms. Therefore, it is important to evaluate antimicrobial activities of indigenous plant which are commonly used by pastoral communities for milk preservation. Therefore, this study is aimed at assessing two local milk preservation substances for total microbiological load of milk.

MATERIALS AND METHODS

Study Area

The study was carried in Animal Science Laboratory of Kebbi State University of Science and Technology Aliero. Aliero Is Town in Kebbi state, Northern Nigeria.

Experimental Design

The experiment was conducted using a completely randomize design (CRD) consisting of three treatments replicated four times. The treatments were two traditional milk preservation substances (*Olea Africana* (Charcoal) and *xylopia aethopion* ('kimba'). The three (3) litres of milk was divided i to two (1 liter each) for the two treatments respectively. Each treatment was replicated four (4) times i.e. 250ml and one (1g) of *xylopia aethopica* (kimba) was added to first treatment and one (1g) of *Olea Africana* charchol was added to second treatment with the exception of control. Data was taken after an interval of 6 hours. The experiment lasted for 24 hours.

Microbiological Analysis

Nutrient agar medium

The medium was prepared by 7g of nutrient agar in 240mls of distal water. The mixture was dissolved on hot plate and mouth of the conical flask was covered as curved with cotton wool and aluminum. The medium was sterilized using an autoclave at 121°c for 15 minutes. The medium was allowed to cold to 45°c and dispensed into sterile petri-dishes in the manner of (Oyeleke and Manga, 2008). Five folds serial diilution were prepared and labeled as 10^{-1} , 10^{-2}, 10^{-3}, $10^{-4,}$ and 10^{-5} in order to obtain discrete colony. An inoculum (0.1ml) from the last dilution (10^{-5} was be pipette and dispense onto the solidified nutrient agar medium, sterile bent glass rod was used to spread the inoculums for even growth. This was incubated at 37°c for 24hrs. After incubation plate showing between 3 – 11 colonies on agar plates was counted. The colonies are efficiently counted by inverting the plate and each colony counted was marked with marker to avoid recounting. Biochemical tests were carried out as outlined by Cheesebrough *et, al*. (2002).

RESULT AND DISCUSSION

Heterotrophic bacterial count from milk samples preserved using traditional preservatives.

Table 1 shows the result of Heterotrophic bacterial count from milk samples preserved using two traditional preservatives (*Olea Africana* (Charcoal) and *xylopia aethopion* ('kimba'). Results indicate that there was no significant difference ($P > 0.05$) between treatments at 0 hours of preservation. However, there was significant difference ($P < 0.05$) among all hours of preservation across all treatments. The mean total bacterial count is also significantly different indicating that *xylopia aethopica* ('kimba') has lower bacterial count than *Olea Africana* (Charcoal).

Table 1: Heterotrophic bacterial count from milk samples preserved using traditional preservatives.

Treatment (cfu/ml)	Times (hrs)					
	0hr	6hrs	12hrs	18hrs	24hrs	Mean
Control	7.3	6.8^{c}	7.5^{c}	8.0^{c}	8.8^{c}	7.7^{c}
X. aethopica	7.4	7.8^{b}	6.4^{a}	5.0^{a}	4.5^{a}	6.3^{a}
Olea Africana	7.5	7.3^{a}	7.1^{b}	6.5^{b}	5.5^{b}	6.8^{b}
S.E	0.117	0.047	0.061	0.058	0.047	0.047

The significant differences observed at 6, 12, 18 and 24 hours among the treatments with *Xylopia aethopica* recording lower (6.3cfu/ml) than *Olea Africana* (6.8 cfu/ml) and control (7.7 cfu/ml) might be as a result of *xylopia aethopica* having antimicrobial effect as widely reported (Samah *et al.*, 2019; Davide *et al.*, 2016; Kassahun, 2013). A trend was also observed in the bacterial count across the treatments. Bacterial count in control increased with increase in storage time. But, bacterial count decreases with increased in storage time there by suggesting that the preservatives might have exhibited their antimicrobial effect as the storage time is prolonged.

Incidence of some bacteria in milk samples treated with two traditional preservatives

Results in Table 4.3 shows the morphological characteristics of some bacteria isolated from milk samples treated with two traditional preservatives (*Olea Africana* (Charcoal) and *xylopia aethopion* ('kimba'). The result indicated that *Staphylococcus*, *E.coli* and *Bacillus spp.* were the bacteria isolated with *Staphylococcus* and *E.coli* having more incidence of occurrence.

Table 4.3 Incidence of some bacteria in milk samples treated with two traditional preservatives

Treatments	**Incidence**		
	E.coli	*Staphylococcus* spp	*Bacillus*
Control	0	4	0
Olea Africana	3	1	1
xylopia aethopion	1	3	1
Percentage(%)	**33.33(%)**	**66.66(%)**	**16.66(%)**

From the results, it was observed that *E.coli* and *Bacillus spp.* were not found in the control samples but were however observed in treated samples. The presence of these pathogens in the samples could only mean that they might be introduced along with the test preservative which might not be qualitative as reported by Samah *et al*, (2019) that only the highest quality herbs or spices can be added to dairy products to combat contaminating microorganisms.

CONCLUSION

From the research findings, it was concluded that preservation time lead to increase in bacterial count in control samples. However, for the treated samples, a decrease in microbial count was observed with increase in preservation time. The mean total bacterial count among the treatments indicated that *xylopia aethopion* ('kimba') has lower bacterial count than *Olea Africana* (Charcoal).

ABSTRACT
The study was conducted to investigated the physical hygiene and grade characteristics of eggs produced from commercial poultry farms within and around Brinin Kebbi metropolis. All viable commercial poultry farms covering 50 kilometers radius in and around Birnin kebbi metropolis were surveyed in a preliminary survey, and five (5) farms were identified to be operating in a relatively consistent commercial quantities. Three crates of fresh eggs (containing 30 eggs per each crate) were purchased from each farm. Therefore, a total of 450 eggs were used for the study. The physical characteristics determined include egg size, cracks, stains, dirt, texture, ridges, colour and shape of eggs while the eggs from various farms were graded using the USDA standard grading characteristics based on size classification of the eggs. Results on physical characteristics indicated that there was significant differences ($P<0.05$) on egg weight and number of dirty eggs among farms. However, there was no significant differences ($P>0.05$) between the farms on egg cracks, egg stains, egg textures and ridges on eggs. Farm B had higher egg weight (66.1g) while Farm E had the least (2.67) dirty eggs. Generally, egg size classification across the farms studied conforms to the USDA standards of jumbo, Extra-large and Large eggs. No medium eggs, small eggs and pwewee eggs were recorded among the farms studied. The study concluded that most of the eggs produced from selected farms are of good size and weight but have stains, dirts and cracks which could raise safety concerns. All eggs from the farms studied favorably conform to the USDA standards based on the size of the eggs.

Keywords: Hygiene, Grade Characteristics, Eggs, Poultry Farms

INTRODUCTION
Eggs are very important for feeding people as they have high nutritive value and are suitable for Processing and 50g of the edible part of a hen egg contains 72.5-75.0 g of water, 12.5-13.3 g of protein,10.7-11.6 g of fat, 0.7 g of carbohydrates and 1.0-1.1 g of mineral substance. The human body also makes good use of the nutritive value of eggs: proteins are utilized at 97%, fats 95%, carbohydrates 98% and minerals 76%. The content of essential amino acids in eggs is also very important, especially leucine, isoleucine, lysine, arginine, valine and phenylalanine. Eggs are also rich in vitamins - especially A, K and B complex - and also in different micro- and macro-minerals (USDA, 2015). According to Dudusola (2010) and Pasquoal *et al.*, (2012), eggs are highly versatile food containing many essential nutrients. Eggs of most species of birds may have similarities in nutritional composition and potential food usage, however, information on egg quality characteristics and utilization of egg for food and other purposes have been limited mostly to chicken eggs. Egg quality is composed of those characteristics of an egg that affects its acceptability to consumers such as cleanliness, freshness, egg weight, shell quality; yolk index, albumen index, Haugh unit and chemical composition (Mahdabi *et al.*, 2012, Song et al., 2000).

Grading refers to the process of grouping eggs according to similar characteristics, such as quality and weight. Egg grading is dependent upon examination of internal quality factors (e.g., condition of the egg white and yolk, air cell size). According to Abanikannda and Leigh (2012), egg grading generally involves the sorting of products according to quality, size, weight and other factors that determine the relative value of the product (USDA, 2005). It entails the grouping of eggs into lots, having similar quality and weight. The grade of an egg is determined by factors like its quality, soundness and weight, but the factor with the lowest grade determines the overall grade of the egg (Jacob *et al.*, 2002). Chukwuka *et al.*, 2011) reported that under the European Union of egg marketing regulations enforced in all European Union countries, eggs are classified as either class A or B eggs (CEU 2006) and eggs graded as A can be sold for direct human consumption or retailed (CEU, 2006). Similarly, the United States Department of Agriculture (USDA) has developed three grades of eggs based on the

interior quality of the egg, appearance and condition of the egg shell. The USDA grade AA and US grade

According to Abisogun *et al.* (2012), the major challenges of marketing livestock products are appropriate pricing, preservation and storage. The usual practice of small holder poultry farms is to sell eggs unsorted which results in loss of income, decreased marketability and increased wastages. Sorting and grading of eggs in to fairly homogenous sizes by small holder commercial egg producers could lead to an increase in the consumer's preference which will consequently result in increased marketability and revenue. Hence, this research will attempt to study the practice of egg grading in kebbi state by obtaining first-hand information on the knowledge attitude and practice of egg grading from the commercial egg producers and also to determine the quality of the eggs produced if they conform to the international standards. Therefore**,** this study seek to evaluate physical hygiene grade characteristics and determination of the conformity of egg from commercial poultry farms around Birnin Kebbi metropolis to USDA standards.

MATERIALS AND METHODS

Study Area

The study was conducted at the Animal Science Laboratory of Kebbi State University of Science and Technology, Aliero, Kebbi State. The study evaluated some hygiene and grade characteristics of eggs produced from selected commercial poultry farms around Birnin kebbi metropolis.

Sampling and Sample Size

All viable commercial poultry farms covering 50 kilometers radius in and around Birnin kebbi metropolis were surveyed in a preliminary survey, and five (5) farms were identified to be operating in a relatively consistent commercial quantities. Three crates of fresh eggs (containing 30 eggs per each crate) was purchased from each farm as per the arrangement of the eggs by the farms. Therefore, a total of 450 eggs were used for the study.

Data Collection

Hygiene grade characteristics of eggs

The physical characteristics determined, include egg size, cracks, stains, dirt, texture, ridges, colour and shape of eggs. Egg size was determined by measuring the weight of each individual egg using a sensitive digital weighing balance. Cracks were determined by counting the number of eggs that have any visible crack on the shell surface. Stains were determined by counting the number of eggs that have any prominent, moderate and localized stains on the surfaces of egg shells. Dirty eggs were determined by counting the number of eggs that had adhering dirt or foreign materials on the shell. Texture of the eggs was determined by counting the number of eggs that have extremely rough surfaces and large calcium deposits. Ridges on eggs were determined by observing the eggs that have pronounced ridges on the shells.

USDA Grade characteristics of eggs

The eggs from various farms was graded using the standard grading characteristics based on size on the size of eggs. Eggs were measured by weight using digital weighing balance and classified as follows: Jumbo (>71g), Extra Large (61 – 70g), Large (51 – 60g), Medium (40 – 50g), Small (30 – 40g) and Pwewee (< 30g).

Data Analysis

Analysis of Variance (ANOVA) was used to compare the Physical characteristics and to determine the conformity between eggs produced from selected commercial poultry farms.

RESULTS AND DISCUSSION

Evaluation of Hygiene and Grade Characteristics of Egg Produced From Commercial Poultry Farms Within and around Birnin Kebbi Metropolis.

The results on the Table 1 indicate that there was significant differences (P<0.05) on egg weight and number of dirty eggs among farms. However, there was no significant differences (P>0.05) between the farms on egg cracks, egg stains, egg textures and ridges on eggs.

Table 1: physical Hygiene characteristics of egg produced from commercial poultry farms within and around Birnin Kebbi Metropolis.

FARM	PARAMETERS					
	Weight (G)	Cracks	Stains	Dirty Egg	Texture	Ridges
A	59.5^{bc}	2.00	25.00	16.00^{b}	12.7	5.32
B	66.1^{a}	1.00	24.33	15.33^{b}	3.67	4.99
C	60.3^{b}	0.00	21.67	11.33^{ab}	2.00	8.66
D	55.9^{bc}	1.00	20.33	8.67^{ab}	0.33	6.99
E	55.1^{c}	1.67	19.67	2.67^{a}	0.00	7.66
SEM	**1.04**	**0.650**	**2.211**	**2.271**	**0.856**	**1.342**

Means with difference superscript along the same column with a subset differ significantly (P<0.05)

Egg Weight in farm B had higher weight (66.1g) than other farms. This might be as a result of weight, breed and age of the laying birds from which the eggs were obtained. It has been demonstrated that there is correlation between body size and egg size within the breed, and also, age may have tendency to influence producing heavy weight eggs (Blanco *et al.*, 2014; Aygun and Yetisir, 2010; Begli *et al.*, 2010; Alkan *et al.*,2010). Majority of the farms studied had recorded cracks eggs. This could probably be as a result of poor handling during egg collection.

Determination of Conformity of Eggs Produced From Commercial Poultry Farms around Birnin Kebbi Metropolis to USDA grade standards

Results on the Table 2 shows that there was significant differences (P< 0.05) on egg size across the farms studied for jumbo, extra-large and large eggs. However, there was no significant differences (P>0.05) among the farms on Medium, small and peewee eggs.

Table 2: USDA standard grade characterization of eggs produced from commercial poultry farms within and around Birnin Kebbi Metropolis .

FARM	PARAMETERS					
	Jumbo	Ex-Large	Large	Medium	Small	Pwewee
A	1.33^{b}	18.33^{a}	24.33^{a}	3.33	0.000	0.000
B	6.33^{a}	12.33^{ab}	22.00^{a}	3.00	0.000	0.000
C	1.00^{b}	10.33^{ab}	15.33^{a}	2.00	0.000	0.000
D	0.00^{b}	4.67^{b}	15.00^{a}	1.00	0.000	0.000
E	0.00^{b}	2.00^{b}	5.00^{b}	0.00	0.000	0.000
S.E	**0.56**	**2.41**	**2.08**	**1.11**	**0.00**	**0.00**

Means with difference superscript along the same column with a subset differ significantly (P<0.05)

Based on Jumbo size eggs, farm B had higher (6.33) number of Jumbo eggs followed by farm A (1.33) and C (1.00). The high number may be due to breed or age of the laying birds. Based on Extra-large eggs, farm A had higher number of eggs (18.33), followed by farm B (12.33) and C (10.33). Farm E had lesser (2.00) number of eggs. Based on Large eggs, farm A had higher (24.33) number of eggs, followed by farm B (22.00) and C (15.33). Farm E had lesser (5.00) number of eggs. There was no small and pwewee eggs recorded among all the farms studied in the current study. This shows that,

most eggs produced by commercial farms within and around Birnin Kebbi metropolis fairly conform to the UDSA standard.

CONCLUSION

The study concluded that there is awareness of egg grading among poultry personnel but the system is not adequately practiced. Most of the eggs produced from selected farms are good size and weight but have stains, dirt's and cracks which could raise safety concerns. All eggs from the farms studied favourably conforms to the USDA standards based on the size of the eggs.

ABSTRACT

To determine the effects of housing system and cut-part used on quality attributes of ground turkey patties, 200 four-week old poults were raised in two different housing systems (deep litter and outdoor run) for 10 weeks. Afterwards, fresh breast and thigh from slaughtered carcasses were collected and used as the raw material for ground patties which were subjected to physiochemical and sensory analysis. Data obtained were arranged in a 2 × 2 factorial layout and subjected to Analysis of Variance. Results showed housing system effect was negligible ($p>0.05$) on physicochemical and sensory analysis of ground turkey patties. However, ranges of values recorded for pH (6.45 – 6.74), cooking loss (25.06 – 28.85%), chilling loss (4.41 – 7.92%), and diameter shrinkage (11.77 – 14.58%) revealed patties prepared from thigh was significantly ($p<0.05$) higher. Sensory scores; appearance (3.90 – 4.92), flavour (5.53 – 6.23) and overall acceptability (5.48 - 6.65) were significantly ($p<0.05$) higher in breast patties while oiliness was significantly ($p<0.05$) higher in thigh patties. Therefore, the use of turkey breast for ground patties production is recommended.

Keywords: turkey, housing system, cut-up part, ground patties, sensory

INTRODUCTION

Value-added poultry products present enormous opportunities for poultry producers, processors and sellers. Unlike fresh meat, many meat products can be made shelf-stable (Heinz and Hautzinger, 2007). A typical example is patties; a minced meat mixed with condiments and spices, shaped and then cooked by frying, grilling or baking (Gujral *et al*., 2002). However, since meat quality is influenced by many interacting factors before and after slaughter, the consumers of many meat products are getting more concerned about the origin and safety of the meat used for processing (Araújo *et al.*, 2011). Thus, the purpose of investigation was to determine the quality attributes of ground turkey patties as affected by housing system and cut-parts used on.

MATERIALS AND METHODS

Experimental Site

Turkeys were reared in the Turkey Unit of the Directorate of University Farms, Federal University of Agriculture, Abeokuta while patties production and analysis were carried out in the Animal Products and Processing Laboratory of the Department of Animal Production and Health of the same institution.

Ground patties preparation

A total of 200 four-weeks old poults from local strain were divided into two different housing systems (deep litter and outdoor run) and fed commercial turkey starter *ad libitum* for 10 weeks. The birds were each subdivided into 10 replicates consisting of 10 birds per replicate. At the end of the trial, two birds per replicate were selected and slaughtered. The birds were bled completely followed by removal of skin. Fresh breast and thigh were collected and used as the raw material for patties production. Two hundred grams (200 g) of fresh breast and thigh, respectively from each replicate were processed into patties as described by Heinz and Hautzinger (2007). The meats were manually

cut into small pieces and minced using a food processor and seasonings (2.4 g Salt, 0.3 g black pepper, 0.06 g nutmeg, 0.1 g ginger and 0.06 g coriander) were added to the minced followed by mixing for 5 minutes. Afterwards, fat (10 g of butter) was added and mixed for another 10 min until they homogenized. The homogenous mixture (approximately 80 g) was transferred to a patty shaper, pressed and a round-shaped patty was obtained. The shaped patties were cooked to an internal temperature of 74º C in a microwave.

Data collection

1. Physicochemical analyses:

- pH Measurement: Ten (10) g of prepared patty samples were homogenized with 90 ml of distilled water (in the ratio of 1:9), using a laboratory blender for 1 min at low speed setting. Digital pH meter was used after standardizing it with two-buffer solutions; one in pH 7.0, and the other in pH 4.0. The pH of patties was obtained in the slurry with the direct insertion probe electrode of the pH meter.
- Chilling Loss (%) = $\frac{(\text{Weight of raw patty} - \text{Weight of chilled patty after 24 hours})}{\text{Weight of raw patty}} \times 100$
- Cooking loss (%) = $\frac{(\text{Weight of raw patty} - \text{Cooked Patty weight})}{\text{Weight of raw patty}} \times 100$
- Diameter shrinkage (%) = $\frac{(\text{Diameter of raw patty} - \text{Diameter of cooked patty})}{\text{Diameter of raw patty}} \times 100$

2. Sensory Evaluation:

A total of 20 untrained panellists, all of whom were college students' ages ranging 18 to 30 years and 60% of whom were male, evaluated the patties. Panellist were screened and trained accordingly. Hedonic testing was used to assess the consumer acceptance of patties from each treatment. The patties were cut into cubes (1.3 cm × 1.3 cm x cooked patties thickness) and panellists were instructed to taste patty samples from left to right and to take water between each sample. The serving order of patties was also rotated to reduce potential bias caused by positions. Panellists rated sensory attributes using hedonic scales based on a 9-point Likert scale for appearance (1 = extremely bumpy, 9 = extremely smooth), oiliness (1 = extremely dry, 9 = extremely oily), chewiness (1 = extremely chewy, 9 = extremely crumbly), flavour (1 = extremely bland, 9 = extremely tasty), and overall acceptability (1 = dislike extremely, 9 = like extremely).

Statistical Analysis

The data obtained were arranged in a 2 × 2 factorial were analyzed with Analysis of Variance (ANOVA) using the GLM procedure of statistical analysis software Minitab® version 17.1.0. Significant ($p<0.05$) differences among treatment means were determined using Tukey Test as contained in the Minitab® software.

RESULTS AND DISCUSSION

Though literature (Sogunle *et al*., 2012; Damaziak *et al*., 2013) has firmly established housing system as a major factor influencing physical and sensory properties of meat, this study observed housing system effect was negligible on physiochemical properties of ground turkey patties (Table 1). This could be due to the fact that raw meats that were obtained from turkey carcasses were processed into patties using similar degree of mincing to achieve similar particle size and structure. This corroborates the report of Fernández–López *et al.* (2000) that cutting and mincing of raw meat were particularly important processes that greatly tenderized the initial material thus leading to a homogenous final product. However, the effect of cut-part used significantly ($p<0.05$) affected all parameters measured. Ranges of values recorded for pH (6.45 – 6.74), cooking loss (25.06 – 28.85%), chilling loss (4.41 – 7.92%), and diameter shrinkage (11.77 – 14.58) revealed patties prepared from thigh was significantly ($p<0.05$) higher.

In Table 2, housing system effects on sensory analysis of ground turkey patties was not significant. However, the effect of cut-part significantly ($p<0.05$) affected all parameters measured except chewiness. The range of sensory scores; appearance (3.90 – 4.92), oiliness (4.28 – 6.20), flavour (5.53 – 6.23) and overall acceptability (5.48 - 6.65) were significantly ($p<0.05$) higher in breast patties. However, the score for oiliness was higher in thigh patties which could be traced to the fat content of the raw material used for patty production. Earlier studies (Huda *et al.,* 2011; Chen *et al.,* 2016)

reported higher fat content in the thigh of poultry when comparing with breast. Thus, indicating that a raw material with a high fat content will equally increase the oiliness of the final product. Furthermore, interaction between sex and muscle type significantly ($p<0.05$) influenced patty appearance.

CONCLUSION AND RECOMMENDATION

From this study, breast patties had reduced oiliness score as well as better pH and overall acceptability. Therefore, the use of turkey breast as raw material for ground patties production was recommended.

EVALUATION OF *OCIMUM GRATISSIMUM* AND *OCIMUM CANUM* ON THE CARCASS AND ORGANOLEPTIC PROPERTIES OF BROILER CHICKENS MEAT

Salihu, E.A., Onimisi, P.A., Omage, J.J., Taruwa, A., Yaqoob, R.
Department of Animal Science, Ahmadu Bello University, Zaria

ABSTRACT
The study was carried out to determine the effect of *Ocimum gratissimum* and *Ocimum canum* on the carcass characteristics and organoleptic properties of broiler chickens. A total of 396 day old Cobb 500 broiler chicks were randomly allotted to six dietary treatments each replicated thrice with 22 birds in a completely randomized design. Six treatment diets were formulated containing 0g of experimental materials as control, 400 and 800g of *O. gratissimum* (T2 and T3), 400 and 800g of *O. canum* (T4 and T5) while oxytetracycline as recommended by the manufacturer was used as positive control (T6). All data collected were subjected to analysis of variance and significant differences among treatment means were compared using Tukey procedures. Carcass characteristics of cut parts showed that birds on 400g of *O. gratissimum*, 800g of *O. canum* and antibiotics growth promoters (AGPs) had higher ($p<0.05$) drumstick and breast cut percentages. Organ weights were significantly higher ($p<0.05$) for birds fed diets containing *Ocimum spp.* at 800g/100kg diets. Abdominal fat were lower for birds fed diets containing *O. gratissimum* and *O. canum* at 800g/100kg diets. The result of sensory analysis showed that the meat of broiler chickens in the treatment groups supplemented with *O. gratissimum* and *O. canum* had higher eating and sensory attributes. Inclusion of *O. gratissimum* and *O. canum* in broiler chickens diets significantly improved carcass traits and eating quality.
Keywords: Sensory, quality, essential oil, antibiotics, phytobiotics.

INTRODUCTION
Antibiotics growth promoters (AGPs) have been used for about 50 years to enhance growth performance (Dibner and Richards, 2005). It has been used widely not only to prevent and treat poultry diseases, but also for the improvement of meat and egg production (Ogle, 2013). Natural growth promoters (NGPs) such as prebiotics, probiotics, synbiotics, enzymes and plant extracts can be used to feed broilers without any adverse effect on the performance of birds (Akhtar *et al*., 1984). *Ocimum gratissimum* and *Ocimum canum* as NGPs can be used as an alternative to common artificial growth promoters like antibiotics both to improve growth performance, carcass characteristics and eating quality. These aromatic leaves has been reported to retain their flavor and other qualities even after drying (Mandal *et al*., 2010). The study was undertaken therefore to evaluate the essential oil of *Ocimum gratissimum* and *Ocimum canum* leaves as additives on the carcass and organoleptic assessment of broiler chickens meat.

MATERIALS AND METHODS
Experimental site
The experiment was conducted at the Poultry Unit of the Department of Animal Science Teaching and Research farm, Ahmadu Bello University, Zaria, Kaduna State. Zaria is in the Northern Guinea Savannah zone, on longitude 11° 09' 01.78'' N and 7°39'14.79''E 671m above sea level with a mean annual rainfall of 700-1400mm (IARMS, 2019).
Experimental design and management of birds
Three hundred and ninety six day old Cobb 500 broiler chicks were allotted to six dietary treatments with 3 replicates of 22 birds each in a completely randomized design (CRD). The birds were housed in deep litter pens and managed with all necessary routine management practices. Feed and water were provided *ad libitum* throughout the experimental period. Six treatment diets were formulated to meet the requirements of the birds for the starter and finisher phases respectively containing 0g, 400g and 800g of *Ocimum gratissimum* and 400g and 800g of *Ocimum canum* as additives and oxytetracycline as recommended by manufacturer as positive control.

Carcass analysis
At the end of the finisher phase, 3 chickens were randomly selected from each treatment, representing the average weight of the group for carcass evaluation. The selected birds were starved of feed, bled by severing the jugular vein and then scalded in hot water to remove the feathers. Live weight for

each chicken, dressed weight, prime cuts and weight of organs were measured. Dressing percentage was calculated. The organs and cut parts were expressed as a percentage of live weight and dressed weight respectively.

Sensory evaluation

The meat was assessed for flavour, tenderness, juiceness, texture, colour and overall acceptability with a structured questionnaire on a 5-point Hedonic scale (5-like very much, 4-like, 3-neither like nor dislike, 2-dislike, 1-dislike very much) using 30 semi-trained panelists in the Faculty of Agriculture, Ahmadu Bello University, Zaria. All needed accessories were provided; clean water, tooth-picks, detergent, biscuit and serviette were provided for the entire panelist before the evaluation. Each sample was blind coded by the researcher to reduce bias. The samples were processed by grilling at the animal product and processing laboratory of the Department of Animal Science, Ahmadu Bello University, Zaria.

Statistical Analysis

All data obtained from the experiment were statistically analysed using the General Linear Model Procedure of Statistical Analysis Systems software package while significant difference between treatments means were separated using Tukey Procedure (SAS, 2002).

RESULTS AND DISCUSSION

Carcass characteristics of broiler chickens fed diets containing *Ocimum gratissimum* and *Ocimum canum*

The carcass characteristics of broiler chickens fed diets containing *Ocimum gratissimum* and *Ocimum canum* is presented in Table 1. There were significant differences ($p<0.05$) in all parameters measured except for thigh, back, gizzard and lungs percentages. The results obtained showed that birds fed dietary supplements of *Ocimum canum* at 800g/100kg diet and AGPs had higher ($p<0.05$) dressed weight and dressing percentage than those fed diets containing *Ocimum gratissimum* and the control. Result of the cut parts showed that birds on 400g of *Ocimum gratissimum*, 800g of *Ocimum canum* and AGPs had higher ($p<0.05$) drumstick and breast cut percentages. Organ weights were significantly higher ($p<0.05$) for birds fed diets containing *Ocimum gratissimum* and *Ocimum canum* at 800g/100kg diets. The enlargement of these organs may be due to their involvement in detoxification of the materials. Studies have reported that the use of antibiotics as a growth promoter has ability to improve weight gain as well as carcass yield of birds (Al-Kassie, 2010). The result is in agreement with Khaksar *et al*. (2012) who reported significant improvements in some carcass traits due to inclusion of thyme essential oils. However, Schulze *et al*. (2008) did not observe a significant effect in the broiler carcass yield due to the dietary inclusion of essential oil blend based on thyme and cinnamon. Abdominal fat were lower for birds fed diets containing *Ocimum gratissimum* and *Ocimum canum* at 800g/100kg diets. Percent abdominal fats reduces as the inclusion levels of the experimental materials increases. The findings of this study agrees with that of Myandoab and HosseiniMansoub (2012) who reported that licorice extract lowered abdominal fat level.

^{abc}Means with the same superscripts along the rows are not significantly different (p>0.05), SEM: standard error of means, Oxytet: Oxytetracycline.

Sensory attributes of meat from broiler chickens fed diets containing *Ocimum gratissimum* and *Ocimum canum*

The organoleptic evaluation of food products to any food processing technology is very important in determining the consumer acceptability. The result of sensory analysis for the meat of broiler chickens fed dietary supplement of *Ocimum gratissimum* and *Ocimum canum* is presented in Table 2. The results obtained shows that there were significant differences (P< 0.05) for all the sensory parameters evaluated. Meat of the broiler chickens in the treatment groups supplemented with *Ocimum gratissimum* and *Ocimum canum* had higher eating and sensory attributes. Sensory parameters had higher organoleptic attributes for the birds in the treatment groups fed diets supplemented with *Ocimum gratissimum* and *Ocimum canum* than the control and AGP groups. This implies that addition of these phytogenic feed materials improved the eating quality of broiler chicken meat which may be due to higher aromatic fluids and essential oil in these botanical which makes them to maintain desirable culinary properties. Okubanjo *et al*. (2010) in their study also reported higher culinary properties for spent layers chicken meat tenderized with an additive.

Table 2: Sensory evaluation of broiler chicken meat fed diet containing *Ocimum gratissimum* and *Ocimum canum*

Parameters	Inclusion levels of experimental materials (g/100kg diet)						SEM
		Ocimum gratissimum		*Ocimum canum*			
	0	400	800	400	800	Oxytet	
Colour	4.13^{bc}	4.68^{ab}	4.87^{a}	4.61^{ab}	4.84^{a}	3.87^{c}	0.34
Texture	3.97^{bc}	4.65^{ab}	4.87^{a}	4.55^{ab}	4.77^{a}	3.84^{c}	0.35
Flavour	3.45^{c}	4.85^{a}	4.87^{a}	4.58^{ab}	4.81^{a}	3.77^{bc}	0.42
Tenderness	3.74^{c}	4.42^{b}	4.87^{a}	4.74^{ab}	4.65^{ab}	3.97^{c}	0.34
Juiciness	3.32^{c}	4.55^{a}	4.88^{a}	4.61^{a}	4.84^{a}	4.03^{b}	0.37
Acceptability	3.45^{b}	4.77^{a}	4.94^{a}	4.84^{a}	4.94^{a}	3.48^{b}	0.37

^{abc}Means with the same superscripts along the rows are not significantly different (p>0.05), SEM: standard error of means, Oxytet-Oxytetracycline.

CONCLUSION

Addition of *Ocimum gratissimum* and *Ocimum canum* in broiler chickens diets at 800g/100kg diet significantly improved carcass characteristics and organoleptic properties of broiler chicken meat.

RECOMMENDATIONS

Ocimum gratissimum and *Ocimum canum* at 800g/100kg diets as an alternative to synthetic antibiotic growth promoters for improved carcass traits and better eating quality of broiler meat.

ABSTRACT
This study was conducted to investigate the sensory characteristics of muscle obtained from broiler breast meat fed Mannan oligosaccharides (MOS), ginger and garlic supplemented with ROVABIO enzymes. One hundred and twenty (120) broiler birds were assigned to four treatment groups of ten birds per replicate of three replicates per treatment. In treatment 1, the birds were fed control diets with ROVABIO enzymes only, while treatments 2, 3 and 4 were fed control diets supplemented with MOS, ginger and garlic supplemented with ROVABIO enzyme respectively. Sensory characteristics such as Color, juiciness, Meaty flavor, Tenderness, Saltiness, overall flavor and acceptability were measured using a 9 point hedonic scale. Results showed no significant difference (P>0.05) amongst treatment means.
***Keywords**:* Mannan Oligosaccharides, Ginger and Garlic, Enzymes

INTRODUCTION
There has been a resurgence of interest in improving the physicochemical and sensory properties of meat, as well as its storage life. In pursuit of improved chicken healthiness and in order to fulfil consumer expectations in relation to food quality, poultry producers more and more commonly apply natural feeding supplements, mainly herbs (Gardzielewska *et al*., 2003). Spices are very common as useful additives in broiler diets (Zhang *et al*., 2009). The supplementation of spices and herbs have many benefits to broilers health and performance such as having anti oxidative potential (Hui, 1996), antimicrobial activity and enhancing digestion by stimulating endogenous enzymes (Dorman and Deans, 2000). A major problem in the meat industry is a reduction in the acceptability and nutritional quality of meat as well as changes in flavor due to the process of lipid oxidation. Therefore, the development of new convenient meat and meat products with natural flavor and taste. (Cannon *et al*., 1995). As a result, an approach to overcoming the lipid oxidation problem of the meat industry is to use dietary garlic and ginger supplementation in animals which can reduce lipid stability (Kim *et al*., 2005).

Mannan Oligosaccharides (MOS) are widely used in nutrition as natural additives and has been used in poultry which showed an improvement in performance, feed conversion and meat quality. Pelicano *et al*. (2003) reported that the concomitant use of MOS in water and feed increases meat quality in relation to color, pH and tenderness. ROVABIO® enzyme is a unique enzyme known to reduce feed costs while consistently maintaining or increasing animal performance and high carcass yield. Hence this study.

MATERIALS AND METHODS
This study was carried out at the meat quality laboratory of the Department of Animal Production and Health, Federal University of Agriculture (FUNAAB), Abeokuta, Ogun State.
A total of 120 broiler birds, were divided into four treatment groups. Each group containing three (3) replicates of 10 birds.
Experimental Layout and Birds Management: Each birds were fed diets containing; Treatment l = Control feed supplemented with ROVABIO® enzyme; Treatment 2 = Feed supplemented with ROVABIO® enzyme containing 0.5g/kg Mannan Oligosaccharide (MOS); Treatment 3 = Feed supplemented with ROVABIO® enzyme containing 0.5g/kg ginger; Treatment 4 = Feed supplemented with ROVABIO® enzyme containing 0.5g/kg garlic were fed to all the birds for 6 weeks after brooding with commercial ration for 2 weeks. The experimental diet used for this study is stated thus:Crude protein 23, 5%, Crude fat 4.31 and Metabolisable Energy (MJ/kg) 10.94Mj/ kg.

Daily routine management was carried out such as supply of clean water, feed, observing for sick birds, checking for mortalities and appropriate record keeping.

Slaughtering and processing of birds: At the end of the 8th week, three birds per treatment were killed using the traditional method. Feathers were removed by scalding in hot water at 60°C. Breast muscle was excised to determine sensory quality characteristics.

Sensory evaluations: samples of chicken meat cooked at 70° C for 30 minutes were assessed by ten (10) panelists, where some meat qualities parameters such as color, juiciness, meaty flavor, tenderness, saltiness, overall flavor and overall acceptability were scored using a 9-point Hedonic scale (1=dislike extremely, 2=dislike very much, 3=dislike moderately, 4=dislike slightly, 5=intermediate, 6=like slightly, 7=like moderately, 8=like very much, 9=like extremely) as described by Sanwo *et al.* (Sanwo *et al*., 2014)

Statistical Analysis

All the data obtained were subjected to a completely randomized design in a one way analysis of variance using SPSS 16 (2005) the means were separated using the Duncan's Multiple Range Test (DMRT) (Steel *et al.,* 1997).

RESULTS AND DISCUSSION

The results of the sensory evaluation of broiler breast muscle fed Mannan oligosaccharides, ginger and garlic with enzyme is presented in Table 1. All values obtained were not significant (P>0.05) in this study. However numerically, meat obtained from birds fed the control diet were most preferred in color, juiciness, meaty flavor, and overall acceptability except for saltiness and overall flavor which were most preferred in meat of birds fed diet containing control diet, Mannan Oligosaccharides and Enzyme. Birrenkott *et al*. (2000) reported no difference in flavor in eggs from hens consuming up to 3% dietary garlic powder. Their results may be because of differences in supplemental levels, feeding duration, or preparation method. Nassu *et al*. (2003) reported that an antioxidant such as garlic directly retards oxidized aroma and flavor. Although, results did not show significant differences, the increase in flavor of ginger and garlic-treated samples could be attributed to flavor-producing reactions that occur during cooking (Pawer *et al*., 2007). However, closely similar values were obtained for overall flavor in treatments 3 and 4. Also, difference in sensory attributes between the treatments recorded higher tenderness score for the samples obtained from treatment 4 which had garlic supplementation (7.19) but had the lowest value for juiciness. Dietary supplementation with MOS treatment resulted in a less desirable color and flavor score (5.71 and 5.77 respectively). Meat from birds fed MOS were saltier than meat from birds fed other supplements with ginger having the lowest value for saltiness.

In conclusion meat of chickens obtained from broilers birds fed mannan oligosaccharides, ginger and garlic supplemented with enzymes did not have any effect on the sensory characteristics

ABSTRACT
This study aims at identifying a suitable method that will significantly reduce the rate at which biological and physiochemical changes occur within the egg with respect to storage and temperature. A total of 600 fertile and non-fertile eggs of Lohmann brown hen were collected from Poultry Division of National Veterinary Research Institute, Plateau State (NVRI) in four successive weeks and used for this study. The eggs were stored at room temperature (ambient) and refrigeration at 10°C for 0, 5, 10, 15 and 20 days. Egg were boiled, served to taste panelists of 20 trained personals in a 2 x 2 Factorial arrangement in a completely randomized design. Data obtained were analyzed using ANOVA at $\alpha_{0.05.}$ The results reveals that there was no significant difference ($p>0.05$) existed among odour, aroma, taste, texture and overall acceptability for all the treatments. However, there was significant difference ($p<0.05$) between fertile and non-fertile eggs colour. The colour and texture was observed to be statistically significant ($p<0.05$) in all the storage days 0, 5, 10, 15 and 20 for both fertile and non-fertile eggs stored in room and refrigerator temperature. The colour of non-fertile eggs was recorded to be the highest at day 10 of refrigerator temperature. While the texture of fertile eggs was recorded to be the highest at day 10 and 15 of room temperature. There is no adverse effect of storage days and temperature on sensory evaluation of eggs from both the fertile and non-fertile.

Keywords: Sensory evaluation, storage days, storage temperature, fertile eggs and non-fertile eggs.

INTRODUCTION
Eggs are highly palatable and can be prepared or utilized in a number of ways. Eggs are perfectly balanced foods containing proteins, vitamins (except vitamin C) and minerals required for good health by both the young and old (NECC, 2014). Eggs could be fertile, non-fertile and unfertile. If the egg is infertile, the germinal disk contains the genetic material from the hen only. If the egg is fertile, it contains genetic material from both parents and is where embryonic development begins. The yolk material serves as a food source for embryonic development (Jacqueline *et al.*, 1998).

The main degradation factors for eggs are storage days (time), Bell (1996), temperature, humidity, air movement, and handling (Stadelman 1995; Samli *et al.*, 2005). Internal quality deterioration of eggs can be retarded significantly by maintaining storage temperature, because quality deterioration occurs faster at high temperatures than at refrigerated temperatures during storage (Zeidler, 20023). Therefore, the present study has been undertaken to determine the effects of storage days and temperature on sensory qualities of fertile and non-fertile eggs.

MATERIALS AND METHODS
Experimental site: The experiment was conducted at microbiology and biotechnology laboratory of the Pharmaceutical sciences, University of Jos, Jos-North Local Government Area (LGA) of Plateau State. It is situated at the extreme North of the State and located between latitude 9^0 E55' North of the Greenwich meridian and longitude 8^0 E54' East of the Equator (Haruna *et al.*, 2007).
Collection of experimental material
A total of 600 fertile and non-fertile eggs was collected from Poultry Division of National Veterinary Research Institute, Plateau State (NVRI) in four successive weeks were used for this study. Eggs were

obtained from Isa brown female chickens. The eggs were stored at room temperature (ambient) and refrigeration at 10°C for 0, 5, 10, 15 and 20 days and humidity was 55 to 60% for all treatments.

Sensory evaluation

A total of 20 trained individuals aged between 20 and 40 years were used to assess two replicate of the prepared eggs. The samples were evaluated using a 9-point hedonic scale for flavor, colour, juiciness, tenderness, and overall acceptability The scale had a maximum score of 9 while the lowest score of 1 was assigned to the poorest condition (Mahendraker *et al.*, 1988).

Experimental design

2 x 2 Factorial arrangement in a completely randomized design.

Statistical analysis

Data collected were analyzed using General linear model of SAS (SAS 2010). Statistical variations were observed and means were separated using Duncan's multiple range test.

RESULTS AND DISCUSSIONS

The main effect of temperature difference on sensory evaluation of fertile and non-fertile eggs are shown in Table 1. There was no significant difference ($p>0.05$) that existed for odour, aroma, taste, texture and overall acceptability for all the treatments. However, there was significant difference ($p<0.05$) between fertile and non-fertile eggs colour. The highest colour was recorded non-fertile egg stored under room temperature which the least colour was observed on fertile egg stored under room temperature. The result obtained for colour could be due to fertilization process and moisture content that losses during storage.

The interaction effect of storage days and temperature difference on sensory evaluation of fertile and non-fertile eggs is presented in Table 2. The colour and texture was observed to be statistically significant ($p<0.05$) in all the storage days 0, 5, 10, 15 and 20 for both fertile and non-fertile eggs stored in room and refrigerator temperature. The colour of non-fertile eggs was recorded to be the highest at day 10 of refrigerator temperature. While the texture of fertile eggs was recorded to be the highest at day 10 and 15 of room temperature.

Table 1: Main effect of temperature difference on sensory evaluation of fertile and non-fertile eggs

Parameter	Fertile Egg		Non-Fertile Egg		SEM

ABSTRACT

This experiment was carried out at Post-Graduate Laboratory, Department of Chemistry, University of Jos, Jos Plateau state. Twenty spent layers' hen was used for this study. The fresh turmeric was purchased at Fari gada market, washed and blended with distilled water and the deboned spent hen meat was cut into primal cut. The breast, thigh and drumstick were mainly used. The marinated carcass was kept in the refrigerator at the temperature of 10^0C overnight in 0%, 5%, 10% and 15% of 1L inclusion levels respectively. On the basis of this experiment, the following meat quality and tenderness parameters were evaluated, shear force (SF), water holding capacity (WHC), extract released volume (ERV) and pH, in a completely randomized design. Data were analyzed using descriptive statistic and ANOVA at $\alpha_{0.05.}$ As the levels of inclusions increased, the shear force value decreases. 15% of turmeric extract had the lowest shear force value while control without turmeric extract had the highest shear force values. As the inclusion level increased, the water holding capacity increases. More so, the extract released volume result shows that the control had the lowest value of (17.50%) without turmeric extract while spent layer meat tendered with turmeric extract at 5% had the highest value of (43.75%). The mean pH value was higher in meat from 15% turmeric extract while the control meat had the lowest pH value. In conclusion, spent layers meat can be marinated in turmeric extract up to 10 – 15% /L due to improvement of tenderness.

Keywords: Turmeric extract, spent layer, tenderness, marinate and shear force

INTRODUCTION

Tenderness has been shown to have the largest role in consumer purchasing decisions (Mennecke, Townsend, Hayes, & Lonergan, 2007). The tenderness of a piece of meat is a result of several factors which can be considered sequentially. Spent layers are raised to lay eggs, and when their productivity declines, they are processed for their meat which is tough. A number of attempts have been made to tenderize and improve the qualities of meat such as spent layer meat.

There have also been attempts to physically tenderize meat by pressure treatments, electrical stimulation and the use of enzymes Proteolytic enzymes derived from plants such as papain, bromelain and ficin have been widely used as meat tenderizers in most parts of the world (Wada *et al.*, 2002). Such Proteolytic plant enzymes can be found in turmeric. The aim of the study is to seek the effect of the endogenous enzyme level of turmeric as a meat tenderizer on spent layer meat.

MATERIALS AND METHODS

Experimental site

This experiment was carried out at Post-Graduate Laboratory, Department of Chemistry, Faculty of Natural Science, University of Jos, Jos Plateau state. On latitude 9.9181^0N and longitude 8.8804^0E

Methodology

Twenty spent layers' was used for this study. The birds were slaughtered following standard procedure, dressed hygienically and manually deboned. The fresh turmeric was obtained from Our Lady of the Angels Cistercian Monastery, P. O. Box 6976, Nsugbe, Onitsha Anambra State, Nigeria., washed and blended with distilled water and the deboned spent hen meat was cut into primal cut. The breast, thigh and drumstick were mainly used. The marinated carcass was kept in the refrigerator at the temperature of 4^0C overnight to ensure easy mincing and marinated in 0%, 5%, 10%and 15% of 1L inclusion levels respectively.

On the basis of this experiment, the following meat quality and tenderness parameters were evaluated.

Shear Force Value

The objective evaluation of tenderness was performed using the modified Warner Bratzler shear force procedure (Bouton and Haris, 1978).

Physical evaluation

1. **Water holding capacity**

Water Holding Capacity (WHC) was determined according to Wardlaw, Maccaskill, and Acton (1973).

2. **Determination of extract release volume (ERV)**

The technique was first described in Jay, 1964, has been shown to be a value in determining incipient spoilage in meat as well as in predicting refrigerator shelf life.

3. **pH**

pH value was taken according to method described by AOAC (2000).

Experimental Design and layout

Completely randomized design.

Data analysis

The data obtained was statistically analyzed with the SPSS program for Windows (SPSS version 11.5, SPSS Inc., Chicago, IL, USA). Duncan's multiple-range test was used to compare the different between the means.

EFFECT OF MAIZE REPLACED WITH COCONUT CAKE MEAL ON GROWTH PERFORMANCE, CARCASS CHARACTERISTICS AND ECONOMICS OF PRODUCTION OF NOILER STRAIN OF CHICKEN

M. A. Ayoola (PhD) & O. A. Dada

Animal Production Unit, Department of Agriculture, Adeyemi College of Education, Ondo.
Email: mayoola1@yahoo.co.uk

ABSTRACT
A research was conducted to evaluate the effect of replacing maize with varying levels of coconut cake meal (CCM) in the diet on the performance, carcass characteristics and economics of production of noiler strain of chicken. Five treatment diets were formulated in which CCM replaced maize at 0, 10, 20, 30 and 40% levels using a completely randomized design in two replications with ten birds per replicate. The study lasted for 8 weeks during which growth performance, carcass characteristics and economics of production were assessed after the experiment. The results showed that feed intake were significantly higher ($P<0.05$) in noiler fed 30-40% levels of maize replaced with CCM when compared with the control. Also, tested diets have no significant effect on the final weight, total and daily weight gain of birds fed the 40% level of maize replacement with CCM when compared with the control. Price/Kg feed reduced with increased level of CCM in the diet. Also, Price/Kg bird produced reduced for birds at 40% level of maize replacement but not statistically ($P>0.05$) different. Tested diets exert no significant difference ($P>0.05$) on the percentage weight of primal parts and vital organs of the noiler birds. It could therefore be suggested that maize could be replaced with CCM up to 40% level in noiler diet as this will reduce the Price/Kg of feed and the competition for maize between man and livestock industry.

INTRODUCTION
Poultry is one of the fastest means to achieving appreciable improvement in the nutritional standard of the populace because of its short generation interval, quick turnover rate and relatively low capital investment (Ani and Okeke, 2011).

In Nigeria, where the production of animal protein falls far short of meeting the demands of a rapidly growing population, poultry is the most common livestock kept (Obi, 2001). With the increasing population in Nigeria, there is need to fast track the process of poultry production especially meat and egg so as to meet up with protein needs of the population. To achieve this, a dual purpose chicken breed like Noiler is unavoidable. Noiler is an hybrid of broiler and cockerel with high resistance of cockerel and meat characteristics of broilers (Agricinfo.com, 2018).

Feed remains the most expensive input in poultry production with cereal grain constituting more than 40% of the feed cost (Oyedeji *et al,* 2003). Several workers have emphasized the need for utilizing alternative feed ingredients which have no competition between human and livestock industry (Fanimo *et al., 2007*; Nsa *et al.*, 2010).

Coconut meal is a by-product of coconut extraction. It is relatively high in residual oil which makes it a valuable energy source with high potential to serve as alternative to maize in ration formulation (Daghir, 2008)and noiler diet. Sundu *et al.*, (2009) reported possible utilization of coconut meal in broiler diet, However little or no information is available on the utilization of coconut cake meal as partial replacement of maize in noiler diet. This research is therefore conducted to assess the effect of replacing maize with coconut cake meal on growth performance, carcass characteristics and economics of production of noiler strain of chicken.

MATERIALS AND METHODS
One hundred, five weeks old noilers were used for this experiment. The birds were randomly allotted to five experimental groups, replicated twice with ten (10) birds per replicate in a completely randomized design.. The initial weights of the birds were taken before the commencement of the trail. Experimental diets were formulated such that maize was replaced with coconut cake meal at 0, 10, 20, 30, and 40% levels.

Table 1: Percentage Composition of Experimental Diet

Ingredients	Levels of Replacement (%)				
	0	10	20	30	40
Maize	65.0	58.5	52.0	45.5	39.0
Coconut Cake	0.0	6.5	13.0	19.5	26.0
Concentrate	27.5	27.5	27.5	27.5	27.5
Wheat Offal	7.5	7.5	7.5	7.5	7.5
Total	100	100	100	100	100

Birds were fed twice daily for a period of 56 days. Feeds were weighed before given to birds and the weight of leftover were also taken on daily basis to determine the feed consumption. Weekly weight gain were determined throughout the experimental period.

At the end of the eight weeks feeding trial, 4 birds were selected per treatment making a total of 20 birds for carcass and organ evaluation. The birds were slaughtered following the conventional method and allowed to bleed. These were later defeathered eviscerated and cut into primal parts. The weights of parts and organs were taken. Cost of diets was calculated by summing up the cost of each ingredient that make up 25kg of each treatment diet, which was thereafter reduced to cost in naira per kilogramme of diet.
Data collected were analyzed using Analysis of Variance (ANOVA) and the significant differences between means were separated using Duncan Multiple Range Test with the aid of Statistical Package for Social Sciences (SPSS) Version 20.

RESULTS AND DISCUSSION

Table 2: Effect of replacing maize with coconut cake meal on the growth performance and economics of production of Noiler strain of chicken.

Parameters	Levels of Replacement (%)					SEM
	0	10	20	30	40

Total Weight Gain (g)	1419.5^{b}	1279.75^{ab}	1414.15^{ab}	1233.5^{a}	1290.5^{ab}	23.81
Weekly Weight Gain (g)	177.44^{b}	159.97^{ab}	176.63^{b}	151.82^{a}	157.06^{ab}	2.96
Daily Weight Gain (g)	25.35^{b}	22.85^{ab}	25.23^{b}	21.69^{a}	23.05^{ab}	0.43
Total Feed Intake (g)	5223.2^{a}	5425.85^{b}	5538.5^{c}	5571.0^{c}	5657.50^{d}	16.17
Weekly Feed Intake (g)	672.0^{a}	676.55^{a}	692.10^{b}	696.38^{b}	706.10^{c}	1.84
Daily Feed Intake (g)	95.10^{a}	96.65^{a}	98.87^{b}	99.49^{b}	100.10^{c}	0.026
Feed/ Gain Ratio	3.88^{a}	4.39^{abc}	4.04^{ab}	4.66^{c}	4.54^{bc}	0.08
Feed Efficiency	0.27^{c}	0.24^{ab}	0.26^{bc}	0.22^{a}	0.25^{a}	0.01
Price/Kg Feed (₦)	126.1^{e}	118.93^{b}	111.78^{c}	104.64^{b}	97.68^{a}	1.01
Feed /Kg Bird (₦)	489.90^{ab}	522.10^{b}	451.37^{ab}	485.59^{ab}	443.47^{a}	9.08

abc: Mean value within row carrying different super scripts differ significantly (P<0.05).
NS: Non Significant

The result shows that there is no significant (P>0.05) difference in the initial weight of birds used for this experiment and thus has no influence on final weight gain.

There is no significant difference in the final weight, total and daily weight gain of birds fed 40% level of maize replaced with coconut cake meal when compared with those fed the control. This result is contrary to the observation of Bernade *et al,* (2001) who reported that the final weight of the broiler birds fed coconut cake meal based diet was significantly higher when compared with the control.

Result shows that the total and daily feed intake of noiler fed maize replaced with coconut cake diet at 30-40% level of replacement were significantly higher when compared with the control. This result is similar to that of Bawa *et al.*,(2006) who reported that feed intake is significantly higher in rabbit fed 40% levels of graded palm kernel cake when compared with the control while feed efficiency is significantly lower at these levels of replacement when compared with the control. Price/Kg feed reduced with increased levels of coconut cake meal in the diets. The cost of the diets was influenced by the low cost of CCM when compared with maize that was replaced Price/Kg bird produced in naira is lower in birds fed 40% level of maize replacement when compared with the control though not statistically (P>0.05) different. This results was in conformity with that of Onunkwo *et al* (2018) when they fed duck with maize replaced with Palm Kernel Cake Meal (PKCM) . They reported significant low reduction in the price of feed and that of duck eggs produce with maize replace with PCKM diets.

Intestine WT (%)	3.93	4.28	4.77	4.23	3.90	0.16NS

abc: Mean within a row carrying different super scripts differ significantly (P<0.05).
NS: Non Significant; SEM- Standard Error of the Mean

The result shows that there is no significant difference in the percentage weight of primal parts of noiler fed maize replaced with coconut cake meal across the treatments. Test diets exert no significant difference on the internal and external offals of the experimental bird. This result is in agreement with Medegu, (2010) who reported no significant difference in the fat weight of broiler placed on varying levels of coconut cake meal diet.
Percentage weight of vital organs like heart and liver were not influenced by the diets which suggests that inclusion of coconut cake meal in noiler diet is not deleterious to the birds.

CONCLUSION

Coconut cake inclusion in noiler diet significantly increased bird feed intake at 30-40% levels of maize replacement. However, the diet exerts no significant difference in birds final weight, total and daily weight gain at 40%level of maize replacement when compared with the control. Birds primal parts and offals percentage weights were not influenced by the tested diets. It could therefore be suggested that coconut cake meal could be incorporated in noiler die up to 40% level of inclusiont,

this will reduce the Price per Kg of feed and the Price/Kg of birds produced, particularly in Nigeria where the waste is of no economic value in human diet.

RECOMMENDATION

The following recommendations were made

i. Coconut cake meal may replace maize up to 40% with satisfactory results in the diets of noiler.
ii. Maize replaced with coconut cake meal at 40% gave the satisfactory result economically.
iii. Coconut cake meal to be used should not be stored for long time before use to avoid rancidity of the feed ingredient.

NUTRITIONAL QUALITYAND MICROBIOLOGICAL PROPERTIES OF MEAT FLOSS PREPARED FROM MUTTON

***Akinleye S. B., Omojola, A. B., Kassim O. R. & Iyanda O. D.**
Meat Science Laboratory, Department of Animal Science, University of Ibadan, Oyo State.
Corresponding Author: bamideleakinleye@yahoo.com

ABSTRACT
Mutton is an excellent source of biological value with its inherent low fat content, however, it has untapped market as a good potential for value added meat products. Therefore, it is necessary to appraise the nutrient composition of meat floss (MF) from different breeds of ram.
Five kilogram of *Semitendonisus* muscle was harvested from carcasses of four breeds of rams consisting of West African Dwarf (WAD), Yankasa (YK), Uda (UD) and Balami (BA) intensively fattened for ninety days. Cooking loss (CL), water holding capacity (WHC), moisture contents (MC), crude protein (CP) and ether extract (EE) of mutton and freshly prepared meat floss (MF) were determined. Thiobarbituric Acid Reactive Substances (TBARmgMDA/100g) and microbiological counts (MC) (log 10^2cfu/g): Total Aerobic Counts (TAC), Total Coliform Counts (TCC) and Total Fungal Counts (TFC)) at the seventh day were determined. The CL (38.19%, 39.51%) of WAD and YK mutton were significantly higher ($P<0.05$) while their WHC (61.49%, 59.97%) were lower than UD and BA. The CP (23.16%) and EE (5.85%) of BAM were higher ($P<0.05$). The CP were (46.75%, 48.73%, 47.82%, 49.60%) and EE (25.69%, 25.46%, 25.88%, 27.35%) for WAD, YK, UD and BA, respectively. The TBAR ranged from 1.12-1.17 mgMDA/100g. The mean MC (log 10^2cfu/g) on the MF from WMF was 6.76cfu/g while YMF, UMFand BMF for TAC were 4.38, 3.96 and 3.58cfu/g, respectively. The keeping qualities value of the MF does not exceed the threshold values of stored meat products, therefore, it can be inferred that MF from mutton has a high nutrient and keeping qualities profile.
Keywords: Keeping quality, Mutton, Nutrient profile, *Semitendinosus*

INTRODUCTION
Sheep production is indispensable to meet protein and some domestic needs of people throughout the world as they are sources of income and raw materials (Mapiliyao *et al*., 2012). Mutton has a high biological value with its inherent low fat contents. However, it has received little attention in consumption pattern as compared with other sources of meat such as beef and chevon, therefore has an untapped market value as a good potential for value added meat products. MF is among the popular traditional foods that constitutes an important part of Nigerian meal. Considerable progress has been made in standardization of product profile and mechanization of traditional meat products. In Nigeria, particularly in rural communities and towns, processing of carcass usually takes place under very unhygienic conditions. This coupled with high ambient temperature, high humidity, shortage of portable water and poor handling practices exposes meat products like MF to microbial contamination and rapid deterioration. Therefore, the microbiological testing at various stages of food production is relevant to reveal and understand the characteristic trends in distribution of microbiological contamination (ICMSF, 2011). Information available on meat floss specifically is usually centred on other sources of meat while little or none is available on processed mutton. However, if such information is available, it might bring into limelight the nutritional quality inherent in mutton and also help in changing the consumption pattern of the meat. Therefore, this study aimed at assessing the nutritional and keeping qualities of meat floss prepared from mutton of different breeds of ram.

MATERIALS AND METHODS
Experimental design
The study was a completely randomized design and each treatment was replicated thrice.
Meat sample: source, collection and preparation
The *Semitendinosus* used for this study was harvested from the skinned mutton carcasses of four breeds of rams (BA, UD, YK and WAD breeds) intensively fattened for ninety days. They were cut into chunks with average weight of 100g. Thirty chunks were randomly selected to have three kilograms of fresh mutton for each breed.

Production of meat floss

The steps involved in production of the meat floss were spice mixture preparation, meat preparation, cooking, shredding, frying and de-oiling following Kassim (2013). The meat chunks were cooked in a pot on an electirc hot plate (Pifco Japan Model number ECP 2002) with water added at the ratio of 1.5 litres to 1.0 kg of meat and the cooking recipe added at a ratio of 1 g to 100 g of meat. The cooking was done at an internal temperature of 72°C until the broth completely dried on the broiled mutton. The meat samples were removed from the pot and spread on a tray to equilibrate to room temperature. The cooled meat was shredded separately by pounding with a local mortar and pestle with shredding recipe at a ratio of 1.00g to 20.00g meat. The shredded meat was deep-fried in soya oil (pre-heated to 180°C) in the ratio of 1 litre to 500g of meat. The meat was fried at 70 strokes per minute for 20 minutes until they turned golden brown in colour. The products were emptied into a colander, pressure applied to drain oil and obtain a dry spongy product. Upon cooling the meat floss were separated into strands and immediately packed into an air tight container and left at room temperature.

Parameters measured

Meat Quality

Cooking loss (CL)

Cooking loss was determined (following the procedure of Honikel, 1987) in the *Semitendinosus* muscles of each breed and samples were taken in triplicates.

Thermal shortening

This was carried out according to the procedure described by Mahendraker *et al*. (1988). Cores of 0.5 cm in diameter were taken from the *semitendinosus* muscle of each breed. Each breed was replicated thrice and the average taken.

Water holding capacity (WHC)
WHC was evaluated using a method adapted from Hamm (1960), based on meat water loss when pressure is applied on it. This was determined by the press method described by Wierbicki and Deatherage (1958) as modified by Tsai and Ockerman (1981).

Product yield
The product yields of the meat floss were determined by measuring the weight of the MF for each treatment and were calculated as the ratio of cooked weight to raw weight expressed as percentage.

Microbial analysis
The microbial quality determination was carried out on the freshly prepared meat floss. The Total Aerobic Counts (TAC), Total Coliform Counts (TCC) and Total Fungi Counts (TFC) were carried out following the procedure of Garbutt (1997).

Statistical analysis
Data collected were analysed using Analysis of Variance (ANOVA) and significant means were separated using Duncan Multiple Range Test (DMRT) at 5% level of probability.

RESULTS AND DISCUSSION

The physical measured traits of mutton used in the production of meat floss are presented in Table (2). The CL ($P<0.05$) of *Semitendinosus* from YK (39.59%) and WAD (38.19%) were significantly different than 34.70% and 30.20% obtained for UD and BA, respectively. This same trend could be noticed in their TS with YK (34.67%) and WAD (33.34%) having the highest TS shrinkage than UD (29.62%) and BA (26.40%). WHC is one of the major quality characteristics of fresh meat, as it affects some major characteristics of cooked meat such as product yield, appearance and sensory properties. WHC obtained from *Semitendinosus* muscles of mutton used in this study were between 59.97 and 71.60%. BA and UD had the highest ($P<0.05$) value while WAD and YK had similar ($P>0.05$) values which were the least (Table2). The denaturation and aggregation of sarcomere could be responsible for the shrinkage observed in the thermal shortening of the mutton because the extent of sarcoplasmic and myofibrillar protein during cooking depends on the resistance of the muscle fibres to compression (Sheffler and Gerrard, 2007).

Table 2: Physical properties of raw *Semitendinosus* muscles from different breeds of rams used in meat floss production

Parameter (%)	WAD	YK	UD	BA	SEM
Cooking Loss	38.19^{a}	39.51^{a}	34.70^{b}	30.20^{c}	0.25
Thermal Shortening	34.67^{a}	33.34^{a}	29.62^{b}	26.40^{c}	0.18
Water Holding Capacity	61.49^{c}	59.97^{c}	65.60^{b}	71.76^{a}	0.14

[a, b, c] Means with different superscripts in the same row are significantly different ($P<0.05$) WAD: West African Dwarf; YK: Yankasa; UD: Uda; BA:Balami

Chemical composition of raw *Semitendinosus* muscles from different breeds of rams used for the production of meat floss
The chemical compositions of the mutton used are displayed in Table 3. The moisture content of the muscles ranged from 69.57% to 69.86% while the crude protein contents, ash, ether extracts and cholesterol of the muscles differ significantly ($P<0.05$). It ranged from 22.58% to 23.16%; 1.13%-1.30%, 5.85%to 6.44% and 0.21% to 0.29% for crude protein, ash, ether extracts and cholesterol, respectively. The average chemical analysis values for the *Semitendonisus* muscle in the present study are in agreement with the reported values in food composition tables of National Food Institute, (2009 and Chuaynukool *et al*., 2007). The differences in fat content in the meat samples could be due to the differences in genetic and non-genetic factors as reported by Bogosavljevic-Boskovic *et al*. (2010). The low moisture contents of the meat floss as compared to its raw muscles could be attributed to the fact that MF preparation involves a high thermal processing method and most of the water contained in the meat would have been dried-off during the process. It was observed that MF from BA muscle had the highest nutrient profile especially in crude protein contents, ash and ether extracts. This could be attributed to the fact that it was the muscle that has the highest nutrient profile in the raw state. It could also be as a result of its high water holding capacity because nutrient composition of a muscle

after thermal treatment depend on the ability of the muscle to hold on to its inherent water which contain the nutrients of the muscle. During thermal treatment, water would be lost with some nutrients but a muscle with high water holding capacity would have a low cooking loss thereby retaining most of its nutrients. The high product yield of MF from the mutton could be attributed to the procedure because water holding capacity and cooking loss are inversely correlated (Nasiru *et al*., 2011). The lower product yield of meat floss from WAD muscle might be attributed to the excessive fat separation and water release during cooking (Pietrasik and Shand, 2003). The increase in the ash contents of the MF compared to the raw meat could have been contributed by the added ingredients used during production. Similar observations were reported by Ogunsola and Omojola (2008) who reported that the high ash contents of kilishi is due to individual mineral levels of the spices used to give accumulative mineral level during processing. Also, the average total ash values of MF in the present study is in agreement with the reported values in food composition tables of National Food Institute, (2011) for meat products. The increasing level of cholesterol in processed samples might be as a result of the conversion of other substances from food into cholesterol during thermal degradation (Chizzolini *et al*, 1999).

Table 3: Product yield and chemical composition of freshly prepared meat floss from four *Semitendinosus* muscles of different breeds of rams

Parameter (%)	WMF	YMF	UMF	BMF	SEM
Moisture Content	10.52^{a}	10.49^{ab}	10.63^{a}	10.20^{b}	0.05
Crude Protein	46.75^{d}	48.73^{b}	47.82^{c}	49.60^{a}	0.04
Ether Extract	25.69^{c}	25.46^{d}	25.88^{b}	27.35^{a}	0.03
Ash	7.28^{c}	7.31^{c}	7.96^{a}	7.75^{b}	0.03
Cholesterol mg/g	10.11^{ab}	8.33^{c}	11.33^{a}	9.00^{bc}	0.01
Product Yield	67.07^{b}	68.42^{b}	72.31^{a}	74.44^{a}	0.58

$^{a, b, c}$ Means with different superscripts in the same row are significantly different (P<0.05). WMF = West African Dwarf Meat floss; YMF = Yankasa Meat floss; UMF =Uda Meat floss

Microbial loads of mf produced from different breeds of ram

The microbiological counts (10^{2}cfu/g) and the TBARS (mg/kg) of the meat floss is displayed in Table (4). The result revealed that there were significant differences (P<0.05) in all the microbial assessment among the products. The total aerobic counts (TAC) were 1.13, 0.73, 0.66, 0.60; while the total coliforms counts (TCC) were 0.20, 0.20, 0.36, 0.23 and the total fungal counts were 1.03, 0.46, 0.29, 0.20 for WFM, YMF, UMF and BMF meat floss, respectively. Microbial assessment of food provide a general indication of the microbiological quality of the products. The microoganisms isolated in food could come from different sources such as processing, cooking and the environment. The high fat content also can acts as a medium for the growth of microorganisms (Kumar and Sharma, 2004). The microbial counts recorded for coliforms and fungi were well below the levels of $\log10^{4}$ cfu/g and $\log10^{3}$ cfu/g that could cause microbial spoilage (Jay, 1996). Lipid oxidation is a major cause of food deterioration as it decreases nutritional properties of foods and the generation of potentially toxic reaction products. TBARS values of MF samples were illustrated in Table 4, from which it is apparent that BMF samples exhibit 0.39 mg MDA/kg meat. However, the mean TBARS values of all the MF samples in this study were found to be lower than 2.0 mg MDA/kg, accepted as the critical value of lipid oxidation for meat and meat products (D'agata *et al*., 2010).

Table 4: Microbiological quality (log 10^{2}cfu/g) and Thiobarbituric reactive substances of meat floss prepared from *Semitendinosus* muscles of different breeds of rams

Parameter	WMF	YMF	UMF	BMF	SEM
Total Aerobic Counts	1.13^{a}	0.73^{b}	0.66^{c}	0.60^{c}	0.22
Total Coliform Counts	0.20^{b}	0.20^{b}	0.36^{a}	0.23^{b}	0.24
Total Fungal Counts	1.03^{a}	0.46^{b}	0.29^{c}	0.20^{d}	0.06
TBARS(mg MDA/100g)	0.38	0.37	0.38	0.39	0.03

$^{a, b, c}$ Means with different superscripts in the same row are significantly different (P<0.05). WMF=West African Dwarf Meat floss; YMF = Yankasa Meat floss UMF = Uda Meat floss; BMF = Balami Meat floss

CONCLUSION

The nutritional and keeping qualities of meat floss as revealed in this study indicated that mutton is a meat with high biological value which is inversely proportional to its consumption pattern. It could be recommended that the spices should be subjected to treatment that would reduce the microbial load of the products to avoid introduction of pathogens that might bring about spoilage and contamination of the product.

ABSTRACT

This Supervised Enterprise Project (SEP) was conducted in order to create awareness, empower and impart the skills and knowledge of sustainable techniques of milk processing by converting it to yoghurt. The project empowered thirty rural women leaders in Rano town, Rano LGA of Kano State on how to make yoghurt from fermented cows' milk (nono), thus helping them economically. One hundred questionnaires were distributed to one hundred households in order to assess socio-economic aspects of milk producers in Rano LGA. Chi-square and simple descriptive statistics were used to analyse and describe the data collected. Majority of the farmers had poor knowledge of improved yoghurt processing prior to this project. However, all the farmers reported to have improved their yoghurt processing skills after the project. Furthermore, majority of the farmers indicated willingness to adopt the technology acquired. Chi-square analysis showed that there was a significant ($p<0.05$) difference in willingness to adopt the yoghurt technology between owners of large and small herds, which indicates that, farmers with large number of animals in their herd were more willing to adopt yoghurt technologies than those with fewer animals.

Keywords: Yoghurt, women, empowerment

INTRODUCTION

Fresh Milk is highly perishable, as such, it should be immediately consumed in its fresh form (Yahuza, 2000). Fresh Milk can also be processed into fermented products which could improve the quality and nutritive value (Cashman, 2002).

The problem of low milk yield and of low quality in dairy cattle under tropical environment is held as one of the most important limiting factor to the rapid growth of the dairy industry in Nigeria, and the problem is attributed to a number of factors, which included climate, genetic potential of breeds, inadequate nutrition, diseases and poor management (National Livestock Project Division, 1992). In recent time under nutrition and low protein caloric intake has been recognized in developing countries of the world. The measures to be adopted to correct the nutritional deficiencies in both child and adult population in these countries are still subject to widely differing opinions.

On one hand, loss of milk quality largely due to lack of techniques for improving preservation and lifespan of fermented cow's milk (nono) was identified as a major challenge that requires intervention. Furthermore, improved milk processing techniques can increase output and quality of the milk and hence invariably increase sales and consumption. When there is an increase in sales, the women's income will increase, thus their livelihoods and that of their families will be improved. Milk processing into yoghurt may be of immense help to curb the problem of milk spoilage which leads to immeasurable losses to farmers. The project will also improve the storability of milk for the producers to target better markets and prices. More so, an increased consumption of milk and yoghurt by the people will increase their protein intake and thus increase their health (Barr *et al*., 2000).

Project Context

The project was conducted as a Supervised Enterprise Project which is an organizational component of Sasakawa Africa Fund for Extension Education (SAFE). The project empowered rural women on how to make yoghurt from fermented cows' milk (nono), thus helping them economically.

MATERIALS AND METHODS

The Study Area

The training was conducted in Rano town, Rano Local Government Area (LGA) of Kano State. Kano is located in the North-Western part of Nigeria at latitude 12°3'N and longitude 8°32'E with an average temperature of 26.2 °C with warmest temperature being 38 °C in April and the coolest temperature being 13 °C in January and December. The state also receives an average of 873 mm of precipitation annually. The months with the driest weather are January and December. Mean relative humidity was recorded as 31.1% (KNARDA, 2008). On the other hand, Rano has an area of 520Km^2 and a tropical climate. The temperature and rainfall averages are 25.8 °C and 865 mm respectively (Climate-Data.org, 2015). Inhabitants are mostly Fulani cattle rearers and, therefore milk production is one of the major economic activities in the area.

Preliminary Activities

A need assessment exercise was carried out at Unguwar Dam, Rano Local Government area, Kano State. The inhabitants were mostly farmers engaging in both crops and animal husbandry. They cultivate crops in both raining and dry seasons. A stakeholders meeting was conducted to identify the areas of priority which people of the study area will mostly benefit from. Both the first and the second stakeholders meetings employed the use of focus group discussion. The first community meeting was conducted on 20th May, 2016 including various stakeholders of the projects. The target farmers were women cooperative societies to assess their various needs.

The project began by introducing the research student to women groups in the LGA and a convenient location was selected for a one-day training. Thirty women leaders were selected after they have obtained proper recommendations from their district heads and Local Government supervisors. Materials required for the training were purchased in Singer market in Kano and a date was set and communicated to all the participants via short message service (SMS).

Sampling

One hundred questionnaires were distributed to one hundred households to assess socio-economic aspects of milk production in Rano LGA. The questionnaires were distributed in all the ten (10) wards of the LGA. Ten questionnaires were distributed in each of the wards and the ten households selected within each ward were randomly selected.

Inputs Used

The materials to use include water, Potassium sorbate powder ($C_6H_7KO_2$ _ preservative), Sodium Benzoate powder ($C_7H_5NaO_2$ _to hinder sourness), evaporated milk, powdered coconut flavour, sugar, cow milk (nono) and custard powder (predominantly made of starch). Equipment includes hand gloves, fine wire mesh sieve, 25 litres plastic containers, spatula, and spoon.

Yoghurt Preparation Methods

On the day of the training, the participants were seated and provided with sample materials that they will practice with. The participants were told the importance of the training and the objectives. The need to train them, so that they train their group members was then emphasized. The student trainer led the training and demonstrated the step-by-step procedures of making yoghurt from cow milk (nono) while each participant used the equipment and materials provided to practically do what the trainer did. Each participant wore hand gloves and was lectured on the importance of hygiene. Furthermore, the training was video recorded to the participants in case they wish to refer to the procedures later.

Participants were guided on how to make a sample of 20 litres of yoghurt from cow milk (nono) as a group. One kilogramme of custard powder was put in a 25 litre plastic container. Five litres of cold water were poured onto the custard and smoothly mixed into paste. Ten litres of previously boiled (100°C) water was then poured to form a thick liquid paste, which was continuously stirred to avoid lumps. Five litres of finely churned cow milk (nono) was then added to the mixture and then thoroughly mixed. After a fine mixture was obtained, a fine sieve was then used to pass the liquid and to ensure no lumps were left in the liquid. Thereafter, two tins of evaporated milk (410g, 380ml) were also added.

Ten grammes of Potassium sorbate powder (as a preservative), and ten grammes of Sodium benzoate powder (to hinder sourness) together with thirty grammes of coconut flavour were mixed with half

cup of cold water and added to the mixture. Three hundred grammes of sugar was then added to taste. The diagrammatic representation of the procedure is shown in figure 1 below:

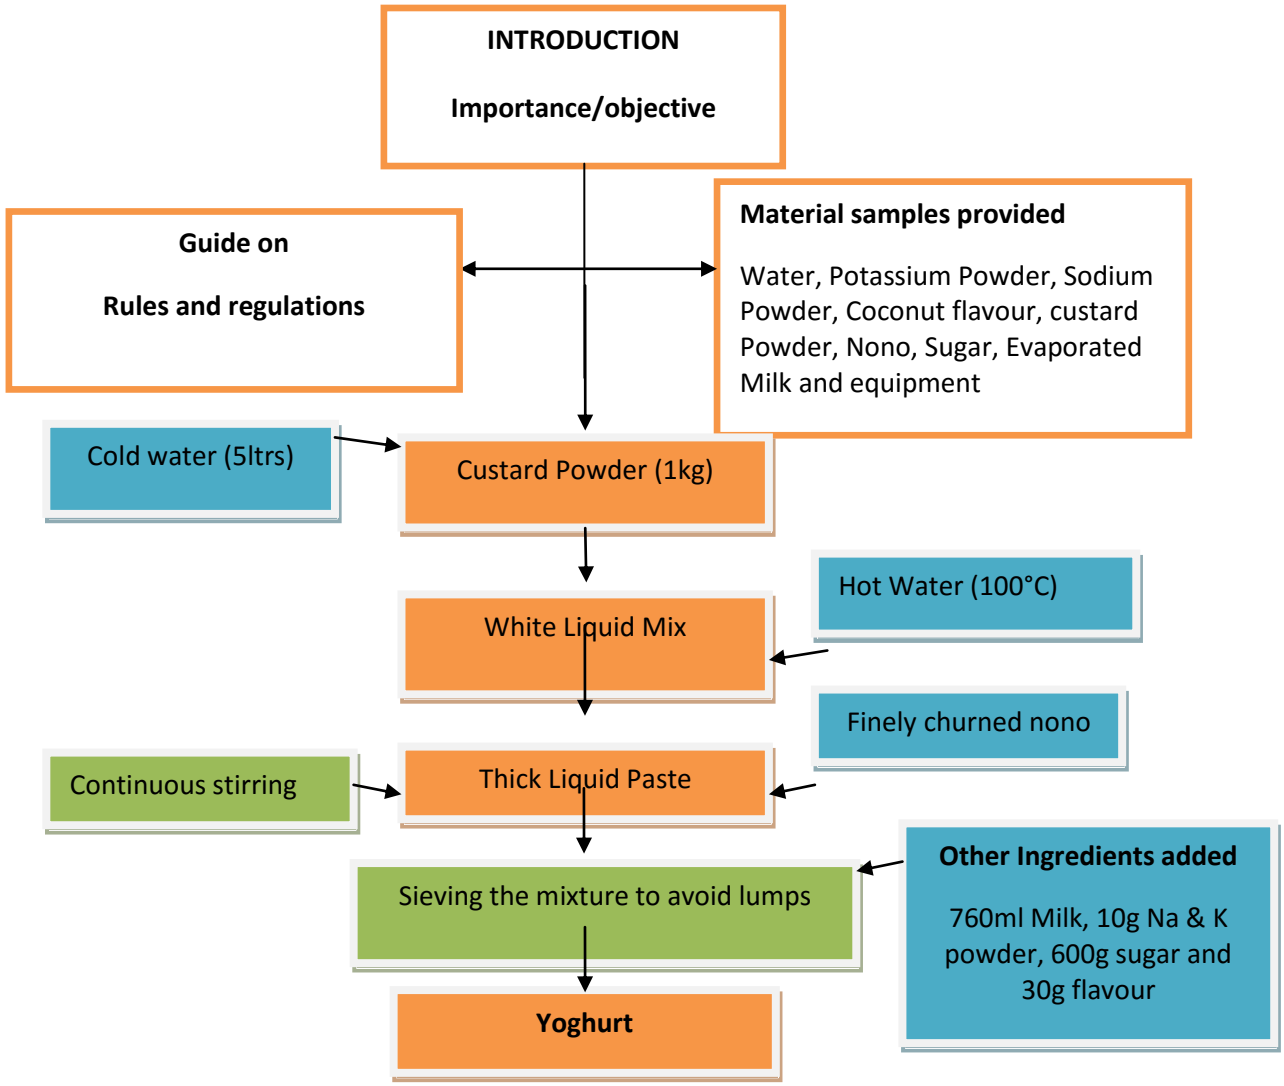

Figure 1: Diagrammatic representation of yoghurt making process

Packaging

An optional way of packaging and branding the yoghurt was taught to the participants. Participants were shown how to keep yoghurt by simply pouring it in used water bottles and then sold. A second option was to buy new empty bottles with sealing caps. Yoghurt should be filled up in the bottles and sold. Additionally, a trade name could be obtained and printed slips could then be attached to the bottles to further enhance the brand. However, license and approval must be sought for from relevant agencies.

Tools of Data Collection

Questionnaire/interview schedule were used to collect primary data from the respondents. Secondary data was also collected from journals, textbooks and relevant websites.

Data Analysis

Simple descriptive statistics were used to describe the socioeconomic data of the respondents. Chi-square analysis was used to establish relationship between herd size and willingness to adopt yoghurt processing technology by the farmers with the aid of MAXSTAT©, VERSION 3.06 Statistical Package. Cost benefit analysis was used to ascertain the profitability of yoghurt production.

RESULTS AND DISCUSSION

Attempt was made to measure the impact of the yoghurt processing project on the participant farmers' experience, interest and willingness to adopt the new skills taught.

From table 1 below, majority (61.4%) of the participant farmers had poor experience of improved yoghurt processing before this project. This was followed by those with good experience level that were around 22.8%, excellent level 10.5% and fair level with 5.3%.

Also, after the training, majority (54.4%) of the participants reported to have gained improvement in their yoghurt processing skills. The fact that majority of the participants' skills were improved could be attributed to the techniques involved which ensured learning by doing through participatory action research as opined by Attah-Krah and Francis (1987). However, 45.6% of them reported no improvement in their skills. This non-improvement in skills as reported by the minority might be connected with the fact that, some participants did not fully participate in the training or some were naturally laggards.

Table 1: Impact Assessment of Yoghurt processing amongst farmers in Rano town, Rano LGA, Kano State

Variable	Frequency	Percentage (%)
Experience before Training		
Excellent	6	10.5
Good	13	22.8
Fair	3	5.3
Poor	35	61.4
Total	57	100
Skills Improvement after the Training		
Yes	31	54.4
No	26	45.6
Total	57	100
Intention to Adopt the Technologies		
Yes	30	52.6
No	27	47.4
Total	57	100
Reasons for adoption		
Improve income	20	35.1
Reduce spoilage	24	42.1
Better Market	9	15.8
Others	4	7.0
Total	57	100

Source: Field Survey (2017)

From Table 1 above, 30 farmers (52.6%) showed willingness to adopt the new yoghurt technology they were taught during this project. This was probably due to simplicity of the procedures employed, availability and affordability of the ingredients and the practical and participatory approach used in the training sessions. Those who showed no interest to adopt the technology formed the minority (47.4%). Most of those willing to adopt the yoghurt technology mentioned that their reason was to improve income (35.1%) which was slightly lower than those who wanted to reduce spoilage (42.1%). A fraction of the farmers, i.e. 15.8% and 7.0% were willing to adopt the technology for a better market and other reasons respectively.

Table 2: Chi-Square Analysis of Willingness to adopt Yoghurt Technology between Small and Large Herd Owners amongst farmers in Rano town, Rano LGA, Kano State.

Response	Expected Frequencies	
	Small Herd Owners	Large Herd Owners
Yes	14.74	15.26
No	13.26	13.74

Chi square value = 14.75; Critical Chi square value= 3.84*; P value= 0.0001

The Chi-square analysis (Table 2) shows that, there was a significant ($p<0.05$) difference in the willingness to adopt the yoghurt technology between small herd and large herd owners in the study area. Thus, Number of cows owned by a farmer determines farmers' willingness to adopt milk processing technologies in the area. Those possessing large number of animals (above ten) were more willing to adopt the technology than those with fewer animals (below ten). It could be concluded that, farmers with large herd size were willing to put in their efforts to commercialize their venture as against the small herd owners who might be keeping the animals for subsistence and farm labour.

CONCLUSION

The thirty women trained were technically and economically empowered with the technical-know-how of yoghurt production that increased their potentials which resulted into more sources of household income and subsequent betterment of living standards. Furthermore, estimates of cost and return of yoghurt production indicated that the venture was profitable and worth adopting by farmers. Additionally, farmers who had larger herds were more willing to commercialize their yoghurt production venture as against the small herd owners who might be keeping the animals for subsistence and farm labour.

RECOMMENDATIONS

The following recommendations were made with regards to the project:

1) The accessibility of yoghurt production materials should be increased, such that the people living in rural communities can purchase the materials and get involved in the production.
2) Furthermore, government intervention is necessary in all aspects of production to provide support to yoghurt producers in terms of materials of production, storage and marketing.
3) The marketing chain needs to be organised such that cooperatives and associations will be created to regulate production and pricing.

ABSTRACT
This study was conducted to determine the effect of cold water neem leaf extract on meat quality of broiler chicken. One hundred and sixty broiler chicks (Cobb) were randomly divided into four groups of 40 birds per treatment. Each group was sub-divided into four replicates of 10 birds. The birds in group 1 served as control and antibiotics were administered to them while 0.1, 0.2 and 0.3% concentration of neem leaf extract were administered to bird on groups 2, 3 and 4, respectively. The period of experiment was six weeks. The birds were fed *ad libitum*. One bird close to average final weight was selected randomly in each replicate and was slaughter at 42nd day of the experiment. Meat samples from breast muscle of the bird were subjected to cooking weight loss, refrigeration weight loss and sensory evaluation. The data obtained were subjected to one-way Analysis of Variance in a completely randomized design (RCD). The cooking loss increased ($P<0.05$) with higher concentration of the extract while refrigeration weight loss percentages were similar ($P>0.05$) across the treatments. The result on Sensory evaluation showed that only colour, tenderness and overall flavour were significantly ($P<0.05$) influenced. The study concluded that aqueous Neem (*Azadirachta indica*) leaf extract (ANLE) administration in drinking water of broiler chicken as alternative to antibiotics did not pose any adverse threat on the meat quality.
Keywords: neem extract, refrigeration and cooking losses, sensory evaluation, broiler chicken

INTRODUCTION
Medicinal plants extracts were developed and proposed for use in food as natural antimicrobials (Hsieh and Mau, 2001). Beneficial effects of herbal extracts or active substances in animal nutrition includes the stimulation of appetite and feed intake, the improvement of endogenous digestive enzyme secretion, activation of immune response and antibacterial, anti-viral, antioxidant and anthelminthic actions. Generally, plant extracts have no problem of antimicrobial resistance (Tipu *et al*., 2006) and broilers fed on herbal feed additives were accepted well by consumers (Hernandez *et al.,* 2004).

Aqueous extract of Neem leaves has a good therapeutic potential as anti-hyperglycemic agent, antibacterial agent and could be used for controlling airborne bacterial contamination in the residential premise (Mishra *et al.,* 2013). It was shown that Neem leaves extract acts as a growth promoter (Landy *et al.,* 2011), improves performance and hematological parameters (Nayaka *et al.,* 2013) and immune response (Jawad *et al*., 2013) in broilers. Due to paucity of information on the effect of neem leaf extract on meat quality, this study was designed to investigated the effect of cold water extraction of neem leaves on eat quality of broiler chickens.

MATERIALS AND METHODS
Experimental site: The rearing of birds took place at the Poultry Units of the Teaching and Research Farm, while the meat quality section was carried out at the Meat Processing Laboratory, Department of Animal Production and Health, College of Animal Science and livestock Production, of Federal University of Agriculture Abeokuta (FUNAAB).

Source and preparation of the extract: Fresh neem (*Azadirachta indica*) leaves were harvested, rinsed thoroughly with water to remove all the dirt from it then pounded in a mortar with pestle to increase the surface area for better extraction. The pounded leaves were weighed on the sensitive scale at 1, 2 and 3g, which were needed for the experiment. The weighed freshly pounded neem leaves were added to clean cold water (at room temperature) at 1g of neem leaves to 1 litre of water, 2g of neem leaves to 1 litre of water, and 3g of neem leaves to 1 litre of water and thereafter was left for 12 hours at room temperature and was sieve before it was offered to the birds.

Experimental Design: A Completely Randomized Design (CRD) was adopted for this experiment. The one hundred and sixty 7 days old broiler chicks of Cobb strain were allocated into four treatments with each treatment contains 40 birds. Each treatment was further sub-divided into four replicates of ten birds each. The period of the experiment lasted for six weeks. The treatment groups are; Treatment 1 (Control) was administered antibiotics (Enrofloxacin at the manufacture's recommendation), Treatment 2 (0.1%) of neem extract in drinking water, Treatment 3 (0.2%) of neem extract in drinking water and Treatment 4 (0.3%) of neem extract in drinking water. Starter broiler diet of 23% CP and 11.47 MJ/Kg was supplied *ad libitum* for the first three weeks while finisher broiler diet of 20.10%CP and 11.62 MJ/Kg was supplied during the last three weeks of the experiment.

Data Collection: At the 42nd day of the experiment, one broiler chicken close to average final weight was selected randomly from each replicate and was slaughtered. After dressing, breast meat sample of 54.13-54.80g from each broiler chicken was cooked separately at 70°C for 15 minutes in a water bath (Egbeyale *et al*., 2012). The difference between the weights before and after cooking gave the cooking weight loss of the meat samples. Meat samples of another set of 51.20-54.50g were cut from the breast muscles of the slaughtered broiler chicken. Each sample was weighed and labeled according to the treatment before being stored in a refrigerator at about 10°C for 24 hours (Egbeyale *et al*., 2012).

Sensory evaluation: For sensory evaluation, a uniform size of cooked chicken breast meat was sliced into cubes and the cooked chicken breast meat was labeled according to each treatment and samples were allowed to cool before serving the panel. Eight educated panelists were isolated from each other, so as to prevent communication and each panelist was asked to rinse his/her mouth with ordinary water after each sample testing to avoid any carry over effects. The panelist evaluated the meat colour, flavour, juiciness, aroma, texture, saltiness and overall acceptability. The evaluators were asked to score the sample on nine points scale according to Egbeyale *et al*. (2012)

Statistical analysis: Data collected were subjected to one-way Analysis of Variance (ANOVA) and differences in means were separated using Duncan Multiple Range Test (SAS 2012) at 5% significance level.

RESULTS

The effect of aqueous neem leaf extract (ANLE) on cooking and refrigeration weight losses of broiler chicken is present in Table 1. Cooking weight loss (CWL) was significantly ($p<0.05$) influenced. The CWL of meat from birds on 0.3%ANLE were significantly higher than the control. However, the meat from birds that drank water containing 0.1 and 0.2% ANLE recorded values similar to both control and 0.3%ANLE group. The refrigeration weight loss and percentage refrigeration loss did not show any significant ($p>0.05$) different among the treatments.

Table 1: Effect of cold water neem (A*zadirachta indica*) leave extract on cooking and refrigeration loss of broiler chicken

	Inclusion level of NLE (%)			
Parameters	0	0.1	0.2	0.3
Cooking				
Weight before cooking (g)	54.80±0.47	54.13±0.78	55.33±1.36	54.30±1.11
Weight after cooking (g)	49. 15±0.37	47. 13±0.95	48. 90±1.26	46.98±1.36

$^{a,b;}$ Means on the same row with different superscripts are significantly ($p<0.05$) different

DISCUSSION

The cooking loss values reported in this study are lower than the values reported by Gohar *et al*. (2012) who compared cooking loss in broiler and layer meat and reported that cooking loss in broiler meat was in the range of 15.55 to 36.00%. The increase in the cooking weight losses with increasing levels of ANLE obtained in this study is in accordance with the results of the work of Ncube *et al*. (2018) who studied the effect of *Acacia angustissima* leaf meal on yield of carcass components and meat quality of broilers and reported that increasing levels of the leaf meal resulted in drier meat. High cooking loss also implies the less ability of the meat to hold water during processing and storage (Abu *et al*., 2015). According to Michalczuk *et al*. (2014), high meat cooking loss has an adverse effect on sensory perception as it reduces juiciness. The influence of ANLE on tenderness and overall flavour is consistent with results published by Jang *et al.* (2008) on the enhancement of flavour after feeding a mixture of herbal tree extracts to broilers. Similarly, the result agrees with Aderinola *et al.* (2013) who reported enhanced flavour of meat from *Moringa oleifera*-fed broilers. These similarities in juiciness and meaty flavour are in agreement with findings of Bonsu *et al*. (2012) who studied the medicinal response of broiler chickens to diets containing neem (*Azadirachta indica*) leaf meal. Egbeyale *et al*. (2012) in their study of meat qualities characteristics of broiler chicken fed varying levels of *Ocimum gratissimum* reported that parameters such as juiciness, saltiness and overall acceptability were not significantly influenced. However, the authors reported that overall flavour were significantly influenced which is in accordance with the results of this study.

CONCLUSION AND RECOMMENDATION

Aqueous extracts of neem (*Azadirachta indica*) leaf at 0.3% could be administered in the drinking water of broiler since it does not compromise the quality of meat.

ABSTRACT
The study conducted investigation on proximate composition of ginger root and garlic bulb powder as phytobiotics for processing meat in Edo State. The copped ginger root and garlic bulb were sun dried for three weeks, milled separately into powder form using a milling machine with particle of 0.15mm sieve powder size. It was established that the moisture content of ginger root and garlic bulb powder were (22.5, 48.00 %), crude fiber (5.50, 3.00%), Ash (8.00, 6.00 %), crude protein (9.10,16.28%),ether extract (7.00,5.00%) and nitrogen free extract (70.40,69.72%). The analysis of ginger and garlic used in this study showed that ginger and garlic contained considerable amount of crude protein (CP) and thus can be used to augment protein content of poultry products.
Keywords: Ginger root, Garlic bulb, Crude fibre, Crude Protein and Proximate.

INTRODUCTION

Poultry production in the developing countries has been gaining popularity due to its contribution to meeting protein requirement of man, job creation, as well as socio-cultural and religious functions. According to Oboh and Igene (2006), poultry industry in Nigeria comprises of production of chickens, turkeys, ducks, and pigeons to mention a few. 84% of these are indigenous and 16% are exotic groups (Food and Agricultural Organization, FAO, 2008). Antibiotics as feed additives are widely used as therapeutic agent and also as growth promoters in poultry production all over the world but over the years, there has been growing concern about the public health risk resulting from antibiotic resistance. Antibiotics sometimes cause drug interactions that make medication ineffective, cause side effects or cause damage to a patient's biological systems. Mixing alcohol with antibiotics may decrease their effectiveness or may cause nausea, vomiting and respiratory effects. Antibiotics sometimes make birth control pills ineffective. Carcinogenic responses and other side effects of antibiotic residues in poultry products and meat make its use a serious call for concern. The extensive use of antibiotic growth promoters in poultry industry has resulted in rapid appearance of resistant form of microorganisms less sensitive to antibiotics (Sudipto, 2010). Over the years, there has been need for the use of alternative form of antibiotics and spices and some plant leaves have been found to be phytobiotic and various researchers have reported their success stories. Otoikhian, Emakpo and Imasuen (2007) for example, reported that ginger can successfully be used as a phytobiotic substance in poultry production. Natural products plant origin like spices, herbs and many plant extracts can be considered as alternative to antibiotics as well as growth promoters in improving broiler performance (Fenelli, Castro, Toranzo and Castro, 1998). Garlic is active against microorganisms that are resistant to synthetic antibiotics and the combination of garlic extracts with antibiotics has been reported to lead to partial and total synergism (Didry, Dubreuil, and Pinkas, 1992). Ginger is used worldwide as a cooking spice, condiment and herbal remedy. The Chinese have used ginger as a spice in processing broiler meat for at least 2,500 years as a digestive aid and anti-nausea remedy and to treat bleeding disorders and rheumatism. It has also been used to treat baldness, toothache, snake bite and respiratory conditions (Duke and Ayensu, 1985). In Traditional Chinese Medicine (TCM), ginger is considered a pungent dry warming herb used for ailments triggered by cold and damp weather. Ginger is used extensively in *Ayurveda*, the traditional medicine of India, to block excessive clotting (i.e. heart disease), reduce cholesterol and fight arthritis. In Malaysia and Indonesia, ginger soup is given to nursing mothers for 30 days after their delivery to keep them warm and to help them sweat out impurities. In Arabian medicine, ginger is considered an aphrodisiac (Qureshi, Shah, Tariq and Ageel, 1989). Also, in Africa, it is believed that eating broiler meat processed with ginger regularly will help repel mosquitoes (Duke and Ayensu 1985). The Eclectic

physicians of the 19th century relied on ginger to induce sweating, improve the appetite and curb nausea, and as a tropical counterirritant. Garlic can rightfully be called one of nature's wonderful plants with healing power. Therefore using Garlic in processing broiler meat can inhibit and kill bacteria, fungi, lower blood pressure, blood cholesterol and blood sugar, prevent blood clotting, and contains anti-tumor properties. It can also boost the immune system to fight off potential disease and maintain human health (Abdullah, Kandil, Elkadi, and Carter, 1988). It has the ability to stimulate the lymphatic system which expedites the removal of waste products from the human body. It is also considered an effective antioxidant to protect cells against free radical damage. Garlic can help to prevent some forms of cancer, heart disease, strokes and viral infections (Galeone *et al.*, 2006). The white garlic is said to have medicinal properties while the black fermented garlic is more commonly used for cooking by the Japanese as results have shown that processing broiler meat with this black fermented garlic could result in drop in blood pressure, anti-aging, prevent blood clots, cancer prevention, fall in blood sugar, and enhances immunity of the body (Zhengzou Love Herb Company Limited, 2013).

MATERIALS AND METHODS

The proximate analysis was carried out in Federal University of Agriculture Abeokuita, Ogun State. The ginger and garlic were milled separately into powder form. They were stored in air tight containers prior to the proximate analysis. Aliquet were taken for the proximate analysis which was determined, using the method described by AOAC (2000). The result is presented in the Table below.

RESULT

Proximate composition of ginger and garlic powder used in the study

The result of proximate composition of ginger root and garlic bulb powder used in the formulation of the experimental diets in this study is presented in Table 17. The ginger powder has 5.5% crude fibre, 8.00% crude ash, 9.10% crude protein, 7.00% ether extract and 70.40% Nitrogen free extract. Also the garlic bulb powder used in this study contained 3.00% crude fibre, 6.00% crude ash, 16.28% crude protein, 5.00% ether extract and 69.72% Nitrogen free extract.

Table: Proximate Composition of Ginger and Garlic (g/100g)

Composition	Ginger	Garlic
Moisture (%)	22.5	48.00
Crude fibre (%)	5.50	3.00
Ash (%)	8.00	6.00
Crude protein (%)	9.10	16.28
Ether extract (%)	7.00	5.00
NFE	70.40	69.72

DISCUSSION

Proximate Analysis of Ginger Root and Garlic Bulb Powder

The crude protein content of garlic is more than that of ginger and also more than the crude protein in maize. The values of CP obtained in ginger and garlic bulb powder used in this study were more than the values reported by Otunola et al. (2010). This may be due to different form of processing used in both studies. The high crude protein content of garlic may be due to the presence of active proteinous metabolites such as allicin. The additives also contained appreciable amount of fat and crude ash

which form the minerals that are inorganic components. Also, the low fibre contents in both additives imply that the additives can be used in the diets to complement total dietary fibre. Otunola et al. (2010) also observed low fibre contents in ginger, garlic and pepper.

CONCLUSION

The analysis of ginger and garlic used in this study showed that ginger and garlic contained considerable amount of crude protein (CP) and thus can be used to augment protein content of poultry products.

ABSTRACT

This study evaluated the effect of ginger powder- based diet as a natural tenderizer of spent layer hens' meat. Seventy-two spent layer hens were assigned to four (4) dietary treatment groups with six (6) birds per replicate and three (3) replicates per treatment in a completely randomized design. Dried ginger was milled and added as additive to the basal diet of the birds at 5%, 10% and 15% inclusion levels. After two weeks of feeding trial, the birds were slaughtered and the meat subjected to shear force, extract release volume (ERV) and water holding capacity (WHC) measurements using standard procedures. Data were analyzed using descriptive statistics and ANOVA at $\alpha_{0.05.}$ Based on the result obtained, as the ginger inclusion level increased, the meat tenderness increased. Control was significantly higher in shear force value with least value in meat from birds fed 15% ginger-based diet. Both ERV and WHC values increased as inclusion level of ginger increased. In conclusion, up to 15% ginger powder can be included in diet of spent layer hens to achieve meat tenderness two weeks prior to slaughter.

Keywords: ginger powder, spent layer, tenderization, water holding capacity and shear force

INTRODUCTION

Tenderness is considered to be the most important organoleptic characteristics of meat (Lawrie, 1991). Meat tenderisation could decrease the toughness of meat from spent layer hens as they are known to possess tough meat as a result of the work done during the months of laying. Many enzymes are being used commercially for meat tenderisation through their effect on the structural integrity of collagen, which can be unaffected during post mortem aging of meat (Bailey *et al.*, 1985). Changes in collagen's physicochemical (Stanton and Light, 1990), mechanical (Nishimura *et al.*, 1998) and ultra-structural (Liu *et al.*, 1995) properties have been observed.

A promising protease "Zingibain" isolated from *Zingiber officinale* roscoe (Ginger rhizome) has been reported to have proteolytic activity. Its proteolytic activity on collagen was found to act on actomyosin, and the combined proteolytic of these two muscle proteins improved the tenderness of meat. Besides tenderizing properties, antioxidant and anti-microbial characteristics of ginger extract have been reported by different workers (Mendiratta *et al*,.2000). However, ginger rhizome is used primarily as a flavouring agent for bakery products and as a sausage seasoning. Its utilisation as a meat tenderizing agent is not fully appreciated and the literature available is limited. Therefore, the aim of this study was to evaluate the meat tenderising effect of ginger powder included in diets for spent layer hens.

MATERIALS AND METHODS

Experiment site: The research was carried out in the Poultry Section of Livestock Investigation Department (LID), of National Veterinary Research Institute, Jos South Local Government Area, Plateau State on Latitude 09°44°N and Longitude 08°45°E, with physical features of rocky granites of old volcanoes.

Seventy-two spent layer hens were assigned to four (4) dietary treatment groups with six (6) birds per replicate and three (3) replicate per treatment in a completely randomized design.

Experimental Materials

Dried ginger was purchased at a local market (Bukuru market). The dried ginger was milled and added as additive to the basal diet of the layers in 0%, 5%, 10% and 15% inclusion levels.. The processing (drying and milling) of the materials was monitored. The feeding trial was carried out for (2) two weeks. The birds were fed once a day, feed intake and left over feed was measured daily. Routine management practices were also carried out.

Parameters measured

Shear force determination: The objective evaluation of tenderness was performed using the modified Warner Bratzler shear force procedure (Bouton and Harris, 1978).

Water holding capacity determination: Water Holding Capacity (WHC) was determined according to Wardlaw *et al.* (1973).

Determination of Extract Release Volume (ERV): This was done according to Jay (1964).

Experimental design

The experimental design was a completely randomised design.

Statistical Analysis

The data was statistically analyzed with the SPSS program for Windows (SPSS version 21.0, SPSS Inc., Chicago, IL, USA). Duncan's multiple-range test was used to compare the difference between means.

RESULTS AND DISCUSSION

The shear force of meat from spent layer hens fed ginger-based diet is showed in Figure 1. A consistent pattern was observed in the shear force of the meat obtained. As the inclusion levels of ginger increased, there was decrease in the shear force values. The shear force values of meat indicate tenderness of meat. High shear force values indicates an increased toughness of meat. . However, when the values obtained are low, it shows that the meat is tender. The results obtained could be attributed to the effect of proteolytic enzyme found in the ginger which may have led to more degradation and availability of dietary protein. Naveena and Mendiratta (2001) also observed that in ginger powder treated samples the shear force values were low when compared with the control. Khanna and Panda (2007) also reported a reduction in shear force values of papain-treated spent hen meat. The shear force value of ginger and papain treated samples were almost closer to that of broiler meat

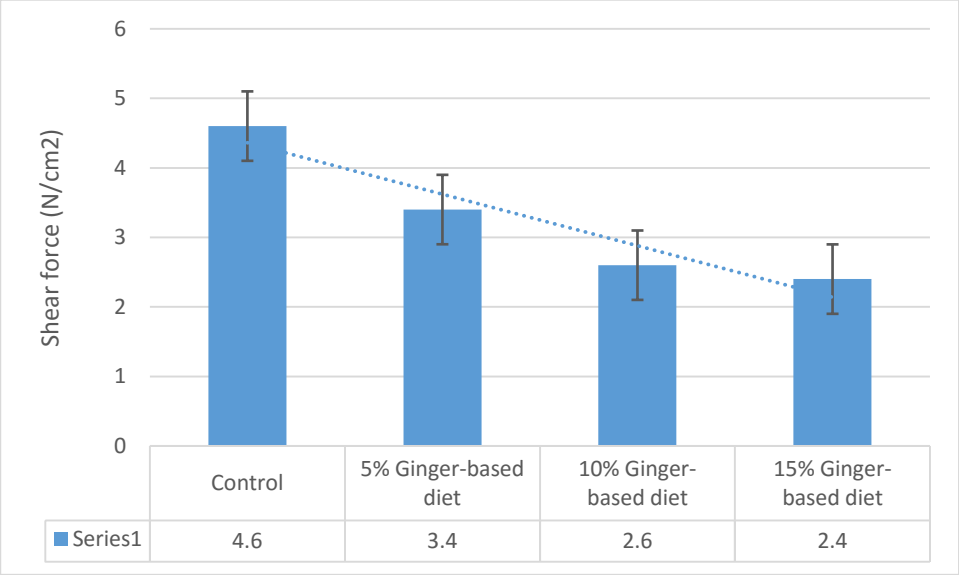

Figure 1: Effect of ginger based diet on shear force value of meat from spent layer hens

Figure 2 shows the water holding capacity and extract release volume of meat from spent layer hens fed ginger-based diet. The water holding capacity (WHC) is the ability of meat to hold on to its water after external pressure was applied. A trend was observed; there was an increase in WHC as the inclusion levels increased. LowerWHC values ranging from 38.70 to 47.00 (%) was reported by Muthulakshmi *et al.* (2018) while higher WHC values than control was in agreement with reports by Naveena and Mendiratta (2001). Khanna and Panda (2007) reported increased WHC of spent hen meat treated with papain and Naveena *et al.* (2004) reported similar results in buffalo meat treated with ginger extract.

Extract release volume (ERV) is a measurement technique that is based on the volume of aqueous extract released by homogenate of meat when allowed to pass through the filter paper for a given period of time By this, meat of good organoleptic and microbial quality release large volume of extract, whereas meat of poor quality releases smaller volume or none. A trend was observed in the result obtained in this study. As the inclusion level increased, the ERV increased. The result obtained shows that as the inclusion level increased the meat organoleptic and microbial quality was improved. This could be due to reported phytochemical substances present in the ginger powder (Mendiratta *et al,*.2000)

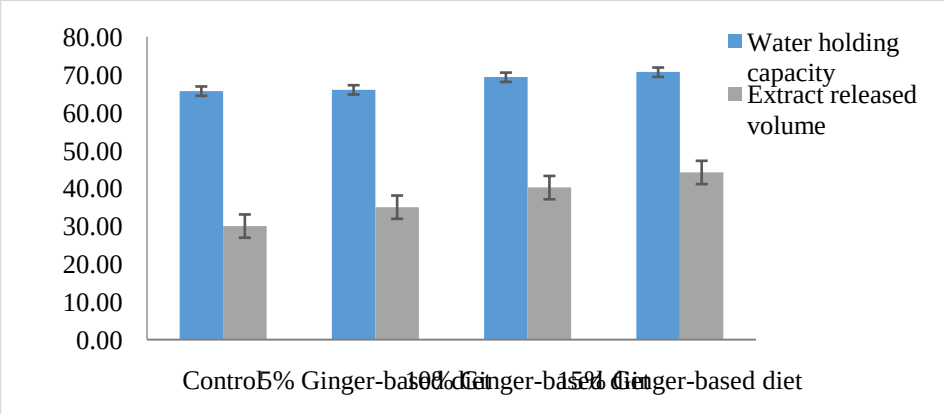

Figure 2: Effect of ginger-based diets on water holding capacity and extract release volume of meat from spen layer hens

CONCLUSION

Addition of 10 to 15% ginger powder into basal diet of spent layer hens is an effective meat tenderizer and the tenderization is achieved through its action on both myofibrillar and connective tissue components of the meat.

ABSTRACT
The hot humid tropical climate of southern Nigeria with its prevailing high ambient temperature and relative humidity imposes a lot of stress on commercial poultry production dominated by small–scale producers who practice mostly mixed farming of broilers and layers in deep litter pens.Many of these poultry farms are however finding it increasingly difficult to survive because of high cost of inputs, such as feeds and feed raw materials. In addition,the hot humid climate exerts continuous heat stress on the high producing imported breeds. However, most small-scale farms still utilize commercially produced feeds in feeding their birds, while the large-scale farms produce their feeds in-house.The major diseases prevalent in the farms are Newcastle, Gomboro, fowl pox, chronic respiratory diseases and coccidiosis.Poultry production remains attractive in the region because birds are able to adapt easily, have low economic value, rapid generation time and high rate of productivity.

Keywords: Poultry, chicken, humid tropics, southern Nigeria

INTRODUCTION
Southern Nigeria is situated in sub-Saharan Africa with coordinates of longitudes 3° and 14^{1} East of the Greenwich Meridian and latitudes 4° and 14^{1} north of the equator. The area is made up of three geo-political zones and seventeen distinct states; the South east (Enugu, Imo, Anambra, Abia and Ebonyi states), South- south (Rivers, AkwaIbom, Cross River, Edo and Bayelsa states) and South west (Oyo, Lagos, Ogun, Ondo, Oshun and Ekiti states). The population of the three southern zones was estimated at 63.813,163 (NPC, 2006). Although there are variations in their socio-cultural characteristics that reflect in observable differences in their languages, culture, religions, food habits and other socio-cultural values, the zones have similar climate which is tropical, wet and humid, while the vegetation consists of dense mangrove/ rain forests (Okeudo, 2004).
This tropical climate has been shown to impose a lot of stress on animals with the high ambient temperature and relative humidity, particularly placing continuous heat stress on high producing imported breeds. These result in reduction in feed intake and growth rate (Okeudo, 2004), especially in intensively reared commercial poultry (Ukwu*et al.*, 2018). The high temperature also increases the rate of ammonia release from poultry dung and in many poultry farms a strong and choking odor fills the air and adversely affect the health of the birds to which the solution is reducing the stocking density and increasing the ventilation (Okoli, 2004).
The objective of this paper is to report the currentintensive poultry production situation in the hot humid tropical environment of southern Nigeria

Types of poultry operations
Small–scale producers dominate the commercial poultry industry in southern Nigeria (Okeudo, 2004). According to the report of a survey on commercial broiler production conducted in the south-east of Nigeria, about 50% of the farms had between 200 and 300 birds, 20% had 400 – 500 birds, 26% had 1000 – 1500 birds and no farm had more than 2700 birds. Specifically, Akandu (2012) reported that the major poultry operations were egg, broilers, feed production and to a lesser extent breeder and turkey productions as well as feed distribution. This study also reported that 48% of broiler farms have 100 - 1000 birds, while another 36% of the farms have 1000 - 5000 birds. The highest percentage of layer farms (34.40%) stocked 1000 - 5000 birds, followed by 21.90% that stocked 100 - 1000 birds and another 15.60% each stocking 5000 - 15000 and 15000 - 30000 birds. These results

show that poultry farmers in Southern Nigeria stock more layers than broilers and are in agreement with the report of USDA (2013) that Nigeria is the leader in Africa with respect to egg production and fourth in broiler production. Ogegbuna (2014) reported that 48% of poultry farmers in south east Nigeria had mixed broiler and layer farms, while 44% reared only broilers. In the south-south, Bassey (2014) reported 40.70, 33.89 and 25.42% for broiler, layer and mixed farming respectively. Oluyemi and Roberts (2000) attributed higher mixed farming activities to the shorter maturing period of broilers and the need for farmers to maximize market opportunities.

Deep litter system is the preferred rearing approach by most of the farmers in the zones (Ugwu, 2009).Akandu (2012) reported a 50.00% adoption of deep litter, 15.60% of cage system and 34.40% of combined approach. This report is however at variance with the results of a focused study on Imo state which showed that most (100%) farmers kept their birds on deep litter probably because of their inability to access battery cages at that time (Okoli*et al.,* 2004). Alimi*et al.* (2006) showed that there has been a steady growth in the Nigerian poultry industry with growth figure standing at 112% during a 14-year period of (1990-2003). It is therefore probable that over the period of eight years from 2004 to 2012 that the farming system in the zone have changed.

Production constraints

According to Okoli*etal*. (2005), many poultry farms are finding it increasingly difficult to survive in the business in southern Nigeria, because of high cost of inputs, particularly high cost of feeds and feed raw materials. For example, in Enugu and Imo states of south eastern Nigeria, high cost of feeds, disease and high cost of day old chicks are considered the key identified constraints to poultry production (Okoli*et al*., 2005). Ugwu (2009), also identified marketing problem as another constraint of the southeast states, which manifests as fluctuations in prices of products and inadequate market outlets, leading to egg glut and spoilage of products during certain periods of the year (Ugwu, 2009). Overall however, poultry keeping has become a practicable livelihood empowerment and poverty reduction venture in the region, just as in other developing countries. Poultry production is attractive in the region because birds are able to adapt easily, have low economic value, rapid generation time and high rate of productivity that results in the production of meat within eight weeks and eggs within eighteen weeks of first chick being hatched.

Chick quality

In southern Nigeria under review, although day old chicks may be considered available, they are relatively expensive (Okoli*et al*., 2005). In a survey conducted by Ugwu (2009), this high cost was attributed to high transportation costs and other contingent expenses. Commercial chicks raised in Southeastern Nigeria are sourced mostlyfrom Ibadan, Abeokuta and Sapele in Southwestern and South-south regions of Nigeria respectively (Akandu, 2012). Because of the distance between the southeast and these centers of day old chick production, Ukwu (2013) reported that there is always a time-lag between the hatching and on-farm feed and water treatment of considerable percentage of chicks being reared in this area. Delay factors such as poor condition of roads and vehicles used in transportation of chicks as well as delays occasioned by corrupt law enforcement agents have been reported. These factors often occasion delays which may lead to the exhaustion of the chicks with various levels of in-transit and post-transit loss of chick condition and mortality. The occasioned early feed and water denial, as well as transportation stress compromises the development of broiler chicks and prevents them from achieving their growth potential (Ukwu, 2013).

Feed and feeding

Feeding is a critical factor in intensive poultry production all over world, including the study area of southern Nigeria (Oluyemi and Roberts, 2000). The cost of producing meat and egg is heavily burdened by the high cost of feed materials, which is estimated to be more than 70% of the production cost of the finished products (Esonu, 2006). Income from poultry production is thus highly dependent on feed utilization for all types of intensive poultry production in the region. Quality feeds of appropriate nutritional value suitable for efficient production are therefore critical inputs in the enterprise (Omede, 2010). Most small-scale farms utilize commercially produced feeds in feeding their birds, while the large-scale farms produce their feeds in-house (Adene and Oguntade, 2006). The nutritive values of the commercial feeds have been shown to vary widely across brands and types

(Omede, 2010). They have been shown to vary due to factors such as age of feed materials, processing methods, seasonal variations in nutrient contents of feedstuffs and method of conservation as well as possible presence of toxic substances and pathogens (Omede,2010). Therefore, there is perhaps no other factor directly or indirectly related to feed quality in impacting performance of poultry and this is ultimately linked to productivity and profitability of the ventures.

The high cost of conventional feedstuffs has made the search for alternative feed materials, imperative. The use of these alternative feed materials has been shown to be relatively cost effective (Esonu, 2009). Among the alternative feedstuffs that have been utilized in the region are cassava tuber products as sources of energy (Okoli and Udedibie, 2017), cassava leaves as source of protein, minerals and xanthophyll andcassava peel meal when processed adequately. Cassava tubers and cocoyam corms flours have been demonstrated to be good maize replacers in poultry diets when given adequate processing treatment (Abdurashid and Agwunobi, 2012). Also, combinations of different alternative feed materials such as palm kernel cake and cassava tuber flour supplemented with appropriate additives to boost their utilization as poultry feed materials have been reported (Okoli and Udedibie, 2017).

Animal health

The increase in intensive poultry production in southern Nigeria provides the optimum conditions for the concentration and transmission of pathogens, specifically because the crowding of birds in enclosed environments is highly conducive for the transmission of pathogenic organisms. The major poultry diseases in the region are Newcastle, Gomboro, fowl pox, chronic respiratory diseases and coccidiosis (Okoli*et al*., 2005). Etuk*et al*. (2004) reported that coccidiosis is a major disease of the area, whileKanu*et al*.(2019) reported incidence levels of 30.85% for coccidiosis, 30.35% for Newcastle disease, 14.93% for Gomboro disease, 14.43% for chronic respiratory disease and 9.45% for fowl typhoid over a period of five years (2013 – 2017).The reports of Okoli*et al*. (2005) for Imo state, Bassey (2014) for AkwaIbom state and Ogegbuna (2014) for Anambra state show that antibiotics, coccidial drugs and vaccines are the most prescribed animal health products, supporting the report of high occurrence of coccidiosis, Gumboro and New castle diseases in farms. There is however limited access to animal health care services, especially among the small-scale farmers. Ogegbuna, (2014) reported that only 48.00% of poultry farmers in Anambra state retained the services of animal health workers, while Bassey (2014) reported a high 72.00% retainership of animal health workers' services in AkwaIbom state. These workers also reported high level of self-medication and poor consultation of animal health workers by farmers in southern Nigeria and attributed this to high cost of veterinary services, small-size of poultry farms and remote rural locations of many poultry farms.

CONCLUSION

Poultry production remains an attractive venture in southern Nigeria because birds are able to adapt easily, have low economic value, rapid generation time and high rate of productivity.

ABSTRACT
This study was to investigate breed differences in live weight, carcass traits and muscle distribution of Balami (BA), Uda (UD), Yankasa (YK) and West African Dwarf rams (WAD). fForty-eight rams were randomly assigned into four groups of twelve rams per breed in a completely randomized design. Linear measurements were obtained weekly during the fattening period. At the end of the feeding trial, animals were subjected to a 18-hours fast and slaughtered for carcass measurements and muscle distribution. Results showed that BA and UD had higher values for body length (115.75±4.25 and 110.25±1.89), withers height (70.50±5.57 and 69.00±2.16) and heart girth (92.00±2.94 and 84.00±1.41), than YK (96.50±3.87, 60.75±3.30 and 76.75±0.96), respectively which in turn had higher values than WAD (86.50±5.20, 53.25±5.32 and 75.25±3.30). Carcass length, pistola length, and leg length were 75.75±4.79, 60.75±7.14 and 88.00±2.16; 75.50±4.66, 56.00±5.00 and 80.25±5.80; 59.00±7.79, 56.00±10.62 and 71.50±2.65; 60.50±3.11, 53.75±5.91 and 61.00±2.94cm for BA, UD, YK and WAD rams, respectively. BA and UD had higher proportion of muscle distribution and were generally better than the YK and WAD breeds. This may boost their potential for large scale meat production under fattening conditions.
Keywords Breeds, Meat, Growth . Morphology, Carcass, Muscle distribution

INTRODUCTION
Nigeria livestock industry is small and slow-growing relative to the population relying on it for meat (Agboola and Balcilar, 2012). The use of specialised meat breeds to improve animal productivity is desirable in intensive sheep production. Locally adapted breeds of rams have attributes that can be used in a collective and valuable approach to increase meat production and improving their connections to the market (FAO, 2012). Morphometric measurements have been used to evaluate the characteristics of various breeds of animals and could provide first-hand information on the suitability of animals for selection (Yakubu, 2010). Muscularity indicates the amount of muscle tissue, determined by muscle to bone ratio and fatness describes the external and internal deposition of fat in the carcass. According to Srivastava *et al* (1968), body measurements are indices of skeletal development and indirectly help to determine carcass composition. Another parameter that was used over the years to estimate the amount of meat that could be obtained from slaughtered animals is carcass measurement. De Boer *et al* (1974) identified four types of linear carcass measurements. The objectives of the present study were to compare various measurements of body, carcass and tissue distribution for Balami, Uda, Yankasa and West African Dwarf breeds of ram intensively managed.

MATERIALS AND METHODS
Location and management of experimental animals
The study was conducted at the Sheep and Goat unit of the Teaching and Research Farm, University of Ibadan. Twelve rams each of Balami (BA), Uda (UD), Yankasa (YK) and West African Dwarf (WAD) breeds , weighing 17.00± 0.39–19.38±0.39 (12-18 months of age). At the end of the ninety days, four rams in each group whose weights were the closest to average final weight of the rams of their respective breeds were chosen for subsequent carcass analysis.

LINEAR BODY MEASUREMENTS
The six morphometric traits measured were height at wither, pelvis height, body length, heart girth, chest width and chest depth. Measurement (cm) was done using a graduated measuring stick and tape rule. To achieve this, animals were placed on a flat ground and held by two field assistants. The length measurements were carried out using a tape rule while the width measurements (cm) were taken using a calibrated wooden calliper.

SLAUGHTER PROCEDURE

The selected sixteen rams from the four breeds were transported to the slaughterhouse of the Department of Animal Science, University of Ibadan where pre-slaughter live weight was recorded after 18-hours of fasting with free access to water. Exsanguination was carried out by an incision on the jugular furrow at the occipito-atlantal junction close to the head, severing the carotid arteries, jugular veins, trachea, oesophagus and the spinal cord. The head was removed and the carcass was hung by the hind legs using a pulley and then skinned.

EVISCERATION OF CARCASSES AND CARCASS EVALUATION:

Skinning and evisceration was carried out and hot carcass weight was taken on the slaughter floor within 10min post-motem. The carcass was chilled for twenty-four hours at 3°C-4°C and reweighed to get chilled carcass weight. Dimensional measurements taken on the carcasses were: Carcass Length, Length of Hindleg, Length of Foreleg, Heart Girth and Depth of Chest according to the procedures of De Boer *et al.* (1974). Abdominal, pectoral, Kidney and pelvic fats were removed, weighed and calculated as a percentage of the hot carcass weight. Carcasses were split along the midline. The left sides were separated as outlined by Fisher and De Boer (1994). These included carcass length and depth, and leg length. The length of the pistola was obtained following quartering of the carcass side. After a 24-h chilling period (4°C), the right side of each carcass was cut through the spinal column between the 5th and 6th thoracic vertebrae.

DISSECTION OF MUSCLES

Dissection of the chilled half carcass was carried out by making incision at the point of insertion and origin to harvest the following muscles semimembranosus, semitendinosus, biceps femoris, adductor, gluteus medius, deltoideus, supraspinatus, infraspinatus, subscapularis. The muscles were weighed separately, then their relative proportions to the cold carcass weight (CCW) and recorded. Dissection was carried out using the dissecting set apparatus following the procedures of Sisson and Grossman (1953).

STATISTICAL ANALYSES

Data were statistically analysed using the general linear models procedure of the Statistical Analysis System Institute (SAS, 1996).

RESULTS AND DISCUSSION

Body measurements

Linear measurements in relation to weight are shown in Table1 as objective measure of carcass blockiness. BA (115.75±4.25 and 70.50±5.57) and UD (110.25±1.89 and 69.00±2.16) had significantly higher values than YK (96.50±3.87 and 60.75±3.30) and WAD (86.50±5.20 and 53.25±5.32) for body length and wither height, the values for YK were greater than WAD. BA had a significantly pelvis chest than UD (80.25±5.80) and WAD (61.00±2.94), which were not different (P>0.05). When expressed relative to live weight, BA and WAD differed significantly for all values, where as UD (84.00±1.41 and 80.25±5.80) had significantly higher values for heart girth and pelvis height than WAD (75.25±3.30 and 61.00±2.94). The slaughter weight in the present study reflects commercial practices and maintains good comparability with other breed. The findings indicated that body measurements can be used for estimation of body weight of animals in the field where scales are not readily available. Lavvaf *et al*. (2012) observed that chest depth and rump width were suitable factor for predicting hot carcass weight in each of Afshari and Zandi sheep, respectively. These measurements provide important evidences for the growth of the breed and information about the morphological structure and development ability of the animals.

Table 1: Morphometric Measurements of four breeds of rams intensively fattened

Parameters	BA	UD	YK	WAD
Live weigth (kg)	36.59±1.83	37.00±0.82	36.00±1.83	36.39±2.38
Measurements (cm)				
Body length	115.75±4.25^{a}	110.25±1.89^{a}	96.50±3.87^{b}	86.50±5.20^{c}

Heart girth	2.52±0.07^{a}	2.27±0.06^{ab}	2.20±0.12^{bc}	2.40±0.17^{c}
Pelvis heigth	2.41±0.09^{a}	2.17±0.15^{b}	2.05±0.17^{bc}	1.94±0.14^{c}
Chest width	0.51±0.04	0.52±0.02	0.51±0.07	0.57±0.11
Chest depth	0.09±0.07	0.89±0.10	0.85±0.09	0.82±0.08

Means in the same along the same row with different superscripts are significantly different (P<0.05). BA: Balami, UD: Uda, YK: Yankasa, WAD: West African Dwarf

Carcass and measurements

Carcass measurements are presented in Table 2. The proportion of hot carcass weight was 18.72 ±1.85, 18.25±0.87, 17.72±0.17 and 17.72±1.26 for BA, UD, YK and WAD, respectively. Carcass and pistola length were significantly greater for BA (75.75±4.79 and 60.75±7.14) and UD (75.50±4.66 and 56.00±5.00) than YK (59.00±7.79 and 56.00± 10.62) and WAD (60.50±3.11). BA (88.00±2.16) had greater (P<0.05) leg length than both UD (80.25±5.80), YK (71.50±2.65) and WAD (61.00±2.94), which did not differ (P>0.05). When expressed relative to hot carcass weight, carcass length, carcass depth and pistola length were not significant between the breeds but were lower (P<0.05) for WAD. All the four breeds differed significantly for leg length relative to carcass weight, which was greatest for BA (0.46±0.04) and least for WAD (0.39±0.02). Breed significantly affected all carcass measurements except carcass depth, with BA having higher values for all traits. Linear carcass measurements and indexes are used as indicators of carcass conformation and size (Sañudo *et al.* , 1998c) . The results of the current study indicate significant effect of breed on carcass measurements and conformation indexes could be explained by breed specific morphologic characteristics of BA breeds.

Table 2. Hot carcass weight and carcass measurements of of four breeds of rams intensively fattened

Parameters	BA	UD	YK	WAD
Cold Carcass Weigth	18.72 ±1.85	18.25±0.87	17.72±0.17	17.72±1.26
Carcass Measurements (cm)				
Carcass Length	75.75±4.79^{a}	75.50±4.66^{a}	59.00±7.79^{b}	60.50±3.11^{b}
Carcass Depth	24.25±0.96	24.50±0.58	24.75±3.30	24.25±4.03
Pistola Length	60.75±7.14^{a}	56.00±5.00^{b}	56.00±10.62^{b}	53.75±5.91^{c}
Leg Length	88.00±2.16^{a}	80.25±5.80^{b}	71.50±2.65^{c}	61.00±2.94^{d}
Carcass Measurements (cm/100g carcass)				
Carcass Length	0.41±0.02^{a}	0.42±0.02^{a}	0.34±0.04^{b}	0.39±0.05^{ab}
Carcass Depth	0.13±0.01	0.14±0.01	0.14±0.02	0.15±0.01
Pistola Length	0.33±0.01	0.25±0.11	0.32±0.06	0.34±0.01
Leg Length	0.46±0.04^{a}	0.44±0.04^{b}	0.40±0.02^{bc}	0.39±0.02^{c}

Means in the same along the same row with different superscripts are significantly different (P<0.05). BA: Balami, UD: Uda, YK: Yankasa, WAD: West African Dwarf

MUSCLE MEASUREMENTS

Distribution of muscles are shown in Table 3. Weigth of SM and ST were significantly higher for BA (0.54±0.02) and UD (0.59±0.10) than YK (0.49±0.01) with WAD (0.47±0.03) being the lowest (P>0.05), whereas weight of the BF was significantly lower for WAD (0.22±0.06) and YK(0.25±0.05) than BA (0.36±0.01) and UD (0.39±0.06), which did not differ (P>0.05), The weigth of GM was

lower for YK (0.15±0.01) and WAD (0.15±0.02) than BA (0.18±0.01) and UD (0.17±0.01), which were similar (P>0.05). The weight of DP was higher for BA (0.63±0.06) than UD (0.42±0.11), YK (0.38±) and WAD (0.42±0.17), which were not significant to one another (P>0.05). The weight of IF (0.23±0.01), SP (0.18±0.05), DT (0.30±0.02) and SS (0.24±0.08) were significantly greater for BA. The relative weight of the SM was significantly higher for UD (0.51±0.08) and YK (0.45±0.01) than for BA (0.39±0.03)FR and WAD (0.38±0.02). The relative weight of the ST (0.40±0.04), ADD (0.38±0.03), GM (0.14±0.01) and BF (0.34±0.04) was significantly greater for UD than the values recorded for both BA and YK. The greater muscle of BA compared to the UD,YK and WAD breeds reflected the greater fleshiness and carcass conformation. The relative small differences in tissue distribution together with the non-significant differences in the proportion of muscle in the weight suggest that carcass conformation score is not a reliable indicator of traits (McGee *et al*., 2005).

Table 3. Hot carcass weight and percentage proportion of muscles of four breeds of rams intensively fattened

Parameters	Balami	Uda	Yankasa	WAD
Hot Carcass Weigth (HCW)	18.72 ±1.85	18.25±0.87	17.72±0.17	16.82±1.26

Deltoideus	0.21±0.01^{bc}	0.23±0.00^{b}	0.26±0.02^{a}	0.20±0.02^{c}
Subscaplaris	0.17±0.04^{b}	0.22±0.06^{ab}	0.28±0.01^{a}	0.27±0.01^{a}

Means in the same along the same row with different superscripts are significantly different (P<0.05). BA: Balami, UD: Uda, YK: Yankasa, WAD: West African Dwarf

CONCLUSIONS

BA and UD breeds have higher values as demonstrated by the results, the use of BA and UD becomes valuable replacement for meat production. Improvements in genetics and husbandry are needed to improve the potential of these animals for efficient large scale meat production.

ABSTRACT
This review investigated the length-weight relationships (LWR) and condition factors (K) of *Tilapia zilli, Tilapia mariae, Oreochromis niloticus, Barbus occidentalis* and *Barilius loati* from Lower Usuma Reservoir in Abuja. Two thousand four hundred and fifty two (2,452) fish samples were collected for morphometric measurements. The results obtained showed that the growth pattern of the fish species had negatively allometric growth with b values range from 1.4 to 2.3. There was significant difference between LWR (P<0.001). There were strong correlation (0.86 – 0.73) between the length and weight of all the species, except *Tilapia mariae* which was weakly correlated (0.54). The condition factor (K) range from 1.06- 2.02, these were an indication that the fish species were thriving very well in the Reservoir. Futhermore, LWR and K of 5 fish species in Nkoro River Niger delta were reviewed. The exponential equation for the LWR were: *Ethmalosa fimbrata* (Wt= 0.0162 X Tl $^{3.199}$) and *Cynoglossus senegalensis* (Wt = 0.0326 X Tl $^{3.508}$). All species studied exhibited isometric growth pattern with the value of b = 3 except *S. maderensis* and *C. senegalensis* with value of b =3.6 and 3.5 respectively that exhibited positive allometric growth. The value of K ranged from 0.92 to 0.99 for *Ilisha. africana* to *C. senegalensis)*. There was difference in the condition factors for the monthly K for *E. fimbrata* (0.85±0.015) and *I. africana* (0.96±0.061). LWR and K of *Clarias gariepinus*, in Kiri reservoir had a b value of 3.80 which indicated the fish species had allometric growth pattern. Monthly K range from 0.65 - 1.21 with a mean value of 0.78±0.09 and 1.04±0.12. Condition factors of the *C. gariepinus* were not in a good condition of wellbeing.

INTRODUCTION
The condition factor in fish serves as an indicator of physiological state of the fish in relation to its welfare (Le Cren, 1951). Condition factor play an important role in understanding the life cycle of fish species and it contributes to adequate management of these species, hence, maintaining the equilibrium in the ecosystem (Imam *et al,* 2010).
This study reviewed the length and weight relationships (LWR) and condition factors (K) of *Ethmalosa fimbrata, Ilishia africana, Sardinella maderensis, Cynoglossus senegalensis* and *Elops senegalensis* from the Nkoro River and also to assess LWR and K of *Tilapia zilli, Tilapia mariae, Oreochromis niloticus, Barbus occidentalis* and *Barilius loati* from Lower Usuma Reservoir in Abuja as well as *Clarias. gariepinus* in Kiri Reservoir Adamawa State.

STUDY AREA
The Nkoro River is a distributary of the Andoni River in the Niger Delta area of Nigeria. Lower Usuma Reservoir was located in Bwari Area council in Abuja. Kiri reservoir had a coordinates of 9°40′47″N 12°00′51″E on the southern part of Adamawa State, It was situated within Shelleng Local Government Area and Numan Local Government. The Dam is1.2 km long, 20 m high zoned embankment with an internal clay blanket.

FISH SAMPLING TECHNIQUES
Fish species were caught twice a month for a period of twelve months. The fish species were stored in coolers containing ice and transported to the laboratory for further analysis.

DATA COLLECTION
Total Length (TL) of fish species were each measured from the tip of the anterior or part of the month to the caudal fin. The weight of fish species were each measured with digital weighing balance after blot drying with a piece of clean hand towel.

STATISTICAL ANALYSIS

LWR analysis were carried out following the format accepted by FISAT (Gayando and Pauly, 1997). The LWR of the fish species was expressed by equation (Pauly, 1997):

$$W=aLb$$

W=Weight of fish in (g), L=Total Length (TL) of fish in (cm), a=Constant (intercept) and b = The Length exponent (slope)

The condition factor (k) of the experimental fish were estimated from the relationship:

$K = 100/L^3$

K= condition factor, W= weight of fish and L = length of the fish species.

RESULTS AND DISCUSIONS

Table 1: Length-weight Relationships of Fish species in Lower Usuma Reservoir

Fish species	Number of Fish species	Sex	a	b	95% CI for b	r	Significance of r	Pattern
T. zilli	601	M	0.541	2.301	2.279-2.323	0.844	0.001	Negative allometric
	604	F	0.552	2.275	2.251-2.299	0.861	"	Negative allometric
	1205	M+F	0.545	2.291	2.279-2.303	0.857	"	Negative allometric
T. mariae	120	M	0.700	1.570	1.541-1.599	0.536	"	,,
	234	F	0.730	1.442	1.422-1.462	0.543	"	,,
	354	M+F	0.720	1.486	1.470-1.502	0.539	"	,,
O. niloticus	236	M	0.539	2.328	2.295-2.361	0.861	0.001	Negative allometric
	298	F	0.577	2.198	2.165-2.231	0.862	"	"
	534	M+F	0.559	2.259	2.249-2.269	0.866	"	"

* N = Number of sample size; a and b = regression coefficients; CI = confidence interval; r =

correlation coefficient

Source: Dan-kishiya, (2013)

Table 1 shows that LWR of the fish species from lower Usuma Reservoir. The 95% confidence interval values of the exponent 'b' in the LWR varied between 2.2 and 2.3 for *Tilapia zilli*, 1.4 and 1.6 for *Tilapia mariae. Oreochromis niloticus* had values that range between 2.1 to 2.3 while *Barbus occidentalis* and *Barilius loati* had values that range between 1.9 to 2.2 and 2.3 to 2.4, respectively. Analysis of both the males and females separately and combined showed that all the species exhibited negative allometric growth pattern. Similarly, Ibrahim *et al.* (2012) observed allometric growth pattern in Kontagora reservoir in Niger state. There was strong correlation 0.536 between the length and the weight of all the species except *Tilapia mariae* which was weakly correlated. Model equation for *Tilapia zilli*: Weight = 0.541+ 2.301 length. LWR of *C. gariepinus* in River Kiri revealed that b value was 3.18, which exhibited allometric growth and showed linear relationship with significant correlation coefficient of 0.122 ($p<0.05$). King (1991) also reported allometric growth patterns for Tilapia species from Umuoseriche Lake.

Table 2. Mean condition factor (K) of five fish species from Lower Usuma Reservoir

Fish species	Number of fish species	Sex	Mean K	Mean TL(cm)	Mean W(gm)	STD	SE
Tilapia zilli	601	M	2.02	10.397	22.747	0.26	0.011
	604	F	1.96	11.490	29.733	0.29	0.012
	1205	M+F	2.00	10.945	26.249	0.28	0.008
Tilapia mariae	120	M	1.82	7.360	7.215	0.16	0.015
	234	F	1.94	7.465	8.063	0.15	0.010
	354	M+F	1.90	7.429	7.776	0.16	0.009
Oreochromis	236	M	1.93	10.742	23.891	0.25	0.016
niloticus	298	F	1.87	11.944	31.942	0.29	0.017
	534	M+F	1.91	11.413	28.384	0.12	0.005
Barbus	81	M	1.31	10.021	13.233	0.17	0.019
occidentalis	225	F	1.24	10.266	13.406	0.19	0.013
	306	M+F	1.26	10.201	13.361	0.18	0.010
Barilius loati	53	M+F	1.06	12.102	18.759	0.14	0.019

* N = Number of sample size; K= Condition factor; TL= total length; W= weight; STD= standard deviation; SE= standard error
Source: Dan-kishiya, (2013)

There were differences in the condition factors for the males and females as well as combined sexes and the monthly K- factor for each fish species studied. The condition factor for the 5 species recorded ranged from 1.06 to 2.02. *Tilapia zilli* had a range of 1.96 – 2.02 while, *Tilapia mariae* had a range of 1.82 – 1.94 with a monthly range of 1.55-2.85 (fig.2). Others were *Oreochromis niloticus, Barbus occidentalis* and *Barilius loati* with mean K- values of 1.87 – 1.93, 1.24 – 1.31 and 1.06 while there monthly values range from 1.52-2.2 (fig.3), 1.04-1.52 (and 0.82-1.58, respectively. While Ahmed and Saha (1996) recorded a K value that ranged from 0.506 to 3.415 which indicated that the fish species were doing well.

Monthly condition factor for *C. gariepinus* in Kiri reservoir (July) varied between 0.84 and 1.02 with mean value of 0.93 ± 0.07, while in December varied between 0.95 and 1,21 with a mean value of 1.04 ± 0.12. This support the findings of Jafaru (2011) who reported an increase in K during dry season as a result of water clarity during the period. The mean K value obtained in River Nkoro ranged from 0.941 – 0.985 slightly varied with results from others studies. The K value in the study showed the fish species were in good condition. Pauly (1997) reported that data pulling, sex, stages of maturity and stage of stomach affects K value of fish species.

CONCLUSIONS

Growth pattern of the fish species were mostly allometric. However *I. Africana* and *E. senegalensis* had isometric growth pattern. There is direct relationships between the length and weight of *C. gariepinus.* The fish species had moderate condition factors.

ABSTRACT

A ninety days feeding trial was conducted to assess the effects of Pineapple waste (PW) with Yeast supplementation (YS) on performance, rumen parameters and microbial counts of West African Dwarf (WAD) goats. Twelve WAD goats were used for the experiment, using *Panicum maximum* as the basal diet. The experiment had four treatments with three animals per treatment. The total body weight gain of the animals were significantly (P<0.05) higher than the control. Average daily feed intake was significantly different (P<0.05) and the highest value was recorded in goats fed 30% inclusion in the diet (3.90kg). The feed conversion (FCR) ratio was also significantly different (P<0.05) and the lowest FCR was recorded in diet containing 30% inclusion level of Pineapple waste with Yeast supplementation. Rumen parameters such as pH, lactic acid, propionic acid, butyric acid were also significantly (P<0.05) different across the treatments. The total bacteria counts, total fungi counts were also significantly (P<0.05) different across the treatment respectively. The use of Pineapple waste (PW) with yeast supplementation at 30% inclusion level of ruminant feed improved the performance characteristics, rumen fermentation parameters and microbial counts of West African Dwarf Goats.

INTRODUCTION

Nutrition is perhaps the most important consideration in Livestock management. Inadequate supply of both quantity and quality of feeds is responsible for the low livestock productivity. Seasonal variability in Nigeria affects the nutritive quality of natural pastures which in turn, affects animals' live-weight (Suilapwa and Simukoko, 2001).However, to alleviate the shortage in feed during the dry season, farmers collect agro-industrial by-products, dry and store them for later use. The completion between man and livestock for conventional feedstuffs has necessitated the need to explore alternatives feed resources that are rarely consumed by man but which can meet the nutritional requirement of goat with little or no processing (Saksathit *et al.*,2011).

Goats in Nigeria suffer several nutritional stress in the dry season as a result of seasonal variability that affects the availability and nutritive quality of pastures which in turn marked decrease in nutrient intake and utilization. Small ruminant feed requirement in the tropics is aggravated by high cost of conventional feeds and lack of alternative source of feeds particularly during dry season when forages are scarce. This has necessitated the need to search for alternative source that are cheaper and readily available. (Okoruwa and Adewumi, 2010)

Pineapple waste is such an example of Agro-industrial by-products that can be explicated to a good advantage for ruminant animal nutrition in Nigeria. Pineapple waste is usually discarded as waste after processing, is also rich a rich source of energy, but low in protein (Fadel *et al.*, 2000).

Yeast products such as *Saccaromyces cerevisiae* appear to be more useful in manipulating the microbial ecosystem of the rumen to improve feed utilization and productive efficiency of the ruminants. This study is designed to evaluate the performance and rumen fermentation parameters of West African Dwarf goats fed diet containing pineapple wastes with yeast supplementation.

MATERIALS AND METHODS

The experiment was carried out at the Small Ruminant Unit of the Federal College of Animal Health and Production Technology, Moor Plantation, Ibadan, Nigeria. Four experimental concentrate diets containing varying levels of pineapple waste at 0%, 10%, 20% and 30% in replacement of maize bran

with yeast supplementation were formulated. Other fixed ingredients in the diets include wheat offal, dried brewers grain, oyster shell, premix and salt. The gross composition of the experimental diets is as presented in Table 1. Twelve WAD goats aged 6-7 months were used for the experiment. The goats were given prophylactic treatments before the commencement of the experiment and randomly allotted to four treatment groups of 3 animals per treatment having balanced them for weight. The experimental design was a completely randomized design and lasted for 3 months. Fresh water was supplied *ad-libitum* while feeding was done at 07.00 hrs and 16.00 hours Daily feed intake and weight gain were monitored and recorded. Rumen fluid was collected by the use of a suction tube. The rumen fluid was collected and taken to laboratory for analysis to know the volatile fatty acids, the lactic acid, the rumen pH, the ammonia nitrogen and microbial counts.

CHEMICAL ANALYSIS

The proximate composition of experimental diet was carried out according to method of (A.O.A.C,1995) while fibre fractions analysis was done according to (Vansoest and Robertson,1985)

STATISTICAL ANALYSIS

Data obtained was subjected to one-way analysis of variance in a completely Design using (SAS,1999). Significant means were separated using Duncan Multiple Range Test (Duncan,1955)

RESULTS AND DISCUSSION

Ingredients composition of experimental concentrate diets are shown in Table 1. The chemical composition of the experimental diets (Table 2) shows that Crude protein (CP) contents ranged between 162.1g/kg DM in 0% inclusion level to 149.2g/kg DM in treatment 4 and was not consistent with the values of 9500 g/kg DM to 1000 g/kg DM obtained by ARC (1990). The performance characteristics (Table 3) shows that total weight gain and growth rate were significantly different ($P<0.05$). The results obtained from the experiment based on weight gain agrees with the earlier findings of (Okoruwa and Adewumi, 2010) which says higher growth rate and lower feed conversion ratio had indicated better performance of the animals. . Also, the inclusion of yeast (*Saccaromyces cerevisiae*) in the concentrate feed had a positive effect on weight gain which is in line with what was reported by Fickers *et al*. (2005) that supplementation of yeast improved feed utilization and productive efficiency of ruminants.

Table 4 shows the rumen parameters and microbial counts of West African Dwarf goats fed pineapple waste with yeast supplementation. There were significant differences ($p> 0.05$) in the Ammonia nitrogen, Acetic acid, Lactic acid, Propionic acid and Butyric acid respectively. Treatment 4 which had the 30% inclusion of pineapple waste with yeast supplementation had the highest pH (6.10) which was in agreement with the findings of Wells and Russels (1993) whose value was (5.5-7.5) which was recommended to be a standard rumen pH values. Bacteria counts of rumen are dependent on rumen ammonia concentration and pH of the rumen fluid and both are factors dependent on the type of diet fed.

CONCLUSION

It can be concluded from this research work that inclusion of pineapple waste with yeast supplementation in the diet of West African Dwarf (WAD) goats did not have any negative influence on performance characteristics, rumen fluid parameters, and microbial counts.

CHEMICAL COMPOSITION OF MILLET PANICLE WASTE ENSILED WITH POULTRY MANURE AT GRADED LEVELS

N. Kadi[2], Muftau,M. A[1]
Department of animal science, KSUSTA, Kebbi State

ABSTRACT
Millet panicle waste was ensiled with poultry dropping at graded levels; 90:10, 80:20, 70:30, 60:40 (millet panicle waste/poultry dropping) representing B, C, D and E respectively, and 100:00 (control) treatment A. The material ensiled were put in polythene bags replicated three times, the sample were sealed and allow fermentation to take place for a period of 21 days. The resultant silage was analyzed for pH, Crude protein (CP), Crude fiber (CF), Either Extract (EE), ash and Nitrogen Free Extract (NFE). There were significant differences ($p<0.05$) in all the parameters measured except that of Dry matter (DM). Ensiling millet panicle waste increased pH, CP, ash, EE, and NFE, but reduced CF with increased proportion of poultry dropping. Treatment C has the highest CP (4.38) and DM (93.50), with lower CF (1652) compared with control treatment with (33.73). The result suggested that ensiling millet panicle waste with poultry dropping improve its feeding value.

INTRODUCTION
Proper nutrition is necessary for optimum livestock production; unfortunately, there is shortage of forage supply during dry season for ruminant animal especially in the northern part of Nigeria. (Ruthender, 1980). There are many agricultural crop residues with great potential for ruminant feeding. One of such is millet by product known as millet panicle waste.
Presently, the consumption of millet is becoming more pronounced in the most of the northern region especially in villages and semi urban areas where there is availability of millet panicle waste especially during dry season in northern part of Nigeria when people engage in processing of millet. The panicle waste are thrown everywhere during this period of processing. Millet panicle waste is obtainable from processing of millet which is not use for any purpose. The waste are dumped in the water ways causing environmental havoc by blocking drainages or burnt by local people which causes additional environmental pollution by increasing the global warming effect.

Silage making is considered as a technology that increase livestock productivity and minimizes resource degradation and viable option for conserving succulent feeds (Muhammad et *al.,* 2008).

In view of this, the utilization of millet panicle waste as feed for ruminants will drastically reduce the above mentioned problems as well as solving the problem of feed scarcity especially in the dry season. The aim of this study is to find out the chemical composition of millet panicle waste ensiled with poultry droppings at different graded levels

MATERIALS AND METHODS
The experiment was conducted within the Animal Science laboratory of Kebbi State University of science and Technology,

COLLECTION AND PREPARATION OF EXPERIMENTAL MATERIALS

Millet panicle waste was collected from processing points identified within and around Aliero LGA. All foreign materials (stones, irons, polythene) were removed. Poultry manure was obtained from Labana poultry farm Aliero. The collected millet panicle waste and poultry manure were sun dried to a constant weight by spreading on a concrete floor.

ENSILING PROCEDURE

The dried millet panicle waste used for silage was packed in a polythene bags to make compaction easier. (Ogunlolu *et al*; (2010). Millet panicle waste was ensiled with poultry manure in proportions, 100:00, 90:10, 80:20, 70:30 and 60:40, representing treatment A, C, D, and E respectively. Fifteen Polythene bags were used as laboratory silos (Ogunlolu *et al*; 2010). The samples were ensiled for 21 days in triplicates; masking tape was used to further seal the polythene bags after filling with weighed materials and compressed.

At the expiration of the ensiling period, the polythene bags were opened and top most materials was scooped off to avoid contamination with partially ensiled materials. The samples were taken using forceps from each ensiled polythene bag for pH determination and chemical analysis.

EXPERIMENTAL DESIGN AND DATA ANALYSIS

A complete Randomized design (CRD) was used as outlined by Steel and Torrie (1980). There were five treatments designated as A, B, C, D and E with three replicates each.

PROXIMATE ANALYSIS

Crude protein (CP) where measured using kjeldhl method (Nx6.25) while other proximate constituents, Either extract (EE), Ash, Crude fiber (CF) and Nitrogen Free Extract (NFE) were measured according to procedure described by AOAC (2005).

DATA ANALYSIS

Data were analyzed using the general linear model procedures of the (SPSS 2007), and mean separation was done using Duncan multiple range test (DMRT) at 5% probability level.

RESULTS AND DISCUSSION

Table 1: pH properties of ensiled millet panicle waste

Treatments		**pH**
A	100:00	5.45^{c}
B	90:10	5.71^{c}
C	80:20	6.11^{bc}
D	70:30	7.69^{ab}
E	60:40	8.45^{a}
SEM		9.39

abc: means on the same row with different super scripts are significantly ($p<0.05$) different

Table 1: present the pH reading of the silage. Significant differences ($p<0.05$) were observed among the treatments. The highest pH was recorded in treatment E(8.45) with the least in treatment in treatment A. (4.45). This is in accordance with the findings of Rasool *et el*. (1998) Who reported an increase in initial and subsequent pH in sudax grass ensiled with 30% broiler litter and 9%molasses.

Table 2: Proximate analysis millet panicle waste

	Treatments					
Parameters	A (0%)	B (10 %)	C (20 %)	D (30%)	E (40%)	SEM
DM	94.00	92.50	93.50	92.00	91.75	12.27
CP	3.15^{d}	3.68^{c}	4.38^{a}	3.99^{b}	3.98^{b}	0.069
CF	33.73^{d}	22.46^{c}	19.30^{b}	21.06^{bc}	16.52^{a}	7.89
EE	4.25^{ab}	4.05^{ab}	4.95^{ab}	3.25^{c}	5.51^{a}	7.89
ASH	4.25^{d}	6.75c	8.25^{b}	12.25a	11.75a	8.74
NFE	20.47^{d}	75.32^{b}	77.63^{a}	972.02^{c}	72.77^{c}	10.39

abcd: means on the same row with different superscripts are significant ($p<0.05$) different.

Table 2: shows the proximate composition of millet panicle waste. There is no significant ($p<0.05$) difference in the dry matter among the treatments. However, the highest value was obtained in treatment A (94:00) and the least was recorded in treatment E (91.75). This contradicts with Al Rokayan *et al*. (1998) who reported an increase in the dry matter when broiler litter was ensiled with sorghum forage in the proportions of 0:100, 25:75, 35:65, and 45:55.

The values of CP of the resultant silage was observed to have increased ($p<0.05$) with increase proportion of poultry droppings. The CP was highest in treatment C (4.38) than B, D, and E although the increase was not steady across the treatments. This is in line with Ngele *et al*. (2006) who reported an increase in the CP when rice straw was treated with broiler litter at different ratios.

There was significant difference ($p<0.05$) in CF composition of the silage among the treatments. CF of all treatments is lower than the control, the CF was observed to decrease with increased proportion of poultry dropping from (22.46) in treatment B to (16.52) in treatment E. This is in accordance with the findings of Rasool *et al,* (1998) who observed decreased in CF when sudax grass was with broiler litter and molasses.

The EE components of the treatments were significantly ($p<0.05$) affected, the highest EE was recorded in treatment E (5.51) and the least was recorded in treatment D (3.25). The result of this study agreed with that of Mthiyan *et al*. (2001) who observed an increase in EE composition of sugar cane top ensiled with broiler litter and that of Ngele *et al* (2006).

Ensiling millet panicle waste with poultry dropping increases ($p<0.05$) ash content of the resultant silage. Treatment D has highest value (12.25) compared with treatment E, C, B and the control which has least value of (4.25). This is in agreement with the findings of Al Rokayan *et al*. (1998) and that of flachowsky and Hennig (1990) who observed a linear increase in ash content with increased proportion of broiler litter.

Nitrogen Free Extract of the millet panicle waste ensiled with poultry dropping increases ($p<0.05$) with the increase in the level of poultry dropping with treatment C having the highest value (77.63)

and the least was recorded in treatment A (20.47). This observation agreed with the findings of Baba *et al*. (2010).

CONCLUSION

Poultry dropping improved the nutritive value by increasing the CP and lowering the CF of the waste.

ABSTRACT
A feeding trial was conducted to assess the effect of inclusion of ensiled sugarcane waste (ESCW) with poultry litter on rumen fluid characteristics of Yankasa rams in a completely randomized design (CRD) for twelve weeks (84 days). Sugarcane waste was mixed with poultry litter in 3:1 and ensiled for 21 days. The ESCW was used as partial replacement in complete diet. Sixteen Yankasa rams (mean body weight 21.87±2kg and aged 12 to 18 month) were allotted to the four groups on the of body weights into control without ESCW (CG) or control diets partially replaced with ESCW 15% (T1), 30% (T2) or 45% (T3) as treatment groups (TG). Diets were offered *ad-libitum,* along with clean drinking water and mineral salt lick at will. Ten (10mls) of rumen liquor was drawn individually from all experimental animals using rubber stomach tube before feeding (0 hours), at 3 hours and 6 hours after morning feeding for pH and microbial counts determination. The results showed that there were significant ($P<0.05$) differences in bacteria counts at 3 and 6 hours sampling periods while fungi counts were significant ($P<0.05$) different at 0 and 3 hours sampling periods. In conclusion, feeding of ESCW maintained the pH of the rumen fluid at optimum for fibre digestion. The results further indicated that the number of bacteria and fungi in solution were adequate for fibre degradation. Therefore, inclusion of up to 45% ESCW could be done to improve its utilization by Yankasa rams.

Key words: Ensilage rumen pH bacteria fungi

INTRODUCTION
The major constraint to livestock production in developing countries is the scarcity and fluctuation in quantity and quality of year round forage supply. During the dry season, the available forages are very low in protein, energy and minerals leading to a marked decrease in the voluntary feed intake and digestibility (Akinwande *et al.,* 2011). With increasing demand for livestock products as a result of rapid growth in the world economic and shrinking land area, future hope of feeding the ever increasing population will depend on the better utilization of non-conventional feed resources. Any factor affecting rumen microorganism populations directly or indirectly affects yield and feed efficiency ratio (Hobson and Stewart, 1997). Sugarcane (*Saccharum officinarum*) is a typical or sub-tropical perennial grass. Sugarcane waste is obtained when the cane is being processed for chewing (Ashiru *et al*., 2016), it comprises of the top, peels, and bagasse. Sugarcane waste has not gain much attention in ruminant feeding, it is dumped on the street and water ways which often constitute nuisance in the environment by blocking drainage. Although a number of non-conventional feeds are traditionally used in livestock feeding little or no information is known on their effects on the rumen environment.

OBJECTIVES
This study therefore aims at evaluating the effect of ensiled sugarcane waste on rumen fluid characteristics of yankasa rams.

MATERIALS AND METHODS
The study was conducted at the Research Farm, Department of Animal Science, Kano University of Science and Technology, Wudil, Kano State, located in the Sudan Savannah Region of Nigeria. The site is situated between longitude $8^0$25'E and latitude $12^0$58'N. The area has an average annual rainfall of 890mm with a peak in August with an average annual temperature of 38 to 43^0C and relative humidity of 40 to 51% (Olofin *et al*., 2008). There are three distinct seasons recognized in the area viz: dry cold (October to January), dry hot (February to May) and wet (June to September).

ENSILING PROCEDURE AND EXPERIMENTAL MATERIALS

Sugarcane waste (SCW) was collected within and around Kano State, cleaned for extraneous materials like stones, iron and polyethene. Poultry litter (PL) was obtained from a deep litter poultry production system. The collected SCW and PL were sun dried for a period of 3 days during dry season by thinly spreading on a concrete floor. The dried SCW used for the silage were chopped into about 2-3cm length using forage chopper for better compaction (Ogunlolu *et al*., 2010). SCW was ensiled with PL (ESCW) in the ratio 75: 25, for 21 days after wetting with water at the rate of 15 l/25kg mix in a 300 liter capacity plastic water reservoir as silo. Silo filled with weighed materials was covered with polyethene and compressed by human trampling. Five hundred kilograms (500kg) of the ESCW with PL was produced and used to formulate four diets (Table 1). Other concentrate feed ingredients included in the diets were maize, wheat offal, full fat soybean meal, cowpea husk and salt. The diets were fed *ad-libitum* as complete diet to all the experimental rams.

EXPERIMENTAL ANIMALS AND MANAGEMENT

Sixteen male Yankasa rams (Mean body weight 21.87±2kg; aged 12 to 18 months) were purchased from the market and quarantined for two weeks. The rams were treated for internal and external parasites with Ivomec® – super at 200µg/kg body weight subcutaneously before the start of the experiment. Rams were divided into 4 groups of 4 animals each in CRD based on live weight (Steel and Torrie, 1980). Control group (CG) was fed diet without ESCW while other 3 treatment groups (TGs) were fed 15, 30, and 45% of ESCW, respectively replacing the concentrate feedstuffs (Table 1). Rams were housed in individual pens measuring 2m x 1m. The pens were cleaned and disinfected using Omo® detergent and Moriguard®. Water and salt lick were provided *ad libitum*.

DATA COLLECTION

Ten (10mls) of rumen liquor was drawn individually from the all experimental animals using rubber stomach tube before feeding (0 hours), at 3 hours and 6 hours after morning feeding. The collected samples were strained through two layers of cheese cloth (Prigge *et al.*, 1984), the pH was measured immediately using a digital pH meter. Strained rumen fluids were stored in glass bottles and immediately transferred to laboratory for analysis.

CHEMICAL ANALYSIS

Thoroughly mixed representative samples of the experimental diets and faeces were analyzed for dry matter (DM), crude protein (CP), crude fibre (CF), ether extract (EE), ash and nitrogen free extract (NFE) according to AOAC (2005) procedures. The bacteria, protozoa and fungi, in the rumen fluid were estimated at 0, 3, and 6 hours after morning feeding by the method described by Broudiscou *et al*. (1997).

STATISTICAL ANALYSIS

Data were subjected to analysis of variance (ANOVA) using CRD and significant differences between the means were tested by least significant difference (Steel and Torrie, 1980). Differences between the means were considered significant at 5% probability level ($P<0.05$). The data were analyzed using SAS Statistical package (SAS, 1989). The tools of the study were generally linear model(GLM) package of SAS. Where means was separated using the least significant difference (LSD).

RESULTS AND DISCUSSION

Chemical composition (%) of the experimental diets

The results of the chemical composition of experimental diets are presented in Table 2. It can be seen that dry matter varied from 90.78% in CG to 94.80% in TG3. Percent DM values obtained in the present study were comparable and differed slightly from the DM values 94.00 to 95.00% reported by Sirajo *et al*. (2010) for diets containing graded levels of PL waste. Crude protein content of the TGs varied from 14.39 to 14.87% while that of CG was 13.89%. The CP values obtained in the present study were higher than the range of 10 to 12% recommended by Gatenby (2002).

RUMEN FLUID CHARACTERISTICS

The resultS for rumen fluid characteristic of Yankasa rams fed graded levels of ESCW ensiled with PL are shown in Table 3. There were significant (P<0.05) differences among different means of diets at different sampling times for pH, bacteria and fungi, except for 0 hours (before feeding). There were no significant (P>0.05) differences in pH values at all the sampling periods. Rumen pH is an important factor affecting fermentation in the rumen and influences its function. The CG and the TGs had neutral pH values at 0 hours, the pH tended to be more acidic after 3 hours post feeding, but showed less neutral pH at 6 hours of post feeding. According to Campbell *et al*. (1988), changes in pH could be due to plane of feeding. Intake of feed has a major effect on rumen pH which generally declines after feeding (Maekawa *et al*., 2002a). At 3 hours post feeding bacteria counts in TG2 were significantly (P>0.05) higher than those of CG, while at 6 hours, bacteria the CG had significantly (P<0.05) higher bacterial counts. Bacterial count was observed to be the same statistically at 0 hours sampling time for all the treatments, this might be due to the starvation since all animals were not given any feed. The observed increased in bacterial count at 3 hours might be due to bacterial activities in the rumen after feeding which resulted in the conversion of feeds to VFAS. The decrease in bacterial count at 6 hours sampling time might be due to the fact that microorganisms themselves are digested to free up nutrient for the ruminants use (Ensminger, 2002). Similarly fungi counts were significantly (P<0.05) different at 0 and 3 hours sampling. At 0 hours, the CG had significantly (P< 0.05) higher fungal counts while at 3 hours sampling period the CG is comparable to TG3. Fungi appears to be the first organisms to invade and commence digesting the structural plant components, beginning from the inside, they reduce the tensile strength of these particles (Akin *et al*., 1989) and thus increase particle breakdown in rumination. This might be attributable to the fungi's efficient enzymes system which can degrade structural elements of the plant cell wall.

CONCLUSION AND RECOMMENDATION

In conclusion, feeding of ESCW maintained the pH of the rumen fluid at optimum for fibre digestion. The results further indicated that the number of bacteria and fungi in solution were adequate for fibre degradation. Therefore, inclusion of up to 45% ESCW could be done to improve its utilization by Yankasa rams.

NUTRITIVE VALUE AND ANTIOXIDANT PROPERTIES OF SOME CROP RESIDUES USED IN RUMINANT FEEDING

✸Yusuf, H. K. & ◆Garba, Y.
✸Department of Agricultural Science Eductaion, Sa'adatu Rimi College of Education, Kano
◆Centre for Dryland Agriculture, Bayero University, Kano

ABSTRACT
The study was carried out to evaluate the nutritive value and anti-nutritive properties of five common crop residues used in ruminant feeding. The crop residues used were, millet bran, groundnut hay, rice mill waste, cowpea husk and maize cobs. The treatments were laid in a completely randomized design. The samples were shade dried, pulverized and analyzed for nutritive value (proximate constituents) and antioxidant properties which were replicated thrice. Data collected were analyzed using SAS (2000) and means were separated using Tukey's test at P<0.05. The results obtained showed that there was significant (p<0.05) difference among the treatments in all variable evaluated. Cowpea husk had the highest crude protein contents (13.77%) and nitrogen free extract (80.33%) while ash content was found to be highest in groundnut hay (7.15%) and maize cobs had the least dry matter content (90.14%). Alkaloids and saponins levels were highest in groundnut hay (0.70%) and millet bran (2.58%) respectively. Groundnut hay had the least radical scavenging activity (0.29µg/ml) and (0.31µg/ml) at 0.8mg/ml and 1.0mg/l respectively while maize cobs had the highest at both concentrations. The ferric reducing power effect was recorded highest in rice mill waste (0.65µg/ml) at 0.4ml/l and least in maize cobs (0.48µg/ml) at 0.2mg/ml concentrations. It is concluded that in terms of crude protein and nitrogen free extract, cowpea husk proved to be superior. However, groundnut hay had superior ash content. Similarly, cowpea husk had the highest total antioxidant activity.
Key words: crop residues, nutritive value, antioxidant

INTRODUCTION
Human population explosion is a source of worry globally. Food shortages and famine are becoming endemic in many places. To address these problems, scientists are investigating alternative feed sources, evaluating and utilization of food. Thus, feeding grains to ruminants is questioned because Man, a monogastric can utilize grains directly. On the other hand, ruminants are characterized by their ability to convert low quality roughages to meat, milk, natural fibres, leather and manure and other products that are useful to Man (Gertenbach, 2013). Hence, the use of crop residues in ruminant feeding has been advocated. The nutritive value of crop residues is influenced by several factors depending on the type of the crop. It is generally determined by feed composition, intake and utilization efficiency of digested matter (ACP, 2002). Various crop residues have diverse nutritional values and are used by different animal species.
An antioxidant is a molecule that inhibits the oxidation of other molecules or a substance that in small amount will inhibit the oxidation of other compounds (Prakash *et. al.*, nd). Oxidation is a chemical reaction that can produce free radicals, leading to chain reactions that may damage cells. The main characteristic of an antioxidant is its ability to trap free radicals. The aim of this study was to evaluate the nutritive value and anti-nutritive profile of common crop residues used in ruminant feeding.

MATERIALS AND METHODS
SAMPLE COLLECTION:
The crop residues evaluated were millet bran, rice mill waste, groundnut hay, cowpea husk and maize cobs. Maize cobs, cowpea husk and rice mill waste were obtained from the Faculty of Agriculture Farm, Bayero University Kano while groundnut hay and millet bran were obtained from farms in Kibiya Local Government Area.

SAMPLE PREPARATION:
The crop residues were shade-dried, pulverized using a grinder and stored in airtight containers as stated by Seal (2011). Proximate composition and antioxidant concentration as well as its activities were evaluated in the Biochemistry laboratory Bayero University Kano.

PROXIMATE ANALYSIS:
The nutritive value (proximate contents) of the samples comprising moisture, ash, ether extract, crude protein, crude fibre and Nitrogen Free Extract (NFE) were determined according to the standard methods outlined by AOAC (2000).

ANTIOXIDANT TESTS
The antioxidant analysis for the presence of saponins, tannins, alkaloids, and flavonoids were carried out according to the methods described by Ejikeme *et. al,* (2014) and Hassan *et. al,* (2015). Each analysis was carried out in triplicate.

EXTRACTION OF PLANT MATERIAL FOR ANTIOXIDANT ANALYSIS:
One gram of each plant material was soaked in 20ml aqueous methanol (20%) for 18 hours at room temperature. The extracts were filtered and diluted to 50 ml and aliquot were analyzed for their total phenolic content and their free radical scavenging capacity (Seal, 2011).

QUALITATIVE ANALYSES OF ANTIOXIDANT:
Two grams of each sample was measured and poured into a conical flask, 50ml of distilled water was added to the Sample and the mixture was shaken vigorously and allowed to stop for 30 minutes. The mixture was then filtered using Whatman filter paper and few drops of different indicators were added to the filtrate depending on the compound of concern.

ESTIMATION OF ALKALOID CONTENT:
Two and a half grams of each plant sample was weighed into a 250 cm^3 beaker and 200 cm^3 of 10 % acetic acid in ethanol was added to each plant powder and allowed to stand for 4 hours. This was filtered and the extract was concentrated on a water bath to one - quarter of the original volume followed by addition of 15 drops of concentrated ammonium hydroxide drop wise to the extract until the precipitation was complete. The whole mixture was allowed to settle for 3 hours, the supernatant was discarded and the precipitates washed with 20cm^3 of 0.1M of ammonium hydroxide and then filtered using Whatman filter paper. The residue was dried in an oven and weighed using electronic weighing balance (Ejikeme *et. al,* 2014**).**

ESTIMATION OF TOTAL FLAVONOID CONTENT:
The total flavonoid content of crude extract was determined by the aluminium chloride colorimetric method. Fifty microliter of crude extract (1 mg/ml ethanol) were made up to 1 ml with methanol, mixed with 4 ml of distilled water and then 0.3 ml of 5% $NaNO_2$ solution; 0.3 ml of 10% $AlCl_3$ solution was added after 5 min of incubation, and the mixture was allowed to stand for 6 minutes. Then, 2 ml of 1 mol/L NaOH solution were added, and the final volume of the mixture was brought to 10 ml with double-distilled water. The mixture was allowed to stand for 15 min, and absorbance was measured at 510 nm. The total flavonoid content was calculated from a calibration curve, and the result was expressed as mg rutin equivalent per g dry weight (Baba and Malik, 2015)**.**

ESTIMATION OF TOTAL SAPONIN CONTENT:

Fifty microliter of plant extract was added to 250 µL of distilled water. To this, 250 µL of vanillin reagent (800 mg of vanillin in 10 mL of 99.5% ethanol) was added. Then 2.5 mL of 72% sulphuric acid was added and it was mixed very well. This solution was kept in a water bath at 60 °C for 10 min. After 10 min, it was cooled in ice cold water and the absorbance was read at 544 nm. The values were expressed as diosgenin equivalents (mg DE/g extract) derived from a standard curve (Makkar *et. al*, 2007).

DETERMINATION OF TOTAL ANTIOXIDANT ACTIVITY

The antioxidant activity of the extracts was evaluated by the phosphomolybdenum method according to the procedure of Prieto *et al.* (1999). Three mililiter of reagent solution (0.6mM sulfuric acid, 28mM sodium phosphate and 4mM ammonium molybdate) was added to 0.3 ml of the plant extracts. The tubes containing reaction solution were incubated at 95°C for 90 minutes. Then the absorbance of the solution was measured at 695nm using spectrometer against blank after cooling to room temperature.

DETERMINATION OF FREE RADICAL SCAVENGING ACTIVITY (FRSA) USING DPPH METHOD

The free radical scavenging activity of the extract was measured using DPPH by the method of Blios (1958). A 0.1 mM solution of DPPH in methanol was prepared and 1 ml of this solution was added to 3 ml of various concentrations (0.2 to 1.0 mg/l) of sample dissolved in methanol to be tested. After 30 min, absorbance was measured at 517 nm. Ascorbic acid was used as a reference material. The scavenging activity was calculated as follows:

DPPH radical scavenging activity (%) = [(Absorbance of control – Absorbance of sample)/Absorbance of control] × 100 (Babu *et. al*, 2013).

DETERMINATION OF ANTIOXIDANT ACTIVITY USING FERRIC REDUCING ANTIOXIDANT POWER (FRAP)

The reducing power of the extract was determined according to the method of Oyaizu (1986). The mixture was incubated in a water bath at 50°C for 20 minutes. Afterwards, 2.5ml of a 10% (w/v) trichloroacetic acid solution was added and the mixture was then centrifuged at 3000 rpm for 10 minutes. A 2.5ml aliquot of the upper layer was combined with 2.5ml of distilled water and 0.5 ml of a 0.1% (w/v) solution of ferric chloride, and absorbance was measured at 700nm (Babu *et. al*, 2013)

Data Analysis*:*

The data collected were subjected to analysis of variance (ANOVA) using SAS 2000 and means were separated using Tukey's test at ($p<0.05$)

RESULTS AND DISCUSSION

Table 1: Proximate Composition of Some Crop Residues used in Ruminant Feeding

CROP RESIDUES	PARAMETERS (%)					
	Ash	Dry Matter	Crude protein	Crude fibre	Ether extract	Nitrogen free extract
Millet bran	4.98^{b}	94.13	9.42^{b}	6.48^{d}	4.04^{a}	75.07^{b}
Groundnut hay	7.15^{a}	91.98	12.53^{a}	11.50^{c}	1.02^{d}	67.81^{c}
Rice mill waste	4.30^{bc}	93.22	9.15^{b}	40.33^{a}	1.53^{c}	44.69^{e}
Cowpea husk	2.55^{d}	92.26	13.77^{a}	2.79^{e}	0.57^{e}	80.33^{a}

Antioxidant activity (µg/ml)	1.46[d]	2.04[b]	1.28[e]	2.62[a]	1.83[c]

a,b,c,d and e means with different superscripts across rows are significantly different ($p<0.05$)

All the crop residues analyzed in this study had crude protein (CP) content higher than the critical level 7% required for optimum microbial function of the rumen (Van Soest 1982) except maize cobs which has a value (6.59%) closer to that reported by Bogale *et.al* (2008) who treated pea straw. This indicates that there is no need for protein supplementation in the diets of ruminants when these crop

residues are utilized. However, the CP content of groundnut hay was not in line with literary report by Ayoade *et. al,* (1983). These differences may be due to plant varieties, methods of processing and handling of the plant material.

The values of the dry matter (DM) content obtained from this study were comparable where the value obtained for millet bran (94.13%) was similar to 94.2% reported for wheat straw by Bogale *et. al,* (2008). However, DM content of maize cobs (90.14%) obtained in this study differed from report of Olagunju *et .al,* (2013). This result was also not in agreement with reports by Tonamo *et. al,* (2015).

The ash content obtained was in agreement with report by Aregheore and Ikhatua (1999).

The alkaloid levels of crop residues were considerably higher than those reported by Onyeonagu and Njoku (2010).

Tilley and Terry (1963) reported that most crop residues contain saponin but the quantities of saponin produced by the crop residues are too low to pose major animal health problem. The saponin levels obtained in this study (1.94% to 2.58%) are within the range (0.03% - 5.18%) reported for crop residues and agro industrial by products by Onyeonagu and Njoku (2010).

Results with respect to free radical scavenging activity of some common crop residues, where the scavenging effect of rice mill waste increases with an increase in the concentration of the sample from 0.2mg/l to 1.0mg/l is supported with the findings of Senguttuvan *et. al,* (2014) who treated medicinal plants at different concentration of the plant extracts (50µg/ml to 250µg/ml). At 1.0mg/l concentration, rice mill waste and maize cobs showed strong radical scavenging activity of 0.50µg/ml and 0.51µg/ml respectively while ground hay showed relatively poor free radical scavenging activity of 0.31µg/ml. This variation might be due to the phenolic content of the plant extracts (Zahin *et. al,* 2009).

The result obtained from the present study revealed that the ferric reducing antioxidant power of some common crop residues increased with an increase in the concentration of the extracts which is in agreement with reports by Senguttuvan *et. al,* (2014) when medicinal herbs were evaluated.

ABSTRACT
The objective of the study was to determine the effect of sweet potato vine cultivars on *in sacco* nutrients disappearance. Three bucks were cannulated and assigned to switch over design. Samples were incubated for 0, 8, 12, 18, 24, 32 and 48 hours. The result revealed that sweet potato vine cultivars have no significant effect (P>0.05) on dry matter disappearance (76.74 vs 80.41%) for *Danchina* and *King J* respectively. However, the dry matter disappearance of Cowpea (66.05%) was lower. Acid detergent fibre and neutral detergent fibre follows similar pattern with dry matter disappearance. Sweet potato vine cultivars have significant (P<0.05) effect on Crude Protein (CP) disappearance for *Danchina* and King J (80.08 and 90.14%) respectively. It was concluded that *King J* and *Danchina* sweet potato vine cultivars can be fed to animals as a replacement of Cowpea hay as they were proven to be nutritionally good in term of disappearance.
Keywords: disappearance; bucks; cannulated; and vines

INTRODUCTION
Among the livestock that makes up the farm animals in Nigeria, ruminants comprising sheep, goats and cattle, constitute the farm animals largely reared by families in the country's agricultural system. The larger proportion of these animals' are concentrated in the Northern region of the country than the Southern region (Adebowale, 2012). The most difficult problem in ruminant production in the tropics is the scarcity of energy and protein feedstuffs during the dry season (Odeyinka *et al*, 2009). This led to the search for cheap sources of energy and protein feed stuffs to supplement the low quality forages of the dry season (Nworgu, 2006). One of the alternative feed resources during the seasonal nutritional stress is the use of sweet potato vines which has been limited far and it principally consists of vines being fed to livestock as energy and protein supplements. The vines make good feed for ruminant without restriction, which can be fed for milking and fattening animals, and no need to give any supplement as the vines alone can supply all the protein needed by these animals. It also contains nutrients that would sustain acceptable growth in heifers (Sankaran *et al.,* 2012). The aim of the study was to determine the effect of *in sittu* nutrients disappearance by goat bucks fed sweet potato vines.

MATERIALS AND METHODS
Experimental location: The study was conducted at livestock and research farm, faculty of Agriculture Bayero University Kano.
Experimental design: Switch over experimental design was used in the study where two varieties of sweet potato vines (Danchina and King J) and Cowpea hay (Control diets) were fed to the bucks in three different cycles.
Experimental animals and their management: Three bucks with an average initial body weight of 19.43kg were used for the study. The experimental animals were cannulated and allowed to recover for about two weeks. They were offered Danchina vine (Local variety), King J vine (Improved variety) and Cowpea hay (Control diet) as basal feed in the morning hours while the concentrates were also formulated and offered to the animals as a supplements in the evening hours. The ratio of forage to concentrate offered were 60:40.
In sittu procedure was carried out in accordance with Orskov *et al.* (1980). Dried samples of the vines were milled to pass through a 2 mm sieve. Four (4) grams of the vine samples were transferred into the bags and incubated in the rumen of each breed of buck with a permanent cannula in triplicate for 8, 12, 18, 24, 32 and 48 hours.

Dry matter disappearance was estimated as described by Osuji *et al.*, 1993:

$$DMD = \frac{(SWa - BW) \times DMa - (SWb - BW) \times DMb}{(SWa - BW) \times DMa}$$

Where: SWa= weight of original sample + nylon bag
BW = weight of empty nylon bag
SWb=weight of the sample + nylon bag after incubation
DMa = dry matter of feed sample
DMb = dry matter of residue sample

The measure of fraction of the DM, CP, ADF and NDF was expressed as the differences between the amount of the original samples and the remaining in the nylon bags after the incubation. Nutrients disappearance was calculated as the difference between the fractions of nutrients lost during the washing and the truly water soluble fraction (Woods *et al.* 2002).

Chemical analysis: The feed samples which include both the concentrate and the forage were analyzed for proximate composition in accordance with AOAC (2005). The ADF and NDF were analyzed according to Van Soest *et al.*, (1991).

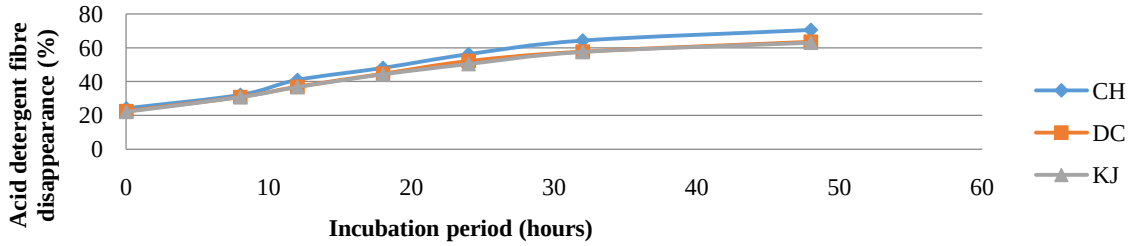
DM: Dry matter, CP: Crude protein, CF: Crude fiber, EE: Ether extract, NFE: Nitrogen Free Extract, ADF: Acid detergent fibre, NDF: Neutral detergent fiber, T1: Concentrate diets to the goats fed cowpea hay, T2: Concentrate diets to the goats fed danchina vine, T3: Concentrate diets to the goats fed king j vine

RESULTS AND DISCUSSION



Nutrients disappearance of sweet potato vines revealed the possible degradation of nutrients incubated *in sacc*o after certain period of time. Sweet potato vines cultivars have no effect ($p>0.05$) on DM disappearance (76.74 vs 80.41 %) for *Danchina* and *King J* respectively. However, *in sacco* DM disappearance of cowpea (66.05%) was lower ($p<0.05$) when compared with the two potato cultivars. The disappearance of *in sacco* CP did not follow the same pattern with the *in sacco* rumen DM disappearance (Figure 1a). There was significant effect ($p<0.05$) between *in sacco* rumen CP disappearance for sweet potato vines (80.08 and 90.14%) for *Danchina* and *King J* respectively) and Cowpea hay (72.10%). Sweet potato vines had increased ($p<0.05$) CP *in sacco* rumen disappearance than Cowpea hay. Figure 1c revealed the disappearance pattern of acid detergent fiber (ADF). Sweet potato vine cultivars have no effect ($p>0.05$) on *in sacco* rumen ADF disappearance. Moreover, there is no significant difference ($p>0.05$) on *in sacco* rumen ADF disappearance between the cowpea hay and the two sweet potato vine cultivars (68.50, 65.39 and 64.38 for cowpea, *Danchina* and *King J* respectively). The disappearance of *In sacco* rumen NDF disappearance follows similar pattern with *In sacco* ADF disappearance (Figure 1d) Based on the findings, sweet potato vine cultivars had more than 50% dry matter disappearance at 48 hours of incubation. This indicated that all the cultivars could be used as feed for livestock due to the forage quality that meet the requirements for feeding livestock as observed by Larbi *et al.*, (2007). The *in sacco* nutrients disappearance indicated that the disappearance features of *Cowpea*, *Danchina* and *King J* vines differed slightly among themselves. This is similar to the report of Chumpawadee *et al.*, (2005). Results of dry matter disappearance observed values are in accordance with the values reported by Chumpawadee *et al.* (2005) but higher than those reported by Fadel *et al.*, (2007). The CP disappearance values obtained were comparable to those obtained by Chumpawadee *et al.* (2005). Greater CP disappearance was reported by Bayourthe *et al.*, (2000) for Pea (*Pisum sativum*) flour. Lower CP disappearance value was obtained by Danesh *et al.*, (2005). The result for the CP disappearance of sweet potato vines in this study showed that nutrient disappearance was comparatively higher. The CP nutrients of *King J* and *Danchina* vines disappeared faster in the rumen than that of the Cowpea. This could be due to greater proteolytic activities of the ruminal microflora there by evoking a higher disappearance Antwi *et al.*, (2014). The Acid detergent fibre and neutral detergent fibre disappearance obtained in this study were comparable to the values reported by Pawelek *et al.*, (2008). The disappearance parameters measured in this study are of paramount importance as they influence rumen fill and hence feed intake (Van Soest, 1987).

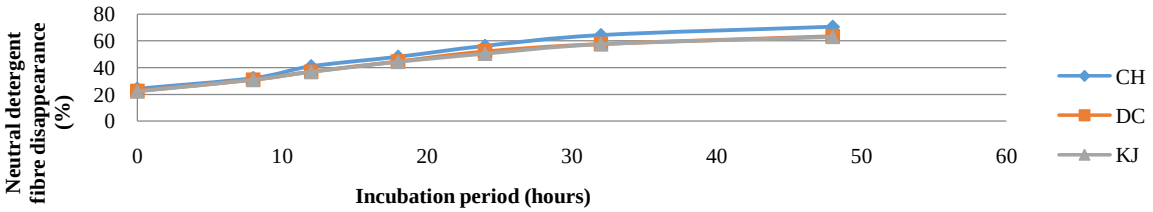

Figure 1: Pattern of disappearance of a) dry matter b) crude protein c) acid detergent fibre d) neutral detergent fibre from CH: cowpea hay, DC: danchina sweet potato vine cultivar, KJ: king j sweet potato vine cultivar during rumen incubation for various times in goat.

CONCLUSION AND RECOMMENDATION

It was concluded that *King J* and *Danchina* sweet potato vine cultivars can be fed to animals as a replacement of Cowpea hay as they were proven to be nutritionally good in term of disappearance. More research should be conducted further with a view to ascertaining the nutritive value of sweet potato vines.

UTILIZATION OF CATTLE FORE-STOMACH DIGESTA ENSILED WITH AFRICAN LOCUST BEAN PULP AND NON PROTEIN NITROGEN SOURCES BY GROWING UDA RAMS

[1]Inuwa, M., [1]Abubakar, M. M., & [1]Bello, K. M.,
[1]Department of Animal Production, Abubakar Tafawa Balewa University, Bauchi,
Corresponding author email: musainuwa211@gmail.com

ABSTRACT
Sixteen growing Uda rams weighing between 20 and 25kg were used to determine the utilization of cattle fore-stomach digesta ensiled with African locust bean pulp (ALBP) and non-protein nitrogen (NPN) sources. The study was conducted in Katagum, Zaki Local Government Area, Bauchi State. The animals were randomly allocated to four dietary treatment groups in a completely randomized design (CRD). The research lasted for eighty four (84) days of feeding and seven (7) days digestibility trials. Data were taken on feed intake and body weight changes. Blood samples were also collected and analyzed for haematological indices. The results showed that feed intake and dry matter intake (%body weight) were significantly (p<0.001) different. The weight gain, ADWG, total feed intake, feed conversion ratio, haemoglobin, park cell volume, red blood cell, white blood cell, mean corpuscular volume, mean corpuscular haemoglobin, mean corpuscular haemoglobin concentration were not significantly different. There was no significant difference in terms of digestibility of DM, CP, CF, EE, and Ash across the treatments. The cost of production showed no significant differences across the treatments means, but treatment A with 40% fore-stomach digesta and 60% African locust bean pulp was recorded the least cost of ₦332.51 and is recommended to farmers for feeding ruminant animals.

Keyword: Rumen Content, African Locust Bean Pulp, Poultry Litter, Non Protein Nitrogen Sources, Growing, Uda Rams

Introduction
Ruminant animals play active role in converting feedstuffs of no human dietary value to meat and milk. Efforts have been on using such feeds to reduce cost of feeds and subsequently cost of animal production. In recent years, several authors (Garba and Maigandi, 2008; Fawolu and Fajemisin, 2011) investigated the use of cheap agro-industrial by-products and waste materials; such as slaughter/abattoir waste and poultry droppings and cassava peels at various levels of inclusions in small ruminant diets to determine their efficiency of utilization in term of growth and production. Also with a view to identifying the most suitable one in terms of nutrition, cost effectiveness and year round availability.
The findings will further buttress the need for the populace in the developing world's to turn to these cheaper sources of protein to combat the problem of malnutrition.

Materials and Methods
Experimental Site
The study was conducted at Katagum, Zaki Local Government Area, Bauchi State.Zaki is a Local Government Area in Bauchi State, Nigeria, and its coordinates are 12º08'N and 10º17'EIt has an area of 1,436km^2 and a population of 191,457 as at 2006 census.The postal code of the area is 752. The predominant ethnic groups in the area are the Hausa with some Kanuri and Kare-Kare in the east of the area. Zaki Local Government Area has two main seasons, the dry season, which last from October to May/June and the rainy season that last from June/July to September. Zaki Local Government Area as part of the sahel region of Nigeria is blessed with abundant livestock resources because of its climate which is more suitable for livestock production, due to absence of Tse-tse fly on the open grassland. The experiment was conducted between the months of July-October 2019.
Experimental Materials

Rumen contents (RC), Africa locust bean powder, poultry litter, Urea, water mixing bowl, masking tape, marker and weighing scale.

Experimental Animals and their Management

Sixteen (16) growing Uda rams weighing between 20 and 25kg and 6-7 months of age were purchased from Gamawa town of Bauchi State for the experiment. The rams were transported to Zaki Local Government Area. On arrival, the rams were quarantined, dewormed and sprayed against ecto parasites (using permethrin). The experimental rams were allocated to four different dietary treatment groups and water was provided *ad-libitum.* The feeding trial lasted for eighty four (84) days.

Experimental Design and Feeding Procedure

The experimental design used was complete randomized design (CRD). A total of 16 growing Uda rams were used, such that each treatment contained four replicates. Each group of four animals was assigned to one of the experimental diets for 84 days feeding trial. Each ram was fed individually at the rateof 2kg/ram body weight. Apart from the experimental diets (Table 1), each animal was fed the concentrate diet with the formulation shown in Table 2 at the rate of 1kg.

RESULTS AND DISCUSSIONS

Chemical Composition of the Experimental Diets

Chemical compositions of the experimental diets are present in table 5.Crude protein content was higher in treatment A (16.43%) which was higher than the 6-8% CP recommended by Norton (2003) for growing sheep and goat. Gatenby (2002) indicated 10-12% CP as moderate level for ruminant production.

The higher CP content in this study could be due to the ensiling effect like rapid increase in soluble component of crude protein due to proteolysis and deamination. The DM value (89.61%) obtained in this study was similar with the values of (87.61-87.71%) observed by ochepo *et al*. (2012) in diets containing sugarcane peels. The higher DM value might be attributed to the types of materials used which were all dried. Higher DM suggest a good source of energy and roughage that could enhance rumination and prevent digestive upset in the rumen.

The crude fibre value (10.11-9.63%) in the present study were lower than the value (31.30-33.60%) obtained by Ahmed *et al*. (2007) when sugarcane baggase was ensiled with chicken manure. This may be as a result of the experimental materials present in the ensiled mass. Ether extract values (8.14 – 6.93%) obtained from this trial was higher than those reported by Tukur and Maigandi (2010). These are authors obtained EE values ranged of (4.3-5.5%) when fattening rams was fed varying levels of fore-stomach digesta (FSD). The higher ether extract (EE) in diets indicate fats content which give rise to high concentration of volatile fatty acid (VFA).

The Ash values 6.52-7,69% in the present study was lower than (12.91-19.54%) reported by Garba *et al*. (2010) when *Guirera Senegalensis* was fed to yankasa rams as complete diets.

GROWTH PERFORMANCE

Growth performance of the experimental animals higher in feed intake is a good indication of proper utilization of the experimental diets (ensiled FSD with ALBP NPN) by the animals, which could also be attributed to the aroma and palatability of the ensiled diets. Initial, final body weight (BW), daily feed intake (DF1) weight gain, average daily weight gain (ADWG), total feed intake, feed conversion ratio and dry matter intake percentage body weight (DMI%BW) of growing uda rams fed graded levels of the experimental diets were shown in table 2.. Statistical analysis revealed that, there was no significant different ($p>0.05$) effects among the experimental diets across the various treatments on the life weight gain and average daily weight gain. The results of voluntary feed intake were varied statistically ($p<0.001$) among the treatments. Treatment D and C had the higher feed intake. Variation in feed intake between treatments could be as a result of better quality of the materials (urea and poultry litter) used to treat fore-stomach digesta (FSD) and African locust bean pulp (ALBP) which might have aided better intake and improved palatability of the diets.

These results are in line reported by Mondal *et al*. (2013) who found that inclusion of Dry rumen contents (DRC) in diets at O, 5 and 10% DRC did not affect final live weight and average daily gain (ADG) in kids and lambs.

Dry matter intake as percentage body weight was significantly different ($p<0.001$) between the treatments. DMI% BW indicates the nutritional quality of the feed with minimal wastage. The DMI% BW generally indicates that the animals on the various diets showed positively DM status by

consuming more than (2) percent of their body weight. The values obtained in this study fail within the range of 2.18-3.78% reported by Olorunnisomo (2010) for sheep fed maize and amaranth fodder.

NUTRIENT DIGESTIBILITY

The result of nutrient digestibility is present in table 3. The result showed that nutrient in the experimental diets was well utilized. The digestibility of the nutrients obtained in this present study was comparably high. Muhammad *et al*. (2016b) observed similar trend when uda rams were fed graded levels of *Parkia biglobosa* yellow fruit pulp. Wada *et al*. (2014) observed medium digestibility (40-60%).

Generally, the entire nutrients digestibility in this study was higher and the high digestibility could the attributed to the inclusion level of urea and poultry litter in the experimental diets as sourec of protein. This agreed with the report of Garba and Maigandi (2008) that adequate nitrogen in diets enhanced the activities of rumen microbes which eventually improved the overall nutrient digestibility.

The dry matter (DM), Crude fibre (CF), Crude protein (CP) Ether extract (EE), and ASH digestibility in present trial were comparable to the finding of Muhammed *et al*. (2016b) and higher than the report of Wada *et al*. (2014a). DM values in this study ranges from 75.63-83.44% and that of Muhammad *et al*. 2016b) ranged from 77.22-78.02%.

CP values obtained in the present research ranges from 78.74-84.58% which is higher than the values 24.48-32.27% reported by Wada *et al*. (2014a).

CONCLUSIONS AND RECOMMENDATION

The result showed that daily feed intake was significantly higher in treatments C (1.21kg) and D (1.22kg) than in treatment A (1.08kg) and B (1.09kg).Dry matter intake as % BW was significantly higher in treatments C and D than in treatment A (1.08kg) and B (1.09kg).

Therefore treatment D was recommended due to the high DFI, weight gain and low in FCR.

ABSTRACT
This study investigated the performance of West African Dwarf (WAD) goats offered *Chromolaena odorata* leaf meal (COLM) as supplement to a guinea grass – based diet. Sun –dried *Chromolaena odorata* leaves were milled and incorporated into a compounded ruminant concentrate diet. Twenty growing WAD goats, aged 5 - 7 months of both sexes, were randomly allotted to four concentrate diets containing graded levels of sun –dried processed COLM at 0, 10, 20 and 30% to make Diets 1, 2, 3 and 4 respectively. Results obtained indicate that goats on Diet 1 gave the best performance in terms of average daily gain (35.95 g/day) and feed conversion ratio (6.93), which was closely followed by goats on Diet 2 (25.0 g/day and 9.12 respectively). The study showed that COLM at 10 % level of inclusion possesses adequate nutritive value to support good growth of West African Dwarf goats without any deleterious effect.

Keywords: COLM, guinea grass, performance, WAD Goats

INTRODUCTION
Diets of small ruminants, such as goats and sheep, in the tropical regions of Africa have been reported to be deficient in protein (Becholie *et al.*, 2005), especially during the periods of drought and as such period, leguminous trees and shrubs provide a suitable source to offset the observed deficit. The recurrent world food crisis has been reported to inform the need to improve the use of local feed resources such as leguminous fodder trees and shrubs for animal nutrition (Alonso-Díaz *et al*., 2010). As such, Animal nutritionists are now focusing on the development of cost effective ways to maximize available feeds and innovatively broaden feed resource base through identification, evaluation and utilization of the many potential wild forages (Lanyasunya *et al*., 2005). *Chromolaena odorata*, a fast growing and invasive multipurpose wild shrub, has the potential of filling the nutritional gap for this class of ruminants. Recent researches on *Chromolaena odorata* has shifted from its eradication as an unwanted plant, to its utilization as a feed resource for livestock (Bamikole *et al*.,2004; Aro *et al.*, 2009; Igboh *et al.*, 2009). However, the use of *Chromolaena odorata* leaf meal in livestock production has been largely constrained by its unpalatable nature when fed fresh to farm animals. Hence, the need for processing the leaves into a more receptive and palatable form, in order to enhance its use in livestock feeding. The aim of this study therefore, was to assess the growth response of WAD goats fed sun – dried *Chromolaena odorata*.

MATERIALS AND METHODS
The experiment was conducted at the Sheep and Goat unit of the Obafemi Awolowo University Teaching and Research Farm, between March and July, 2016. Fresh leaves of *Chromolaena odorata* were harvested and processed into leaf meal by sun – drying. This was done by exposing the freshly harvested *C. odorata* leaves to the radiation effect of the sun, on a clean dry concrete slab for 72 hours. Preliminary investigations about processing methods (air – drying, oven – drying and sun – drying) had revealed sun – drying as the best, as the radiation effect significantly reduced the anti – nutritive contents of *C. odorata*, compared to the other two processing methods. The sun – dried C. odorata was subsequently ground using a hammer mill, to become *Chromolaena odorata* leaf meal (COLM). The COLM was incorporated into a typical ruminant concentrate diet in graded levels of 10, 20 and 30%, with 0% serving as the control, as contained in Table 1. Twenty growing West African Dwarf (WAD) goats of mixed sexes, aged 5 to 7 months were randomly allotted to four experimental diets comprising COLM at 0, 10, 20 and 30% inclusion level, which were fed to the WAD goats at 2% body weight with a basal ration of *Panicum maximum* at 3% of their body weight, in a completely randomized design. The growth trial lasted 98 days, including initial feed adaptation of 14 days. Goats

were weighed weekly throughout the duration of the experiment. Parameters measured include daily feed intake, average daily gain, total weight gain and feed conversion ratio. Laboratory analysis of diets was carried out using the procedure of AOAC (2000). Data collected were subjected to a one-way analysis of variance using the General Linear Model (GLM) procedures of SAS (2003) while differences between means were separated using the Duncan's Multiple Range Test of the same package.

Table 1: Gross composition of experimental diets for WAD goats

Ingredients	Diet 1	Diet 2	Diet 3	Diet 4
COLM	-	10.00	20.00	30.00
Corn bran	45.00	45.00	45.00	45.00
BDG	35.00	25.00	15.00	5.00
Palm Kernel Cake	17.50	17.50	17.50	17.50
Bone meal	1.50	1.50	1.50	1.50
Salt	0.50	0.50	0.50	0.50
Vitamin	0.50	0.50	0.50	0.50
Total	100	100	100	100

RESULTS AND DISCUSSION

The chemical composition of the compounded concentrate diets fed to the WAD goats is shown in Table 2. The dry matter, crude protein, crude fibre, ether extract, ash, neutral detergent fibre, acid detergent fibre and acid detergent lignin contents of the diets increased with increasing level of *Chromolaena odorata* leaf Meal (COLM) inclusion. The CP contents, which is about the most critical nutrient, in all the diets were far above the 8% needed to provide the minimum ammonia levels required for microbial activities in the rumen (Norton, 1994).

Table 2: The chemical composition of experimental diets offered to WAD goats

Parameter(g/100g)	Diet 1	Diet 2	Diet 3	Diet 4
Dry Matter	92.82	93.11	93.22	93.45
Crude protein	16.90	18.50	18.76	19.53
Crude fibre	14.52	15.15	15.27	16.32
Ether Extract	8.55	8.60	10.19	11.12
Ash	7.52	8.18	9.62	9.05
Nitrogen free Extract	52.51	49.57	46.16	43.98
Fibre Analysis				
Neutral detergent fibre	51.87	54.33	58.10	66.53
Acid detergent fibre	30.05	30.99	32.24	34.04
Acid detergent lignin	15.51	17.88	18.54	19.25
Hemicellulose	21.82	23.34	25.87	32.49
Cellulose	12.54	13.11	13.70	17.79

Diet 1 (Control): 0% COLM inclusion; Diet 2: 10% COLM inclusion; Diet 3: 20% COLM inclusion; Diet 4: 30% COLM inclusion

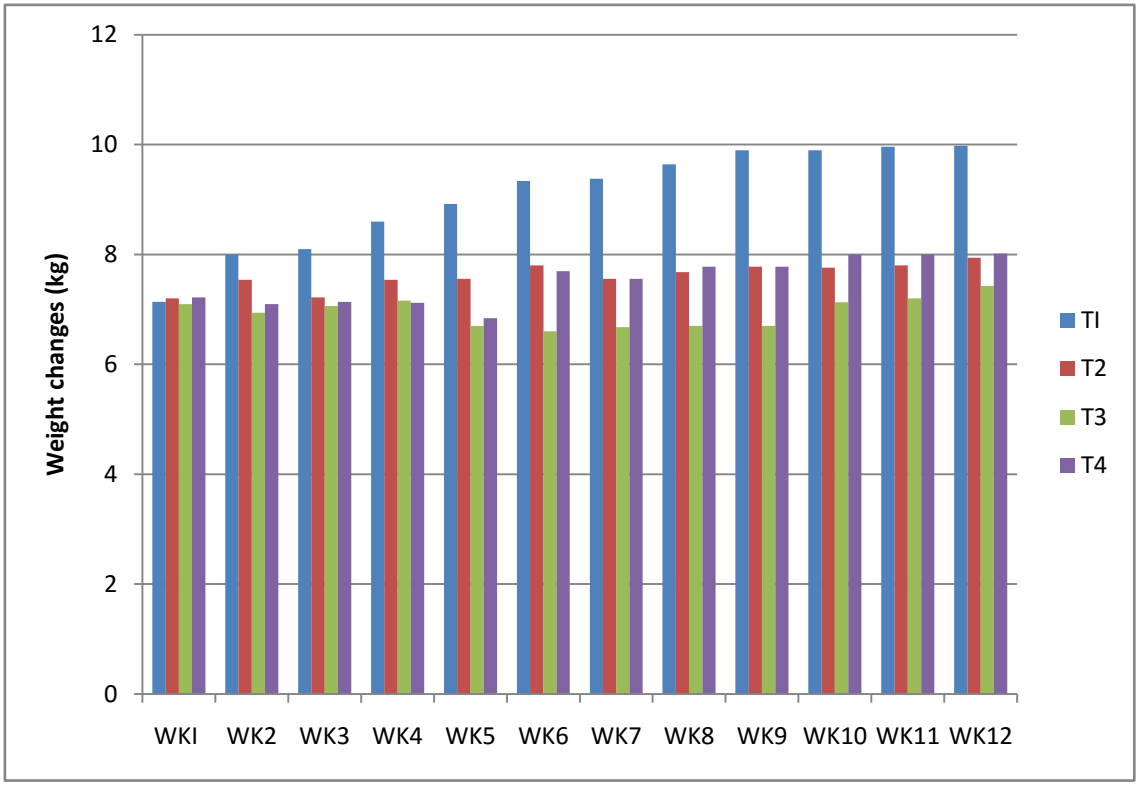

Table 3 shows the Performance characteristics of the WAD goats fed the experimental diets. Average daily intake decreased with increasing content of COLM inclusion in the diet (Table 3). This can be attributed to the bitter taste of *C. odorata,* which is a reflection of its saponin and tannin contents (Igboh *et al*., 2009). Sun –drying method has been reported to reduce the anti– nutrient contents of *C. odorata* and improve acceptance and palatability (Fasuyi *et al.,* 2005). The observed decreased feed intake is in agreement with previous reports on *C. odorata* when fed to birds (Aro *et al*., 1990) and albino rats (Akinmutimi and Akufo, 2006). Average daily gain decreased with increasing COLM content in the diets. Highest ($P<0.05$) daily gain (35.95 g/day) was observed for goats on Diet 1 and the least (15.71 g/day) recorded for goats on Diet 4. The decreasing weight gain could also be attributed to the effect of the reduced feed intake, as well as poor nutrient utilization, although the goats were all in positive weight balance. In terms of efficiency of feed utilization, the WAD goats recorded better performance with decreasing COLM content in the diets, as reflected by the Feed

Table 3: Performance characteristics of WAD goats fed experimental diets

Parameter	Diet 1	Diet 2	Diet 3	Diet 4	SEM (±)	PROB
ADFI (g/day)	249.04[a]	227.99[b]	217.94[c]	220.97[bc]	4.64	0.001
Initial weight (kg)	7.14	7.20	7.23	7.22	0.24	0.99
Final weight (kg)	10.16	9.30	9.37	8.54	0.32	0.34
Total weight gain (kg)	3.02[a]	2.10[ab]	1.70[b]	1.32[b]	0.22	0.01
Ave. daily gain (g/day)	35.95[a]	25.00[ab]	20.24[b]	15.71[b]	2.59	0.01
FCR	6.93[b]	9.12[ab]	10.77[ab]	14.07[a]	1.42	0.03

[a,b,c] means with different superscript differ significantly (P<0.05);Diet 1 (Control): 0% COLM inclusion; Diet 2: 10% COLM inclusion; Diet 3: 20% COLM inclusion; Diet 4: 30% COLM inclusion; ADFI: Average daily feed intake; FCR: Feed conversion ratio.

conversion ratio which increased with increasing content of COLM although the differences in the FCR values of Diets 1, 2 and 3 were not significant (P >0.05). The implication of this is that the WAD goats could tolerate COLM in their diets up to 20% inclusion level without any negative performance.

T1 = Diet 1(0% COLM); T2 = Diet 2 (10% COLM); T3 = Diet 3 (20% COLM); T4 = Diet 4 (30% COLM)
Figure 1: Growth response of WAD goats to the experimental diets

Figure 1 shows the growth response of the WAD goats on the COLM diets. Goats on Diet 1, which is the control diet, without COLM inclusion maintained a consistent daily weight gain throughout the period of the study while for the goats on Diets 2, 3 and 4, a clearly demarcated three growth phases played out. Phase one (Week 1 – 4) recorded a fairly steady increase in body weight gain across the treatment diets while in Phase 2 (Week 5 – 8), a negative growth response was observed. Phase 3

(Week 9 – 12) depicted a period of physiological adaptation to the COLM diets, where the goats exhibited compensatory growth response after the phase of growth depression.

CONCLUSION AND RECOMMENDATIONS

The study concluded that WAD goats can tolerate *Chromolaena odorata* leaf meal (COLM) in their diets up till 30% inclusion level, but best response is obtained at 10% level of inclusion. It is recommended that for optimum performance, COLM should not be fed to goats for more than 4 weeks at a stretch.

ABSTRACT

An experiment was conducted to determine the effect of substituting maize grain with maize cobs treated with 25% urea plus 75% wood ash (WA) on chemical composition and *in sacco* degradability. Maize grain was substituted with graded levels of 25U75WA in the dietary ingredients and the treatments were: 100M = 100% maize grain, 66M34C = 66% maize grain plus 34% treated maize cobs, 34M66C = 34% maize grain plus 66% treated maize cobs and 100C = 100% treated maize cobs. Samples were analyzed for dry matter (DM), organic matter (OM), ash, crude protein (CP), neutral detergent fibre (NDF), acid detergent fibre (ADF) and acid detergent lignin (ADL); they were incubated *in sacco* for 6, 12, 24, 48 and 72 hrs and their DM degradation kinetics described using the equation $y = a + b (1- e^{-ct})$. Results indicated that as maize grain is substituted with treated maize cobs, NDF, ADF and ADL also increased, however only the neutral detergent soluble (NDS) for treatment 100C was reduced. At 72 hrs of incubation, treatment 34M66C had the highest DM degradation, rapidly soluble fraction 'a' and potential degradability 'a+b'. It was concluded that maize cobs treated with combinations of urea and WA could substitute 66% of maize grain in ruminant diets.
Key word: Maize cob, maize grain, in sacco, urea, wood ash.

INTRODUCTION

Domestic ash left after burning of wood for cooking is alkaline, can improve the digestibility of crop residues the same way as urea and is available at household level at no cost to the farmer. Most researches have centered investigations on use of either urea (Sundstol and Coxworth, 1984; Preston, 1985; Chenost, 1995) or wood ash (Adebowale *et al*., 1991; Ramirez *et al.,* 1992., Solomon *et al*., 2012) as source of crop residue treatments but not their combinations. The combination is expected to reduce cost of treatment, improve digestibility at the same time incorporating both nitrogen present in urea and minerals from ash into the crop residue. After maize harvest and shelling of the grains, the cobs are left in the homestead as waste and in some cases burnt. Meanwhile livestock compete with man for grain, therefore there is need to conserve grains for human consumption by either partially or completely replacing it with urea-wood ash treated maize cobs which are rich in energy, nitrogen and minerals (Chenost, 1995; Solomon *et al.,*2012). The objectives of this study was to determine the effect of substituting maize grain with cobs treated with combinations of urea and wood ash on chemical composition and *in sacco* degradability.

MATERIAL AND METHODS

Location of Study, Sample Collection and Treatment

The study was conducted at the Botswana University of Agriculture and Natural Resources, Content Farm located 10 Km north of Gaborone in South Eastern Botswana. Maize cobs treated with a combination of 25% urea and 75% WA were used to substitute graded level of maize grain in a complete diet as shown in Table 1.

Laboratory Analysis

Dry matter (DM, ID number 930.15) for all samples were determined by drying in forced air oven at 60° C for 24 hr. Organic matter (OM, ID number 942.05) and ash were obtained by difference in weight after ignition at 550° C in a muffle furnace (Muffle Furnace Size 3, Gallenkamp, UK). The

NDF, ADF and ADL were determined with ANKOM fiber analyzer (Ankom Technology Corporation, Fairport, NY, USA) according to the procedure of Van Soest *et al*, (1991). In the analysis of NDF, sodium sulphite and alpha amylase were also added. Nitrogen was determined by the Kjeldahl method (ID number 955.04) according to AOAC (1999) and CP determined as N*6.25 (ID number 954.01).

IN SACCO DEGRADABILITY

The *in sacco* DM degradability analysis for the various treatments was carried out according to the procedure of Mehrez and Orskov (1977). Various samples were milled through a 3mm sieve and 2g weighed into nylon bags (pore size 20µ) in duplicates. These were then incubated for 6, 12, 24, 48 and 72 hours in two fistulated steers (5 treatments × 5 time periods × 2 fistulated steers). The procedure was repeated three times and means for each incubation used as replicates. The steers were fed commercial concentrate combined with crushed maize cobs for 5 days to get rumen microbes adapted to the feed. After removal, the nylon bags were thoroughly washed with cold running water until no further coloured liquid could be extruded, followed by drying at 60 ^{0}C for 48 hours. The dry matter losses for each incubation time were then determined according to the formula proposed by Osuji *et al.* (1993)

The DM degradation data were then fitted to the exponential equation $\mathbf{P= a + b (1 –e^{-ct})}$ (Orskov and McDonald, 1979): where P = DM disappearance in rumen at time't', a = the rapidly soluble fraction, b = the insoluble but fermentable fraction, c = the constant rate of degradation of 'b' (% per hour), a + b = Potential degradability. ed = a + bc/ (c + k) where k = the ruminal passage rate assumed at 3%$^-$h.

STATISTICAL ANALYSIS

I*n sacco* degradability constants were generated with Non Linear Model (NLIN) SAS programme using the code of Osuji *et al*. (1993) and effects of treatment carried out using GLM procedure of SAS (2002) and means separated using Duncan's multiple range test (Steel and Torrie, 1984).

Results

Table 1: Ingredients and chemical composition (g/kg) of experimental diet

DM= dry matter, OM=organic matter, CP=crude protein, NDF=neutral detergent fibre, ADF=acid detergent fibre, ADL=acid detergent lignin, HC=hemicellulose, NDS=neutral detergent soluble, ME=metabolizable energy, DCP= Di calcium phosphate. 100M= 100% maize, 66M34C=66% maize 34% treated maize cobs, 34M66C=34% maize

66% treated maize cobs, 100= 100% treated maize cobs.

Ingredients and chemical composition of experimental diet are shown in Table 1. It was observed that the NDF, ADF and ADL of the experimental diets increased as the maize was substituted with urea-wood ash treated maize cobs; however, treatment 100C had the lowest NDS. The result indicated that treatment 33M66C had the highest DM degradation at all the time intervals (Table 2), while the highest 'a', 'a+b' and 'ed' were also recorded for treatment 33M66C (Table 3)

100M= 100% maize, 66M34C=66%maize 34% treated maize cobs, 34M66C=34% maize 66% treated maize cobs, 100= 100% treated maize cobs, a= rapidly soluble fraction, b= insoluble but fermentable fraction, c= degradation rate/h, a+b= potential degradability, ed= effective degradability.

DISCUSSION

It was observed that the more the substitutions of maize grain with treated maize cobs, the more the ash content of the feed. The high amount of ash in the feed may supply more minerals to the animals and rumen microbes (Imbeah, 1999). However the substitution also led to increase in NDF, ADF and ADL and reduction in NDS of treatment 100C. The higher NDS content of treatments 100M, 66M34C and 34M66C could be attributed to their maize contents that were mostly cell soluble compared to treatment 100C that was characterized by higher contents of NDF, ADF and ADL which can negatively affect digestibility. Various authors have also reported increases in NDF, ADF and ADL contents of feeds when energy source is substituted with maize cobs (Khan *et al*., 2006; Wanapat *et al*., 2012). The reason for the high NDF and ADF contents of treatment 100C based diet was because of its high crude fibre content.

At 72 hours of *in sacco* degradability, treatment 34M66C had the highest percent degradability probably because it had better colonization and attachment by rumen microbes due to its low maize grain contents compared to treatments 100M and 34M66C. When diets have high grain contents, they are fermented rapidly by rumen microbes to VFAs which leads to a drop in rumen pH. A drop in rumen pH depresses the activities of rumen microbes thereby impacting negatively on digestibility of fibrous materials. However, the impact of low pH may not be significant under *in sacco* condition due to dilution resulting from entry and exit of other particles surrounding the nylon bags. The fact that treatment 34M66C had the highest degradation (%) after 72 hours of incubation and highest potential degradability 'a+b,' implied that it was superior to the other treatments in terms of digestibility. Carro *et al*. (1991) reported that the fraction that would be degraded when samples were incubated indefinitely in the rumen was the potential degradability and did not indicate the *in vivo* condition. Khazaal *et al.* (1995) reported that potential degradability of feed pointed to the quality of feed because it was associated with the degradability of feed. Therefore, feeds with higher 'a+b' fractions may degrade faster than those with lower 'a+b' fractions.

CONCLUSION

It was therefore concluded that 66% of maize cobs could replace maize grain in ruminants' diets.

ACKNOWLEDGEMENT

ABSTRACT
Ruminant production in very prominent in livestock production. They are available all over Nigeria where pasture constitute their major source of feed. However, utilization of the available pasture depends on the microbes in the rumen which then determines the overall wellbeing of these animals and their productive capacity. Additives have been used to improve the ability of these microbes to productively utilize the feedstuff and consequently, the digestibility. The additives in use previously have been demonstrated to impact negatively on the health of the animals. Probiotics then became prominent as an additives because of the ability to improve the productive capacity of the microbes in the rumen without any known negative effect on the health of the animals. The study then reviewed probiotics use in ruminants and concluded that it improves the productivity of ruminants due to improved microbial activities.

Keywords: Probiotics, ruminant, feed, microorganism, Nigeria

INTRODUCTION
Due to its multi-purpose functions, small ruminant production has been given a pride of place in animal production in Nigeria. This contributes greatly to Nigeria's animal protein potential (Aruwayo , 2018). It constitutes a profitable business for rural families and the success depends mainly on the feeding and feeding stuffs available and the efficiency with which the microbes in these animals ' digestive systems are mobilized and used to improve the digestibility and feed utilization. Abd El-Tawab *et al*. (2016) documented feed to be major a component of livestock production and that exemplary attention has been paid to improving animal output in its utilization capacity. Efforts being made to boost the use of feed which necessitated use of additives has proved to be one of the successful among other methods of improving feed utilization. This research paper dwelt on the effect of probiotics as a class of feed additives on productivity and health condition of ruminant livestock.

FEED ADDITIVES
McDonald *et al*. (2010) reported that feed additives are materials used to improve the usefulness of nutrients and to exert their effects on the animal intestines or on the gut wall cells. Fanelli (2012) has documented his intention to promote animal growth by increasing the quality and palatability of feed Chahal et al. (2008) reported that feed additives in feed for ruminants lead to improved production of animal protein for human consumption, thus reducing the cost of animal products. Feed additives used in feeds include antibiotics, probiotics, oligosaccharides, enzymes and organic acids. Antibiotics was one of the prominent additives used to improve the consumption of feed and increase production. Nevertheless, because of the recorded residue impact on livestock items, it gradually lost prominence because of the residue effect recorded on livestock products. Morril *et al.* (1977) stated that in the past, antibiotic growth promoters were commonly used as animal feed additives to improve feed intake, increase production, and prevent infections. Nevertheless, the use of antibiotics was banned which brought probiotics into the limelight and accepted that they were healthy for the animals. The term ‘ probiotics' was used by Lilly and Stillwell (1965) to identify growth enhancing substances generated by a ciliate protozoan which enhanced the growth of any other ciliate. Now, probiotics encompasses a far wider category of species. Probiotics was described as "species and compounds that promote intestinal microbial stability which include live and non living organisms (Parker, 1974).
The United Nations Joint Food and Agriculture Organization (FAO) and World Health Organization (

WHO) Working Group classified probiotics as ' live micro-organisms which endow advantages in health on the host when administered in sufficient quantities ' (FAO / WHO, 2001).

PROBIOTICS USE

Probiotics constitute viable microorganisms and, when used in large numbers (Rook and Burnet 2005), the microflora can transform the digestive system of ruminants, resulting in improved health and growth. They are living microbes and are feed supplements that are beneficial to the host through improvement of its microbial bowel balance. Such species are genetically robust, capable of producing antimicrobials and altering the colonic flora in favor of a healthy configuration and thus cause luminous or systemic effects that are useful for the health of the host (Kaur et al., 2002; Parvez *et al*., 2006). Bacteria and yeasts are significant probiotics used in the ruminant development. Probiotics have been used in ruminant diets for the improvement of the health, productivity and health of the animals.

It has also been documented that probiotics regulate rumen pH, increase the production of volatile fatty acids and promote protozoan use for lactic acid, resulting in highly efficient rumen work. Despite not being non-pathogenic to animals, microbes that are employed as probiotics are chosen considering their longevity in the gastro intestine along with their capacity to resist low pH and high levels of the bile acids. Furthermore, those selected strain can withstand processes of production, transport, storing and application, preserving the viability and desired features (Collins *et al*., 1998). The ability by the prospective probiotic micro-organisms geared towards resisting the digestive tract may be verified in vitro with low pH challenges (H) (Hood and Zoitola, 1988; Collado and Sanz, 2006). Their capacity to condone acidic environment and bile differs among strains (Mishra and Prasad, 2005). Additional attractive trait is the capacity to bind to the epithelium of the intestines facilitating colonization of the intestine by the probiotic strain(s) (Guarner and Schaafsma, 1998). Furthermore, the capacity of growing fast on cheap media becomes a necessary requirement (Collins, Thornton and Sullivan, 1998) in profitable production.

Probiotics can enhance the amount of helpful microbes plus lactobacilli and bifidobacteria, inhibiting the growth of deleterious microbes through the production of constraining substances like bacteria or/and organic acids. As a result, probiotic characteristics lead to improved animal health, increased productivity (Isolauri *et al*. 2004), and improved the immunity of the host (Patel *et al*., 2015).

Yeast feeding makes the rumen pH stable, raises total volatile fatty acids (VFAs) and decreases ammonia (Erasmus *et al*. 1992, Newbold *et al*. 1996, Abd El-Tawab 2007, Bakr *et al*. 2015). In addition, the probiotics use have been demonstrated to possess capacity to boost production of milk and may decrease those risk of neonatal diarrhea and mortality. Yeast utilization in the feed of rumen lowers the redox capacity which results in better situations for the growth of stringent anaerobic microorganisms, produces specific factors such as vitamin B12 or branched chain fatty acids, thus arousing microbial biomass production in the rumen (Jouany, 2006; Chaucheyras — Durand *et al*., 2008). In addition, rumen acidosis is decreased by yeast supplementation, promoting growth and operation of the lactic acid-using rumen bacterium Selenomonas ruminantium (Nisbet and Martin, 1991). Yeast operations also results in rumen fermentation stimulation and leads to enhanced digestibility and feed use. The enhanced bacterial population is fundamental to the yeast's operation in enhancing the productive capacity of ruminants (Wallace and Newbold 1992). Yeasts can promote cellulolytic bacteria's growing and enzymatic activity, and increase microbial protein production and fiber digestibility (Bomba *et al.* 2002).

Use of probiotic strains, both individual and combined, could have considerable effect on absorption and utilisation of feed, daily increase of body weight and total body weight of various animals, including sheep, goats (Chiofalo, 2004), cattle, and horses (de Rezende, 2012). An addition of probiotic microorganisms to feed results in improved quantity and quality of milk, meat and eggs. The efficacy of probiotics in combating diarrhea has been well studied. Recombined probiotics constitutes one of the most novel biomedical applications of genetically modified organisms (GMO) (Musa,2009). The absence of clinical side effects is an important benefit of probiotics. However,

despite the fact that the micro-organisms used as probiotics in the feed of ruminants, there should be precaution in their use because some might be dangerous to animals, human beings and the environment.

CONCLUSION:

From this study, it was clearly shown that probiotics use in ruminants' has improved their utilization of feed. This is because probiotics enhance the capacity of the rumen microbes to utilize feed better in the rumen.

RESULTS AND DISCUSSIONS

Figure 1 shows the shear force of spent layers' meat tendered with turmeric extract. As the levels of inclusions increased, the shear force value decreases. 15% of turmeric extract had the lowest shear force value while control without turmeric extract had the highest shear force values. The shear force values indicate tenderness of meat. When the value obtained is higher, it denotes that the meat will be tough but when the values obtained was lower, it shows that the meat will be tender. In this study a trend was observed in the shear force value of the meat. As the inclusion levels of turmeric extract increased, there was decrease in the shear forces. These results might be attributed to the effect of proteolytic enzyme found in the turmeric which may lead to more degradation and availability of dietary protein. Shear force values in our experiment are in agreement with Naveena *et al.,* 2004 reported significant reduction of shear force value in all enzyme treated samples compared to control. Similar result was also obtained in the work of Verma, *et al*. (2018).

The water holding capacity of meat from spent layer tendered with turmeric extract results was showed in Table 1. A consistent value was observed for water holding capacity. As the inclusion level increased, the water holding capacity increases. More so, the extract released volume result shows that the control had the lowest value of (17.50%) without turmeric extract while spent layer meat tendered

with turmeric extract at 5% had the highest value of (43.75%). The water holding capacity (WHC) is the ability of meat to hold water after external pressure was applied. Turmeric treated sample had higher WHC than control which are in agreement with Naveena and Mendiratta (2001).

Extract released volume is a technique that is based on the volume of aqueous extract released by homogenate of meat when allow to pass through the filter paper for a given period of time, by this meat of good organoleptic and microbial quality release large volume of extract, whereas meat of poor quality releases smaller volume or none. The result obtained shows that as the inclusion level increased the meat organoleptic and microbial quality was improved. This could be due to phytochemical substances present in the turmeric extract.

The mean pH value was higher in meat from 15% turmeric extract while the control meat had the lowest pH value. The result obtained from pH.

CONCLUSION

In conclusion, spent layers meat can be marinated in turmeric extract up to 10 – 15% /L due to improvement of tenderness.

ABSTRACT
The study was carried out to assess the minerals composition of raw meat and *Balangu* offered for sale at retail outlets in Hadejia Local Government Area of Jigawa State. Triplicate raw meat and *Balangu* samples sold in three different locations namely: Atafi (T1), Yayari (T2) and Yan-Koli (T3) were purchased using simple random sampling method. The samples were collected fortnightly from 3rd to 17th April, 2018 given a total of fifty four samples. The samples were immediately packaged in Ziploc bags and transported to Soil Science Laboratory, Bayero University, Kano for minerals analysis. Data obtained on Calcium (Ca), Magnesium (Mg), Copper (Cu) Iron (Fe) and Zinc (Zn) using Atomic Absorption Spectrophotometer (Buck Scientific Model 210 VGP), and Sodium (Na) and Potassium (K) using Flame Photometer were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability. Results showed that *Balangu* obtained from T2 has highest values for Mg (2.50 mg/kg), Cu (20.47 mg/kg), Fe (4.88 mg/kg) and K (1.16 mg/kg) while lowest values for Ca (2.71 mg/kg), Mg (0.83 mg/kg), Na (1.58 mg/kg) and K (0.78 mg/kg) were reported from T3. It was concluded that higher values of Mg and Fe were reported at T2 for both raw and processed meat.

Key words: Raw Meat, Minerals, *Balangu*, Outlet and Hadejia

INTRODUCTION
Meat is an animal flesh that is eaten as food. Humans have hunted and killed animals for meat since prehistoric time (FAO, 2006). The advance of civilization allowed the domestication of animals such as cattle, goats, sheep and chickens and eventually their use in meat production at industrial scale (Abubakar *et al.*, 2016). Meat is mainly composed of protein, fat, minerals and water. It is normally eaten after cooked and mixed with spices for better taste. Unprocessed meat is easy to spoilage within hours or days as a result of infection with or decomposition by some microbes such as bacteria and fungi (Singh *et al.*, 2014). Meat can be broadly classified as red meat such as beef, mutton and chevon while that from chicken, turkey, duck and goose are considered as white meat (Williams *et al.*, 2006).
In the content of nutrition, a mineral is chemical element required as an essential nutrient by organisms to perform functions necessary for life (Wilcox, 2005). Mineral is one of the six groups of essential nutrients, the others are carbohydrates, fat, protein, vitamin, and water (Yasmine, 2009). Minerals are classified into two groups which are major or macro minerals (Wan Zabri and Wahid, 1985) such as Calcium (Ca), Phosphorous (P), Potassium (K), Sodium (Na), Magnesium (Mg) and Sulphur (S), while the second group is micro or trace minerals such as Iron (Fe), Manganese (Mn), Copper (Cu), Iodine (I), Zinc (Zn), Cobalt (Co), Fluorine (F) and Selenium (Se). The body needs large amount of macro minerals and small amount of micro minerals (Yasmine, 2009).
Meat is produced by killing an animal and cutting flesh out of it, these procedures are called slaughtering and butchering, respectively. Meat is cooked and processed into difference ways such as *Balangu*, *Kilishi*, *Tsire*, and *Dambun-Nama*. The aim of the research is to determine the minerals contents of *Balangu* offered for sale at Hadejia Metropolis.

MATERIALS AND METHODS
The research was conducted at Hadejia Local Government Area of Jigawa State. Hadejia is one of the oldest Local Government Areas created since 1975, from the then Kano State (now Jigawa State) of the northern Nigeria. Hadejia Emirate comprises of Hadejia, Mallam-Madori, Kafin-Hausa, Birniwa, Guri, Kaugama, KiriKasamma and Auyo Local Government Areas. It is 6,880 square kilometer and

located in the Northern Sudan Savannah Zone of Nigeria. It lies approximately between longitude 10.00 ^{0} E and latitude 12.25^0 N. The population of the study area was 47,400 (NPC, 2006). The major tribes of the town are Hausa, Fulani and Kanuri. The town is served by Federal Truck linking it to Nguru in the East, Kano in the North, Katagum in the South and Dutse (capital of the state) in the South-West. It is bounded on the immediate south by Hadejia River. The railway line from Kano to Nguru passes through the Kaugama, Mallam-Madori and Birniwa at the Northern sector of the town.

The area is covered by palatable grasses, shrubs and legumes which gave a quality land for good grazing. It has an annual rainfall ranging from 100-110mm which is accompanied by heavy wind. The temperature ranged from 31 to 40^0 C. There are two seasons in a year, it has about 6-8 months of dry season and the rainy season lasts for about 4 months.

Balangu is prepared basically from boneless meat of animal which may be cattle, sheep, goat or camel. The flesh meat from hind limbs (*Longissimus dorsi*) is commonly used (Abubakar *et al.*, 2014). The flesh meat is washed with clean water and sliced into thin sheets of not less than 1 cm in thickness, then placed over fire on a wire mesh and continuously turned over until it was well roasted. Groundnut oil, salt and spices were sprinkled during roasting to bring out the taste.

Triplicate raw meat and *Balangu* samples sold in three different locations namely Atafi (T1), Yayari (T2) and Yan-Koli (T3) in Hadejia metropolis were purchased using simple random sampling method. Three samples from each outlet were collected fortnightly from 3rd to 17th April, 2018. A total of fifty four meat samples as shown in Table 1 were collected. The samples were immediately packaged in Ziploc bags and transported to Soil Science Laboratory, Bayero University, Kano for minerals analysis.

One (1g) gram from both raw and processed meat products (*Balangu*) were collected from the three different treatments for minerals determination. The minerals determined were Ca, Mg, Cu, Fe and Zn using Atomic Absorption Spectrophotometer (Buck Scientific Model 210 VGP), and Na and K using Flame Photometer. The experiment was laid in a Completely Randomized Design (CRD). Each location serves as a treatment. Data obtained were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability.

Table 1: Total Number of Samples Collected for Minerals Assessment

S/No.	Type of meat	Number of Samples
1	Raw	27
2	*Balangu*	27
	Total	54

RESULTS

The result of the minerals composition of raw meat (mg/kg) offered for sale at Hadejia Metropolis is presented in Table 2. There was significant difference (P<0.05) in Ca, Mg,Cu, Fe, Zn, Na and K between the three treatments. Highest values for Ca (3.54 mg/kg), Na (8.53 mg/kg) and K (3.57 mg/kg) were observed in T3 while lowest values for Ca (2.29 mg/kg) and Zn (8.16 mg/kg) were determined from T2.

Table 3 presents the minerals composition of *Balangu* (mg/kg) offered for sale at Hadejia Metropolis. There was significant difference (P<0.05) in Ca, Mg, Cu, Fe, Zn, Na and K between the three treatments. Highest values for Mg (2.50 mg/kg), Cu (20.47 mg/kg), Fe (4.88 mg/kg) and K (1.16 mg/kg) were realized in T2 while lowest values for Ca (2.71 mg/kg), Mg (0.83 mg/kg), Na (1.58 mg/kg) and K (0.78 mg/kg) were reported in T3.

Table 2: Minerals Composition of Raw Meat (mg /kg) Offered for Sale at Hadejia Metropolis

Mineral	Treatment			
	T1	T2	T3	SE(±)
Ca	2.71[b]	2.29[c]	3.54[a]	0.005
Mg	1.25[b]	1.27[a]	1.25[b]	0.003
Cu	1.57[a]	1.42[b]	1.27[c]	0.011
Fe	0.64[b]	0.93[a]	0.54[c]	0.012
Zn	13.46[a]	8.16[c]	10.20[b]	0.005

Fe	1.79[b]	4.88[a]	4.88[a]	0.001
Zn	1.79[c]	3.57[b]	5.36[a]	0.001
Na	1.87[a]	1.72[b]	1.58[c]	0.001
K	1.09[b]	1.16[a]	0.78[c]	0.001

[a, b and c] means on the same row having different superscripts are significantly different at P<0.05

DISCUSSIONS

Zapata *et al.* (1988) reported Ca values of 4.71 and 5.69 mg/100g in broiler chicken light meat and dark meat, respectively. These means values are slightly higher than those found in this study. Lower level of Ca in chicken meat compared to this was found by Hamm and Searcy (1981). Similar to the studies of Grzeskowiak *et al.* (2011) and Polawska *et al*. (2011) P and K content are lower.

Calcium is responsible for strong bones and teeth. It also helps in the transmission of nerves impulses, contractions of muscle, blood clothing, activation of enzyme reactions and secretion of hormone. The Recommended Daily Allowance (RDA) value for Calcium is 50 mg, this indicates that *Balangu* is rich in calcium and should be consumed by both young and old people.

The iron content as reported by Asibey (1974) in the meat of Wild Grass-cutter (4.36 mg/kg), Domesticated Grass-cutter (3.75 mg/kg), Mutton (3.10 mg/kg) and pork (3.10 mg/kg) were similar to the values obtained in this work.

CONCLUSION

Higher values of Mg and Fe were reported at T2 for both raw and processed meat.

ABSTRACT

Fat is one of the main components of meat sausages, along with muscle tissue and water, therefore, it has a substantial effect on emulsion stability in meat products. It is traditionally produced from pork and lard, but there is insufficient knowledge on the yield and nutritive qualities of breakfast sausage prepared with other animal fats. Investigations were carried out in a completely randomized design to study the effect of different fats on various physical, chemical and sensory properties of breakfast sausage. Three treatments were evaluated to test the effect of different animal fats on sausage production: sausage produced with lard (LS), sausage produced with tallow (TS) and sausage produced with sheep fat (SFS). The results obtained showed the yield from the three fat types when used for production of breakfast sausage were 83.85%, 78.52%, and 76.45% for lard, tallow and sheepfat, respectively. The mean pH value of breakfast sausage were ($P<0.05$) 6.46, 6.25 and 6.51 for LS, TS and SFS, respectively. Water Holding Capacity of LS (84.78%) and TS (84.82%) were similar and significantly ($P<0.05$) higher than SFS (82.69%), Crude protein (31.77 %) and ashes (4.83%) of sausages with lard were higher (LS)while the SFS had (25.47%) and (3.39%) for crude protein and ashes, respectively. The aim of this study was to evaluate the influence of different types of animal fats on the physical, chemical composition and sensory evaluation of breakfast sausages.

Key Words: Physical, Chemical, Sensory evaluation, Breakfast sausages, Animal fats.

INTRODUCTION

Sausage is a food that contains an amount of protein with a widespread consumption. Other than protein, it has a high content of fats. Sausage industries need to select a number of various ingredients in the appropriate amount to manufacture and obtain the desired quality and safe product [Savadkoohi, *et al*., 2014]. Fat is one of the main components of meat sausages, along with muscle tissue and water, therefore, it has a substantial effect on emulsion stability in meat products. Hence, it is important to obtain reliable, practical, technological and scientific information about the type of fat used. Fat in the diets serves not only as nutrient in the human body, but also as source of essential fatty acids and essential components of cell membrane [Pearson, 1987]. Sausages contain fat which is important in the processing, textural, and sensory characteristics of sausage products. It interacts with other components present within a meat system and helps to develop what can be a more consumer acceptable product. There is limited research available, regarding the effects of fat on processing, textural, and sensory characteristics in sausage products. Thus, the objectives of this study were to evaluate the physico-chemical, textural and sensory properties of cooked sausages as affected by tallow, lard and sheep fat.

MATERIALS AND METHODS

Preparation/processing of breakfast sausages

Semitendonisus muscle (6kg) tallow, lard and sheep fat used for this project were purchased from carcass of animals' slaughtered one hour postmortem at Bodija market in Ibadan. The formulation of breakfast sausages and composition of non-meat ingredients are presented in Table 1. The meat was chopped and minced using a 5mm sieve in a tabletop mincer (Breville, Model UTP141, United Kingdom).The minced meat was apportioned into three groups of 2 kg. Group one contained 20% lard as emulsifier (LS) while groups 2 (TS) and 3 (SFS) contained tallow and sheep fat each at 20% inclusion level. Each treatment was replicated four times in a completely randomized design. Slurry of salt (NaCl), sodium nitrite, phosphate and sugar was prepared in the proportion shown in Table 1. All other ingredients were added in equal amounts (g/100g) as shown in Table 1. The minced meat and the other ingredients were mixed thoroughly in a mixer (Oster 8-Speed Blender Model, MG—MB

E103TI -Mexico) for 5 minutes. The thoroughly mixed meat samples were stuffed into natural casing (conditioned pig intestine) of about 2 cm diameter. The stuffed casings were twisted at 10cm intervals to obtain shorter linked units.

Table 1: Sausage formulation of different animal fats types

Ingredients	LS	TS	SFS
Beef	65.00	65.00	65.00
Fat	20.00	20.00	20.00

Common salt	2.00	2.00	2.00
Sugar	1.00	1.00	1.00
SodiumNitrate	0.01	0.01	0.01
Phosphate	0.30	0.30	0.30
Icewater	3.00	3.00	3.00
Dry spices	2.00	2.00	2.00
Onion	1.31	1.31	1.31
Garlic	0.69	0.69	0.69
Ginger	0.69	0.69	0.69
Total	100	100	100

Determination of physical properties of the product

Cooking loss:

Samples were taken from the prepared sausage for analysis. Sausages from the different treatments were weighed using an electronic scale (Cuisinart KML-K03BV36246-China) before cooking into an internal temperature of 75°C and after cooking.

PRODUCT YIELD (PY)

The cooked and uncooked sausages were weighed, and the product yield was calculated as follows: the weight of the cooked sausage sample divided by the weight of the uncooked sausage sample multiplied by 100 [Yang *et al*., 2007].

WATER HOLDING CAPACITY:

This was determined following a slightly modified method [Suzuki et al., 1991]. The amount of water released from the samples was measure indirectly by measuring the area of the filter paper wetted relative to the area of pressed sample. The water holding capacity (WHC) of the meat was then calculated as follows [Suzuki *et al*., 199]

CHEMICAL ANALYSIS:

Moisture content, crude protein, ether extract and ash of sausage using different animal fats were determined using the analytical methods [AOAC, 2000].

SENSORY EVALUATION

Sensory evaluation was conducted on freshly prepared sausage (day 0). A total of twenty panelists (60% male and 40% female) with age ranging between 22 and 40 years were trained according to the British Standard Institution [BSI, 1993] guidelines to evaluate the product.

STATISTICAL ANALYSIS

All data obtained were subjected to analysis of variance and the means were compared using the Duncan‘s Multiple Range Test (DMRT). The SAS computer soft ware package [SAS, 1991] was used for all statistical analysis.

RESULTS AND DISCUSSION

Cooking Characteristics

Cooking characteristics of breakfast sausage as affected by different animal fats such as product yield, cooking loss, cold shortening and WHC was investigated, and the obtained results are presented in Table 2. The use of different animal fats showed a significant effect ($P<0.05$) on the PY of the

sausages. LS had the highest PY (83.85%) value, while TS and SFS had 78.52% and 76.45%,respectively for PY (Table 2The highest product yield percentage recorded in LS might be due to the fact that LS had the highest water holding capacity and water holding capacity and yield are directly proportional. The cooking loss (10.00%) of beef sausage prepared from lard in this study was lower than the cooking loss of (19.88%) obtained for comparison of textural properties of low-fat chevon, beef, pork and mixed-meat sausages [Gadiyaram and G. Kannan]. Similar results were reported for fermented sausages in which 10 and 20% of the total pork backfat was replaced by olive oil [Bloukas *et al*.,1997]. The inclusion of different types of fat in the processing may change the fatty acids of the meat products [Lima *et al*., 2004]. Cooking loss is an important variable to predict the juiciness and tenderness of the meat and its derivatives, because the dryness of meat affects the sensory characteristics [Guerrero *et al*., 2013]. WHC was influenced (P<0.05) by different animal fats; LS (84.78%) and TS (84.82%) had the highest WHC, and SFS (82.69%) had the lowest; these results showed that different types of fats improve the water holding capacity. WHC of some fibers is related to the type and amount of their polysaccharides; large particles are associated with open structures that improve the properties of hydration and fat absorption capacity.

Table 2: pH, Product yield and physical characteristics of sausage produced using three different fats

Parameter (%)	LS	TS	SFS	SEM
Product Yield	83.85[a]	78.52[b]	76.45[c]	2.23
Cooking Loss	10.10[b]	10.26[b]	12.20[a]	3.36
Cold Shortening	17.74[c]	18.73[b]	19.63[a]	0.69
Water Holdig Capacity	84.78[a]	84.82[a]	82.69[b]	3.36
pH	6..46[b]	6.25[c]	6.51[a]	0.07

[abc]:Means with the same superscript on the same row are not significantly(P> 0.05) different

PROXIMATE COMPOSITION

Table 3 showed the chemical composition values obtained from the three treatments. Results showed that there was a significant difference for moisture content, crude protein, ether extract and ash. The moisture of TS (76.10%) was higher than that of LS (71.47%), and TS (76.33%) had the highest value. Lipids are highly efficient sources of energy and they contain more than twice the energy of carbohydrate and protein [Okazumi *et al*., 2000]. In the present study lipid content varies from 5.20% to 7.27% and shows a significance difference between the three treatments (P<0.05). Highest lipid content was found in LS (7.27%) and the lowest was found in TL (5.20%). High lipid LS have less water and more protein than TL and SFS. There is also concern that low levels of fat will lead to products that is perceived as dry and less tasty. The minimum requirement for an acceptable level of consumer satisfaction for meat products is 3–4% ether–extract on a fresh uncooked basis [Savell and Cross, 1986]. The mean level of protein determined from the sausage was high. However our determinations showed that SFS had a remarkably lowest protein content than LS (31.77%) and TS (28.35%), respectively. The highest crude protein contents of the LS products can be explained by the differences in fat content from the carcasses of different species of farm animals, therefore, its addition to meat products has the advantage of increasing the crude protein contents of the final product. [FAO, 1991] indicated that the most valuable component of meat, from the nutritional and processing points of view is protein, also indicates their biological value, thus meat with higher protein levels are graded higher in terms of quality, than those with lower crude protein levels [Lawrie and Ledward, 2006].

Table 3: Proximate composition of sausage prepared using three different animal fats

Parameters	LS	TS	SFS	SEM
Moisture Content	71.47[c]	76.10[b]	76.33[a]	1.78
Crude Protein	31.77[a]	28.35[b]	25.47[c]	1.59
Ether Extract	7.27[a]	5.60[c]	6.83[b]	0.58
Ash	4.83[a]	4.40[b]	3.39[c]	0.33

[abc]:Means with the same superscript on the same row are not significantly($P > 0.05$) different

SENSORY EVALUATION

Mean scores that the panelists gave for the three treatmens of products are shown in Table 4. Colour, flavour, juiciness, tenderness and overall acceptability were significantly different with respect to different sources of fats, whereas no significant differences in aroma were found among the three treatments. In meat products, fat contributes to the flavour, texture, juiciness, and overall acceptability of lubricity of the product [Mugueza *et al*., 2002]. Juiciness also has an important role in overall quality of meat products [Chambers and Bowers, 1993]. LS sausages obtained the highest score for colour (5.43), flavour (5.83), juiciness (5.63), tenderness (6.13) and overall acceptability (6.38). These results indicate that the higher acceptability of LS sausages may be related only to appearance traits and fat content because differences in fat content improved texture attributes.

Table 4: Sensory evaluation of sausage prepared using three different fats

Parameter (%)	LS	TS	SFS	SEM
Aroma	5.50	5.57	5.71	0.28
Colour	5.43[a]	4.50[c]	4.77[b]	0.22
Flavour	5.83[a]	4.90[b]	4.47[c]	0.29
Juiciness	5.63[a]	5.37[b]	4.83[c]	0.20
Tenderness	6.13[a]	5.10[ab]	4.87[b]	0.25
Overall Aceeptability	6.83[a]	5.03[b]	5.73[ab]	0.31

[abc]:Means with the same superscript on the same row are not significantly($P>0.05$) different

CONCLUSION

This study was conducted to evaluate the effect of various types of animal fats on the physico-chemical and sensory characteristics of the final products. The moisture and fat contents of breakfast sausages varied from 71.47%-76.33% and 5.60-7.26%, respectively, whereas, the protein content ranged from 25.47 to 31.77%. Sensory evaluation results indicated that the most appropriate fat content (%) to have better sensory properties was LS. Further research should be performed to analyze the proportion of lard fat require for the production of breakfast sausages.

EFFECT OF AGING DURATION ON THE QUALITY PARAMETERS OF GRILLED LOCAL CHICKENS

Zakka G. C., Gandi B.R., Musa J. and Kachong Y.K.
Department of Animal Science, Kaduna State University.
Corresponding Authors mail: zakkaxtian@gmail.com.

ABSTRACT
This study evaluated the effect of aging duration on the sensory attributes of grilled local chickens. Sixteen roasters (24 weeks old) of the Fulani ecotype were conventionally slaughtered, dressed and randomly allotted into four treatments with four replicates per treatment in a completely randomized design. Carcass from birds were aged at 4°C for 0, 24, 48 and 72 hours corresponding to the various treatments (T1, T2, T3 and T4 respectively). Meat samples from each treatment were grilled and evaluated for their sensory and physical parameters. Results obtained for sensory evaluation on a 9 point hedonic scale was statistically significant (P<0.05), with T4 having the highest values in terms of tenderness (8.90), juiciness (8.45), aroma (8.55) and overall acceptability (8.75), while T1 had the least mean values. A decline in pH was recorded for T2, T3 and T4 (5.86%, 5.60% and 5.36% respectively). Treatment four had the highest thermal shortening (22.5%) statistically significant (P<0.05), while T1 was the lowest (6.75%). Percent cooking was highest in T1 (31.3%) and T4 recorded the lowest value (12.5%) which was statistically significant (P<0.05). Treatment one was significantly the highest (88.3%) in water holding capacity while T4 was the lowest (52%). From these observations, it was concluded that local chickens aged for 72 hours before grilling possess the best physical and sensory qualities.

Key words: Aging, Grilled, Local, Chickens, Sensory.

INTRODUCTION
In Nigeria, local Chickens are grown for their meat as well as their eggs. These chickens are grown in their natural environments without much interference from farmers. The population of the Nigerian local chickens is estimated to be about 149.4 million (FLD, 2015) with the vast majority being raised by farmers living in rural areas. The population outstrips that of the exotic which accounts for only 11.8%. The local chickens account for about 69% and 12% of poultry meat and total egg production respectively (FLD, 2015).

Grilled chicken is one of the world's most popular grilled dishes, it consists of chicken parts or entire chickens that are barbecued or smoked (Campbell *et al*., 2016). Grilled chicken is often seasoned or coated in a spice rub, barbecue rub, or both then coated with tomato based barbecue sauce and grilled.

Aging is a process of preparing meat for consumption, mainly by breaking down the connective tissue, it involves storing meat without protective packaging at refrigeration temperatures for few hours to five weeks to allow the natural enzymatic and biochemical processes that result in improved tenderness and the development of the unique flavor. The key effect of aging is the concentration and saturation of the natural flavor, as well as the tenderization of the meat texture (Stenstrom *et al*., 2014).

In Nigeria, many people love the flavor of grilled local Chickens compared to the exotic broiler birds, but meat from these birds are often associated with problem of toughness, local poultry meat can therefore benefit from conditioning or aging which is known to improve meat quality especially the textural characteristics.

This study was necessitated by the limited availability of information and research on the aspect of value addition to meat products obtained from our own indigenous breeds of chicken. Addressing factors that affect meat quality from these chickens will enhance formulation of grading standards and increase acceptability of meat produced from local chickens in various niche market segments such as tourist hotels and supermarkets.

The objectives of this study was to determine the effects of varying aging durations on the sensory qualities of grilled local chickens, determine the physical properties of grilled chickens aged at different durations and to determine the effect of aging on nutrient profile of chickens.

MATERIALS AND METHOD

The study was conducted in Department of animal science Kaduna State University (KASU) located at Kafanchan Jama'a Local Government Kaduna state, latitude 9.58° N, longitude 8.29° E and situated at an elevation of 733m above sea level (world atlas, 2018). Sixteen rosters (24 weeks old) from the Fulani ecotype breeds were conventionally slaughtered and randomly allotted into four treatments (T1, T2, T3 and T4). Treatment one was grilled immediately after slaughter, while T2, T3 and T4 were held at 4°C for 24, 48 and 72hours respectively before grilling, after which meat samples from each treatment were collected for sensory evaluation using 20 semi-trained sensory panelists, a 9 point hedonic scale was used with a score of 9 indicating "like extremely", 5 "neither like nor dislike" and 1 "dislike extremely". Physical parameters such as percent cooking loss, water holding capacity and thermal shortening were evaluated alongside proximate compositions of the meat samples.

Proximate analyses was carried out at the Food Science Departmental Laboratory of Kaduna State Polytechnique using AOAC (2011) methods which include protein determination using Kjeldahl, fat extraction via Soxhlet, crude fiber determination using digestion with sulphuric acid, moisture determination by drying the sample for 16-18 hours at 100-102°C in an oven and mineral, by ashing the sample at 550°C for 9 hours in a furnace oven. Percentage cooking loss was determined using the formula; $\%\ cooking\ loss = \frac{initial\ sample\ weight - grilled\ sample\ weight}{initial\ sample\ weight} \times 100$

(Petracci and Baéza, 2009).

Thermal shortening determined according to the procedure described by Mahendraker *et al.*, (1998) which is; $(initial\ length - final\ length) \times 100$. Water holding capacity (WHC) was calculated using the formulae developed by Suzuki *et al.*, (1997) which is; $WHC = \frac{100-(Ar-Am)\times 9.47}{Wm \times Mc} \times 100$. Where Ar = Area of water released from meat (cm^2), Am = Area of meat sample (cm^2), Wm = Weight of meat in mg, Mc = Moisture content of meat % and 9.47 is a constant factor. Data obtained from sensory evaluation and that of physical parameters of chickens were analyzed by one way ANOVA using IBM SPSS statistics software (21) and Tukey HSD was used for mean comparisons, test of significance and standard error.

RESULTS AND DISCUSSION

Proximate composition of grilled local chickens aged at different durations is shown in table 1. There was an increase in moisture content for T2, T3 and T4 (67.5, 67.6 and 67.8%, respectively). Studies conducted by Dashmaa *et al.*, (2016) explained that during aging process, the juices are absorbed back into the meat, this may account for the increase in moisture content. There was a decrease in dry matter content for T2, T3 and T4 (32.5, 32.4 and 32.2% respectively). Studies conducted by Dashmaa *et al*, (2016) revealed that during aging of meat, there is natural breakdown of protein, connective tissues and fat components of the meat by enzymes contained in the meat. A decline in pH was observed for T2, T3 and T4 (5.86, 5.60 and 5.36% respectively). The decline in pH was due to anaerobic metabolism of glucose leading to the production of lactic acid which in turn lowers the meat pH (Mbaga *et al*., 2016).

Table 1: Proximate Composition of Grilled Local Chickens Aged at Different Durations

Parameters	**T1**	**T2**	**T3**	**T4**
Moisture (%)	67.2	67.5	67.6	67.8
Dry matter (%)	32.8	32.5	32.4	32.2
Protein (%)	22.1	22.0	21.8	21.5
Fat (%)	2.14	2.12	2.10	2.00
Ash (%)	0.85	0.83	0.825	0.82
Crude fiber (%)	3.01	2.9	2.84	2.60
Carbohydrate (%)	4.71	4.65	4.835	5.28
pH (%)	5.90	5.86	5.60	5.36

KEY: **T1**: chickens aged for 0hours. **T2**: chickens aged for 24hours.
T3: chickens aged for 48hours **T4**: chickens aged for 72hours.

Physical Composition of Grilled Local Chickens Aged at Different Durations

Mean values for physical properties of grilled local chickens aged at different durations is presented in table 3. The highest value for percent cooking loss was recorded in T1 (31.3%) and the lowest was T4 (12.5%) which was statistically ($P<0.05$) significant. Mushi *et al*. (2009) explained that cooking loss in meat depends on ultimate pH. From table 1, there was a decline in pH for T2, T3 and T4 (5.86%, 5.60% and 5.36% respectively) this may account for the decrease in cooking loss. The highest value for water holding capacity (WHC) was recorded at T1 (88.3%) and the lowest was T4 (52.0%) which was statistically ($P<0.05$) significant. Bendall (1979) explained that pH influences the color and WHC of meat, and in table 2, a decline in pH was observed, this could be the reason for the decrease in WHC.

Table 3: Mean Values for Physical Properties of Grilled Local Chickens Aged at Different Durations

Parameters	**T1**	**T2**	**T3**	**T4**	**SEM**
Cooking loss (%)	31.3^{a}	22.5^{b}	17.5^{bc}	12.5^{c}	2.3783
Water holding capacity (%)	88.3^{a}	74.3^{b}	64.8^{c}	52.0^{d}	1.6646
Thermal shortening (%)	6.75^{c}	13.8^{b}	19.0^{ab}	22.5^{a}	1.8085

Means on the same column with different superscripts are significantly ($P<0.05$) different.

SENSORY QUALITIES OF GRILLED LOCAL CHICKENS AGED AT DIFFERENT DURATIONS

Table 4 shows the mean values for the sensory qualities of grilled local chickens aged at different durations. Mean scores for aroma obtained at T2, T3 and T4 (8.10, 8.40 and 8.55 respectively) were statistically the same ($P>0.05$) while T1 had the lowest score (7.45) which was statistically significant ($P<0.05$). When aged meat is being cooked, flavor precursors react with each other to form new molecules or volatile compounds that enrich the aroma further (Kemp *et al*., 2009). Mean values for taste obtained from T1, T2, T3 and T4 (7.95, 8.05, 8.15 and 8.25 respectively were statistically ($P>0.05$) the same. Mean scores for color obtained from T1, T2, T3 and T4 (8.40, 8.05, 7.95 and 7.65 respectively) were statically ($P<0.05$) different, with T1 having the highest score, while T4 had the lowest score, reason being that meat samples appeared darker with successive increase in aging

duration. Mean scores for tenderness obtained from T1, T2, T3 and T4 (7.20, 8.10, 8.45 and 8.90 respectively) were statistically (P<0.05) different with T4 recording the highest tenderness, while T1 was the lowest. Tenderness during aging is brought about by natural breakdown of fat, proteins and connective tissues by enzymes contained in the meat (John *et al*., 2007).The highest mean value for juiciness was recorded in T4 (8.4500) and the lowest was T1 (7.25) which was significantly (P<0.05) different. Mean scores for T2 and T3 (7.65 and 7.85 respectively) were statistically the same (P>0.05). Studies conducted by Dashmaa *et al*, (2016) showed that beef steaks were significantly juicier 21days after aging than 14days, and steaks aged for 14days were statistically juicier than those aged for 7days. Overall acceptability recorded for T1, T2, T3 and T4 (7.90, 8.20, 8.45 and 8.75 respectively) was statistically significant (P<0.05) with T4 having the highest mean value (8.75), and T1 having the lowest score of 7.90. This result is similar to that given by Smith *et al*. (2012), which showed that broiler chickens aged for 8-12hours significantly recorded the best overall acceptability.

Table 4: Mean Scores for Sensory Qualities of Grilled Local Chickens Aged at Different Durations

Parameters	**T1**	**T2**	**T3**	**T4**	**S.E.M**
Aroma	7.45^{b}	8.10^{a}	8.40^{a}	8.55^{a}	0.33
Taste	7.95^{a}	8.05^{a}	8.15^{a}	8.25^{a}	0.30
Color	8.40^{a}	8.05^{b}	7.95^{c}	7.65^{d}	0.28
Tenderness	7.20^{d}	8.10^{c}	8.45^{b}	8.90^{a}	0.34
Juiciness	7.25^{c}	7.65^{b}	7.85^{b}	8.45^{a}	0.33
Overall	7.90^{d}	8.20^{c}	8.45^{b}	8.75^{a}	0.25

Means in the same Colum with different superscript are significantly (P<0.05) different. *Rated on a nine-point hedonic scale, higher value indicates higher preference.

CONCLUSION AND RECOMMENDATION

Results obtained from this study shows that 72hours is the best duration to age local chickens before grilling because it recorded the highest value for tenderness, juiciness, aroma and overall acceptability as well as having no notable change in crude protein, minerals, and carbohydrate contents. Aging of local chickens for 72hours is again commendable because it recorded favorable changes in physical parameters such as thermal shortening, percent cooking loss and water holding capacity although further research could be carried out using longer durations of time and other different processing techniques e.g. boiling.

ABSTRACT

The study was carried out to assess the minerals composition of *Tsire* offered for sale at retail outlets in Hadejia Local Government Area of Jigawa State. Triplicate raw meat and *Tsire* samples sold in three different locations namely: Gagulmari (T1), Dubantu (T2) and Matsaro (T3) were purchased using simple random sampling method. Three samples from each outlet were collected fortnightly from 3rd to 17th April, 2018. Each location serves as a treatment; treatments were replicated three (3) times making a total of fifty four samples. The samples were immediately packaged in Ziploc bags and transported to Soil Science Laboratory, Bayero University, Kano for minerals analysis. The minerals determined were Calcium (Ca), Magnesium, Copper (Cu) and Iron (Fe) using Atomic Absorption Spectrophotometer (Buck Scientific Model 210 VGP), and Sodium (Na) and Potassium (K) using Flame Photometer. The experiment was laid in a Completely Randomized Design (CRD). Data obtained were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability. Results showed that there were significant differences ($P< 0.05$) in Calcium and Potassium between the treatments in both raw meat and *Tsire*. It was concluded that higher values of calcium and copper were reported at TI for both raw and processed meat.

Key words: Minerals, *Tsire*, Outlet, Hadejia and Jigawa

INTRODUCTION

Meat is an animal's flesh that is eaten as food; human has hunted and killed animals for meat since prehistoric time. The advance of civilization allowed the domestication of animals such as chickens, sheep, goats, pigs and cattle and eventually their uses in meat production at an industrial scale (Muhammad *et al*., 2012). Meat is mainly composed of proteins, fats and water. It is normally eaten after it has been cooked and seasoned or processed in variety of ways (Lawrie *et al*., 2006).

Most often, meat refers to the skeletal muscles, associated fat and other tissues and offal. Meat is sometimes also used in a more restrictive sense as the flesh of mammalian species such as cattle, sheep, goats, camels, pigs and dogs raised and prepared for human consumption. Meat obtained from poultry, cattle, sheep and goat are called chicken, beef mutton and chevon, respectively (FAO, 2007).

Poultry is raised for the production of meat and eggs; cattle for meat, milk and hide; sheep and goats for meat, milk and skin; pigs for meat: and camel for meat, milk and hide (Purchas *et al*., 2005). Poultry are now found in almost all parts of the world, regardless of the climatic condition. There is an estimated one domestic chicken for every human being in the world (FAO, 2007).

Muscle tissues is very rich in protein containing all the essential amino acids; it is also a good source of Zinc, Selenium, Phosphorous, Iron, Niacin, Chloride, Riboflavin, Vitamin B6, B12 and Vitamin K (Jokanovic *et al.*, 2014). The fat contain of meat can vary widely depending on species and breed of animals, the way the animals were raised, including what it was fed, the anatomical part of the body and the methods of butchering and cooking (Prasanna *et al.*, 2014).

Meat contains quality protein, vitamins, fatty acids and minerals. Meat has an alluring aroma, social value, is prestigious and yield income (Amanda *et al.*, 2007). In many parts of the world, meat makes

up a considerable portion of a typical diet. It contributes protein, minerals, vitamin and fat and these nutrients are important for their beneficial effect on well being. Understanding the nutrients composition of meat can help to make positive choice when selecting food for daily diet (FAO/WHO, 1997).

Meat is cooked and processed into difference ways such as *Tsire, Balangu, Kilishi and Dambun-Nama*.

The aim of the research is to examine the minerals contents of *Tsire* offered for sale at Hadejia Metropolis.

MATERIALS AND METHODS

The research was conducted at Hadejia Local Government Area of Jigawa State. Hadejia is one of the oldest Local Government Areas created since 1975, from the then Kano State (now Jigawa State) of the northern Nigeria. Hadejia Emirate comprises of Hadejia, Mallam -Madori, Kafin-Hausa, Birniwa, Guri, Kaugama, KiriKasamma and Auyo Local Government areas. It is 6,880 square kilometer and located in the Northern Savannah Zone of Nigeria.

Hadejia town is the capital of Hadejia Emirate and is located at the central part of the emirate. It lies approximately between longitude 10.00 ^{0} E and latitude 12.25^0 N. The population of the area was 47,400 (NPC, 2006). The major tribes of the town are Hausa, Fulani and Kanuri. The town is served by Federal Truck linking it to Nguru in the East, Kano in the North, Katagum in the South and Dutse (capital of the state) in the South-West.

The area has an annual rainfall ranging from 100-110mm which is accompanied by heavy wind. The temperature ranged from 31 to 40^0 C. There are two seasons in a year, it has about 6-8 months of dry season and the rainy season lasts for about 4 months.

Tsire is a boneless lean meat which is cut into pieces and sliced with a sharp knife, staked on a wooden/iron stick and heavily dusted with a mixture of spices made up of groundnut cake paste, red pepper, seasoning, salt, ground ginger, garlic, ground nut oil and other aromatic spices. The staked meat is roasted around a glowing charcoal fire as described by Abubakar *et al.* (2014).

Triplicate raw meat and *Tsire* samples sold in three different locations namely Atafi (T1), Yayari (T2) and Yan-Koli (T3) in Hadejia metropolis were purchased using simple random sampling method. Three samples from each outlet were collected fortnightly from 3rd to 17th April, 2018. A total of fifty four meat samples (Table 1) were collected. The samples were immediately packaged in Ziploc bags and transported to Soil Science Laboratory, Bayero University, Kano for minerals analysis.

Table 1: Total Number of Samples Collected for Minerals Assessment

S/No.	Type of meat	Number of Samples
1	Raw	27
2	*Tsire*	27
	Total	54

One (1g) gram from both raw and processed meat products (*Tsire*) were collected from the three different treatments and inoculated in a vacuum plastic container which were immediately transported to the laboratory for analysis. The minerals determined were Calcium (Ca), Magnesium (Mg), Copper (Cu) and Iron (Fe) using Atomic Absorption Spectrophotometer (Buck Scientific Model 210 VGP), and Sodium (Na) and Potassium (K) using Flame Photometer.

The experiment was laid in a Completely Randomized Design (CRD). Data obtained were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability.

RESULTS AND DISCUSSIONS

The minerals composition of raw meat (mg/kg) offered for sale at Hadejia Metropolis is presented at Table 2. There was significant difference ($P< 0.05$) in Ca, Mg and K between the treatments. Highest values (mg/kg) for Cu (6.10), Fe (5.36) and K (1.29) were reported at T3 while lowest values (mg/kg) for Ca (3.13) and K (1.24) were reported at T 2.

Table 2: Minerals Composition of Raw Meat (mg/kg) Offered for Sale at Hadejia Metropolis

Minerals	Treatment			
	T1	T2	T3	SE(±)
Ca	4.17[a]	3.13[c]	3.33[b]	0.003
Mg	2.09[b]	2.50[a]	0.83[c]	0.005
Cu	6.10[a]	3.66[b]	6.10[a]	0.005
Fe	3.57[b]	3.57[b]	5.36[a]	0.004
Na	2.01[b]	2.29[a]	2.01[b]	0.005
K	1.27[b]	1.24[c]	1.29[a]	0.107

[a, b and c] means on the same row having different superscripts are statistically different

Table 3 showed the results of the minerals composition of *Tsire* (mg/kg) offered for sale at Hadejia metropolis. There was significant difference (P<0.05) in Ca, Cu, Fe and K between three treatments. Highest values (mg/kg) for Ca (3.75), Mg (1.67), Cu (29.59), Fe (8.54) and Na (2.15) were reported for T1 while lowest values (mg/kg) for Ca (2.50), Cu (19.39), Fe (4.75) and K (1.17) were reported from T3.

Table 3: Minerals Composition of *Tsire* (mg/kg) Offered for Sale at Hadejia Metropolis

Minerals)	Treatment			
	T1	T2	T3	SE(±)
Ca	3.75[a]	2.92[b]	2.50[c]	0.001
Mg	1.67[a]	1.33[b]	1.25[b]	0.047
Cu	29.59[a]	24.49[b]	19.39[c]	0.001
Fe	8.54[b]	7.32[b]	4.75[c]	0.079
Na	2.15[a]	1.70[b]	1.48[b]	0.125
K	1.40[a]	1.24[b]	1.17[c]	0.002

[a, b and c] means on the same raw having different superscripts are statistically different

Abulude (2004) reported higher Cu (10.23 mg 100 g^{-1}) and lower Ca, Mg and Na contents which is similar to this finding. Dietary Cu is not toxic to humans because its intake is usually low and body can usually regulate its storage through binary excretion. Meat is a good source of K, Mg, Ca, Na and Fe. The amount of Zn obtained in this report suggests that the sample could provide a significant portion of Zn. Meat is the richest source of Zn in the diet and supplies one third to one half of the total Zn intake for meat eaters. Similar Fe (5.20 mg 100 g^{-1}) in millipede content obtained by Abulude and Folorunso (2003) is comparably with the current results. Fe in meat is well absorbs (20-30%). It also enhances the absorption of Fe from other sources. Inadequate Fe in the diet is associated with poorer learning and decrease cognitive development (FAO/WHO, 1997). The differences in the minerals contents of the samples could be due to soil, water, plant nutrient content and the rate of mineral uptake by animal.

ABSTRACT

This study was designed to investigate the chemical composition of meat floss prepared from broiler chickens fed diets containing varying energy levels. A total of 270 day old broiler chicks were weighed and randomly allocated to three treatments (A, B and C) of ninety birds per treatment, each treatment having three replications of thirty birds. Three experimental diets comprising three energy levels of 2, 400 (A); 2, 600 (B) and 2, 800 ME Kcal/Kg (C) were formulated and fed to the chickens. The crude protein of the starter and finisher diets were fixed at 24 and 20%, respectively. At the end of 8th weeks, 3 birds were randomly taken from each replication which were used for the preparation of meat floss. Triplicate samples of the raw and chicken meat floss were analysed for moisture, crude protein, ash and ether extract. Data obtained were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability. Results showed that the raw meat of broiler chickens fed diet containing 2, 800 Kcal/kg has the highest values of ash and crude protein while that fed diet containing 2, 400 Kcal/kg has the highest ether extract value. Meat floss of birds fed diet containing 2, 400 Kcal/kg has the highest mean values of ash and moisture. In conclusion there was noticeable increase in the nutrient profile of the chicken meat floss over their raw counterparts.

Key words: Broiler Chicken, Meat Floss, Diets, Energy Levels and Chemical Composition

INTRODUCTION

Meat is defined by the *Codex Alimentarius* as all parts of an animal that are intended for use and have been judged as safe and suitable for human consumption (FAO, 2006). It is the term used for the flesh of the animals used for food, especially that of cattle, sheep, goat and swine, as distinct from game, poultry and fish: sometimes it is inclusive of all animal flesh (Muhammad *et al*., 2012). FAO (2007) reported that meat and meat products contain significant levels of protein, vitamins and minerals which are essential for human growth and development.

Dambun-Nama (Meat Floss) is a Nigerian traditionally spiced, cooked, pounded, shredded and dried meat product which is commonly prepared using chicken meat, beef, chevon, mutton or camel meat and is popularly consumed in the Northern parts of Nigeria. The product was developed as a means of preserving meat in the absence of facilities for refrigerated storage by the early Fulani and Hausa herdsmen (Sanwo *et al*., 2011). The aim of the research is to examine the minerals contents of *Tsire* offered for sale at Hadejia Metropolis.

MATERIALS AND METHODS

The research was conducted at the Poultry Demonstration Farm of the Department of Animal Health and Production, Binyaminu Usman Polytechnic, Hadejia, Jigawa State. A total of 270 day old broiler chicks of Zartech strain were purchased from an accredited distributor. The chicks on arrival were weighed and randomly allocated to three treatments (A, B and C) of ninety birds per treatment, each treatment having three replications of thirty birds. The birds were managed under deep litter system with wood shaving as litter materials.Three experimental diets comprising three energy levels of 2, 400 (A), 2, 600 (B) and 2, 800 MEKcal/Kg (C) were formulated and fed to the chickens. The crude protein of the starter and finisher diets were fixed at 24 and 20%, respectively.

The floss was prepared following the method described by Eke *et* a*l*. (2012) as showed in Figure 1.

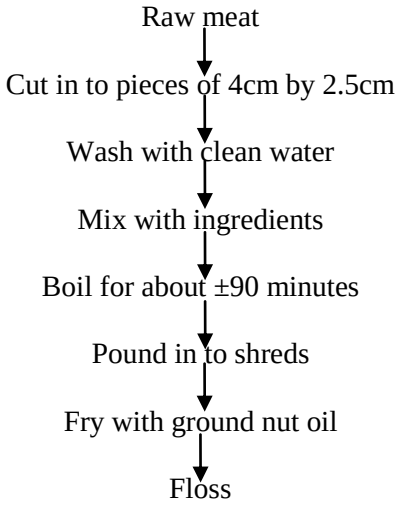

Figure 1**:** Chicken meat floss preparation. Source: Eke *et* a*l*., 2012

Triplicate samples of the raw and chicken meat floss were taken to Biochemistry Laboratory of Bayero University, Kano for the proximate analysis The meat floss samples produced from broiler chickens fed different energy levels were assessed for moisture, crude protein, ash and ether extract according to the procedure of AOAC (2007). Moisture content was determined gravimetrically (Oluwatosin *et al*., 2007) by drying 6 g of meat at 105°C. Crude protein was determined by Kjeldahl method according to the NF V 04-407 norm and using a Kjeltec Auto Sampler System 1035 Analyzer. The total ash content was determined according to the NF V 04-404 French standard method, about 6 g of samples were ashed in an oven maintained at 550°C to determine ash content. The fat content was determined by Soxhlet method according to the NF V 04-402 standard ISO 1443: 1973, using petroleum ether at 40-60 °C. Each analysis was repeated twice.
Data obtained were subjected to Analysis of Variance (ANOVA) using the General Linear Model Univariate Procedure of SPSS 17.0 and significant differences of means were compared using LSD at 5% level of probability.

RESULTS AND DISCUSSIONS

The chemical composition of raw meat prepared from broiler chickens fed diets containing varying energy levels is presented in Table 1. Results showed that the raw meat of broiler chickens fed diet containing 2, 800 Kcal/kg has the highest values of ash and crude protein. The raw meat of broiler chickens fed diet containing 2, 400 Kcal/kg has the highest ether extract value. There is significant ($P<0.05$) differences in all the parameters (ash, moisture, crude protein and ether extract) measured across the three treatments.
Table 2 shows the chemical composition of meat floss prepared from broiler chicken fed diets containing varying energy levels. Results showed that there were significant ($P< 0.05$) differences across treatments. Chicken meat floss of birds fed diet containing 2, 400 Kcal/kg has the highest mean values of ash and moisture.

Table 1: Chemical Composition (%) of Raw Broiler chicken Meat Fed Diets Containing Varying Energy Levels (Kcal/kg)

Parameter (%)	Energy Level (Kcal/kg)			
	2 400	2 600	2 800	SE (±)
Ash	3.05[c]	3.53[b]	4.30[a]	0.02
Moisture	69.02[a]	68.82 [b]	68.90[b]	0.05
Crude Protein	11.29[c]	12.07[b]	12.97[a]	0.01
Ether Extract	16.47[a]	15.58[b]	13.79[c]	0.01

Means along the same row having different superscripts (P<0.05) differ

Table 2: Chemical Composition (%) of Meat Floss Prepared from Broiler Chickens Fed Diets Containing Varying Energy Levels

Parameter (%)	Energy Level (Kcal/kg)			
	2 400	2 600	2 800	SE (±)
Ash	7.47[a]	7.75[a]	6.00[b]	0.00
Moisture	9.03[a]	8.75[c]	8.88[b]	0.05
Crude Protein	58.57[b]	59.40[a]	58.75[b]	0.00
Ether Extract	24.92[b]	24.10[c]	26.37[a]	0.00

Means along the same row having different superscripts (P<0.05) differ

Abubakar *et al*. (2016) reported crude protein value of raw meat as 15.68 ±0.01 which agrees with the findings (11.29 to 12.97%) of this work. Huss (1988) observed that the chemical composition of animals varies from species to species as well as from individual animals depending on age, sex, environment and season. Proteins are powerful compounds that build and repair tissues; it also helps to maintain the body's structure. Protein speeds up chemical reaction in the body, serves as chemical messenger, fight infection and transport oxygen from the lungs to the body tissue. Poultry broiler chickens have recently been shown to fall into a group of high-protein foods that can help keep post-meal insulin levels within a desirable range (Nwosu *et al.*, 1980). There was noticeable increase in the nutrient profile of the chicken meat floss over their raw counterparts (Tables 1 and 2).

Prasanna and Sahitya (2014) reported fat values of raw meat from 13.74 ± 18 to 22.39 ± 91, which is similar to that reported in this work. Valsta *et al*. (2005) documented that appropriate manipulation with broiler chicken diet could modify fatty acid profile in meat and increase its nutritional value, which is in agreement with the work of Castellini *et al*. (2012), who stated that chemical composition of meat depended on type of the diet. The crude fat determined was 16.27% for birds fed diet containing 2, 400 Kcal/kg, 15.58% for birds fed 2, 600 Kcal/kg and 13.79% for birds fed diet containing 2, 800 Kcal/kg, which were within the range (3.70 to 18.06%) reported by Ogunmola *et al*. (2013). Birds fed diet containing 2, 800 Kcal/kg has the least crude fat percentage followed by those fed diet containing 2, 6000 Kcal/kg and the highest value was determined in birds fed diets containing 2, 400 Kcal/kg, thus, there was progressive increase in fat content as the energy level decreases. Possible reason for the high fat content from broiler chickens fed diet containing 2, 400 Kcal/kg may be as a result of high feed intake at both starter and finisher stages. Fats play an important role in building the membranes that surround our cells, in helping blood to clot. Also, presence of fat in the right proportion in the body helps the body to absorb certain vitamins and also to prevent the body from extreme cold and heat.

Ash value ranged (6.00 to 7.75%) for chicken meat floss of this study is in conformity with the work of Abubakar *et al.* (2014) who reported 6.2, 6.3 and 7.1% for shredded meat prepared from beef,

mutton and chevon, respectively. Similar results (4.87±0.11 to 5.60±0.14) were reported by Bulus and Ibe (2016). Eke *et al.* (2012) reported ash values of 5.76 ± 0.02 (Laboratory *Dambun- Nama*) and 4.90 ± 0.04 (Traditional *Dambun-Nama*) which were within the range obtained in this study. The same authors reported crude protein values of 46.51 ±0.03 (Laboratory *Dambun-Nama*) and 39.19 ± 0.03 (Traditional *Dambun-Nama*) which were similar with the result of this findings. Ash in food determines largely the extent to which the dietary minerals would be available in a particular food sample. It also determines the rate at which food substances would make available the amount of energy locked in it (Nwosu, 1979).

The moisture content of the chicken meat floss obtained in this study was within the range values of intermediate moisture products reported by Ogunsola and Omojola (2008). Differences in moisture content may be related to water holding capacity and lipid content of the samples.

ABSTRACT

Contamination of ready-to-eat meat products has been reported by many researchers. It is an established fact that, meat and meat products provide an excellent growth medium for bacteria, yeasts, moulds and protozoans. Therefore, this study was aimed at evaluating the microbiological attributes of Avian Based grinded meat (*Dambun Nama*) prepared from chickens, ducks, guinea fowls and quails. Aerobic Mesophilic Plate Count (APC), Total Coliform Count (TCC) and fungal species were evaluated using standard techniques. The result shows that, the product prepared from chickens had the highest APC (2.54×10^3 cfu/g). However, the product prepared from chickens, ducks and guinea fowls recorded the same values for TCC (3 MPN/g), while that of quails had the lowest TCC (< 3 MPN/g). *Escherichia coli* and *Staphylococcus* were present in all the samples while the presence of *Enterobacter* and *Klebsiella* was found in the product prepared from chickens. *Salmonella* was only present in the product prepared from ducks. *Candida*, *Penicillium* and *Rhizoctonia* were detected in the product prepared from chickens while *Aspergillus* and *Rhizoctonia* were detected in that of guinea fowls and quails, respectively. It can be concluded that, the avian based grinded meat had satisfactory microbial quality. Therefore, the study recommends maintenance of personal hygiene while processing, handling and selling the products, alongside proper storage to improve its safety and shelf life.

Key words: Microbial, Contamination, Avian, Grinded meat

INTRODUCTION

Meat contains important nutrients such as amino acids, vitamins, minerals and fatty acids which are essential for human growth and development (Campbell *et al*., 2003). However, the handling and processing methods by the local manufacturers as well as the hawking system of meat and meat products exposes it to both pre – and post – processing contamination, and thus may pose danger to public health. Hence, the need to improve its processing, handling, storage, distribution and overall quality. Umar (2015) reasoned that meat and meat products provide an excellent growth medium for microbes including bacteria, fungi and protozoans. Microbial growth can lead to slime formation, structural components degradation, off odor and appearance (Russell *et al*., 1996). Therefore, unless dried, cured, smoked, or fermented in some way, meat has a tendency to spoil rapidly (Robert, 1994). Poor sanitary practices increase microbial damage resulting in reduced color, flavor and product safety (Umar, 2015). Numerous studies have reported that meat products sold in Nigeria are contaminated with various species of bacteria and fungi (Ologhobo *et al*., 2010, Salihu *et al*., 2010, Umar, 2015, Dahiru and Maigari, 2019). *Staphylococus aureus*, *Escherichia coli* and *Corynebacterium* spp, isolated in meat products are potentially pathogenic (Abubakar *et al*., 2010). Similarly, fungal species such as *Aspergillus niger*, *Aspergillus fumigatus*, *Rhizophus nigricans* and *Hansenula anomala* could affect meat products on storage and could be dangerous (Abubakar *et al*., 2010, Umar, 2015). Most food poisoning results from mishandling foodstuffs, inappropriate temperature of storage, cross contamination and incorrect reheating (Umar, 2015). Considering the high demand of ready to eat meat products and their economic values, coupled with the fact that, grinded meat (*Dambun Nama*) is highly relished by people and incessantly hawked in Kano State, the present study is justified.

MATERIALS AND METHODS

Experimental Design and Preparation of *Dambun Nama*

Chickens, ducks, guinea fowls, quails and the ingredients (onions, ginger, salt, seasonings, sweet pepper, hot pepper, garlic and vegetable oil) were purchased from Rimi market, located in Kano metropolis, Kano State, Nigeria. The *Dambun Nama* was prepared at the Department of Animal Science, Faculty of Agriculture, Bayero University, Kano. The samples were aseptically placed in clean, sterile plastic containers immediately after collection and subsequently transported to the Post Graduate laboratory of the Department of Microbiology, Bayero University, Kano, for analysis.

MICROBIOLOGICAL EVALUATIONS

Samples of *Dambun Nama* were stored at room temperature in sterile plastic containers for 2 weeks. The sample preparation was carried out according to the method described by Food and Agricultural Organization, FAO (2010). Aerobic mesophilic bacterial count was carried out according to Abdullahi *et al*. (2004), and the colonies obtained were counted, averaged and multiplied by the dilution factor to give the number of colony forming units per gram of a sample (cfu/g). The detection and enumeration of coliforms was carried out according to the method described by Atlas (1997). The number of gas positive tubes was compared with the most probable number (MPN) table to estimate the most probable number of coliforms per gram of sample. Three different microbial culture media (nutrient agar and MacConkey agar for bacterial analysis and potato dextrose agar for fungal evaluation) were prepared, and were aseptically distributed into sterile Petri plates. One gram of the meat product was thoroughly agitated in 9 ml of sterile water, serially diluted to 10 - 3 and plated. Following incubation (at 37^0C for 24 hours and 25^0C for 3-5 days for bacteria and fungi, respectively), plate counts and possible identification of the isolates was carried out. The characteristics of the isolates was referred to Bergey‟s Manual of Determinative Bacteriology for identification. Gram staining and other biochemical tests such as IMVIC (Indole, methyl red, Voges-Proskauer Tests and citrate utilization), Catalase, Coagulase, and Triple Sugar Iron Agar Test (TSI) were conducted according to procedure for the identification of bacterial colonies as described by Atlas (1997). Members of the enterobacteriacea family were further confirmed using API 20E identification kit, while yeast and mold counts was carried out according to the method of Atlas (1997), and identified using a color guide and microscopy.

RESULTS AND DISCUSSION

The Aerobic Plate Counts (APC) and Total Coliform Count (TCC) of the avian based *Dambun Nama* is presented in Table 1. Chickens had the highest APC while quails had the least APC. *Dambun Nama* prepared from chickens, ducks and guinea fowls recorded the same values for TCC, while that of quails had the lowest TCC values. The occurrence of bacteria in the experimental *Dambun Nama* indicated that *E. coli* and *Staphylococcus* were detected in all the samples. The presence of *Enterobacter* and *Klebsiella* was confirmed in *Dambun Nama* prepared from chicken meat while *Salmonella* was only detected in the product made from duck meat (Table 2). The occurrence of fungal species is presented in Table 3 where *Candida, Penicillium* mould and *Rhizoctonia* spp. were detected in *Dambun Nama* prepared from chickens. *Aspergillus niger, Penicillium* mould and *Rhizoctonia* species were detected in the product made from ducks. However, *A. niger* was the only fungal species detected in the product prepared from guinea fowl meat, while *Rhizoctonia* spp. was the only fungal species detected from the product obtained from quails.

The low bacterial counts from the products in this study is generally attributed to the clean environment, good personal hygiene of the processor, and the use of clean utensils during processing and packaging. Thus possible cross contamination of the finished product from adjacent raw meat through unclean hands of the handlers and/or flies was minimized. This is in agreement with Shamsuddeen (2009), Fonkem *et al*. (2010) and Inusa and Sa'id (2017). The degree of meat spoilage is usually influenced in part by the microbial load at the beginning of production, packaging and handling of the finished product (Inusa and Sa'id, 2017). The International Commission on

Microbiological Specifications for Foods (ICMSF, 1996) reported the limits for total aerobic bacterial and fungal counts to be in the order of ≤ 103 as acceptable and 104 to 105 tolerable for ready to eat foods. Similarly, London Health Protection Agency, (LHPA, 2009) put <106cfu/g as satisfactory limit, and 106 to <107cfu/g as acceptable range. Thus, the levels of microbiological contamination in the present study, although very low, might portend public health concern as conditions favoring growth and proliferation of microbes prevails in most of the retail outlets. Okonko *et al*. (2013) isolated *Bacillus* species, *Staphylococcus aureus* and *Escherichia coli* in *Dambun Nama* samples from Port Harcourt, Rivers State. Moreover, in addition to *Bacillus cereus*, Edema *et al*. (2008) isolated, *Staphylococcus aureus* and *Salmonella* spp from a study on *Dambun Nama* samples retailed at some selected cities in Southwestern Nigeria. In another study, Fonkem *et al*. (2010) isolated *E. coli* and *Staphylococcus aureus* from Cameroonian *Dambun Nama* while Shamsuddeen (2009) reported the presence of *E. coli*, *Salmonella* species, *Staphylococci* and *Clostridium perfringens* in spices used in the production of *Dambun Nama*.

Abdullahi *et al*. (2004) reasoned that, differences in meat handling practices, ingredients, processing methods and variation in environmental factors may influence the microbial load of meat products. The findings of this study agrees with the work of Badau *et al*. (2001) who reported the presence of *Aspergillus* and *Penicillium mould* in *Dambun Nama* among hawkers in Maiduguri, Borno State. The study also, is in agreement with the report of Abolama and Egbebi (2007) in Ado Ekiti, Ekiti State where *Aspregillus niger*, *Penicillium* and *Rhyzoctonia* were reported. Similarly, Umar (2015) reported the presence of *Aspregillus niger*, *Penicillium*, *Rhyzoctonia* and *Trichophyton* in a study of *Dambun Nama* sold in Kano Metropolis, Kano State. In a more recent study of *Dambun Nama* prepared from goat meat, Garba (2017) reported the presence of *Aspregillus niger*, *Penicillium* and *Candida*. The presence of variety of mould species are points of great concern. This is because, mould like *Aspergillus niger* has the ability to produce extracellular metabolites called mycotoxins (Umar, 2015). One popular example is the aflatoxins which are a group of highly toxic metabolites produced by the fungi of the genus *Aspergillus*.

Table 1: Microbiological Quality of Avian based Grinded Meat

	Microbial count	
Avian Species	APC (cfu/g)	TCC (MPN/g)
Chickens	2.54×10^3	3
Ducks	2.39×10^3	3
Guinea Fowls	2.08×10^3	3
Quails	1.71×10^3	<3

APC: Aerobic Plate Count
TCC: Total Coliform Count

Table 2: Occurrence of Bacteria in Avian Based Grinded Meat

Chickens	+	+	+	-	+
Ducks	+	-	-	+	+
Guinea Fowls	+	-	-	-	+
Quails	+	-	-	-	+

+ indicates presence; - indicates absence

Table 3: Occurrence of Fungal Species in Avian Based Grinded Meat

Avian Species	*Aspergillus niger*	*Candida*	*Penicillium*	*Rhizoctonia spp*
Chickens	-	+	+	+
Ducks	+	-	+	+
Guinea Fowls	+	-	-	-
Quails	-	-	-	+

+ indicates presence; - indicates absence

CONCLUSION AND RECOMMENDATIONS

It can be concluded that, the avian based grinded meat had satisfactory microbial quality. Therefore, the study recommends maintenance of personal hygiene while processing, handling and selling the products, alongside proper storage to improve its safety and shelf life.

ABSTRACT

This study was conducted to evaluate the sensory and chemical properties of grinded meat, locally called *Dambun Nama*, prepared from chickens, ducks, guinea fowls and quails. Fifteen (15) semi-trained panelists were used to determine the sensory properties of the Avian Based *Dambun Nama* (ABDN) using a 7 – point hedonic scale. The ash content, moisture, crude protein, ether extract and mineral concentrations of ABDN were evaluated using standard procedures. The result revealed that ABDN prepared from quails had significantly ($p < 0.05$) higher ash contents (2.67%), while that of ducks had significantly ($p < 0.05$) higher moisture (12.17%). Overall, ABDN prepared from quails had the highest acceptability (6.80 ± 0.41), although not significantly different ($p > 0.05$). However, the product prepared from ducks had significantly ($p < 0.05$) higher crude protein (23.70%) and ether extracts (53.73%), while that from chickens had higher concentrations of Ca (225.4 mg/kg), K (22.09 mg/kg), Mg (8.19 mg/kg) and Zn (0.09mg/kg). ABDN prepared from quails recorded higher value of Na (67.90mg/kg), whereas, that of ducks and guinea fowls had higher concentrations of Cu (0.06 mg/kg) and Fe (0.07mg/kg), respectively. Conclusively, the avian based *Dambun Nama* was highly nutritious, palatable and generally accepted. Thus, highly nutritious foods such as *Dambun Nama* are particularly required for malnourished people especially children and women.

Key words: Chemical, Sensory, Avian, *Dambun Nama*

INTRODUCTION

The provision of adequate food to the ever increasing teeming population of the world is one of the greatest challenge to mankind (Abubakar *et al*., 2011). In 2010, the World Population Data Sheet (WPDS), estimated 6.892 billion people that may reach 7 billion in 2011 and 8 billion in 2024. Thus, the feeding of almost 7 billion people is an enormous task that must be taken seriously. According to the Food and Agricultural Organization, FAO (2010a), global per capita output of meat consumption, which at present averages 41.9 kg per year, varies greatly not only between developed countries (80.7 kg) and developing countries (31.6 kg) of the world, but even within communities in a country. Speedy (2003) had shown that while some countries consume more than 100 kg meat per annum, others consume less than 10 kg, which is insufficient and often leads to under-nourishment and malnutrition (FAO, 2010b). The high cost of meat is enough to make developing countries, including Nigeria, have limited access to meat and meat products. This is due to the fact that production and rearing of animals is far below demand and the preservative technology is grossly inadequate, resulting in high perishability of meat and meat products (Eke *et al*., 2012). Fresh meat is highly perishable, and to prevent its spoilage, meat is usually processed into products using many techniques such as grounded meat, locally called *Dambun Nama* (Abubakar *et al.*, 2011).

Dambun Nama is a significant portion of the diet of a large active population in Northern Nigeria (Salihu *et al*., 2010). In Kano State, it is usually sold as ready to eat meat products, which could be prepared locally for travelers and, especially during festivities. It is an indisputable fact that, reduction of protein malnutrition in the sub-Saharan African countries requires evaluation of simple, appropriate and affordable technologies applicable to local environment. As such, all avenues of meat preservation should be exploited so as to meet the animal protein requirement of the increasing world

population. Therefore, the purpose of this study is to evaluate the sensory and chemical properties of grinded meat, prepared under standard laboratory conditions, from some common avian species.

MATERIALS AND METHODS

Experimental Animals and Design: The avian species used for the experiment include; chickens, ducks, guinea fowls and quails. The birds were approximately of the same age and were purchased from Rimi market, located in Kano metropolis, Kano State, Nigeria. The ingredients (onions, ginger, salt, seasonings, sweet pepper, hot pepper, garlic and vegetable oil) were equally purchased from Rimi market. Completely randomized design (CRD) was employed where four treatments representing the four different avian species were used with each treatment replicated three times.

Preparation of *Dambun Nama*: Preparation of *Dambun Nama* was conducted at the Department of Animal Science, Faculty of Agriculture, Bayero University, Kano. The meat was cut into pieces of approximately 4cm by 2.5 cm dimension, washed with water, mixed with spices, boiled and pounded into shreds. It was then shallow- fried using vegetable oil in a stainless steel pot to obtain a brownish product known as *Dambun Nama*. The product was cooled and packaged in low density plastic containers, from where samples was drawn for subsequent analysis.

Determination of Organoleptic Properties: The organoleptic quality assessment of *Dambun Nama* was undertaken using a 7-point hedonic scale (7 = Very much liked, 6 = Liked a lot, 5 = Liked, 4 = neither liked nor disliked, 3 = Disliked, 2 = Much disliked, 1 = Very much disliked) as reported by Beinner *et al*. (2010), where 15 semi-trained panelists were used. The evaluation was based on aroma, tenderness, color, flavor, texture, juiciness and general acceptability of the product.

Determination of Chemical Properties: The ash, moisture, crude protein, ether extract contents and some selected mineral constituents (Ca, Mg, K, Na, Fe, Cu, Zn) of the samples were determined according to the methods described by the Association of Analytical Chemists, AOAC (2007).

RESULTS AND DISCUSSION

Sensory Evaluation of Avian Based *Dambun Nama*

The mean sensory scores for the experimental *Dambun Nama* is presented in Table 1. All the parameters examined were not significantly ($p = 0.1645$) affected by meat type. The range of values (6.00 – 6.80) obtained are higher than those reported by Ogunsola and Omojola (2008) which ranges between 2.33 and 4.47 in their study on quantitative evaluation of *Dambun Nama* prepared from beef and pork. They are also higher than the values obtained by Onwuka and Nwosuagwu (2005) with a range between 1.90 and 6.00 in a study on the effect of four local vegetable leaves on the protein and microbial content of smoked and dried beef. In terms of flavor, the product prepared from quails was rated highest, also products prepared from chickens, ducks and guinea fowls were rated same. This may be due to the standardization of ingredient mix (Omojola, 2008). However, the contributions of each of the ingredients to the overall *Dambun Nama* flavor and quality was not clearly ascertained. A similar view had been reported by Eke *et al*. (2012) in their preliminary studies on the production and quality evaluation of *Dambun Nama*. Flavor, texture and appearance are perhaps the most important characteristics of food because they are the attribute the consumers can readily assessed. Consumers often base their meat purchasing decisions on appearance, but usually make rapid purchases based on product flavor and texture (Schilling *et al*., 2009). Murano (2005) noted that two types of senses are involved in sensory perception: chemical (taste and odor) and physical (sight, sound and touch). Food flavor is an overall impression combining taste, odor, mouth-feel factors and trigeminal perception. Guinea fowl products are rated highest in aroma, texture and juiciness, but least preferred in terms of color, whereby panelists preferred the color of the product prepared from Chickens. Although *Dambun Nama* prepared from ducks had lower acceptability compared to other products, it was rated highest in terms of tenderness, which reflects consumers less familiarity and acceptability of the product in the study area. Miller *et al*. (1995) reported that mode of processing especially shredding and pounding had a significant effect on meat tenderness. Tenderness in meat is one of the important desires of the consumer, considering the amount of time and resources expended in an attempt to improve it (Farouk *et al*., 1992). Eke *et al*. (2012) reasoned that, the traditionally processed *Dambun Nama* delicacy is highly acceptable to consumers because of its soft and tender taste compared to the hard, non-soft products.

CHEMICAL COMPOSITION OF AVIAN BASED *DAMBUN NAMA*

The result of the chemical composition of avian based *Dambun Nama* is presented in Table 2 and 3. *Dambun Nama* prepared from quails had the highest ash content while *Dambun Nama* prepared from ducks had the least ash content. The ash content had an inverse relation to the moisture content. The higher the ash content the lower the moisture content (Umar, 2015), and hence the higher the shelf life. This implies that, the product obtained from ducks may have shorter shelf life. High moisture content favors the growth of many spoilage and pathogenic microbes and this is one of the reasons why meat is considered as an excellent medium to support microbial growth (Adams and Moss, 1995). Therefore, the product obtained from ducks would be more prone to spoilage since it has the highest moisture content. However, the result shows that *Dambun Nama* prepared from ducks had the highest crude protein and ether extract, while that prepared from guinea fowls and chickens had the least crude protein and ether extract, respectively. Calcium (Ca), Magnesium (Mg), Sodium (Na), Potassium (K), Cupper (Cu) and Zinc (Zn) were the predominant minerals found in Avian Based *Dambun Nama*. Ca is an important component of bones, thus if the ratio of Ca/P is above one, the food is considered good. K and Na are required for maintaining the osmotic balance of body fluids, pH of the body, regulation of muscle and nerve irritability, control glucose absorption and enhance normal retention of protein during growth (Fasasi *et al*., 2010; NRC, 1989). Na/K ratio in the body is of great importance for prevention of high blood pressure. On the other hand, Zn keeps the immune system strong, promotes healthy skin, growth, development and reproductive health. Thus, the present study shows that the product could be incorporated in the daily balanced diet.

CONCLUSION AND RECOMMENDATIONS

It can be concluded that, the Avian Based *Dambun Nama* was highly nutritious, palatable and generally accepted, which could be useful for malnourished communities or especially among children and women Further studies to determine the hazards associated with the products and also to evaluate all critical control points during processing and packaging of the product is recommended.

Table 1: Mean Sensory Scores for Avian Based *Dambun Nama*

ABSTRACT

This study was carried out to assess the quality of Chevon Suya (tsire) as affected by the addition of varied levels of Spring Onion (*Allium fistulosum*) leaf powder. Spring Onion powder (SOP) was added to suya spices at 5% and 10% inclusion levels (Treatment 1: Control, 2: 5% SOP and 3: 10% SOP). in a completely randomized design. Products yield (%), pH, oxidative rancidity (mg/g) and microbial load (cfu/g) were assessed on prepared Chevon Suya. Data were analysed using descriptive statistics and ANOVA at $\alpha_{0.05.}$ Reduction in PY, OR, and ML was observed as the SOP inclusion level increased while pH increased with increasing SOP inclusion. Product yield was 94.8% in control Suya and 73.54% in 10% SOP Suya while Oxidative rancidity was 8.56mg/g in control Suya and 7.29mg/g in 10% SOP Suya. Microbial load decreased from 5.19cfu/g in control to 4.28cfu/g in 10% SOP Suya. The pH increased from 6.47 to 6.92. The result obtained shows that SOP has acceptable antioxidant and antimicrobial activities. SOP could be used up to 10% in spices for Chevon Suya production.

Keywords: Chevon, Suya, Spring Onion (*Allium fistulosum*), Antioxidant

INTRODUCTION

Plants contain different bioactive compounds such as carotenoids, phenolic compounds, tocopherols, carotenoids most of which have been reported to have a variety of biological effects such as antioxidant, anti-carcinogenic, anti-inflammatory, and anti-microbial activities (Ehsani *et al.*, 2017). The Allium group is one of the world's most widely cultivated vegetable groups, with their culinary and medicinal uses. Their antimicrobial activity, long recognised in folk remedies has also been validated (Malairajan *et al.*, 2006).

Suya is an intermediate moisture meat product that is easy to prepare and is highly relished. It is a traditional spicy, ready-to-eat, barbecued, smoked or roasted meat product prepared from beef, mutton or chevon (Oshibanjo *et al.*, 2019). Spring onion is a promising source of bioactive compounds such as quercetin and flavonoids that exhibit various biological activities (Ding *et al.*, 2015) which can be harnessed in meat and meat product preservation.

This study therefore assessed the quality of cheron suya (tsire) as affected by the addition of varied levels of Spring Onion (*Allium fistulosum*) leaf powder..

MATERIALS AND METHODS

EXPERIMENTAL SITE

The experiment was conducted at the Animal Products and Processing laboratory, Faculty of Agriculture, University of Jos , Plateau state, Nigeria.

PREPARATION OF SPRING ONION LEAF POWDER

Fresh Spring Onion Leaves was purchased from the Farin-Gada Market Jos, thoroughly washed with clean distilled water and dried under shade for four days to maintain their greenish colour and nutritive potency. The leaves were thereafter ground and sieved with 0.2mm fine mesh to obtain the Spring Onions leaves powder which were then stored in air tight containers and properly labelled.

MEAT PREPARATION

A mature buck was purchased, rested, stunned using physical method then slaughtered. It was hoisted, skinned and eviscerated. Carcass was cut into its primal parts and refrigerated overnight. The meat was deboned and trimmed of all connective tissues. It was cut into pieces and sliced in the same direction of the muscle fiber. Meat was staked on already tagged slender wooden sticks, meat sheets were weighed and randomly assigned into three treatments with ten replicates per treatment.

PREPARATION OF SUYA INGREDIENTS

Spices were purchased at the Jos Farin-Gada Market, Jos, Plateau State and were thoroughly mixed based on the composition stated below.

Table 1. Composition of suya ingredients with different levels of leek leaf powder

Ingredients	Control	5% SOP	10% SOP
Groundnut cake	52.00	47.00	42.00
Leaf powder	0.00	5.00	10.00
Ginger	6.00	6.00	6.00
Garlic powder	6.00	6.00	6.00
Red dried pepper	12.00	12.00	12.00
Salt	8.50	8.50	8.50
Turmeric	6.00	6.00	6.00
Maggi	7.50	7.50	7.50
Groundnut oil	2.00	2.00	2.00
TOTAL	100.00	100.00	100.00

*SOP: Spring onion powder

PREPARATION OF SUYA

The already staked meat was properly coated with the formulated ingredients (Table 1) and each treatment were labeled using a masking tape at the bottom of the sticks. The weight of each suya was determined after roasting and this was used in calculating the percentage loss and the product yield.

PARAMETERS MEASURED

pH determination

The pH was determined using a digital pH meter model PHS-25 Microfield England according to the method described by AOAC (2010)

PRODUCT YIELD

The meat was cut, weighed and roasted on a fire from wood to an internal temperature of about 72°C. Each roasted sample was cooled to room temperature, blotted dry and weighed.

$$\text{Product yield} = \frac{\text{Weight before roasting} - \text{Weight after roasting}}{\text{Weight before roasting}} \times 100$$

OXIDATIVE RANCIDITY DETERMINATION

Thiobarbituric acid value (TBA) was estimated by modified methods of Buege and Aust, (1976)

MICROBIAL LOAD DETERMINATION

Microbial count was done using pour plate method according to Harrigan W. F and McCanee M. E. (1976).

EXPERIMENTAL DESIGN

The experimental design was a completely randomized design

STATISTICAL ANALYSIS

Data collected were analyzed using General Linear Model of SAS (2019) with storage days and method as fixed factors. Statistical variations were observed and means were separated using Duncan's multiple range test.

RESULTS AND DISCUSSION

Product yield of Suya prepared with spring onion powder-based spices is presented in table 1. The control has the highest product yield of 94.8%. The product yield decreased from 84.38 to 73.54% in the Suya with the Spring onion powder as its inclusion level increased. This agrees with reports by Omojola (2008) on the yield and organoleptic characteristics of Suya prepared from three different muscles of matured bulls.. The result obtained in this study could be due to low water holding capacity of the test ingredient.

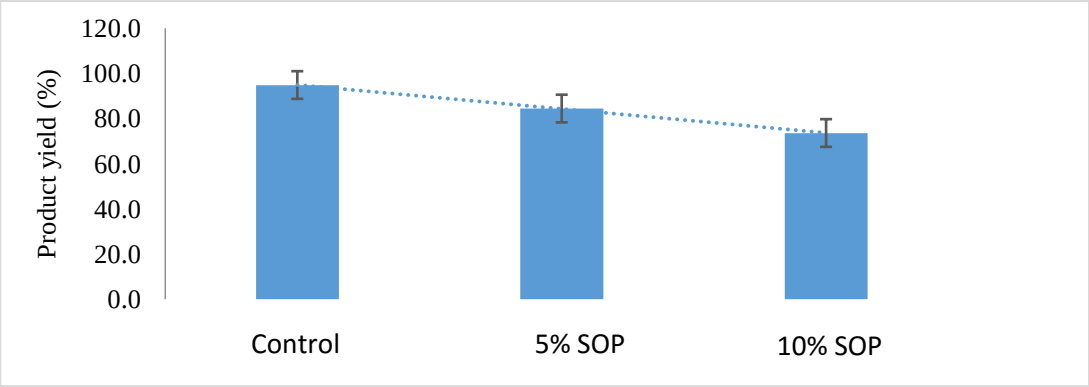

Figure 1: Product yield of Suya prepared with spring onion powder-based spices

*SOP: Spring onion powder

Figure 2 shows the physicochemical properties and microbial count of chevon Suya prepared with spring onion powder. The pH value of chevon Suya was significantly higher in 10% spring onions with least pH in the control treatment. The oxidative rancidity ranged from 7.29 to 8.56 mg/g. This result shows that as the inclusion level of Spring Onion increased, the oxidative rancidity values decreased. This could be due to the antioxidant activity and phytochemical substance presence in the spring onion.

Oxidative rancidity value determines the extent of lipid oxidation. Results on oxidative rancidity of this study is similar to reports by Magra *et al*. (2006) and Zaki *et al.*, (2018). There was significant difference ($p<0.05$) in Aerobic bacteria count (CFU/g) among the treatment with the control having the highest value (5.19 CFU/g) and 10% spring onion having the least value (4.28 CFU/g). Total aerobic plate counts for chevon suya treated with spring onion powder are acceptable when compared to suggested range of 2.5×10^5- 1.0×10^8 CFU/g by Pearson (1996) as cited by Fakolade (2012). The result obtained in this study could be due to the antimicrobial activity and the phenols presence in the tested ingredient.

CONCLUSION

Spring onion powder could be added to spices used in Suya production up to 10% because of its high antioxidant and antimicrobial properties

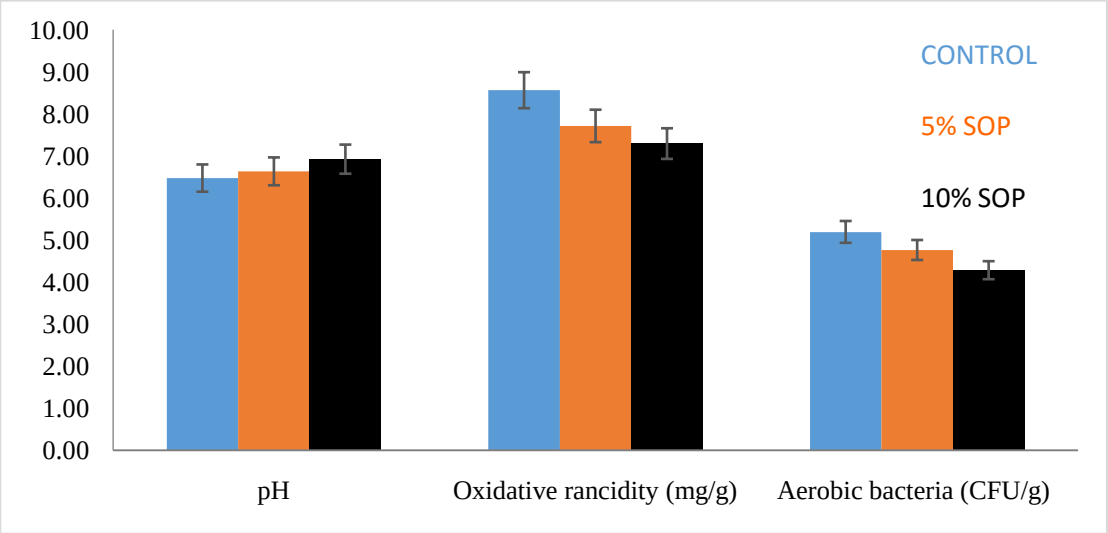

Figure 2: physciochemical and microbial count of chevon Suya prepared with natural antioxidant

ABSTRACT

A comparative study of the sensory qualities of *tsire* prepared with baobab seed powder and groundnut cake powder was conducted in this study. Spiced (Baobab/Kulikuli + spices) and unspiced (Baobab/Kulikuli + no added spices) *tsire* samples were prepared to determine their proximate and organoleptic/sensory quality attributes which included: colour, flavour, texture, juiciness, tenderness, firmness fatness and overall acceptability. Thirty Semi-trained panelists were used to assess the meat samples based on a nine-point hedonic scale. The results were subjected to analysis of variance in a complete randomized design. Results from the study indicated that, there was no significant difference ($P>0.05$) in the general acceptability of the *tsire* prepared from spiced or unspiced ingredients. The *tsire* prepared from spiced baobab seed powder showed significantly ($P<0.05$) higher organoleptic qualities compared to that produced from groundnut cake powder. From the result of this study, it has shown that baobab seed powder could be used to process *tsire*.

Key words: Tsire, Baobab Seed Powder, Groundnut Cake Powder, Acceptability

INTRODUCTION

Meat is the flesh and tissues or organs of animals with a highly nutritive value used as a food ingredient that is consumed by human beings, which provides quality protein (essential amino acids), minerals like iron and essential vitamins (Sebibe, 2014). There are different types of meat depending on the specie of animal from which they are obtained, for example, mutton from sheep, chevon from goat, beef from cattle, pork from pig and chicken from poultry (Soniran and Okunbanjo, 2002). In various parts of Nigeria meat is widely processed into different forms such as *Tsire, Balangu, Kilishi, Dambun-nama* (meat floss), *Banda* and *Kundi* (Ribah *et al.*, 2013; Inyang *et al*., 2005), according to culture and availability and consumed as a delicacy or source of protein (Olaoye and Onilude, 2010). However, other reasons for meat preference and consumption besides nutritional value or protein are: socio cultural, income level, religion, age, sex, individual differences, enjoyment, affluence, prestige and sensory properties.

The consumption of meat and its products like *tsire, balango, ganda, kundi, dambunnama (*meat floss) and *kilishi* has increased both from northern to southern part of Nigeria as well as other African countries (Igene and Mohammed, 1983; Inyang *et al*., 2004; Inyang *et al.*, 2005; Igene, 2008 and Omojola, 2008). These meat products vary in their quality attributes due in part to the ingredients used which might help to avoid associated spoilage, and thus increasing their shelf life as well as sensory properties.

Tsire is a roasted Nigerian spicy snack meat product that is popularly consumed and relished cosmopolitantly.

There is high demand for the utilization of groundnut and its products for both humans and animals as indicated by (Boli et al., 2014; and Ademola *et al*., 2015). *Kulikuli* is produced through roasting groundnut, grinding it, extracting its oil and then frying it to obtain the final product (Adjou *et al.*, 2012). *Kulikuli* powder is one of the major ingredients in the production of *Tsire.* However due to cost effect, variety and possible toxic issues (aflatoxin) associated to *Kulikuli* other ingredients could be used. Therefore, a cheaper and nutritiously similar ingredient such as baobab seed powder may be used as either supplement, replacement and value addition in the production of *Tsire*.

Food and agricultural scientists undergo series of research to discover wild and under-exploited native plants for possible potential value chain sources of food and value addition for increase food production (Vietmeyer and Janick 1996; Oelke *et al*., 1997). Several reports have also indicated that lots of lesser-known native crop species are high in nutrients and could possibly relieve critical food shortages if given adequate promotion and research attention (Murray *et al*., 2001). Baobab is good in nutrients like protein, vitamins, minerals, fibre and believed to have less microbial invasion. Processed baobab seeds are used as flavouring for soups, and also as a side dish, substituting peanut. (Addy and Eteshola, 1984). The seeds are also pressed for oil but the by-product, baobab seed cake is typically underutilized (Osman 2004) making baobab powder an amazing ingredient for this experiment.

MATERIALS AND METHODOLOGY

Experimental site

The study was conducted in the Animal Products and Processing Laboratory of the Department of Animal Science Faculty of Agriculture, Ahmadu Bello University Zaria, which is located between latitude 11°and 12° on an altitude of 646m above the see level (GPS, 2018). The area falls within the Northern-Guinea Savannah of Nigeria, with an average annual rainfall of 1100mm and varying temperature from 26°C to 35°C depending on the season. The mean relative humidity during the harmattan period and the wet season were 21% and 72% respectively (IAR, 2018).

EXPERIMENTAL MATERIALS

Chevon (goat meat), skewers (*geza*), 20kg weighing balance, 2kg sensitive kitchen scale, knife, ground nut cake powder, baobab seed powder, curry, common salt, seasoning cube, vegetable oil, dry pepper, sieve, trays, buckets, wire mesh, charcoal, paper tape, rubber containers, foil paper, tissue paper.

SAMPLE PREPARATION

Raw chevon of about 5kg was obtained from the Animal Products and Processing Laboratory of the Department of Animal Science Ahmadu Bello University Zaria. The meat (chevon) was deboned and cut into strips then further sliced into thin sheets using knife as outlined by Oyadeyi *et al*.,(2014).

INGREDIENT PREPARATION AND SKEWERING PROCESS

The ingredients were sourced from Tudun Wada Zaria market. The baobab seed was roasted for about 30 minutes, then dried and grinded finely into powder. Both baobab and *kulikuli* powder and other ingredients were mixed in a specific ratio of 100% as shown in table 4.

A total of fourty pieces of wooden skewers were used for four treatments 1,2,3,4, as plain *kulikuli*, plain baobab seed powder, spiced *kulikuli* and spiced baobab seed powder (ten each). The meat was skewered by piercing it at the center of the skewers with four slices of meat per skewer and then pressed and coated properly with the spice mix that was spread on a tray. The coated meat was then grilled on a smokeless fire made from charcoal that was medium hot at around 140°C for about 35 minutes with regular turning. The distance of the sticks from the center of the fire was about 25-30cm with regular turning of the product and intermittent addition of vegetable oil of about 2-3ml as described by (Igene and Mohammed 1983; Omojola, 2008) .

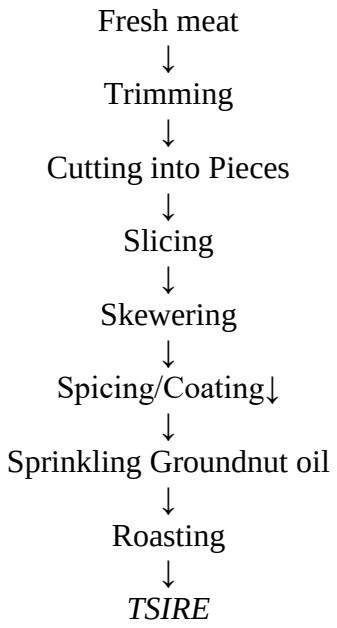

Figure 1: *Tsire* processing

SENSORY EVALUATION

A total of thirty semi-trained panelists (male and female) were used for the sensory evaluation of the meat samples using a 9-point hedonic scale; 1=like extremely; 2=like very much; 3=like moderately; 4=like slightly; 5=neither like nor dislike; 6=dislike slightly; 7=dislike moderately; 8=dislike very much; 9=dislike extremely for meat eating quality attributes (colour, texture, tenderness, aroma, juiciness, and overall acceptability). A blind coding and two equal order of arrangement were used for the meat samples as shown in Appendix I. During the evaluation, crackers biscuits and sachet water were provided for all the panelists.

STATISTICAL ANALYSIS

The data collected was subjected to analysis of variance (ANOVA) using (SAS 2004), the treatment means were separated using Duncan Mean Range Test (DMRT).

RESULTS AND DISCUSSION

PROXIMATE COMPOSITION

The Proximate compositions of baobab and *kulikuli* were presented in Table 1. The protein content of baobab seed 26.71% which is compared though lower by that obtained by Ajayi *et al.* (2006) 36.00% and was higher than 13.40% of *kulikuli*. Baobab seed 35.48% had higher lipid content than 23.21% of *kulikuli.* The lipid content is within the range obtained by Ajayi *et al.* (2006) which was 33.00%. The NFE content of *kulikuli* was 52.19% which was higher than that of baobab seed of 15.55%. Ajayi *et*

al. (2006) reported 39.90% of carbohydrate. The fibre content (2.35 %) of baobab was higher than 0.26% that of *kulikuli* but lower than that obtained by Ajayi *et al.* (2006) which was 6.71%. the ash content of 14.51% of the baobab seed powder was higher than that of *kulikuli* (4.63%) and that obtained by Ajayi *et al.* (2006) 7.50%. These differences might be dew to sources of the seeds, moisture content of 7.76% which was higher than that 5.02% of (Ajayi *et al.* 2006).

SENSORY SCORES OF *TSIRE* PRODUCED FROM BAOBAB AND *KULIKULI*

The result of the sensory evaluation was presented in table 2 showed that there was no significant difference (P>0.05) in the general acceptability between the *tsire* that was produced from plain baobab and plain *kulikuli* from the mean values. There was significant difference (P>0.05) in the mean values of *tsire* produced from the spiced baobab compared to spiced *kulikuli*. However, since the cost of production affected the profitability of any production the result on Table 3, showed that, the use of *kulikuli* was more costlier than the use of baobab seeds.

CONCLUSION

It can be concluded from the study that, baobab seed has high protein and fibre contents as compared to *kulikuli*. Baobab seed could be used as a supplement or replacement of *kulikuli* in the production of *tsire*. The use of baobab seed powder is more cost effective than using *kulikuli*.

RECOMMENDATIONS

It can be recommended that;

Baobab should be used as a supplement or replacement for *kulikuli* in the production of *tsire*. More research on the availability, acceptability and utilization of baobab and other related food materials could be conducted for value addition.

ABSTRACT

This Supervised Enterprise Project (SEP) was conducted in order to create awareness, empower and impart the skills and knowledge of sustainable techniques of milk processing by converting it to yoghurt. The project empowered thirty rural women leaders in Rano town, Rano LGA of Kano State on how to make yoghurt from fermented cows' milk (nono), thus helping them economically. One hundred questionnaires were distributed to one hundred households in order to assess socio-economic aspects of milk producers in Rano LGA. Chi-square and simple descriptive statistics were used to analyse and describe the data collected. Majority of the farmers had poor knowledge of improved yoghurt processing prior to this project. However, all the farmers reported to have improved their yoghurt processing skills after the project. Furthermore, majority of the farmers indicated willingness to adopt the technology acquired. Chi-square analysis showed that there was a significant ($p<0.05$) difference in willingness to adopt the yoghurt technology between owners of large and small herds, which indicates that, farmers with large number of animals in their herd were more willing to adopt yoghurt technologies than those with fewer animals.

Keywords: Yoghurt, women, empowerment

INTRODUCTION

Fresh Milk is highly perishable, as such, it should be immediately consumed in its fresh form (Yahuza, 2000). Fresh Milk can also be processed into fermented products which could improve the quality and nutritive value (Cashman, 2002).

The problem of low milk yield and of low quality in dairy cattle under tropical environment is held as one of the most important limiting factor to the rapid growth of the dairy industry in Nigeria, and the problem is attributed to a number of factors, which included climate, genetic potential of breeds, inadequate nutrition, diseases and poor management (National Livestock Project Division, 1992). In recent time under nutrition and low protein caloric intake has been recognized in developing countries of the world. The measures to be adopted to correct the nutritional deficiencies in both child and adult population in these countries are still subject to widely differing opinions.

On one hand, loss of milk quality largely due to lack of techniques for improving preservation and lifespan of fermented cow's milk (nono) was identified as a major challenge that requires intervention. Furthermore, improved milk processing techniques can increase output and quality of the milk and hence invariably increase sales and consumption. When there is an increase in sales, the women's income will increase, thus their livelihoods and that of their families will be improved. Milk processing into yoghurt may be of immense help to curb the problem of milk spoilage which leads to immeasurable losses to farmers. The project will also improve the storability of milk for the producers to target better markets and prices. More so, an increased consumption of milk and yoghurt by the people will increase their protein intake and thus increase their health (Barr *et al*., 2000).

PROJECT CONTEXT

The project was conducted as a Supervised Enterprise Project which is an organizational component of Sasakawa Africa Fund for Extension Education (SAFE). The project empowered rural women on how to make yoghurt from fermented cows' milk (nono), thus helping them economically.

MATERIALS AND METHODS

THE STUDY AREA

The training was conducted in Rano town, Rano Local Government Area (LGA) of Kano State. Kano is located in the North-Western part of Nigeria at latitude 12°3'N and longitude 8°32'E with an average temperature of 26.2 °C with warmest temperature being 38 °C in April and the coolest temperature being 13 °C in January and December. The state also receives an average of 873 mm of precipitation annually. The months with the driest weather are January and December. Mean relative humidity was recorded as 31.1% (KNARDA, 2008). On the other hand, Rano has an area of 520Km^2 and a tropical climate. The temperature and rainfall averages are 25.8 °C and 865 mm respectively (Climate-Data.org, 2015). Inhabitants are mostly Fulani cattle rearers and, therefore milk production is one of the major economic activities in the area.

PRELIMINARY ACTIVITIES

A need assessment exercise was carried out at Unguwar Dam, Rano Local Government area, Kano State. The inhabitants were mostly farmers engaging in both crops and animal husbandry. They cultivate crops in both raining and dry seasons. A stakeholders meeting was conducted to identify the areas of priority which people of the study area will mostly benefit from. Both the first and the second stakeholders meetings employed the use of focus group discussion. The first community meeting was conducted on 20th May, 2016 including various stakeholders of the projects. The target farmers were women cooperative societies to assess their various needs.

The project began by introducing the research student to women groups in the LGA and a convenient location was selected for a one-day training. Thirty women leaders were selected after they have obtained proper recommendations from their district heads and Local Government supervisors. Materials required for the training were purchased in Singer market in Kano and a date was set and communicated to all the participants via short message service (SMS).

SAMPLING

One hundred questionnaires were distributed to one hundred households to assess socio-economic aspects of milk production in Rano LGA. The questionnaires were distributed in all the ten (10) wards of the LGA. Ten questionnaires were distributed in each of the wards and the ten households selected within each ward were randomly selected.

INPUTS USED

The materials to use include water, Potassium sorbate powder ($C_6H_7KO_2$ _ preservative), Sodium Benzoate powder ($C_7H_5NaO_2$ _to hinder sourness), evaporated milk, powdered coconut flavour, sugar, cow milk (nono) and custard powder (predominantly made of starch). Equipment includes hand gloves, fine wire mesh sieve, 25 litres plastic containers, spatula, and spoon.

YOGHURT PREPARATION METHODS

On the day of the training, the participants were seated and provided with sample materials that they will practice with. The participants were told the importance of the training and the objectives. The need to train them, so that they train their group members was then emphasized. The student trainer led the training and demonstrated the step-by-step procedures of making yoghurt from cow milk (nono) while each participant used the equipment and materials provided to practically do what the trainer did. Each participant wore hand gloves and was lectured on the importance of hygiene. Furthermore, the training was video recorded to the participants in case they wish to refer to the procedures later.

Participants were guided on how to make a sample of 20 litres of yoghurt from cow milk (nono) as a group. One kilogramme of custard powder was put in a 25 litre plastic container. Five litres of cold water were poured onto the custard and smoothly mixed into paste. Ten litres of previously boiled (100°C) water was then poured to form a thick liquid paste, which was continuously stirred to avoid lumps. Five litres of finely churned cow milk (nono) was then added to the mixture and then thoroughly mixed. After a fine mixture was obtained, a fine sieve was then used to pass the liquid and

to ensure no lumps were left in the liquid. Thereafter, two tins of evaporated milk (410g, 380ml) were also added.

Ten grammes of Potassium sorbate powder (as a preservative), and ten grammes of Sodium benzoate powder (to hinder sourness) together with thirty grammes of coconut flavour were mixed with half cup of cold water and added to the mixture. Three hundred grammes of sugar was then added to taste. The diagrammatic representation of the procedure is shown in figure 1 below:

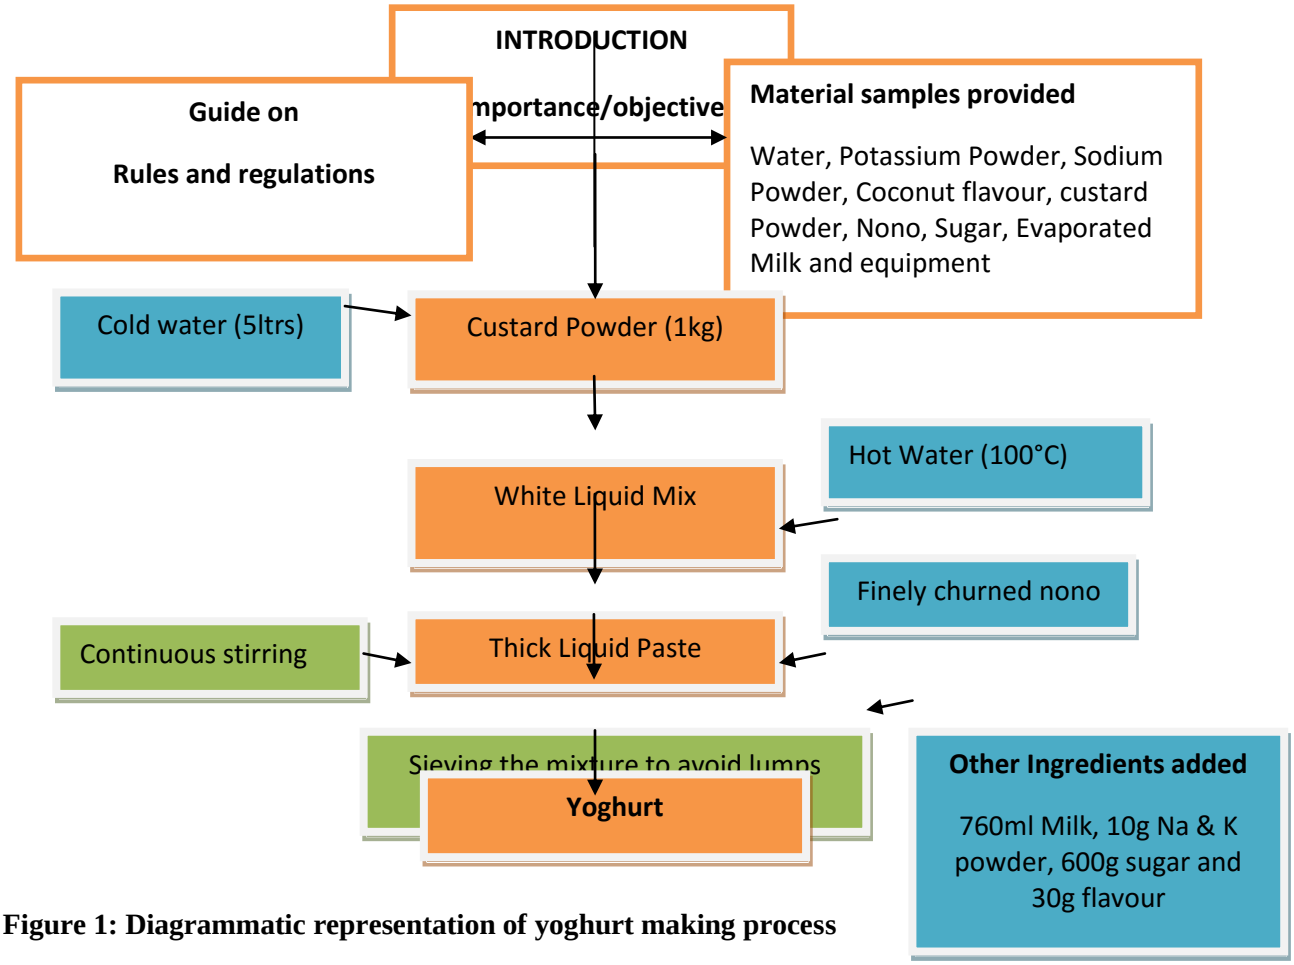

Figure 1: Diagrammatic representation of yoghurt making process

PACKAGING

An optional way of packaging and branding the yoghurt was taught to the participants. Participants were shown how to keep yoghurt by simply pouring it in used water bottles and then sold. A second option was to buy new empty bottles with sealing caps. Yoghurt should be filled up in the bottles and sold. Additionally, a trade name could be obtained and printed slips could then be attached to the bottles to further enhance the brand. However, license and approval must be sought for from relevant agencies.

TOOLS OF DATA COLLECTION

Questionnaire/interview schedule were used to collect primary data from the respondents. Secondary data was also collected from journals, textbooks and relevant websites.

DATA ANALYSIS

Simple descriptive statistics were used to describe the socioeconomic data of the respondents. Chi-square analysis was used to establish relationship between herd size and willingness to adopt yoghurt processing technology by the farmers with the aid of MAXSTAT©, VERSION 3.06 Statistical Package. Cost benefit analysis was used to ascertain the profitability of yoghurt production.

RESULTS AND DISCUSSION

Attempt was made to measure the impact of the yoghurt processing project on the participant farmers' experience, interest and willingness to adopt the new skills taught.

From table 1 below, majority (61.4%) of the participant farmers had poor experience of improved yoghurt processing before this project. This was followed by those with good experience level that were around 22.8%, excellent level 10.5% and fair level with 5.3%.

Also, after the training, majority (54.4%) of the participants reported to have gained improvement in their yoghurt processing skills. The fact that majority of the participants' skills were improved could be attributed to the techniques involved which ensured learning by doing through participatory action research as opined by Attah-Krah and Francis (1987). However, 45.6% of them reported no improvement in their skills. This non-improvement in skills as reported by the minority might be connected with the fact that, some participants did not fully participate in the training or some were naturally laggards.

Table 1: Impact Assessment of Yoghurt Processing amongst farmers in Rano town, Rano LGA, Kano State

Variable	Frequency	Percentage (%)
Experience before Training		
Excellent	6	10.5
Good	13	22.8
Fair	3	5.3
Poor	35	61.4
Total	57	100
Skills Improvement after the Training		
Yes	31	54.4
No	26	45.6
Total	57	100
Intention to Adopt the Technologies		
Yes	30	52.6
No	27	47.4
Total	57	100

Reasons for adoption		
Improve income	20	35.1
Reduce spoilage	24	42.1
Better Market	9	15.8
Others	4	7.0
Total	57	100

Source: Field Survey (2017)

From Table 1 above, 30 farmers (52.6%) showed willingness to adopt the new yoghurt technology they were taught during this project. This was probably due to simplicity of the procedures employed, availability and affordability of the ingredients and the practical and participatory approach used in the training sessions. Those who showed no interest to adopt the technology formed the minority (47.4%). Most of those willing to adopt the yoghurt technology mentioned that their reason was to improve income (35.1%) which was slightly lower than those who wanted to reduce spoilage (42.1%). A fraction of the farmers, i.e. 15.8% and 7.0% were willing to adopt the technology for a better market and other reasons respectively.

Table 2: Chi-Square Analysis of Willingness to adopt Yoghurt Technology between Small and Large Herd Owners amongst farmers in Rano town, Rano LGA, Kano State.

Response	Expected Frequencies	
	Small Herd Owners	Large Herd Owners
Yes	14.74	15.26
No	13.26	13.74

Chi square value = 14.75; Critical Chi square value= 3.84*; P value= 0.0001

The Chi-square analysis (Table 2) shows that, there was a significant ($p<0.05$) difference in the willingness to adopt the yoghurt technology between small herd and large herd owners in the study area. Thus, Number of cows owned by a farmer determines farmers' willingness to adopt milk processing technologies in the area. Those possessing large number of animals (above ten) were more willing to adopt the technology than those with fewer animals (below ten). It could be concluded that, farmers with large herd size were willing to put in their efforts to commercialize their venture as against the small herd owners who might be keeping the animals for subsistence and farm labour.

CONCLUSION

The thirty women trained were technically and economically empowered with the technical-know-how of yoghurt production that increased their potentials which resulted into more sources of

household income and subsequent betterment of living standards. Furthermore, estimates of cost and return of yoghurt production indicated that the venture was profitable and worth adopting by farmers. Additionally, farmers who had larger herds were more willing to commercialize their yoghurt production venture as against the small herd owners who might be keeping the animals for subsistence and farm labour.

RECOMMENDATIONS

The following recommendations were made with regards to the project:

4) The accessibility of yoghurt production materials should be increased, such that the people living in rural communities can purchase the materials and get involved in the production.
5) Furthermore, government intervention is necessary in all aspects of production to provide support to yoghurt producers in terms of materials of production, storage and marketing.
6) The marketing chain needs to be organised such that cooperatives and associations will be created to regulate production and pricing.

TEACHING ANIMAL PRODUCTS IN NIGERIA: FROM MEAT SCIENCE TO TROPICAL ANIMAL PRODUCTS INDUSTRY

E.B. Sonaiya
Department of Animal Sciences, Obafemi Awolowo University, Ile-Ife, Osun State.

ABSTRACT
At the introduction of courses in animal products (AP) in Nigeria, meat science was the main focus of the training. In response to graduate unemployment and the paradigm shift to entrepreneurship, self-employment and job creation for university graduates the curriculum was expanded to include topics in economics and marketing and to emphasize the business dimension of AP. For the curriculum review to be successful, there was the need to generate greater passion on the part of the teacher and the student to teach and learn, respectively, all the technical, as well as the business aspects of courses in AP. One well-tested way to generate student interest is to make textbooks available online in Open Access format that can be downloaded onto the smart phone. An Open Access e-book on the tropical animal products industry in Nigeria developed in compliance with instructional design directives evoked a higher student performance.
Key words: Teaching, Products, Course, e-book, Open-access

INTRODUCTION
In the early 1970s and 1980s, the first lecturers in animal products in Nigeria were trained in meat science (mostly in the US); for example: Professors Okubanjo (UI), Igene (UniMaid and UniBen), Sonaiya (OAU) and Aduku (ABU). Typical textbooks used and recommended were: Judkins and Keener, 1961, *Milk Production and Processing*; Lawrie, 1966, *Meat Science;* Zottola, 1972, *Introduction to Meat Microbiology*; Kramlich, et.al., 1973, *Processed Meats;* Forrest et al., 1975, *Principles of Meat Science*; Mountney, 1976, *Poultry Products Technology*; Price and Schweigert, 1978, *The Science of Meat and Meat Products*; and Frazier and Westhoff, 1978, *Food Microbiology*. By the middle to late 1980s, efforts were made to produce original textbooks that would accommodate the peculiarities of handling animal products in Nigeria. Three such texts were: Sonaiya, 1984, *Animal Products*; Ikeme, 1990, *Meat Science and Technology – A comprehensive Approach*; and Aduku and Olukosi, 1991, *Animal Products - Processing & Handling in the Tropics*. It was clear that the curriculum needed to be expanded to include topics in economics and marketing of animal products. In the same period, Taylor and Kauffman (1983) reported that the challenges facing the teaching of animal science included increased need for computer integration, improved communication skills, integration of business and economics into the livestock management systems and the approaches that will motivate students to learn and think. In Nigeria, the value chain approach to AP opens up investment opportunities in the AP industry (Sonaiya, 1998).
A hypothesis of this paper is that making textbooks available online in an Open Access format with lots of illustrations and downloadable onto the smart phone will lead to improved student performance.

MATERIALS AND METHODS
The response to changing needs for course content and student orientation must be accompanied by textbooks / instructional materials that are available online as electronic books in an Open Access format that makes access via the Internet as easy for the student as Facebook. To prepare adequate AP instructional materials requires the author to be familiar with curriculum and instructional design. In curriculum design, a course like Animal Products, as a segment of a B.Sc. / B. Agric. Animal Science (which can be visualized thus: Programme ← Courses ← Modules ← Study Units ← Sections ←

Sub-Sections), must contain at least 3 modules. A module is a number of logically and thematically related study units. A study unit is the smallest segment of a course material that treats a topic which should adequately engage a learner for 3–4 hours of study. Each study unit can be viewed as an individual lecture and, depending on the topic, can be up to 25 pages (Times Roman,13-point size, single spacing) or as brief as 7 pages. The content of a typical study unit (NOUN, 2012) is shown in Table 1.

Table 1. Content of a typical study unit.

Study Unit Title:
1.0 Introduction
2.0 Objectives
3.0 Main Content
- 3.1
- 3.2
  - 3.2.1
  - 3.2.2
  - 3.2.3
- 3.3
- 3.4

5.0 Summary
6.0 Tutor-Marked Assignment
7.0 References/Further Readings

Table 2. Content of "Tropical Animal Products Industry in Nigeria".

Module 1. Introduction to animal products, animal by-products and animal products industry
Units
17. Introduction to animal products and by-products
18. Introduction to the animal products industry
19. Products of captured, hunted and harvested free-living animals
20. Products of domesticated food animals
21. Products from other domesticated ruminants and herbivores
22. Products from insects and special animals
23. Animal fibres and inedible animal products

Module 2. Meat production and primary processing
24. Animal growth and development
25. Animal body composition
26. Primary processing systems
27. Slaughter and conversion of muscle to meat
28. Meat processing, preservation and storage

Module 3. Secondary processing, product hygiene and safety
29. Secondary processing of meat animal products
30. Processing of egg and milk
31. Animal products hygiene and inspection

Module 4. Technical and economic aspects of animal products industry
32. Distribution and sale of animals and animal products
17. Economic and social value of animal products
18. Animal products science &technology

The textbook author's role is to analyse the course description and break it into appropriate study units, write appropriate learning objectives for each unit, select relevant content to attain these objectives and design relevant questions / activities to assess learners' attainment of stated objectives. Course learning materials are to be self-instructional; i.e. to "replicate what the teacher does in the classroom". The materials must be interactive and must stimulate independent learning; should be self-explanatory, self-contained, self-directing, self-motivating and self-evaluating. Self-assessment exercises (SAE) use questions, exercises and activities to enable learners review what they have learnt and assess/evaluate themselves. Tutor-marked assignments (TMA) are needed at the end of every study unit and at the end of every module. These are short answer or essay questions, projects or practicals for students to carry out which can serve the purpose of continuous assessment (CA). Summative assessment (SA) is the end of semester examination. The content of "Tropical Animal Products Industry in Nigeria" (Sonaiya et. al. 2019), an Open Access e-book that was developed in line with instructional design directive, is shown in Table 2. The material was made available to the class via Google drive and class performance without (in the 2017/2018 session) and with the drive (in the 2018/2019 session) was recorded and charted.

RESULT

The class performance without and with The Tropical Animal Products Industry in Nigeria (TAPIN) drive is shown on Figures 1 and 2. With an enrolment of 43 students in Figure 1, 54% of the class scored less than 50% and only 2% scored 70% of the 50 marks obtainable. In Figure 2, enrolment was 51 and 0% of the class scored less than 50% while 23% scored 70% and above of the 72 marks obtainable.

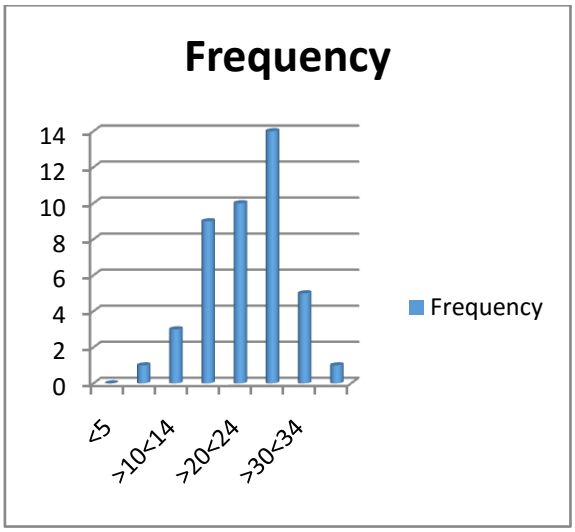

Figure 1. Class score without use of TAPIN

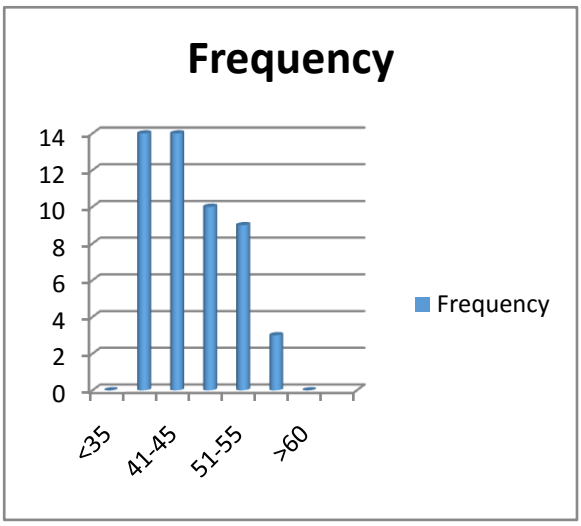

Figure 2. Class score with use of TAPIN

DISCUSSION

Animal products – meat, egg and milk – have great potential for balanced human nutrition, physical and mental development in the tropical countries of the third world. The next generation of Nigerians needs animal production scientists that are well trained and knowledgeable about the science, business, economics and politics of animal products and can leverage their knowledge to create viable businesses in "Animal Agriculture [which is] the goldmine of Nigeria's agro-revolution".

CONCLUSION AND RECOMMENDATION

In order to promote entrepreneurship in the AP industry, animal product scientists must apply the value chain approach in teaching about meat, milk and egg. To achieve this, Open Access e-books on the tropical animal products industry in Nigeria are needed. For the entire animal production science profession, a redesign of the curriculum is also recommended.

NUTRIENT COMPOSITION AND VALUE OF SELECTED GAME MEAT: A REVIEW

Waba, Y.E.[1] and Saidu, I.[2]

1.Department of Animal Health and Production, Federal Polytechnic Bali, Taraba State
2.Department of Animal Health and Production, Bauchi State College of Agriculture Bauchi

ABSTRACT
Now days people consider game meat to be healthier and safe products, and therefore associate to healthier and tasty meat arising from game animals. Because of this an overview is presented on the global human usage of unconventional animal species (ungulates, lagomorphs, other landed wild mammals and birds) that are hunted for human consumptions. The nutritional values of these species is discussed, focusing on their potentials for food security**.** One of the most valuable foods is meat, due to its nutritional value, largely determined by the essential amino acids, fatty acids, vitamins, minerals, etc. The importance of wildlife to local communities is now globally recognized in community-based. The results presented in this review are mostly on the proximate and biochemical composition of some selected species of game animals. Warthog and domestic pig meat was compared**,** where warthog presented a higher (74.04,1.69, 22.14 and 1.29, for moisture, total lipids, proteins and ash respectively) values (Table 2). Likewise, macro and micronutrient in domestic pigs and wild boars was also reviewed (Tables 8&9). The results showed that K and Ca values (11239.00[a] and 208[a]) in wild boars was significantly (P<0.05)higher than in domestic pigs. Micronutrient in wild boars shows significant (P<0.05) differences, with levels of Fe, Zn and Cu higher (136, 91 and 90.3% respectively) above that of domestic pigs. Chemical composition of Hartebeest was also compared in different regions and among sex (Table 3), where values for nutrient compositions did not differ except ash content for sex, where females exhibit higher (1,3±0.18) value than in males(1.2±0.20).Chemical compositions in ostrich was found to be higher than in beef and chicken particularly for fat content (0.90-1.34%)(Table 10).It was also observed among all the animals species studied that cholesterol levels ranges between 64.41-95.01 mg/100g in both fat and muscles (Table 13).The review therefore highlights not only the economic importance of wildlife, through consumptive and non-consumptive uses, but also present the potentials of nutritional value.
Key Words; Nutrients, composition, Game, meat,

Introduction
In a global sense, game refers to wild animal and birds, with the term game being used for culinary purpose to describe all birds and animals that are hunted for food (Costa *at al.,* 2016). In the European union (EU), wild game is defined as being, wild ungulates and lagomorphs, as well as other land mammals that are hunted for human consumption and are considered to be wild game under the applicable law in the member state concerned. These includes mammals living in enclosed territory under conditions of freedom similar to those of wild game and wild birds that are hunted for human consumption, (Costa *et al*., 2016). Around the world, a vast number of wild animals are harvested for several reasons, including for food purpose and sport hunting, with the type and range of animals hunted, depending on climate, animal diversity, tradition, local taste, legislations and local perception on what can or cannot be legitimately hunted. Red meat is an important source of minerals (mainly Zn, Fe, and Mn) in human diet, as provides highly bioavailable elements required for normal development and health (Nikolic *et al*., 2015), Tomovic *et al.,* 2015). Macro and micro nutrients, serve many functions in the human organism. They are the building material of bones, teeth, skin and hair and are fundamental components for metabolic processes, maintenance of acid base equilibrium and regulation of water and electrolyte metabolism (Soetan *et al*., 2010; Ustymowicz-Farbiszewska *et al*., 2014).
According to Onyongo *et al*. (1998), the decrease in the per capita supply of high quality protein and the increase in the world's population have intensified the need to search for other sources of protein. Although there is an increase in the demand for game, and tendency for the meat to be sold under the generic name of game meat or venison with no specific indication of species. Therefore, the objectives of the review is to present the analyzed data on the nutrient composition and food values of must wild animals which may not be readily available for use by institutions and individual needs

particularly in the health institutions and to give an insight on the comparative analysis of selected elements in some carcass parts of wild or game meat.

Chemical composition of meat and nutritional considerations

Now days, consumers are increasingly demanding for healthy and safe products as they are concerned about the food they eat. In general, consumers associate game to a healthier, thinner, and tasty meat arising from animal that supposed to be free of hormones and generally be considered to be highly nutritious (Costa *et al*., 2016).

Table1: Proximate composition of meats from different game species (g/100g; mean values are given).

Animal species		**Proximate composition(g/100g)**			
		Moisture	**protein**	**Fat**	**Ash**
Ungulates

Source: Costa *et al*. (2016)

Table I shows a results on the proximate Composition of different game meat. The values presented shows that evaluated animal proteins content are generally higher than 20% with some species presenting levels around 25% protein. On the contrary, total fat content can be considered as being low, as it is generally inferior to 5%, with some species including different ungulates, lagomorphs, and game birds presenting levels less than 0.5% fat. Currently it is a general agreement that total fat intake is certainly related to health risks, however it is also accepted that both quantities and qualitative aspects are important. Thus the type of consumed fat or fatty acids is of critical importance.

Table 2: Mean mineral concentration per 100g of edible raw tissue of Reindeer meat

Element	Mean ±SD					
	Meat (n=29)	Liver (n=29)	Tallow (n=15)	Bone marrow (n=9)	RDA Male	Female
Zn(mg)	6.8±0.2	3.5±1.7	0.2±1.0*	0.1±0.1*	7mg	9mg
Ca(mg)	5.4±10	6.4±1.1	5.1±2.1	339.7±277.3*	1g	1g
Fe(mg)	3.3±0.7	41.1±21.7	4.1±1.5	3.1±1.30	16mg	9mg
Se(mg)	3.0±3.2	48.7±48.9	0.8±1.6	0.2±0.5	40mg	50mg

Source: Ammar *et al*. (2012)

Mean mineral concentrations (mg/100g) of edible raw tissue for Ca, Fe and Zn was reported by Ammar *et al*. (2012**)** (Table 2). The highest concentration of 339.70±277.30mg/100g was found in bone marrow (P<0.01). The Ca concentration in meat and tallow were higher (5.40±1.0 iron and 5. 10±2.10mg/100g), when compared to iron of 3.3±0.7 and 4.1±1.5mg/100g respectively). Liver appeared to be the best source of Fe in terms of mean concentration at 41.10+±21.70 mg/100g (P<0.01). There were no differences in Fe concentration of meat, tallow and bone marrow (P>0.05), with the following concentration 3.3± 0.70, 4.10±1.50 and 3.1±1. 30mg/100g. Liver also had the highest Se content of 48.70±48.90mg/100g(p<0.01). The Se concentrations in meat, liver, tallow and bone marrow (Table 2) were characterized by variations among districts and from animals within the same districts (result not shown), with one animal demonstrating a remarkable high Se concentration (data not show). These variations have resulted in standard deviations similar or higher than the mean concentration. The Zn in liver was the only mineral that was significantly correlated with meat (r= 0.77, P<0.01). As expected the result from Table 2 revealed considerable differences in nutrient levels between the meat and the rest of the studied tissues. These differences were statistically significant (P<0.05), except for Se and Fe in tallow and bone marrow.

Table 3: Biochemical Composition of Game Meat

Group	N	Protein%	Fat%	Cholesterol(Mg100g-1)
Elk	8	22.72	1.33	64.41
Deer	18	22.36	1.90	70.57
Roe deer	16	22.82	1.59	67.92
Wild boar	12	22.92	2.82	95.07
Beef	15	19.61	1.48	76.31
Pork	15	21.32	2.77	57.85

Source: Vita *et al*. (2013)

Cholesterol found in muscles is free cholesterol and it is not related to that in animal blood, i.e. "good" or "bad" cholesterol. It is found in both fat and muscle in the range 64.41 to 95.07 mg 100 g-1 among animal species (Table 3). From a nutritional point of view, in terms of cholesterol, none of ruminant meats is superior (preferred) over others. The exception is wild boar meat, in which higher cholesterol levels can be explained by the high level of adrenaline under stress during the hunting season. The cholesterol levels statistically differed between animals ($F = 2.55$, $P < 0.05$) (Vita *et al*. ,2013). The human body requires the essential amino acids lysine, isoleucine, phenylalanine, tryptophan, leucine, methionine, threonine, and valine. Each of these amino acids have a role in the human body. Game muscle protein contains all essential necessary amino acids. Wild deer, roe deer and elk meat samples are similar in the summed concentrations of essential amino acids. Wild boar and pork samples, differed most in the summed concentrations of essential amino acids: 24.14 and 12.35 g 100 g-1, indicating the relatively higher biological protein value of wild boar over pork (Vita *et al*.,2013).

ABSTRACT

The study was conducted to assess constraints affecting goat production and marketing practices in Makoda and Ungogo Local Governments Areas of Kano State, Nigeria. The study describe socioeconomic characteristics of goat rearers, as well as major constraints affecting goat production in the study area. A multistage sampling technique was used to select 130 farmers used for the study. Data were collected through the use of structured questionnaires which was later analyzed using descriptive statistics, (frequencies and percentages). Findings revealed average age of 44 (43.65) years among the respondents. Majority 56.92% of them were males, 83.85% were married and have average household size of 8 people among the respondents. Majority 56.92% of the farmers were found to be literate. The result further shows 60.77% of them as mixed farmers and 68.46% of them have average 13 years of farming experience with average flock size of 6 goats among the farmers. Diseases, inadequacy of feeds, poor markets and lack of promising breeds were identified from the study as major constraints affecting goats' production and their prices in the area. It is concluded from the study that farmers could obtain better goat prices and income to solve a lot of their economic, social and domestic needs if necessary veterinary extension personnel and facilities as well as means of making feeds more adequate year – round, introducing more promising breeds together with mass enlighten campaigns are made available at the reach of the farmers in the study area.

Key words: Assessment, Constraints. Goat, Marketing, and Production

INTRODUCTION

Small ruminants (sheep and goats) contribute significantly to meat (and sometimes milk) production in Africa and hence, in meeting the current short fall created by the fast rising human population (Mukasa-Mugerwa, 1996). Gall (1981) reported that goat is numerous and widely distributed (scattered) in the tropics. In Nigeria, as at 2010, it was reported to have population of 34.5 million and 56 million sheep and goats respectively (FAO, 2010). Goats are small ruminant widely distributed throughout the geographical and climatic region of Nigeria. Goats adapt quickly and can be productive under almost any condition if they are properly managed (Jasen and Burg, 2004). Goat farming is not a new enterprise. Rearing goats is a profitable business. Goat production over the years in Nigeria has resulted in poverty alleviation and supply of high quality animal protein in order to meet the demand of animal protein for the country's teeming population (Anaeto *et al*, 2011). Goat farming can be suited with production of other livestock such as, sheep and cattle on low-quality grazing land. In tropical Africa and indeed in Nigeria, most sheep and goats are owned by farmers whose system of production and management are essentially traditional. About 96% of the traditionally managed goats are under free roaming and tethering system. Goats play significant role in the socio-economic wellbeing of the people. They are slaughtered during ceremonies and festivals, offer employments and serves as source of income to the farmers to meet their daily cash needs. In addition to miscellaneous functions, they also provide a source of investment, savings and as an insurance against disaster (Danguguwa, 1997). The skin of red Sokoto goats is well known for it is superior quality and command of high premium in the world markets (Ghude, 2017). Small ruminants play significant role in the food chain over livelihood of rural households, where they are reared largely by women and children (Lebbia, 2004).

Goat marketing is the most important and easiest step of goat farming business. Goat products like meat and milk has a huge local and global demand and popularity. Almost all types of people like goat milk and its meat. Therefore, good market is already available in almost every part of the world.

Commercial goat producers can target the international market and export the products to foreign countries (Mcreight, 2015). The marketing of goats and goat products in tropics varies and depends on location and prevailing product condition.

The viability of goat's enterprise depends not only on technical and biological efficiency, but also on a well-organized production and marketing system. At present goats production and marketing are characterized by tradition, poor management, unrealistic pricing, inadequate promising breeds as well as inadequate and inefficient feed and feeding system. Hence this study is design to investigate socio-economic characteristics of goat producers, as well as to identify major constraints affecting production and marketing in the study area.

METHODOLOGY

The research was conducted in Makoda and Ungogo local governments' areas, Kano state. Makoda has an area of 441 km^2 and Ungogo has an area of 204 km^2. Makoda has a population of 222, 399, while Ungogo has population of 369,657 at the 2006 census (NPC, 2006). The main livestock species in the study area are cattle, goats, sheep and also some species of poultry. Millet, rice, sorghum, groundnut, bean, maize and cassava are the major crops grown in the area. Multi stage sampling procedure involving purposive, proportionate and random techniques were used. Makoda and Ungogo local government areas were first purposively selected based on the existence of famous Dambatta Sunday market and growing Kwanar Ungogo small ruminant abattoir. In the second stage, sixty percent (60%) of wards of the two selected local governments areas of the study area was Proportionately taken giving a total of 13 wards (5 in Makoda and 8 in Ungogo local government).While in the third stage 10 farmers that were actively rearing goats were randomly selected in each of the 13 wards selected for the study in the areas. This gave a total of 130 goats producers selected and involved in the study. Data were collected from the respondents and analyzed using descriptive statistics that include frequencies, percentages, maximum, mean and minimum.

RESULTS AND DISCUSSION

Result in Table 1 shows the average age of the respondents was 44 years and this implies that the respondents in the study area are within the age range regarded as economically active innovative and productive. According to Ayoola (1999) young or middle age farmers are more flexible in decision making, risk taking and adoption of new ideas and technologies than older ones. The average household size of the respondents as indicated in Table 1 was 8. This implies that the more the household members, the more their contribution to the family farm/flock activities. The result is in line with finding of Bakoji *et, al*, (2012), who stressed that large household size assist to provide cheap family labour for an entrepreneurship activity like farming. By experience in farming, the result revealed a mean experience of 13 years among the respondents. This implies that the more years spent in farming, the more experience gained by farmers. The result is in line with Ihenacho (2000) who indicated that farming experience of farmers affect their managerial know – how and decision making to a large extent.

Table 1: Quantitative socio-economic characteristics of the respondents

Variable	Mean	Maximum	Minimum
Age	43.65	69	25
Farming Experience	12.68	41	02
Household size	7.92	20	01
Flock size	6.40	16	02

Source: Field survey, 2018.

Result of the study in Table 2 also shows that majority (56.90%) of the respondents were male and the remaining 43.10% were female. This impliedly shows that goat rearing among females in the area is regarded as an important economic enterprise. Majority (83.80%) of the respondents were married, with few (6.10% and 5.40%) Divorcees and widows. Only 3.8% of the respondents were singles. This finding supports the assertion by Ekong (2010) that early marriage is practiced more in rural areas than in urban centers, due to low levels of education, lower aspiration and dependence on agriculture

for livelihood. The results of the study shows that majority (56.90%) of the respondents were literates. This implies that respondents in the study area had one form of education or the other. USAID (2010) observed that the more educated the farmer is, the more the chances that the farmer would adopt innovations. Majority (57.70%) had contact with extension/veterinary extension practitioners. Extension service constitute a driving force for any agricultural development. Contacts with extension agent exposes farmers to information on new ideas, technologies and demonstrated by extension agents on regular basis (Herath and Takeya, 2003).

Table 2: Qualitative socio-economic characteristics of the respondents

Variable	Frequency	Percentage
Sex		
Male	74	56.90
Female	56	43,10
Marital status		
Divorced	06	06.10

Diseases, inadequate feeds, poor markets, lack of promising breeds, thefts as well as parasites shown in Table 3 are the most important constraints affecting goat production and marketing in the study area.

Table 3: Constraints militating against effective goat production

Constraints	Frequency	Percentage	Ranking
Diseases	92	70.77	1st
Inadequate feeds	75	57.69	2nd
Poor markets	31	23.85	3rd
Lack of promising breeds	25	19.23	4th
Thefts	22	16.92	5th
Parasites	15	11.54	6th

Source: Field survey, 2018.

CONCLUSION

It is concluded from this study that goat production and marketing is being constrained by a number of factors in the study area apart from non-existence of a single goat marketers or producers cooperative society in the study area. Diseases, inadequate feeds, poor markets, lack of promising breeds, thefts as well as parasitic problems were the major challenges faced by goat marketing in the study area. To reduce food insecurity, unemployment and industrial under- development through improving better goat prices and income, the following recommendations should were made.

- The farmers should be adequately mobilized/ sensitized by extension workers to form smallholder goat marketing/producers cooperative societies.
- More extension/veterinary extension personnel should be employed so as to improve easy accessibility to them by the farmers.

- Agricultural input stores such as Kano State Agricultural Supply Company (KASCO) in Kano state should be re-sustained by government.
- Superior more promising breeds better than the farmers own breeds, should be brought and be made available to the farmers by government, Non-governmental organizations, development partners etc. at affordable prices.

ABSTRACT
The study investigated the marketing of poultry egg in Ondo-West local government area of Ondo State, Nigeria. The multi-stage sampling technique was employed in the selection of one hundred and twenty-five (125) poultry egg marketers for the study. Primary data collected with the aid of structured questionnaire were analysed using descriptive statistics and gross margin analysis. Result showed the mean age of respondents as 44.2±9.7 years, 63.2% were female and 36.8% were male and 72.0% were married. The mean household size was 7±3 members and 58.4% had secondary education. Price fluctuation constitutes a major challenge in poultry egg marketing. The gross margin was ₦48611.37. Marketing of poultry egg has improved the average household means of livelihoods and generate income. Hence, poultry egg marketing should be encouraged in terms of access to credit, information and provision of storage facilities.

Keywords: gross margin, marketing, poultry egg, profitability.

INTRODUCTION
The marketing of poultry eggs has been given much attention in both urban and rural areas of Ondo State and Nigeria in general. This is not unconnected with the importance of egg in the diet of an average Nigerian and consumption in every home. Poultry eggs rank second to cow milk in terms of nutritive value and are the most economically produced animal protein (Nahid and Mohammad, 2015). Animal protein is an essential part of human nutrition because of its biological significance. Iwena (2007) reported that proteins are required for the growth of young ones, formation of gametes in reproduction, formation of digestive juices, repair of worn-out tissues or cells, production of anti-bodies as well as enzymes and hormones in the body. Poultry egg marketing forms a good source of income, employment and vital source of food (protein) in the households. Marketing of poultry eggs like other agricultural products serves as means of livelihoods in both the rural areas and the urban centers. Tijani *et al*. (2006) posited that animal proteins are more biologically complete than vegetable proteins with regards to their amino-acids composition.The sales of poultry eggs contributed about 10.36% in the livestock sub-sector to the Gross Domestic Product (GDP) in the Nigeria economy (Central Bank of Nigeria, 2010). Eggs are major sources of animal protein in human diet. According to Okafor *et al*. (2007) poultry goes a long way in providing animal protein for the populace because it yields quickest returns and provides for meat and eggs in a very short time.Poultry eggs are among the most versatile food in the kitchen of an average home, and it can be served in several ways on their own, eggs add texture and moisture to baked foods and complement both sweetened savoury dishes. In the diet, poultry eggs can also boast of rich nutritional profile, provide a wide range of vitamins, minerals, and other nutrients, however, it is low calorie content.
According to Dietary for Americans 2015-2020, Poultry eggs are good sources of inexpensive high quality protein. However, despite the relative importance of eggs as sources of food, protein, income and means of livelihoods to the people, the marketing and distribution of poultry eggs is beset by serious problems both in the rural and urban areas of the country and the study area in particular. These problems include; price fluctuations, high cost of transportation, inadequate supply, and high cost of feeding, poor availability of labour, inconsistent government policies on marketing agricultural products, among others. According to Olanloye (1998) and Nahid and Mohammed (2015) farm product marketing activities is hampered by; price fluctuations, product glut, and inadequacy and poor transportation. Malnutrition and hunger have remained among the most critical problems facing the world poor. Moreover, the dearth in the quantity and quality of dietary protein supply in Nigeria is a challenge that is beyond dependence on plant protein source alone. Most countries in sub-Saharan

Africa including Nigeria are faced with the problem of insufficient poultry egg production and protein deficiency. Despite the high demand for eggs in the markets, there has been serious problem of inadequacy in meeting the needs of the consumers. Hence, the need to investigate the economic analysis of poultry egg marketing, identify the challenges facing poultry egg marketing and determine the profitability of poultry egg marketing in Ondo-West local government area of Ondo State, Nigeria.

MATERIALS AND METHODS

This study was conducted in Ondo-West Local Government Area of Ondo State Nigeria. The study area consists of 283, 672 people (NPC, 2006). The major occupation is primarily farming however trading activity is also practiced. The multi-stage sampling technique was employed in the selection of respondents. Stage one entailed a purposive selection of Ondo-West local government area due to accessibility and availability of egg marketers. Stage two consisted of the random selection of five major towns while stage three comprised the random selection of ten markets in the study area. In the final stage, One hundred and twenty (125) poultry egg marketers were selected for the study. Data collected with the aid of structured questionnaire were analysed using descriptive statistics and gross margin analysis.

RESULTS AND DISCUSSION

The result revealed (Table 1) that the mean age of respondents was 44.2±9.7 years, which implies that marketers are still at the economic active age, 63.2% were female and 36.8% were male. This indicates that poultry egg marketing is dominated majorly by females and 72.0% were married while 12.0%, 9.6% and 6.4% were widowed, single and divorced, respectively. The mean household size was 7±3 members per household indicating that poultry eggs marketers have a fairly large household size. Marketers with secondary education accounted for 58.4%. This will help the marketers in accessing information and marketing intelligence on poultry egg marketing business, 20.0% accounted for primary education, while 12.0% and 9.6% had no formal education and tertiary education respectively. On the years of experience as poultry egg marketer, the mean years of experience was 9.4±4.6 years. This indicates that the egg marketers in the study area are more experienced in egg marketing business. On sources of capital, 58.6% indicated the cooperative society as their source of credit while (21.6%) obtained credit from money lenders to start egg marketing business, others, 12.0% and 8.0% patronised friends/relatives and commercial banks for capital to finance the egg marketing business, respectively. On the quantity of poultry egg sold by marketers, 50.4% indicated that the sold between 30 and 50 crates while 24.0% sold between 51 and 70 crates of eggs, moreover, 12%, 9.6% and 4% respectively sold between 71 and 90 crates, less than 30 crates and more than 90 crates of poultry eggs. This implied that there is much demand for poultry eggs in the study area.

Source: Field Survey, 2019

Table 2 revealed the challenges facing poultry egg marketers in the study area. Inadequate capital outlay accounted for 32.0% while price fluctuation in the price of poultry egg in the market represented 48.8%. This is in agreement with Nahid and Mohammed (2015) who identified price fluctuation and shortage of capital as some of the challenges in egg business. Others are; poor storage facilities represents 8.8%, 6.4% and 4.0% indicated labour problems and small-size of the business as the challenges facing the poultry egg marketers.

Table 2: Challenges facing poultry egg marketers n = 125

PROFITABILITY ANALYSIS OF POULTRY EGG MARKETING

The profitability analysis in this study was determined using the gross margin analysis, net farm income and the cost benefit ratio thus;

G**ross margin analysis (GM):** $GM = TR - TVC$ ……1

Where; GM = Gross Margin, TR= Total Revenue and TR = Q.P.....2

Q represents the number of crates; P = Price per crate; and TVC= Total Variable Cost.

Net Income (NI): Net Income = TR - TC.....3

Where, TR= Total Revenue; TC= Total cost;

Benefit-Cost Ratio (B/C): The Benefit-Cost ratio is used to determine the profitability of poultry egg marketing business. It helps to ascertain the gain over every naira invested in the poultry egg marketing. This is expressed as; TR/TC.....4

The result of the profitability analysis indicated that ₦48611.37 was realized as gross margin while ₦18065.56 was the net income (net profit). The return on a naira invested in poultry egg marketing was 1.16. This showed that on every naira invested in the sale of poultry egg marketing ₦0.16 was realized as gain. This indicated that the marketing of poultry egg in the study area is profitable. However, the variable costs accounted for 71.6% in the cost of production while the fixed cost represented 28.4%.

Table 3: Profitability Analysis for Poultry egg marketing

Variables	Amount (₦)		Percentage
Total Revenue		125440.57	
Variable Costs			
Purchase	58375.36		54.4
Transportation	8065.51		7.5
Cost of crates	11850.75		11.0
Total Variable Cost (TVC)		78291.62	
Fixed Cost			
Rent	24000.80		22.4
Security	6545.01		6.1
Total Fixed Cost (TFC)		30545.81	
Total Cost (TFC + TVC)		107375.01	
Returns on Investment			
Gross Margin	48611.37		
Net income	18065.56		
Benefit-Cost Ratio (B/C)	1.16		

Author's Computation, 2019

CONCLUSION AND RECOMMENDATIONS

The study revealed that marketing of poultry egg in the study area is a profitable business and as means of livelihoods to generate income. However, the business is faced with the problems of inadequate capital and price fluctuations. Hence, poultry egg marketing should be encouraged in terms of access to credit, organized marketing and provision of storage facilities.

ABSTRACT

The study analyzed costs and return of Irish potato production under Plateau State Potato Value Chain Support Project (PS-PVCSP). Multi-stage sampling technique was used to select 180 farmers across 17 local government areas. Descriptive statistics and gross margin were used for data analysis. The results show that male and female accounted for 57.78% and 42.22% of Irish potato production, respectively. The result indicated that 47.22% of Irish potato farmers were within age bracket of 36-45 years. The result revealed that majority (62.22%) of the farmers were married with a mean household size of 7 persons. The result also shows that 37.78% of Irish potato farmers had no formal education. The costs of production shows that cost of seed accounted for 51.39% of the total variable costs. This was followed by labour, estimated at 26.09%. Meanwhile, the cost of pesticides appears to be the least, representing less than 0.53% of the total variable cost. Farm gate sales accounted for the largest share of revenue, put at 78.57%. In all, total returns stand at ₦ 699,018.7, while gross margin stood at ₦ 382,842.7. Producers were faced with the incidence of blight, particularly in the wet season, as reported by 22.78%, followed by inadequate capital (15%) and high cost of inputs (11.67%). However, access to micro-credit could have prospect in improving the productivity of farmers and contributing to uplifting the livelihoods of disadvantaged rural farming communities. It can be concluded that Irish potato production in Plateau State is a profitable venture. It was recommended that project should enhance productivities and incomes of Irish potato farmers through provision of inputs as well as infrastructure and institutional development that will enhance capacity building of project beneficiaries and linkages to services such as credit, insurance and market.

Key words: Irish potato, Livelihoods, Production, Value Chain

INRODUCTION

Irish potato (*Solanum tuberosum L.*) belongs to the broad categorization of tuber crops. Irish potato was first introduced in Nigeria in the late 19th Century, through missionary activities (Obigbesan, 2009). The production was encouraged by the British Colonial Government during the Second World War as the tubers were needed to feed their armed forces in West Africa. Since then, the importance of Irish potato has been widely realized such that it is now an important commodity in both local and international trades. Irish potato is about the most fruitful and efficient tuber crop in the world in terms of tuber yields and days to maturity. The crop matures in about 60 to 90 days as compared to 9 and 12 months for yam and cassava, respectively (Kaplinsky and Morris, 2001). Kudi *et al.* (2008) revealed that the Irish potato gives the highest yield per unit area among roots and tuber crops in Nigeria and that it brings more income to farmers than other roots and tuber crops. The total annual production, was estimated at 900, 000 metric tons as at 2010 (Jwanya *et al.,* 2014) per year. Okonkwo *et al.* (2009) noted that at a price of ₦50, 000 per tonne of potato tuber, Nigeria earns over ₦45 billion from sales in the local markets and West African sub-region. Although, production of potato has increased by over 120% in the last 10 years in Nigeria (FAO, 2013), it is still grossly below demand. Apart from low quality seed and poor storage facilities, diseases, particularly blight are also a limiting factor to potato production in Nigeria (Sani *et al.,* 2015).

The production and marketing of Irish potato in the highland zones of Plateau State has become an integral part of the rural economy, both at the rainy and dry seasons, as it is cultivated as rain-fed and dry season crop (Sani *et al.,* 2015). According to Okonkwo *et al.* (1995), planting of rain-fed potato takes place from late March to August depending on local conditions while harvest occurs three to four months later, from July to November. Irrigated production starts from late October through January with harvest between January and April. The attraction to potato production in the state is largely driven by economic benefits.

Irish Potato is important for its contribution to food security and as source of cash income for large proportion of the rural households. However, improving access of potato farmers to the markets and active engagement in the Irish potato value chain are key issues in the study area. Generally, farmers' motivation for cultivating potato is to ensure adequate food supply during food shortage months. It is the best staple food crop during this period, as well as an important source of cash income (Gebremedhin *et al.*, 2013) because of its ability to provide a high yield of high-quality product per unit of input with a shorter crop cycle than major cereal crops like maize (Adane *et al*., 2010). Irish potato is considered a strategic crop by the Plateau State Government targeted at achieving food security and economic benefits to the state and the country at large (Chris, 2013).

The key challenges across the potato value chain in the state include inadequate access to and usage of improved agro-inputs, limited rural infrastructure and institutions, limited value addition, inefficient system for enforcing quality standards, poor knowledge of target market, prevalence of diseases and pests, amongst others. In-spite of these challenges, investment in potato value chain development in the state provides an opportunity for redressing the negative trend in key development outcomes in the state, including, diminished incomes of value chain actors, prevalence of poverty, limited employment creation, potato export and foreign exchange earnings. Therefore, the Plateau State Potato Value Chain Support Project (PS-PVCSP) aims to contribute to employment generation and shared wealth creation along the potato commodity value chain, as well as food security to increase access to rural infrastructure. There has been growing pressure on the governments and project implementers to be accountable and be more responsive to the demands of the citizens and other stakeholders, through showcasing the effect and impact of development interventions, through policies, projects and programmes. This will improve population growth, increase in potatoes production can improve the livelihoods of smallholder potato value chain actors across the state.

Plateau State needs to expand its crop base to meet the growing demand for staple foods for the increasing population. Potatoes offer a good candidate both as a commercial and food security crop. The increase in population coupled with the anticipated fast development of cities and towns following the recent devolution in the country lay a strong basis for promotion of potatoes as a source of fast foods desired in towns. To meet the growing demand for potatoes which is a major constituent of fast foods like chips and crisps, there is need to address factors constraining the production especially of the most popular varieties. The purpose of this study was to avail socio-economic information and other underlying factors that affect Irish potato production. Therefore, the aim of the study was to analyze costs and returns of potato production under Plateau State potato value chain support project (PS-PVCSP). The specific objectives were to:

i. describe the socio-economics characteristics of Irish potato farmers in the study area
ii. determine the costs and returns associated with Irish potato production in the study area
iii. describe the constraints associated with marketing of Irish potato in the study area

MATERIALS AND METHODS

THE STUDY AREA

The study was carried out in Plateau State which is the twelfth largest state of Nigeria; roughly located in the center of the country. It is geographically unique in Nigeria because its boundaries totally surround the Jos Plateau, having the Jos Plateau totally in its central and northern parts, with capital in Jos. It has a population of around 3.5 million people. The state is located between latitude 9°10´ N and longitude 9°45´ E. The altitude ranges from around 1,200 meters (about 4000 feet) to a peak of 1,829 meters above sea level in the Shere Hills range near Jos. Though situated

in the tropical zone, a higher altitude means that the state has a near temperate climate with an average temperature of between 18°C and 22°C. Harmattan winds cause the coldest weather between December and February. The warmest temperatures usually occur in the dry season months of March and April. The mean annual rainfall varies from 131.75 cm in the southern part to 146 cm on the Plateau. The highest rainfall is recorded during the wet season months of July and August. The upland nature of the state makes it the source of many rivers in northern Nigeria, including the Kaduna, Gongola, Hadejia and Yobe rivers. The state share boundaries with Bauchi State to the North East, Kaduna State to the North West, Nasarawa State to the South West and Taraba State to the South East. The state has an estimated area of 26,899 square kilometers.

SAMPLING TECHNIQUES AND SAMPLE SIZE

The sampling technique was multi-stage, which consisted of purposive and simple random sampling techniques. The first stage 9 LGAs out of 17 LGAs were purposively selected based on quantity of Irish potato production. Second stage, two communities were selected from each LGA. While in the final stage, the Yamane sample size determination formula was used to select 180 PVCSP beneficiaries at 5% precision level and 95% confidence level from the available profiles of the potato value chain actors.

$$n = \frac{N}{1+N(e^2)} \qquad \ldots(1)$$

where;
n= Sample size,

N= Population size and

e= level of precision

DATA COLLECTION AND ANALYSIS

Data were collected with aid of structured questionnaire. There are many analytical techniques available for use in research of this nature, and the choice of a particular one depends on the type of data collected in order to achieve the specified objectives. Descriptive statistics and inferential statistics (Gross margin and multiple linear regression analysis) were used for data analysis

GROSS MARGIN ANALYSIS

Olukosi and Ehrabor (2008) defined gross margin as the difference between total revenue and total variable costs. It is used as a measure of enterprise profitability and means of selecting farm plans. The size of gross margin depends on the services provided, market structure, market price, perishability of the product as well as the distance between producers and consumers and may be influenced by market information especially for short-run margins. According to Olukosi and Ehrabor (2008) Gross Margin Analysis (GMA) is one of the widely used analytical techniques for planning and analysis of projects by researchers. Therefore, Gross Margin Analysis (GMA) was used to estimate profit for Irish potato production. GM was calculated using the following formula:

$GM = \Sigma Pi\ Qi - \Sigma C\ j\ X\ j \cdot$ ...(2)

where;

GM = Gross Margin

P_i = Unit price of Irish potato i

Q_i = Quantity of Irish potato produced i

C_j = Unit variable cost of input j

X_j = Quantity of input used

$P_i Q_i$ = Revenue

$C_j X_j$ = Variable cost

RESULTS AND DISCUSSION

SOCIO-ECONOMIC CHARACTERISTICS OF RESPONDENTS

The results of socio-economic characteristics of Irish potato farmers as detailed in Table 1 shows that, male and female accounted for 57.78% and 42.22% of Irish potato production, respectively. This agrees with the findings of Sani *et al.* (2015) that men always have right to land as a productive resource than women in most African societies. This result is also in line with the findings of Jwanya *et al*. (2014) who reported that male dominated Irish potato production in Plateau State, as indicated by 84.17% of the respondents. However, the results indicated that 47.22% of Irish potato farmers were within age bracket of 36-45 years and only 6.67% were above 55 years. The mean age was 38 years, the implications of these result is that farmers are still active with implications for productivity and household food security.

The result in Table 1 further, revealed that majority (62.22%) of the farmers were married and only 10% were single. The high proportion of married farmers is an indication that majority of farmers are likely to have family responsibilities and commitments, especially with regards to household food provision and upkeep, educational and health demands and savings. Furthermore, the result shows that 37.22% of farmers had household size of 6-10 persons with mean household size of 7 persons. This result is in line with the findings of Omolori (2017) who reported that most smallholder farmers in Nigeria maintained household size of between 5 and 12 persons. Large farming households has implications for household expenditures and food security and could as well be of benefit if members of the household are available for farm work.

The result on level of education of farmers under the study is also provided in Table 1. The results show that considerable proportion (37.78%) of Irish potato farmers had no formal education. The low level of formal education is likely to negatively impact on innovation, adoption of new technologies, low quality labour and farm record keeping (Adewunmi and Adebayo, 2008). The implication of this result is that PVCSP project to invest in beneficiary education, through intensive awareness creation. Aside intensifying extension support, project should endeavour to invest in disseminating technological messages in the local languages.

COSTS AND RETURN FOR IRISH POTATO PRODUCTION ENTERPRISE PER HECTARE

Table 2 presents the costs and return profiles of potato production in the study area. A cursory review of the costs of production shows that seed accounted for 51.39% of the total variable costs. This was followed by labour, estimated at 26.09%. Jwanya *et al.* (2014) affirmed that potato seeds and labour accounted for 56.58% and 15.91% of the costs of production under irrigation. This agrees with the findings of Obigbesan (2009) who reported that high cost of seeds, fertilizer and labor are the major challenges in Irish potato industry in most developing African countries. Meanwhile, the cost of

pesticides appears to be the least, representing less than 0.53% of the total variable cost. Farm gate sales accounted for the largest share of revenue, put at 78.57%. In all, total returns stand at ₦ 699,018.7, while gross margin stood at ₦ 382,842.7. Despite the cost of seeds Irish potato production

Table 2: Costs and return for Irish potato production enterprise per hectare

Variable inputs	**Costs**	**Percentage**
Seeds (Kg)	162,481.07	51.39
Labour (Man-hour)	82,492.31	26.09
Fertilizers (Kg)	50,757.98	16.05

CONSTRAINTS ASSOCIATED WITH IRISH POTATO PRODUCTION

The constraints faced by farmers are presented in Table 3. Producers were faced with the incidence of blight, particularly in the wet season, as reported by 22.78%, followed by inadequate capital (15%) and high cost of inputs (11.67%). However, access to micro-credit could have prospect in improving the productivity of farmers and contributing to uplifting the livelihoods of disadvantaged rural farming communities. On the other hand, farmers were faced with constraint of poor road network, problem of insecurity and post-harvest lost among others.

Table 3: Constraints associated with Irish potato production

Constraints	**Frequency**	**Percentage**
Problem of blight	41	22.78
Inadequate capital	27	15.00
High cost of farm inputs	21	11.67
Poor road network	18	10.00
Problem of insecurity	19	10.56
Problem of post-harvest lost	14	7.78
Inadequate of storage facilities	11	6.11
Problem of land tenure system	9	5.00
Problem of climate change	7	3.89

Inadequate of dams or boreholes for irrigation	6	3.33
Lack of modern farming techniques	4	2.22
Poor marketing system	3	1.67
Total	180	100

CONCLUSION

Based on the findings of the study, it can be concluded that Irish potato production was dominated by married men with non-formal education. Despite the cost of seeds, Irish potato production in Plateau State is a profitable venture. However, farmers were faced with problem of disease. The following recommendations emerged from the study findings:

i. Given the skewed proportion of participants in favour of the male, there is the need to enhance female participation through awareness creation and sensitization;
ii. To effectively push the improve technologies and innovations under the project to eliminate blast diseases, it becomes imperative to enhance literacy campaigns, extension support and domicile extension messages in local languages;
iii. To enhance production and incomes of Irish potato farmers the project should provide inputs as well as infrastructure and institutional development that will enhance capacity building of project beneficiaries and linkages to services such as credit, insurance and market.

ABSTRACT
The study determined the factors that influence price of sheep and goats in Bauchi State, Nigeria Multi-stage sampling technique was used to select 321 sheep traders and 220 goat traders. Data were collected with aid of structured questionnaire. Hedonic price regression model was employed for the study. Data analysis was performed using SPSS version 22. Hedonic price models were fitted to a sample of 6,118 sheep and 4,518 goats, respectively, for which data were collected from 14 markets over a 12-month period. The result of the estimated hedonic price regression model explains 74.1% of the variation in prices of sheep and 88.4% of the variation in prices of goats. This shows that about 74.1% and 88.4% of the variation in the prices of sheep and goats was influenced by the combined effects of the independent variables (market location, age of animal, live weight, sex, body condition, breed, coat colour and season) included in the hedonic model. The remaining proportion can be attributed to error term. F-statistics was significant at $P<0.05$, this statistic suggest goodness of fit of the model. Durbin Watson p-value of 1.02 was also reported, which indicates there is a positive first order auto correlation. Based on the findings of the study, it was concluded that, market location, sex, body condition of animal and season significantly ($P<0.05$) influenced selling price of sheep and goats in the study area. The study recommended that sheep and goats breeding strategies and activities should duly consider the preferences expressed through the prices paid for animals, these could enhance the efficiency of sheep and goat pricing system and consequently improve the livelihoods of sheep and goat keepers and traders. It is vital to train producers on the importance of market oriented (commercial) livestock production system.

Keywords: Goat, Hedonic, Price and Sheep

INTRODUCTION
Hedonic models have been widely used to evaluate the implicit prices of many agricultural commodities, especially livestock (Ramesh *et al.,* 2012). The theoretical foundation of the hedonic price model is mainly made up of two parts: Lancaster preference theory and Rosen's characteristic supply-demand equilibrium model. American scholar Lancaster first put forward a new consumer theory. The theory was expanded from the consumer theory of classical economics, also known as Lancaster preference theory. From the product heterogeneity, Lancaster analyzed basic "element" spaces that formed the product, and argued that the demand for the product was not based on the product itself, but on its characteristics. He noted that heterogeneous goods have a series of integrated characteristics, and the goods are sold as the gathering of inherent characteristics. And that households purchase these goods, use them as a kind of "investment", and turn them into utilities. Therefore, he asserted that level of utilities depends on the quantity of different characteristics, hence it is difficult to analyze such goods market with the traditional economic model, because it cannot be considered by a single total price. It is against that backdrop that, Lancaster thought to adopt a series of prices (hedonic price) to express corresponding product characteristics. Therefore, the product price is made up of hedonic prices, with each product characteristic having its own implied price, and all hedonic prices form a price structure (Bassey *et al.,* 2013). Rosen analyzed theoretically the long term and short-term equilibrium of the heterogeneous product market. Rosen's work established the

modelling foundation for the hedonic price theory, based on which, econometrics method can be used to estimate the hedonic price function, get implicit prices of product characteristics, and then analyze the demand of product characteristics.

Various studies (Kadigi *et al.,* 2013; Ramesh *et al.,* 2012; Alemayehu, 2011 and Kassie *et al.,* 2011) have been undertaken to determine factors that influence market prices of livestock especially cattle. Kadigi *et al.* (2013) used several variables as the basis of attributes used in hedonic pricing models. Characteristics used include sex, breed, lot size, frame size, muscling score, body condition, weight, time of sale, market location, among other factors. A hedonic price function relates the price of a product to the various attributes embodied in the commodity (Ramesh *et al.,* 2012). The underlying hypothesis is that products have utility-bearing attributes and the values of those attributes contribute to the price of the product. The observed price of a good is therefore a composite of the implicit values of the product's attributes. Theoretically, the prices traders receive are reflections of the utility anticipated by the buyers and this utility is derived from the attributes of the product as livestock's can be considered as quality (attribute) differentiated goods.

Parish *et al.* (2017) employed a hedonic pricing model to establish indices of genetic worth of a dairy bull in Alberta, Canada. Their study indicated that most important factors used by dairy farmers in valuing dairy bulls are milk volume, protein and fat content, general conformation, body capacity, and popularity of the bull. Kassie *et al.* (2011), similarly applied heteroscedasticity consistent hedonic price modelling to examine factors that influence cattle prices in the rural markets of central Ethiopia. The results of the study showed that season, market location, age, sex and body size are very important determinants of cattle price. Similarly, Fafchamps and Gavian (2009) employed monthly price data of over 20 years in Niger to examine the determinants of sheep and goat prices, reported that season of selling, rainfall pattern, district location and seasonal holidays influence prices of livestock.

This study focuses on the main phenotypic attributes that buyers inspect when buying sheep and goats in addition to external factors such as seasonality. The external features farmers look at and attach value to, are age, colour, body size, sex, and the place where the sheep and goats were brought from. Although in some parts of Bauchi State, economic analysis of livestock marketing has been conducted, yet, studies on sheep and goats' attributes (physical observable character) or factors which are most important in explaining variations in selling prices which can then be matched to preferences of the buyers for live sheep and goats were limited. However, studies on hedonic price analysis of sheep and goats will reveal preference for sheep and goats and other factors (physical observable characters) that influence the selling price. This could be a major input for sheep and goats' breeders, policy makers and buyers and traders as to improve production and quality of the product according to the market demand and gives indications about the market (bargaining) price to the buyers/traders. The outcomes of the study may also serve as reference for researchers to embark upon similar or related researches in other parts of the country with hope to develop a standard of marketing strategy for sheep and goats in the near future. This necessitates an empirical study on market price analysis to determine the factors that influence price of sheep and goats in Bauchi State, Nigeria.

MATERIALS AND METHODS

THE STUDY AREA

Bauchi State is one of the States in the northern part of Nigeria located in the Sudan savannah and the Sahel savannah zones between latitudes 9° 3' and 12° 3' north and longitudes 8° 50' and 11° east of the Greenwich meridian. The Sudan savannah type of vegetation covers the southern

part of the State. While The Sahel type of savannah, also known as semi-desert vegetation, becomes manifest from the middle of the State as one moves from the State's south to its north. The State occupies a land mass of about 49,119km^2 representing about 5.3% of Nigeria's total land mass (BSADP, 2015). Rainfall ranges between 1300 mm per annum in the south and 700 mm per annum in the extreme north. Therefore, there is progressive dryness toward north, culminating in the desert condition in the far north. Temperature ranges from a minimum of 9.11^{0}C in December/January to a maximum of 40.55^{0}C between April and May (BSADP, 2015). According to National Bureau of Statistics (NBS, 2017) Bauchi State has a total estimated population of 4,826,112. This large peasant population of the State engages in crop and livestock production. The major crops grown include sorghum, millet, maize, rice, groundnuts, soya beans, cowpea, sesame etc. While the major livestock reared include cattle, sheep, goats and poultry. Most of the livestock are reared under extensive management system. The predominant small ruminants are goats (breeds include Sokoto red, Sahel and West African Dwarf goat) and sheep (breeds include Uda, Yankasa, Balami and West African Dwarf sheep) while few other breeds are also found. Rearing of small ruminants, crop production and marketing form the major economic activities in the study area.

SAMPLING TECHNIQUES AND SAMPLE SIZE

The sampling technique was multi-stage. In the first stage, Bauchi State was clustered into three Agricultural zones comprising: central (Darazo, Ganjuwa, Ningi, and Warji), northern (Dambam, Gamawa, Giade, Itas-gadau, Jama,are, Katagum, Misau, Shira and Zaki) and western (Alkaleri, Bauchi, Bogoro, Dass, Kirfi, Tafawa Balewa and Toro). In the second stage, eight (8) urban livestock markets and six (6) local livestock markets was purposively selected (14 livestock markets). This was based on fact that, there are well established livestock markets in the selected LGAs and there was sufficient supply and concentration of sheep and goats' traders. In the third stage, 321 sheep and 220 goats' traders from each market were selected using simple random sampling techniques. Data were collected with aid of structured questionnaire from 321 sheep traders and 220 goats' traders from 14 markets over a 12-month period. In addition, a check list was used for observation, inspection and asking the traders verbal questions regarding price as well as sheep and goats characteristics that determine selling price such as age, sex, coat colour, size, breed and body condition. Age was measured approximated by the type and number of teeth following Fikru and Gebeyew (2015) estimation guideline. Information on sex, coat colour and breed was observed through inspection of the sheep and goats. Live weight of sheep and goats was measured in Kilogram using measuring weigh scale (1000kg). The study classifies sheep and goats based on their sizes into small, medium and large, each category weighing approximately 1-30kg, 31–50kg and 51-70kg, respectively. This classification was adopted and modified from Mohammed *et al.* (2013) that classified cattle based on their sizes into small, medium and large, each category weighing approximately 220-350kg, 350–480kg and 480-600kg, respectively in Gombe metropolis.

Data for body condition scoring in sheep and goats was an estimate of the muscle and fat cover of animal by palpation of different regions of the body. The method adopted for this study was originally described by Nsoso *et al.* (2003). The method consists of a scale of six scores, from 1 to 6, based on the fat coverage in the lumbar region. This method was subsequently modified by Khan *et al.* (2006) where sheep and goats body condition were determined by visual assessment to identify any physical deformity. It is done by feel with hand thoracic, hind leg, hump parts and tail of the animal to assess the fat content which indicates the state of health and nutrition of the animal as well as quantity of meat and fat deposited.

A hedonic price regression model was fitted to determine the factors influencing sheep and goat prices. The model was adopted to achieve the objective which is to determine the factors (live weight, sex, coat color, age of animal, breed, body condition and season) that influence price of sheep and goats.

$P = f(X)$ or $P = f(X1 \ldots Xn)$ …(1)

where;

P= Price of Sheep or Goat

X ranges from $X_1, \ldots, X_n$ = Factors

Considering f(X) as a linear function

The hedonic price regression model for sheep is expressed as:

$$P_S = a + b_1D_1 + b_2D_2 + b_3D_3 + b_4D_4 + b_5D_5 + b_6D_6 + b_7D_7 + e \quad ...(2)$$

Where;

P_S = Price of Sheep (₦)

a = Constant

D_1 = Age (1=Immature <1 year, 2= Young 1-3 year, 3= Matured 4-6 year and 4=Aged >6 years)

D_2 = Live weight (kg) (1= <10kg, 2= 10-20kg, 3= 21-30kg, 4= >30kg)

D_3= Sex (1=Ram, 2= Ewe and 3= Castrated)

D_4 = Body condition (1= Lean, 2= Moderate, 3 =Fat and 4= Very fat)

D_5= Breed (1= Yankasa, 2=Uda, 3= Balami and 4= West Africa Dwarf and 5= Otherwise)

D_6 = Coat colour (1= White, 2=Black, 3=Brown and 4 = Otherwise)

D_7 = Season (1= Early dry, 2= Late dry, 3= Early rainy and 4= Late rainy)

The reference group in the hedonic price regression model of sheep is as follows;

D_1 = Age (2= Young 1-3 year)

D_2 = Live weight (kg) (2= 10-20kg)

D_3= Sex (1=Ram)

D_4 = Body condition (2= Moderate)

D_5= Breed (1=Yankasa)

D_6 = Coat colour (1= White)

D_7 = Season (2= Late dry)

The hedonic price regression model of goat is expressed as:

$$P_G = a + b_1D_1 + b_2D_2 + b_3D_3 + b_4D_4 + b_5D_5 + b_6D_6 + b_7D_7 + e \quad ...(3)$$

where;

P_G = Price of goats (₦)

a = Constant

D_1 = Age (1=Immature <1 year, 2= Young 1-3 year, Matured 3-5 year and Aged >6 years)

D_2 = Live weight (kg) (1= <5kg, 2= 5-15kg, 3= 16-25kg, 4= >25kg)

D_3= Sex (1=Bucks, 2= Does and 3= Castrated)

D_4 = Body condition (1= Lean, 2= Moderate, 3 =Fat and 4= Very fat)

D_5= Breed (1= Red Sokoto, 2= Sahel, 3= West Africa Dwarf and 4=Otherwise)

D_6 = Coat colour (1= Red, 2=Black, 3=Brown and 4 = Otherwise)

D_7 = Season (1= Early dry, 2= Late dry, 3= Early rainy and 4= Late rainy)

The reference group in the hedonic price regression model of goats is as follows;

D_1 = Age (2= Young 1-3 year)

D_2 = Live weight (kg) (2= 5-15kg)

D_3= Sex (2=Does)

D_4 = Body condition (2= Moderate)

D_5= Breed (1=Red sokoto)

D_6 = Coat color (1= Red)

D_7 = Season (2= Late dry)

RESULTS AND DISCUSSION

ESTIMATED HEDONIC REGRESSION OF FACTORS THAT INFLUENCE PRICES OF SHEEP

The result of the estimated hedonic price regression model explains 74.1% of the variation in prices of sheep. This shows that about 74.1% of the variation in the prices of sheep was influenced by the combined effects of the independent variables (age of animal, live weight, sex, body condition, breed, coat colour and season) included in the hedonic model. The remaining proportion can be attributed to error term. F-statistics (12.66) was significant at $P<0.05$, this statistic suggest goodness of fit of the model. Durbin Watson p-value of 1.02 was also reported. Which indicates there is a positive first order auto correlation as presented in Table 1.

The location of the 14 weekly markets also has an observed effect on the prices of sheep. Market location were entered as dummy variable. The reference market was Azare market because of sufficient supply and concentration of sheep traders. The estimated coefficient for market locations shows prices are lower in markets located in distant areas than those located in close distance areas. The result of the model also shows that sheep fetch higher prices in Bogoro, Toro, Marrarraba-liman Katagum and Laraski livestock markets when compared to Azare market. This is likely due to the relatively high potential for sheep population in the northern and central zone of Bauchi State and hence high supply. Another reason is that, Azare market is the major market where traders buy sheep (supply) and resale in other markets in Bauchi State. These results imply that buyers and sellers would benefit if they carefully choose market location.

The result further revealed there was significant difference ($P<0.05$) in the price of Ram, when compared with the price of ewe and castrated sheep. Ram attracted the higher price than ewe. The reason was probably because male sheep were preferred than female because of Carcass quality. The result obtained here is also consistent with the findings of Mahmud *et al.* (2014), confirms that other things being equal, price per animal was significantly higher for males as compared to female sheep. The lower price offered for female sheep is mainly because producers only sell female animals at the end of their productive life, which makes them older than Ram and castrates offered for sale. In other hand, castrated sheep attract higher price than Ram and ewe. This is probably because castration is a widely used practice for adding value to the animals. In the overall model, there was a significant difference ($P<0.05$) in the prices of young sheep (reference group) when compared with the price of immature. While the price of matured and aged sheep is higher than the price of young sheep. This can be attributed to carcass difference. Tsedeke *et al.* (2011), also confirms that prices are highest for matured sheep relative to the immature and young sheep. However, Terfa *et al.* (2013), also confirms that age influenced sheep price significantly and negatively, implying that sheep command a higher price up to a very old age and the price will fall down as age goes up.

Live weight of sheep significantly influences market prices of sheep at $P<0.05$. Live weight range between 10-20Kg was used as reference group. Sheep with live weight of 21-30Kg and above significantly influenced prices of sheep at $P<0.05$ and attracted higher prices compared to the reference group (10-20Kg). This is a clear indication of the interests of sheep producers/buyers in the study areas probably because of the reproductive functions they are expected to perform to ensure herd growth and continuity.

The price of *Yankasa* breed of sheep were compared with price of *Uda*, and *West African Dwarf*, the result shows that the price of *Yankasa* breed were found to be statistically significant at $P<0.05$ with negative coefficient, which implies that, prices of *Yankasa* were higher than that of *Uda* and *West African Dwarf*. However, price of *Balami* and other cross breed of sheep were significantly ($P<0.05$) higher when compared with price of *Yankasa*. This probably may arise because of the meat quality and taste of *Yankasa* and *Balam* breed as confirmed by butchers. Another reason is that *Yankasa* was the most commonly breed of sheep reared in the study area, in addition, *Uda and West African Dwarf* placed in the markets by traders' lack sufficient feeding. However, coat colour of sheep were not statistically significant at $P<0.05$. In most cases, coat colour is not given special attention in the study area for sheep. Although some colours are preferred for some ritual ceremonies.

Body condition was another factor that influence market prices of sheep in the study area. The price of moderate sheep was found to be significant at $P<0.05$ and attracted higher price when compared with price lean. Furthermore, the price of fat and very fat sheep was found to be significant at $P<0.05$ with positive coefficient. This implies that fat and very fat sheep attracted higher prices

when compared with moderate (reference group) and lean sheep. The variation in the price of sheep with different body condition score in the study area may be as a result of assessment carried out by buyers in terms of quantity of fat deposit found in very fat animal when compared with moderate and lean.

In the empirical model, the early dry season corresponds to December – February; late dry season (March – May); early rainy season (June – August) and the late rainy season (September – November). The late dry season was used as the reference group for comparison of the influence of season on prices of sheep. The results show there was a significant difference ($P<0.05$) in the price of sheep across season. All the coefficients were negative, meaning that prices of sheep were higher around March to May (late dry season) when compared to price of sheep around December to February (early dry season). This is probably due to shortage of feed and high cost of feed at late dry season linked with poor financial position of rural producers. Similarly, prices of sheep were lower around June to August (early rainy season) and around September to November (late rainy season) when compared to price of sheep around March to May (late dry season). It is the period of rainfall, marketing activities during this time is usually low and therefore prices tend to be low due to low demand.

Table 1: Estimated hedonic regression of factors that influence price of sheep

ESTIMATED HEDONIC PRICE REGRESSION OF FACTORS THAT INFLUENCE PRICE OF GOATS

The result of the estimated hedonic price regression model explains 88.4% of the variation in prices of goats. This shows that about 88.4% of the variation in the prices of goats was influenced by the combined effects of the independent variables (age of animal, live weight, sex, body condition, breed, coat colour and season) included in the hedonic model. The remaining proportion can be attributed to error term. F-statistics (11.8) was significant at P<0.05, this statistic suggest goodness of fit of the model. Durbin Watson p-value of 1.06 was also reported. Which indicates there is a positive first order auto correlation as presented in Table 2.

The location of the 14 weekly markets also has an observed effect on the prices of goats. Market location were entered as dummy variable. The reference market was Azare market because of sufficient supply and concentration of goats' traders. The estimated coefficient for market locations shows prices are lower in markets located in distant areas than those located in close distance areas. The result of the model also shows that goats fetch higher prices in Bogoro, Toro, Marrarraba-liman Katagum and Laraski livestock markets when compared to Azare market. This is likely due to the relatively high potential for goats' population in the northern and central zone of Bauchi State and hence high supply. Another reason is that, Azare market is the major market where traders buy goats (supply) and resale in other markets in Bauchi State. These results imply that buyers and sellers would benefit if they carefully choose market location.

The result further revealed there was significant difference ($P<0.05$) in the price of Does, when compared with the price of Bucks and castrated goats. The reason was probably because Does were preferred than Bucks because of Carcass quality. The result obtained here is also consistent with the findings of Mahmud *et al.* (2014), confirms that other things being equal, price per animal was significantly higher for Does as compared to Bucks. In other hand, castrated goats attract higher price than Bucks. This is probably because castration is a widely used practice for adding value to the animals. In the overall model, there was a significant difference ($P<0.05$) in the prices of young goats (reference group) when compared with the price of immature (<1years). While the price of matured goats (4-6 years) and aged goat (>6 years) was higher than the price of young goats (1-3 years). This can attribute to carcass difference. Tsedeke *et al.* (2011), also confirms that prices are highest for matured goats relative to the immature and young goats. However, Terfa *et al.* (2013), also confirms that age influenced goat price significantly and negatively, implying that goats command a higher price up to a very old age and the price will fall down as age goes up.

Live weight of goats significantly influences market prices at P<0.05. Live weight range between 10-20 Kg was used as reference group. Goats with live weight of 21-30 Kg and above significantly influenced prices of goats at P<0.05 and attracted higher prices compared to the reference group (10-20 Kg). This is a clear indication of the interests of goat producers/buyers in the study areas probably because of the reproductive functions they are expected to perform to ensure herd growth and continuity.

The price of *Red Sokoto* breed of goats where compared with price of *Sahel*, and *West African Dwarf* goat, the result shows that, the price of *Red Sokoto* breed were found to be statistically significant at P<0.05 with negative coefficient, which implies that, prices of *Red Sokoto* were higher than that of *Sahel* and *West African Dwarf* goat. However, price of *Sahel* and another cross breed of goat were significantly (P<0.05) higher when compare with price of *Red Sokoto*. This probably may arise because of the meat quality and taste of *Red Sokoto* and *Sahel* breed as confirmed by butchers. Another reason is that *Red Sokoto* was the most commonly breed of sheep reared in the study area, in addition, *West African Dwarf goat* placed in the markets by trader's lack sufficient feeding. However, coat color of goats where not statistically significant at P<0.05. In most cases, coat colour is not given special attention in the study area for goats. Although some colours are preferred for some ritual ceremonies. Body condition of goats was another factor that influence market prices in the study area. The price of moderate goat was found to be significant at P<0.05 and attracted higher price when compared with price of lean goats. Furthermore, the price of fat and very fat goats was found to be significant at P<0.05 with positive coefficient. This implies that fat and very fat goats attracted higher prices when compared with moderate (reference group) and lean goats. The variation in the prices of goats with different body condition score in the study area may be as a result of assessment carried out by buyers in terms of quantity of fat deposit found in very fat animal when compared with moderate and lean.

In the empirical model, the early dry season corresponds to December – February; late dry season (March – May); early rainy season (June – August) and the late rainy season (September – November). The late dry season was used as the reference group for comparison of the influence of season on prices of goats. The results show there was a significant difference ($P<0.05$) in the price of goats across season. All the coefficients were negative, meaning that prices of goats were higher around March to May (late dry season) when compared to price of goats around December to February (early dry season). This is probably due to shortage of feed and high cost of feed at late dry season linked with poor financial position of rural producers. Similarly, prices of goats were lower around June to August (early rainy season) and around September to November (late rainy season) when compared to price of goats around March to May (late dry season). It is the period of rainfall, marketing activities during this time is usually low and therefore prices tend to be low due to low demand.

CONCLUSION

Based on the findings of the study, it was concluded that, market location, sex, body condition of animal and season significantly ($P<0.05$) influenced selling price of sheep and goats in the study area. Age group and body condition of the traded animals are important observable attributes of the animal reflected in the observed price.

Based on the results of this study, the following recommendations were made:

i. The findings of hedonic price analysis suggested that sheep and goats breeding strategies and activities should duly consider the preferences expressed through the prices paid for animals, these could enhance the efficiency of sheep pricing system and consequently improve the livelihoods of sheep/goats' keepers and traders. It is vital to train producers on the importance of market oriented (commercial) livestock production system.

ii. Live weight is considered a very important variable in determining the price of sheep and goats. Separate weighing machine for small and large animals should be installed at the entry point of market. This will help traders to know the exact weight of animal and brings them at par with other market agents in price bargaining. So, the good quality animals will bring more if they are sold by grade and weight.

ABSTRACTS
This study reports socio-cultural characteristics of poultry farmers in three southern states of Nigeria: Imo, Akwa Ibom and Oyo states. Fifteen poultry farmers were sampled in each state with the aid of well structure questionnaires, making a total of 45 respondents. Data generated were analyzed using descriptive statistics such as means, frequencies and percentages. Gender distribution of the farmers was 66.67% for male and 33.33% for female. The highest number of respondents were within 31- 40 years' age bracket (46.63%), followed by the age group of 41-50 years (22.10%). The results showed that 82.20% of the respondents were married, had formal education up to secondary school level, with 66.60% of them being educated up to tertiary level although most of them in the south east studied courses not related to animal agriculture, while all the graduate respondents of south-south zone studied agriculture and animal production related courses. Many of the poultry farmers (42.20%) had 6 - 10 years' experience in the industry, while another 20.00% had 11-15 years' experience. It was concluded that poultry farmers in Southern Nigeria have formal education they are likely to properly evaluate various production factors and make the appropriate decisions on adoption of modern and recent technologies in poultry production, thus making the dissemination of poultry farming improvement information in the zone easy.

Keywords: Farmers, poultry, animal agriculture, southern Nigeria

INTRODUCTION
The poultry industry has contributed significantly to the growth of the Nigerian economy through direct and indirect impact on national gross domestic product (GDP) and provision of animal protein, employment and income to the different segments of the population (Sonaiya, 1999; Oyesola and Olujide, 2000). Traditional method of poultry keeping exists side by side with the commercial system in the study area (Chima, 2011). Each of these two systems is associated with features of scale, stock, husbandry and productivity. However, between these two distinct prototypes, intermediate grades have evolved over time in response to the natural agro-economy and consumer demands (Adene and Oguntade, 2006). The poultry production systems in Nigeria are influenced by many factors such as health and diseases, housing, feeds and feeding, sales and disposal of products and socio-cultural background of practitioners (Adedeji *et al*., 2014).

The socio-cultural characteristics of farmers include the sex, age and marital status, educational background, field of study for the educated ones and duration of experience in the poultry business (Bassey *et al.,* 2018). The belief system of the farmers may also be of significance. The estimation of the socio-cultural characteristics of poultry farmer in southern Nigeria will among other benefits contribute to knowledge and provide data needed by relevant agencies for policy formulation and intervention strategies.

This study was to evaluated the socio-cultural characteristics of poultry farmers in three southern states of Nigeria namely Imo, Akwa Ibom and Oyo states.

MATERIALS AND METHODS

The study was undertaken in three states: Imo, Akwa Ibom and Oyo representing south east, south-south and south west geo political zones of southern Nigeria respectively. The states were selected purposively because of the high levels of commercial poultry activities reported in them (Akandu, 2012). Each of the three states is divided politically into three senatorial zones, and one of the senatorial zones was selected purposively in each state, namely Owerri, Uyo and Ibadan zones for south east, south-south and south west states respectively. One local government area was also selected purposively from each senatorial zone in which 15 poultry farmers were also selected from a town in each selected local government area. Thus, 90 respondents participated in the study.

SAMPLING TECHNIQUES:

The sampling design was therefore multi-stage sampling. The criteria for selection were those stated above, in addition to willingness to participate in the study and the participant having a functional poultry farming enterprise. The data for the study were generated with the aid of structured questionnaires and personal interviews. The actual survey was preceded by a preliminary informal survey of the study areas through which the researcher familiarized himself with issues associated with poultry farming in the study areas, while also explaining the purpose of the study to the participants.

STATISTICAL ANALYSIS:

Data generated were subjected to descriptive statistics such as frequency counts, percentages and means (SAS, 2001).

RESULTS AND DISCUSSIONS

Table 1 shows the socio-cultural characteristics of poultry farmers in southern Nigerian states of Imo, Akwa Ibom and Oyo. Gender distribution of the farmers as shown in the table was 9(66.67%) for male and 6(33.33%) for female. The highest number of respondents were within 31-40 years age bracket (46.63%) and was followed by the age group of 41-50 years (22.10%). The least value was however recorded by the >60 years group that recorded 6.60%. This indicates that young people are actively in poultry farming in the study area. Similar results were reported by Okoli *et al.* (2004) for Imo state, Bassey (2014) for Akwa Ibom state and Ogegbuna (2014) for Anambra state. Across the zones, south east had the highest number of youthful (20 – 40 years) poultry farmers (73.3%), followed by south west (66.6%) and south-south (33.20%). The marital status results of the respondents showed that 17.76% were single, while 82.20% are married. However, breakdown of the result showed early marriage pattern for southwest zone of the country, where all respondents are married (100%), while the married respondents were 66.66 and 80.00% for south east and south-south zones respectively.

The results of educational qualification of the respondents showed that all had formal education up to secondary school level. The overall secondary school education limit of the respondents were 40.00 and 62.10% for tertiary level. Further breakdown of the results showed that south east with 73.30% had highest number of tertiary education graduates in poultry farming, followed by the 66.70 and 40.0% recorded in the south west and south-south respectively. These results however showed that 66.60% of the tertiary level educated farmers in the southeast studied courses not related to agriculture or animal agriculture, while all the graduate respondents in the south-south zone studied agriculture and animal related courses. Similar results of highly educated small-scale pig farmers have also been reported in Imo state, especially the peri-urban farmers (Okoli *et al.,* 2009; Moses, 2019). However, the overall results of the southern region showed that 12.23% studied agriculture, 23.33% studied animal science, 26.70% studied animal health, 8.90% studied veterinary medicine, while 28.87% studied courses outside the above mentioned disciplines. These results are contrary to the finding of Moses (2019) that most small-scale pig farmers in Imo state studied courses that are not related to agriculture before venturing into livestock farming.

Majority of the poultry farmers (42.20%) spent between 6 and 10 years in the industry. This was followed by the group with 11 - 15 years experience (20.00%). However, the fewer farmers in the studied areas (8.83%) are the group that have more than twenty years of experience in poultry farming. Across states however, Akwa Ibom state recorded the highest value (53.30%) for the 6 -10

years of experience, followed Imo state (40.00%) and Oyo state (33.33%). Similar results were reported by Bassey *et al.* (2018) when comparing farmer years of experience in Akwa Ibom and Anambra state. These results also show that more farmers entered into poultry farming in Akwa Ibom and Imo states than Oyo state in the last 10 years.

Above 20	2(13.30)	1(6.60)	1(6.60)	4(8.83)

CONCLUSION

Poultry farmers in Southern Nigeria have formal education, suggesting that the farmers are likely to properly evaluate various production factors and make the appropriate decisions on adoption of modern and recent technologies in poultry production, thus making easier the dissemination of poultry farming improvement information in the zone.

ABSTRACT
Crop farmers and cattle herders conflict have remained the most prevailing resource-use conflict in Girei Local Government Area of Adamawa State. Social and economic factors confined to inflame violent conflicts. The competition between these two Agricultural land user-groups threats the means of survival in the study area. The study describes socio-economic characteristics of the farmers and herders and determines the causes of conflict in the study area. Primary data were collected by the use structured questionnaire. The data were subjected to simple percentages and chi-square analysis. The study revealed that the major causes of conflict in the study area are the crop damage by cattle, and lawlessness in the society. The findings also revealed that loss of expected yield, loss of cattle and loss of human lives and properties are the major effects of conflict. The study also concludes that the conflicts sometimes spread and lead to ethnic clashes and armed robbery. Therefore it is the interest of the state to address the genuine needs of herders and crop farmers since these two provides employment for almost all the rural people. It is recommended that strange faces identified should be reported and leaders should preach the implications of conflict in the society.
Key Words: Farmers, Herders, Lawlessness, Conflict and Clashes.

INTRODUCTION
One major problem confronting world peace today is the manifestation of conflict in different dimensions across the globe. From Europe to America, Africa to Asia conflicts is common (Jeong, 2008). Conflicts have been defined in different ways by different scholars. Ekong (2003) defined conflict as the form of social interaction in which the actors seek to obtained scarce reward by eliminating or weakening their contenders. Nigeria has experienced and still experiencing conflicts on grave proportions among several ethnic and religious communities. These conflicts vary in dimension, process and groups involved. It was observed by Momale (2003) that while some conflicts arise between same resources user groups, others occur between different user groups such as herders and farmers. Adisa (2012) observed that the farmer-herders conflict has remained the most preponderant resources-use conflict in Nigeria. Social and economic factors continue to provide violent conflicts among the Fulani pastoralist and crop farmers. The intensity and variation of the conflict largely depend on the nature and type of the user groups where the pastoralists grazes. The conflicts over access right to farmland and cattle routes have become ubiquitous and seems to have defied solutions (Abbas, 2009). However, coser (2000) have noted that, the inevitability of conflict in the claim for scarce resources is considered as the bane for struggles over the inestimable value for land and its resource, with the claim for ownership and the claim for its position as a common resource. Historical tension between pastoralist and settled indigenous farmers have intensified in recent years with dwindling natural resources and land availability greatly contributing to the on-going, escalating conflict in the country (Okello *et al.*, 2014). The herder-farmer conflict is now very rampant that almost every settlement that contains both herders and farmers are facing. This study tends to describe the socio-economic characteristics of the respondents, examine the factors responsible for the conflict and determine the major effects of conflicts in the study area.

MATERIALS AND METHODS
The study was conducted in Girei which is one of the 21 Local Government Areas of Adamawa State, and is the headquarter of the local government. It is an agrarian area well suited for rain fed and irrigation due to the presence of the river Benue in the area. Farming is the main occupation of the people with emphasis on the cultivation of cereals and on irrigated lands, vegetable crops like

tomatoes, pepper, onion, carrots and cabbage are grown. Some of the farmers are involved in livestock keeping, but Fulani herdsmen dominate the rearing of livestock in the area. It is located in the central area of Adamawa State. It is located on latitude 9^0 14'N and longitude 12^0 28'E and occupies a land of 8,068km^2 with an altitude of about 185.9m above sea level and posses two distinct seasons which are rainy and dry seasons (Adebayo & Tukur, 1999).

SAMPLING PROCEDURE AND SAMPLING SIZE

A muti stage sampling procedure was used for the study. In the first stage, 3 villages were sampled from a population of 15 villages that made the study area. The purposive selection was made because the sampled area consist of the villages where crop. Cultivation and cattle rearing were most farmers and the areas where crop farmers and cattle herders' conflict occur frequently. The selected villages for the study were koh, Labondo and Gereng. A total of 5 crop farmers and 5 cattle herders from each of the 3 villages in the local government area were chosen randomly, thus giving a total of 15 crop farmers and 15 cattle herders.

METHOD OF DATA COLLECTION

Primary data was collected for the study. The data was obtained through field survey using structured questionnaire. A total of 30 questionnaires were administered throughout the selected three (3) selected villages.

ANALYTICAL TECHNIQUES

The data collected was analyzed using descriptive statistics, specifically frequently counts and percentages while chi-square analysis was also used to achieve the objectives.

RESULT AND DISCUSSION

The results of the socio-economic characteristics of the respondents as presented in Table 1 shows that majority 986.21%) of the respondents were males while 13.79% were females, most (89.66%) of the respondents are married which only 10.34% were females, most (89.66%) of the respondents are married which only 10.34% were single. The study also revealed that most (62.07%) were between the ages of 30-40years, 21.17% are above 40years which only 13.79% are below 30years, 58.62% of the respondents have 6-10 children, 20.69% have 11-15 children while only 6.90% have more than 15 children. The study also revealed that 41.38% are crop farmers, 34.48% are cattle rearers and 24.14 are those that combine crop farming and cattle rearing. Respondents' level of education shows that 51.73% attended only Quranic schools, 34.48% are primary certificate holders, 13.79% are secondary school certificate holders which none studied beyond secondary school. The result also shows that 17.24% of the respondents are Hausa, 13.79% are others who are mostly Sullubawa (cattle herders) and few Kanuri farmers and majority (68.97%) are Fulanis. This report is close to the findings of Akinola and Ironkwe (2012) who reported 63.8% males and 36.2% females, 53.7% are of ages between 41-50years, 25.43% and 31.3 of the respondents had Primary, Secondary and Tertiary certificates among poultry farmers in Rivers State respectively. Socio-economic features of ruminant animals marketers in Alaba-Rago market in Lagos shows that 83.93% are males, 64.29% married, 16.07% widows,53.57% are within the ages of 31-49years while 47.32 had Primary certificate, 33.04, 10.71, 7.14 and 1.79 had SSCE/O/L, OND/NCE, B. Sc/HND and M.Sc. respectively, Lamidi *et al.* (2012). The study revealed that the major causes of conflict in the study area were majorly crop damage by cattle and lawlessness in the society and that lost of crops, lost of animals and sometimes lost of lives as a result of conflict as the major effects of conflict in the study area.

Table 1 Socio-Economic characteristics of the respondents

ABSTRACT
The aim of this study was to evaluate the production capacity of goat in Faskari local government area, Katsina State. Data were obtained using structured questionnaires administered to the respondents in the study area. Data were also generated on breed, sex and age of goats in the study area. A total of 101 goats were randomly sampled for this study. The breeds of goat sampled were Sahelian, Red Sokoto and West African Dwarf (WAD) with 55, 38 and 8 goats respectively. Majority of goats sampled were female, 28 bucks and 71 does. Results also show that the main production constrains in goat production in the study area was marketing. The main purpose of keeping goat was for income source.

KEY WORDS: Assessment, goat, production capacity, Faskari and Katsina State.

INTRODUCTION
Indigenous goats are an important animal genetic resources for African farmers, providing meat, milk, manure, fibers hides, and satisfying various cultural and religious functions. In Africa, the survival of many indigenous goat populations is threatened by diseases, adverse climatic conditions, civil strife, pressure of economic development, abandonment of traditional farming practices, and more importantly through crossbreeding or replacement with animals from the developed world. The Red Sokoto goat or Maradi is the most predominant goat breed and accounts for about 70% of Nigeria's total goat population which has been estimated at 17.5 million (Ademosun, 1994). It was commonly found among the agro pastoralist mainly within the northern sub-humid and semi-arid zones of the country (Akpa *et al.,* 2001). The breed is predominantly reddish brown in colour and was found in the savannah zone of Nigeria (80N -110N) where it constitutes more than 90% of the goat population in that area. The West Africa Dwarf (WAD) goat is widely distributed across the rainforest belt of southern Nigeria. They are short legged and small-bodied animals, weighing between 22 and 26kg. They also present variable coat colors, ranging from black, brown, grey, red and white and sometimes combinations of these in a variety of patterns (Akpa, *et al.,* 2001). Goats are referred to as the "small man's cattle"

MATERIALS AND METHOD
Study Location
This study was conducted across Faskari Local government area (Mairua, Sheme, Dakamawa, Kanonhaki and Daudawa). The study area is located within the North- West part of Nigeria within coordinates $11^0$43'N $7^0$02'E/ 11.717^{0}N 7.033^{0}E. The study area has an average annual Rainfall of 198mm with an average annual Temperature of 28 °C (WIKIPEDIA).

EXPERIMENTAL ANIMALS AND MANAGEMENT

Goats were randomly sampled across the towns in Faskari LGA. Goats were identified by breeds, sex and age. Phenotypical observation was used to identify the breeds and sex. Goats were grouped into ages using their dentition (Wilson and Durkin, 1984). The experimental animals were managed under semi-intensive system. The goat houses were made using corn stalk for fencing and thatched roofing for protection against heat and rainfall. There was no organized health care provision in terms of vaccination and deworming. However, Veterinary officers were called to treat the animals when cases of ill-health occur. The kids were allowed to roam with their dams.

RESULT AND DISCUSSION

Table 1 shows frequency of personal information for the respondents. Majority of the respondents are between 41 to 50 years of age, representing 36.4% out of the total respondents. This result is similar to the report of Adams Ohene-Yankyera (2014), who obtained 47.29 years. Majority of the respondents sampled were male (71 and 28 respectively) representing 71.7 and 28.3% respectively. This finding is similar to that of Akpa *et al.,* (1998*)* who reported that higher number of goat producers are male (72 and 29 respectively). Majority of the respondents had non-formal education. Akpa *et al.,* (1998) asserted that there is need for an increase in the educational status of the farmers in order to improve their rate of adoption in terms of breeding and production practices. Marital status of the respondents revealed that majority of the goat producers are married. The main stable source of income for the respondents was agriculture, where trading and other sources were minor, this shows that most of goat producers depend on Agricultural activities as their source of income with 77 respondents, representing 77.8%.

Table 1: Frequencies Distribution of the Respondents' Personal Information

Parameters	Levels	Frequency	Percentage (%)
Age (years)	20-40	22	22.2
	41-50	36	36.2
	51-60	30	30.3
	61 and above	11	11.3
	Total	99	100
Sex	Male	71	71.7
	Female	28	28.3
	Total	99	100
Educational status	Primary	18	18.2
	Secondary	10	10.1
	Tertiary	07	07.1
	Non-formal education	64	64.6
	Total	99	100
Marital status	Married	86	86.8
	Divorced	04	04.0
	Single	05	05.2
	Widowed	04	04.0
	Total	99	100
Sources of income	Agriculture	77	77.8
	Trading	9	9.1
	Civil servant	10	10.1
	Others	03	3.0
	Total	99	100

Table 2 shows the production characteristics of goat in the study area. Breed of goats produced in the area are mainly Sahel. This result is however in contrast with the report of Ademosun (1994) who reported that Red Sokoto goat or Maradi is the most predominant goat breed in Nigeria, accounting for about 70% of the total goat population estimated at 17.5 million.

Higher number of female (does) goats were sampled in the area than male (bucks), 27.7% and 72.3% respectively. This result if similar with the report of Egwu et al. (1995) who reported that there is preference for keeping young and more productive female animals in the herd for reproduction and multiplication. Goats kept by the producers are majorly between the age of 2 to 4 years, 31.6% and 26.7 % respectively. Majority of goat farmers prefer to keep the animal from age 2 to 4 years for breeding while animal that are above 4 years were majorly sold out or slaughter for festival or for personal consumption (Oseni *et al*., 2008). Majority of the farmers keep flock size of 6-10 goats in the herd, indicating good prospects for goat production in the area.

Major purpose of keeping goat in the study area was for income generation followed by source of manure (57.6% and 25.2% respectively). This observation agrees with the report of Akpa, (2000) who reported that goats are kept primarily for meat and income especially by peasant farmers in Nigeria. Major constrains of goat production in the area were disease outbreak, feed and water shortage and market problems, 17.0%, 34.0%, 3.0% and 46.0% respectively. This result agrees with the finding of (Oseni *et al*., 2008) who reported that labour, disease, feed shortage were the most pertinent constrains in goat production.

Table 2: Frequencies Distribution of Goat Production Capacity

Parameters	Parameters	Frequency	Percentage (%)
Goat breeds	Red Sokoto goat	38	37.62
	Sahelian goat	55	54.46
	West African goat	08	7.92
	Total	101	100.0
Sex	Male	28	27.7
	Female	73	72.3
	Total	101	100.0
Age of the goat (years)	1	4	4.0
	2	34	31.6
	3	24	23.8
	4	27	26.7
	5	14	13.9
	Total	101	100.0
Flock sizes	1-5	23	23.3
	6-10	47	47.5
	11 and above	29	29.2
	Total	99	100.0
Purpose of keeping goat	Income generation	57	57.6
	Meat	6	6.1
	Manure	25	25.2
	Skin	7	7.1
	Religious sacrifices	4	4.0
	Total	99	100.0
Constrain to goat production	Disease	17	17.0
	Feed shortage	35	34.0
	Water shortage	3	3.00
	Marketing problem	46	46.0
	Total	101	100.0

CONCLUSION

Sahelian goats are the most predominant breed kept in the study area majorly for income generation, with more males than females engaged in the production. The average flock size in the area was 6-10 goats. The major production constrains of marketing and feed shortage.

RECOMMENDATIONS

Majority of the goat producers in the study area had non-formal education. Hence, there is need for government and non- governmental organization intervention to increase educational status of the farmers in order to improve their rate of adoption in terms of breeding and production practices. There is also need for concerted efforts towards conservation of the uniqueness of this breed in the area for maximum utilization.

CONTRIBUTIONS OF SMALL RUMINANT PRODUCTION TO FARMERS' LIVELIHOOD IN DERIVED SAVANNAH AREA OF OYO STATE

Sosina A. O.L
Department of Animal Science, University of Ibadan, Ibadan, Nigeria
Corresponding E-mail: dayososina@gmail.com

ABSTRACTS
The impact of small ruminant husbandry to farmers' livelihood is of concern to Government's policy formulation. This study investigated the contribution of small ruminant production to farmers' livelihood in derived savannah area of Oyo State, Nigeria. Small ruminant farmers were purposively selected with the assistance of extension agents using a three tier multi stage sampling technique in which 225 respondents were selected. Parameters measured include livelihood enterprises, % income on household livelihood, record of sales, 5% mortality rate and seasonality. Qualitative and quantitative data collected were transcribed into Microsoft Excel the Feed Assessment Tool (FEAST) Excel macro program. The average household livestock holdings were 20.08±2.16 (sheep), 32.00±3.26 (goats) while average weight of the animals (kg) were 20.00±4.27 (sheep), 15.00±3.89 (Goat). The dominant breed for sheep and goat was West African Dwarf breed. The ranking and % income of the livelihood enterprises were primary (60), secondary (20) and tertiary (10) for Agriculture, Livestock and remittance, respectively. The average household goats sold over the past 3 years were 15.00±1.36 (male) and 10.00 ±1.45 (female) with average weight (Kg) range 15.56±2.78 to 20.67±3.34. The average household sheep sold over the last 3 years were 25.00±3.87 (male) and 30.00±4.28 (female) with average weight (Kg) ranged 25.78±5.27 to 30.89±6.47. The seasonal average sales (₦) ranged 4,000 to 7,000 and 6,000 to 13,000 for goat and sheep, respectively. Agriculture, the main stay of the heterogeneous population in derived savannah area, with small ruminant contribution to the individual household income and livelihood cannot be undermined.

Keywords: Ecological zones, Feed resources, Household income, Livestock enterprises, Policy formulation, Seasonality.

INTRODUCTION
The continuous neglect of small ruminant production had adverse effect on economies of households especially at the system level. If small ruminant production is given the right and needed attention by famers and policy makers, there will be significant reduction in poverty, improve food security which is in line with the sustainable development goals (SDG's). The impacts on food (animal protein) and nutrition security as well as livelihood on national economy are significant and far-reaching. The sustainable livelihood approach (SLA) provides a better understanding of rural livelihood (Sinkaiye and Ajayi, 2012). While assessing the sustainable livelihood, some donor agencies provide framework to evaluate the means of livelihood in the community (Sinkaiye and Ajayi 2012), which provide information on livelihood vulnerability, resistance, risk attitudes and sources of livelihood (ATA, 2013). Average annual household income of respondents was influenced by the location, gender and livelihood enterprises (Haile et al. 2010). Income was higher from the sales of livestock and livestock products in some locations compared with sales from crop products, which was higher than the non-agricultural activities or enterprises. The purpose of the National Livestock Transformation Plan Strategy (NLTPS) was to provide structure for agricultural subsector development that can become a catalyst for building national prosperity. Strategic interventions are aimed at modernizing livestock production through the establishment of ranches, mitigating the escalating crisis between pastoralists and farmers, and improving the broader supporting architecture around these issues (FMANR report 2017).Small ruminant production adoption substantially reduces household poverty and stunting for children younger than age five thus influencing farmers' household nutrition and livelihood (Sosina et al. 2019). Furthermore, beyond nutrition and income roles, livestock serves as a buffer resource for farmers to use in responding to emergencies, such as crop failure, as well as acts as a live bank, facilitating both income distribution and savings (Kabunga 2014). Farmers' livelihood also depend on sales of matured or weaners at village markets especially among women (Sosina 2017). The significant roles played by small ruminant production in the household and national economies cannot be overemphasized. Thus the study investigated the contribution of small ruminant production to farmers' livelihood in derived savannah area of Oyo state.

MATERIALS AND METHODS

The study was conducted in the derived savannah area of Oyo State, ethnically heterogeneous with a high concentration of smallholder crop and livestock farmers. Small ruminant farmers were purposively selected using a three tier multi stage sampling technique of about 225 respondents. Parameters measured includes livelihood enterprises, % income on household livelihood, record of sales, mortality, seasonality. Qualitative and quantitative data collected through questionnaire were transcribed into Microsoft Excel the FEAST Excel macro program (www.ilri.org/feast) (Duncan 2014).

RESULTS AND DISCUSSIONS

Livestock holding of the farmers: The predominant livestock among farmers in the study area were sheep, goat and poultry with the dominant breed of sheep and goat as the West African Dwarf (WAD), the indigenous type. The average household livestock holding of sheep, goat and poultry were 20.08±2.16, 32.00±3.26 and 55.00±7.34, respectively (Table 1). The average live weight per animal (Kg) were 20.00±4.27 (sheep), 15.00±3.89 (Goat) and 2.00±0.78 (poultry).

The average live weight of the dominant livestock agreed with Sosina (2017) who reported similar range of 15-25 Kg for sheep and goat among indigenous WAD breeds. However, this result was in contrast with the report of Amole and Ayantunde (2016) higher weight for other indigenous breeds in the drier and Sahel regions. Sosina (2017) also reported low Tropical Livestock Unit (TLU) for sheep and goat among farmers' in the Ibadan/Ibarapa zone of Oyo state. Chah et al. (2013) reported the high incidence of sheep and goat production in rural areas of Enugu. Nigeria though in contrast with Samireddypalle et al (2014a) reported lower percentage of sheep and goat farmers among peri-urban farmers.

Contributions of the livelihood enterprises: FEAST also provided the opportunity to evaluate the contribution of livelihood activities to household income as in Table 2. FEAST evaluated contributors to the farmer average % of income as agriculture, livestock, business, remittance, labour and others; which agreed with Sosina (2017) who reported similar enterprises contribution to livelihood in Ibadan/Ibarapa area.

The contribution of agriculture to the livelihood activities of household income was 60%. Agriculture form the main stay of the respondents' income which supported FAO (2015) that agriculture remains the highest contributor of the populace especially in the sub-Saharan Africa. However, the result was contrary to that of ATA (2013) reported higher national income accruing from oil than agriculture. The average % contribution of livestock to the farmers' income was 20%, suggested livestock enterprise was ranked next to agriculture among respondents. This was supported by Sosina (2017) that livestock was among the major contributors to farmers' income contrary to Amole and Ayantunde (2016) that ranked livestock ahead of crop agriculture in the contribution of livelihood activities to household income. The contribution of remittance to the average respondents was 10. The remittance was income from wards, relations outside the village or systems level from cities or abroad which are very consistent or monthly (Sosina 2017). Remittance to the livelihood of respondent farmers agreed with the submission of Wassena et al. (2013) that reported high remittance level among farmers in Ethiopia. The % contributions of labour and others to the farmers' income from the study area were 3 and 2 % each. Other contributors to the farmers' income could be inconsistent and unexpected donations and gifts. Haile et al (2010) corroborated the above findings on the contributions of livelihood enterprises to household income with respect to male and female household head (MHHs and FHHs). Basically, the ranking and % income of the livelihood enterprises were primary (60), secondary (20) and tertiary (10) for Agriculture, Livestock and remittance, respectively. The lower ranked contributors to livelihood income were Business, Labour and others were 3%, 5% and 2%, respectively.

Income: The household income and livelihood of farmers' in the study area was dependent on the number of small ruminants put to sale especially female household head (FHHs) (Table 3). The number of male and female animals, sheep and goat put for sales at nearby or village market determines the income and livelihood of the household. Market price of small ruminants is a function of the size and location. The number of male goats and sheep over the past 3 years were (15.34±1.27)

and (25.82 ± 2.38), respectively. The number of female goats and sheep over the past 3 years were (10.27 ± 1.45) and (30.78±3.67), respectively. The approximate weight of male goats and sheep sold over the past 3 years were (15.47± 1.78) and (25.27±2.78), respectively. The approximate weight of female goats and sheep were (20.47±2.67) and (30.72±3.89), respectively. The live weight of male goats and sheep sold were similar to the results of Sosina (2017) of small ruminants sold at village markets and household assets (Babayemi et al. 2014b). However, Duku et al (2010) reported higher live weight and number while examining the dynamics of small ruminant production in the derived savannah.

Average local market price of goat and sheep: The average market prices of sheep and goat largely depends on a number of factors which include the festive periods and market forces of demand and supply (Table 4). Moreover, the average market prices of sheep and goat ranged (6000.02 ± 12.78) to (13000.29 ±13.89) and (4000.13 ± 8.35 to 7000.38 ± 10.89), respectively. The average weight of sheep (male and female) are usually higher than that of goat which also reflect on the market prices as well. The result agreed with the submission of Samireddypalle et al (2014b) and Sosina et al (2019). Furthermore, the breeds and management as well as the physiological state of the small ruminant influences the average market prices. Kabunga (2014) reported higher live weights for sheep and goats in Kenya while lower weights were recorded for indigenous breeds of Ghana (Duku et al 2010).

CONCLUSION

Crop-livestock production system of management is a panacea to crop farmers and pastoralists crises in the tropics. The livelihood of the small holder farmers' is largely influenced by the weight of the animals, number of animals put to sales, prices of the animals and period of sales. Hence, government policies should look for means of increasing livestock production among small holder farmers.

ABSTRACT
The study was conducted to examine the rice farmers' access to agricultural loan and disposable income generation in western zone of Bauchi State, Nigeria. Multistage sample technique was employed to select 313 rice farmers sampled through structured questionnaire. Data were analyzed using multiple regression and binomial logistic regression. The multiple regression results showed that the determinants of the rice farmers' disposable income of farmers' initial capital, farm size, loan amount, market tax and interest rate were significant at P≤0.001 and farm resource at P≤ 0.01. The result of the logit regression disclosed that age, sex, years of experience, interest rate, off farm income, loan distance significantly (P≤0.001) affected the likelihood of farmers' access to loan, membership at (P≤0.05) and disposable income (P≤0.01). The study recommended that credit should be made available at the right time in the farming preparation season and financial institutions or credit sources should be strategically localized to enable easy access by the farmers.

Keywords: Access, Agriculture, Disposable income, Loan, Rice farmers.

INTRODUCTION
Access to loans has been recognized as one of the significant intercession required to quicken development and improvement of farming household in developing countries. Extending agricultural loans is one of the solid alternatives for empowers financial development, decreasing destitution, and improving food security. Hermes and Lensink (2011) contended that, access to loan may add to dependable increments in income from a rise of investment in income-generating activities and a conceivable broadening of source of income for low- income groups, especially rural households from destitution, encourage savings, and improve interest in physical and human capital which vitalizes economic development. Sani (2017) define Agricultural finance as the economic study of the acquisition and utilization of capital in agriculture that is the supply and demand for fund in agriculture. It has been contended that the vast majority of these farmers are excessively poor and cash- strapped to be able to benefit from any form any form of access to loan even if they received adequate supplies of the right inputs, their land has a binding constraint which are so severe that any increase in productivity will fall short of guaranteeing their food security.

Farm income is an important component of rural life. Income is considered as wealth for the households. This household wealth includes the endowment such as land, housing, etc. The probability to access sufficient credit is positively linked to wealth. According Sani (2017) farmers' income is the total savings of the farmer from his farm productive activities. The saving is the total assets plus his wealth and investment; he also defined farmers' disposable income as the summation of the farmers' consumption expenditure from his total savings. A study from Li *et al.* (2011) reveals that farmers' income affects the likelihoods of accessing microcredit in Hubei province China. There is a positive and significant relationship between income and credit access by rural farmers in China. Higher income farmers are likely to have their microcredit application accepted. Household that earn higher income tend to have more investment and might have more confident on repayment of loan.

Rice is a main staple crop in Nigeria cultivated and consumed in all pieces of the nation. It is the Agricultural commodity with the third most astounding overall production after sugarcane and maize (Food and Agriculture Organization [FAO], 2012). Its domestic supply has incredible ramifications for food security and self-sufficiency in the country. Rice production rose gradually over the years with area expansion to overtake major rice producing countries like Cote d'Ivoire and Sierra Leone (Ayanwale and Amusa, 2011). The broad objective of the study was to examine the effects of rice

farmers' access to agricultural loan and income generation, the study determined the factors affecting the disposable income of the farmers; and also estimated the various determinants of the farmers' access to agricultural loans.

MATERIALS AND METHODS

THE STUDY AREA

The study area is western agricultural zone of Bauchi State. It is located between latitude $9^{o}03`$ and $10^{o}30`N$ and longitude $8^{o}50`$ and $11^{o}3E$ of Greenwich meridian in Nigerian Sahel and Sudan Savannah at an altitude of 600m above sea level. The zone consists of 7 Local Government Area (LGA) which includes Alkaleri, Bauchi, Bogoro, Dass, Kirfi, Tafawa Balewa, and Toro. The zone has a population of 2,518,204 people based on 2006 (NPC, 2006) figure and a projected figure of 3,696,723 people at 3.6% growth rate per annum with land area of 24,270.701 km^2 (NPC, 2019). The climate of the area is tropical based on the inter-tropical convergence zone, which gives rise to Northeast and Southwest winds system. The Northeast wind system has a temperature range of $40.55^{o}C$, (maximum) and $9.11^{o}C$ (minimum). The area has an annual rainfall range of 600-1200mm. The area is characterized by distinct rainy (April-October) and dry (November-March) seasons. The economic activities of the zone are rearing of large and small ruminant, crop production, marketing of agricultural products.

SAMPLING TECHNIQUES

A multi-stage random sampling technique was used in selecting the respondents for the study. In the first stage, three (3) Local Government Areas (LGAs); Bauchi, Alkeleri and Dass were selected from the zone using randomly sampling technique. In the second stage, two (2) districts were randomly choosing from each of three (3) LGA selected making a total of six (6) districts. In the third stage, three (3) villages were randomly selected from each of the districts selected using simple random sampling technique making a total of 18 villages. In the final stage, using a confident level of 95%, the sample size of (10%) was proportionately selected from each of the 18 villages to give 312 rice farmers for the study area (Table 1).

METHOD OF DATA COLLECTION

The research utilized primary data. The primary data were collected in the study through the administration of structured questionnaires to respondents with the assistant of trained enumerators.

ANALYTICAL TECHNIQUES

The research employed the use of Multiple Regression and Logit Model to analyze the objectives. The multiple regression model specified was subjected to four (4) functional forms and the lead equation was selected based on the econometric and statistical criteria. The estimated functions were evaluated in terms of the significance of the coefficients and the magnitude of the standard errors. The four functional forms to be fitted are linear, semi log, double-log, and quadratic forms.

The specified model was:

$Y = X_{1,}X_2, X_3, X_{4,}X_{5,}X_6, X_7, X_8, X_9, X_{10}, X_{11}$ …(1)

The explicit form of this function takes the following forms:

1. Linear:

$Y = \beta_\circ + \beta_1X_1 + +\beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + +\beta_7X_7 + \beta_8X_8 + \beta_9X_9 + \beta_{10}X_{10} + \beta_{11}X_{11} + \cup_1$

2. Semi-log: …(2)

$Y = \beta_\circ + \beta_1I_nX_1 + \beta_2I_nX_2 + \beta_3I_nX_3 + \beta_4I_nX_4 + \beta_5I_nX_5 + \beta_6I_nX_6 + \beta_7I_nX_7 + \beta_8I_nX_8 + \beta_9I_nX_9 + \beta_{10}I_nX_{10} + \beta_{11}I_nX_{11} + \cup_1$ …(3)

3. Double-log:

$I_nY = \beta_\circ + \beta_1I_nX_1 + \beta_2I_nX_2 + \beta_3I_nX_3 + \beta_4I_nX_4 + \beta_5I_nX_5 + \beta_6I_nX_6 + \beta_7I_nX_7 + \beta_8I_nX_8 + \beta_9I_nX_9 + \beta_{10}I_nX_{10} + \beta_{11}I_nX_{11} + \cup_1$ ...(4)

4. Quadratic:

$Y = \beta_\circ + \beta_1X_1 + +\beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + +\beta_7X_7 + \beta_8X_8 + \beta_9X_9 + \beta_{10}X_{10} + \beta_{11}X_{11} + \cup_1$ ...(5)

where;

Y = disposable income (₦)
X_1 = initial capital (₦)
X_2 = farm size (hectare)
X_3 = household size (numbers of individual)
X_4 = farm resources (₦)
X_5 = farm output surplus (tonnes)
X_6 = loan amount (₦)
X_7 = labour used (₦)
X_8 = household consumption (₦)
X_9 = membership (yes 1; otherwise 0)
X_{10} = interest rate (%)
X_{11} = market tax (₦)
a = Constant term
$X_1 – X_{11}$= variable input
$b_1 – b_{11}$ = the coefficients of independent variables and
U_1= error terms.

For binary logit models to regress the dependent variable on the independent variables using ordinary least squares would produce nonsensical results as the disturbances are not normally distributed, hence a nonlinear probability function with special limiting properties is employed. (Gujarati, 2009).

$Y= \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \beta_7X_7 + \beta_8X_8 + …Ei$ ….(6)

where Y= Access to loan = 1, otherwise 0.
a = constant
b_1-b_{10} = Regression coefficients;
X_1 = farm size (hectare)
X_2 = sex (male= 1; otherwise 0)
X_3 = age of the respondent (years)
X_4 = loan interest rate (%)

X_5 = education level (years)
X_6 = household size (Number of people)
X_7 = farmer disposable income (₦)
X_8 = off-farm income (yes =1; otherwise 0)
X_9 = marital status (1= yes; otherwise 0)
X_{10} = distance from loan source (1=yes; otherwise 0)
X_{11} = value of collateral (₦)
X_{12} = years of experience (years)
Ei = error term

RESULTS AND DISCUSSION

The econometric model employed in measuring the effects disposable income as a dependent variable (Table 2).

Table 2: Factors Affecting the Disposable Income of the Farmers

Variables	Linear	Quadratic	Semi log	Double log

*significant at 10%, **significant at 5% and ***significant at 1%; values in parenthesis are the t-values.
Source: Field survey, 2019

The double log model was chosen as the lead equation because it has a relative low mean square error, highest level of significant. The econometric result showed that the major determinants of rice farmers' disposable income are initial capital (0.135), interest rate (-26741.36) and farm resources

(0.082). These variables were significant at the 1%, and 10% probability level. The result showed that initial capital and farm resources would increase the disposable income because they have a positive coefficient and these sign are consistent with the a *priori* expectation. Increase of initial capital will lead to more productivity because initial capital can be increased with the aid of loan accessibility. This means that farmers who accessed agricultural credit have higher farm income than those without. This is an important finding since farmers would be able to retrench their credits. Empirically, Shah *et al*. (2008) also estimated a positive effect of credit on crop yield and income of the borrowers over the non-borrowers. Farm resources also have a positive and significant relationship with disposable income. This means that increase in the farm resources will increase the disposable income by 0.072. On the other hand, interest rate had a negative but significant relationship with disposable income. This is because as the interest rate on loan increases, the farmers' disposable income reduces. However, high interest rate reduces the lending capability of the farmers.

The coefficient of multiple determinants (R^2) was 0.760 implying that the explanatory variables in the model were able to explain 76% of the variation in the disposable income. The F statistics is not significant; this means that the overall regression equation was not statistically significant.

FARMERS' ACCESS TO AGRICULTURAL LOANS

The positive sign of age agrees with the *a priori* expectation implied that the younger the farmer, the higher the likelihood of having access to credit and is significant at 1%.Younger farmers are still active, mobile and ready to take risk which may induce them into taking loans. As presented in Table 3, the positive effect of age found in this study corroborates with the finding of Henri-Ukoha *et al.* (2011) who reported that, the age of the farmers, level of education, farming experience, farm size and marital status significantly affect the amount of loan acquired by small scale farmers in Ohafia agricultural zone of Abia State, south-east Nigeria. Sex of the respondent has a positive coefficient of 12.226 and is significant at 1%. This implies that the male farmer have higher credit access compare to their female counterpart. This is in line with the findings of Ololade and Olagunju (2013) who suggested that the males have better access to loan in Oyo State, Nigeria. Farmer disposable income has a positive coefficient of 2.930 and was significant at 10%.the credit need of rice farmer is determine by their disposable income, increase in the farmer disposable income will lead to increase in access credit. This implies that people with higher income tend to take higher credit amount since the anticipated higher disposable income in the future. Also, Adegbite and Adeleye (2011) who found a positive relationship between farmer's income and loan access to microcredit in Oyo State, Nigeria. Membership has an inverse relationship with the loan access and was significant at 1%. This implies that been a member of a cooperative society do not guarantee credit accessibility, the rice farmer need to partake in the activity of the society such as monthly saving, and punctuality. This contradicts the finding of Akinbode (2013) who reported a positive relationship between group membership and access to credit. Interest (26.048) was found to have a positive relationship with access loan and was significant at 1%. It means that a 1% increase in the interest rate results in 26% increase in high access to loan. This agrees with the study of Ololade and Olagunju (2011) who found a significant positive relationship between farmer's access to loan and interest loan charged in Oyo State, Nigeria.

The Cox and Snell R^2 were 0.44 which indicates about 44% of farmers' likelihood of accessing loans is influenced by the explanatory variables included in the model. The log likelihood is statistically showing the overall model fit. If farmers have adequate access to credit, agricultural production can be carried out without disruption on an economically sustainable basis. Access to credit has been said to be able to break the vicious cycle of low productivity and poverty common among peasant farmers in developing countries such as Nigeria.

CONCLUSION AND RECOMMENDATIONS

The major determinants of rice farmers' disposable income were initial capital, interest rate and farm resources while age, sex, disposable income, and membership of cooperative affected the likelihood of the farmers having access to agricultural credit. The study recommended that:

i. Credit should be made available to farmers at the right time in the farming preparation season.
ii. Financial institutions or credit sources should be strategically positioned to be easily accessible to farmers whiles reducing the cumbersome processing for credit among farmers who are less educated.

ABSTRACT
The study examined the analysis of profitability and determined the constraints to small ruminants in Katagum Local Government Area of Bauchi State. A multi-stage sampling technique was used to select 120 sheep farmers in the study area. Data were collected using structured questionnaires and were analysed using farm budget techniques and simple descriptive statistics. The result revealed that purchasing cost for live animal constituted 93.19% of the total marketing costs. Moreover, the result revealed average net income of ₦85,926.28. The return per naira invested was ₦ 0.2015. The gross margin was found to be 88,628.25. Inadequate capital was critical; which was attributed to inadequate sources of credits. Market facilities such as clean environment and security were also lacking. However, improvement in the existing infrastructural facilities will help promote expansion of the present scale of operations. Governments and other financial institutions should do more to extend funds as soft loans to the marketers to improve efficiency.
Keywords: Constraints, Data, Income, Profitability, Questionnaires

INTRODUCTION
In Nigeria, sheep production and marketing are private owned investments, and had been categorised into three, those that are mainly; collection market that serve the function of transferring slaughter stock and live animals from production regions to consumption regions (Francis, 1990). Sheep and goats also serve as important store of wealth and insurance; a function that is extremely important in the absence of well-developed rural financial markets and gave significant covariate risk due to climate, civil unrest, and epidemiological shocks. Sometimes the animals are consumed directly, but more often, are sold; where the proceeds are used to purchase grains and to settle for other bills (Kogsey e*t al.*, 2003). With regards to important due to the fact that sheep and goats are easily managed, that require a relatively small initial investment and their short generation interval lends itself to a fast return to investment. Moreover, small ruminants have often been found to be superior to saving money in the bank, because their net annual returns are much higher than the interest to be realized from the banks' savings. The demand for sheep and their products is destined to increase by more than 250% in Sub-Saharan Africa, especially the West Africa (Fafchamps e*t al.*, 1997). This was because of the population growth, accelerated urbanization, incomes generation and consequently increased purchasing power of the population. In economic terms, small ruminant rearing plays a major role in household incomes. The ultimate goal of intervention aimed at enhancing productivity of small ruminants, needs to consider the market aspect simultaneously. Therefore, farmers need to be aware of the preferred characteristics of the animals as well as price patterns so that they can adequately plan for breeding and fattening programs consistent with the best seasonal prices and consumers' preference. However, marketing system must provide information flows from the consumer back to the producer through some physical and facilitating functions. The producer responds to the price signals by producing commodities in relative quantities dedicated by prices and costs. An important aspect of production and its response to demand and supply is knowledge of markets and marketing systems. Good marketing system reduces the marketing costs, ensures high returns to the producers, provides good quality of agricultural produce at

affordable price to the consumers and minimises the number of intermediaries (Andargachew, K. 1990). The performance of agricultural markets has long been recognised by economists, planners and policy makers as a critical component in the development process.

A multi-stage sampling technique was used to select 120 sheep marketers from the three districts of major small ruminants' markets in the study area. In stage I, Azare livestock market was purposively selected being the largest livestock market of the State, and also assumed to have contained majority of the target population for the study. In stage II, the study area was delineated into two major sheep market districts; the Chinade and Madara district were purposively selected. In stage III, from each of the 3 districts (Azare, Chinade and Madara districts), forty (40) sheep marketers were purposely selected for interview scheduled with questionnaires making a total of one hundred (120) sheep marketers for this study. The data collected were analysed using farm budget techniques and simple descriptive statistics.

RESULTS AND DISCUSSION

PROFITABILITY ANALYSIS OF SHEEP MARKETING IN BAUCHI STATE

The results from table 1 revealed the average total costs of marketing 20 heads of live animals to be ₦21,319.91. The results further revealed the average variable costs to be ₦21,184.81and accounted for 99.37 % of the average total costs of marketing live animals. In terms of returns; the average gross margin (GM) of ₦4,431.41was realised from the sales of 20 heads of live sheep. The result further revealed that the average income ₦4,296.31 perheadoflive animal. Moreover, sheep marketing in Katagum Local Government Area of Bauchi State was regarded profitable as confirmed by the rate of returns to investment as each ₦1 invested on a live sheep will give additional₦0.2015from every live animal. This confirmed that small ruminants' marketing was a profitable venture in Nigeria. The result also implied that99.37% of the total revenues give to pay for the total variable costs of marketing live animals.

Table 1: Profitability analysis of sheep marketing in Katagum Local Government Area of Bauchi State, Nigeria

Variable costs	Amount (₦)	% of TC
Supply cost of animals	397,344.05	93.19
Variable marketing costs	26,352.26	6.18

CONSTRAINTS TO SHEEP MARKETING IN BAUCHI STATE

Table 2 reveals that 98.33 of sheep marketers in Katagum L.G.A. had complained seriously of non-remunerative prices on sales. This corroborates with high marketing costs especially the commission fees, transportation costs as a result of far distance from the source of supply and as well as high purchasing prices of the animals. Inadequate capital (93.33%) was also critical as far as sheep marketing in Katagum L.G.A is concern; this was attributed to

inadequate sources of credits; and had stated that if they had enough money, they would be able to increase the number of animals per supply, thereby making more profit and expand market size. Moreover, inadequate finance hinders marketers from getting the necessary resources and technologies which could assist them achieve higher marketing efficiency. Brokers also create price instability so as to benefit themselves by misinforming traders about the prevailing market prices. This indicated that of the marketers faced difficulties in forecasting their gross returns, leading to poor planning. Also, too much seasonal variation in price especially during religious festivities, such that low price did not offer sufficient incentive for sufficient supply. This necessitated the fact that frequents price variations of farm produce is a major concern to producers, marketers and consumers. Commodity prices may reflect seasonal production patterns by being at the lowest at the peak of production and highest at lean period. In addition, 85.00% of the marketers had complained of transport related problems, which had much dispersion. Most of the marketers depended on commercial vehicle as their means of transportation. In some cases, there were no or the roads were seasonal. This probably increased the transport fares. During the rainy season many of the villages and rural markets were not accessible with the town markets. Increased cost of transportation due to the increased in oil price is also another problem mentioned. However, high transportation costs accounted for high proportion of the total marketing costs in most parts of the country. The result also revealed that, armed robbers used the opportunity of having bad roads; attacked and sometimes even killed marketers. The implication here is that, transportation problems are largely responsible for the slow increase in marketing efficiency and lead to continuous subsistence level of production in many parts of the supply sources. This also made both producers and marketers to resort sales at the nearby markets thereby losing greater proportion of their supposedly income to exploitatively dubious middlemen in the area. Moreover, any of the available modes of transportation in Dambam Local Government Bauchi State had its own inherent problem which results to emaciation, loss and death of the animals in transit. Also, the activities of unregulated livestock produce checking points and theft cases along these routes compound the marketing problems. This drastically reduces the profit of sheep marketers in the study area. Table 2 further revealed that 95.00% of the respondents had problems of low access to formal loan to boost their marketing activities. Lack of credit access associated with the volume of loan, cumbersome procedures, interest rates, lack of collaterals and several trips to the bank before loan was granted were identified as the major marketing problems. Small-scale agribusiness firms faced a number of barriers in obtaining credits because most of them operate within a vicious cycle of poverty that prevent them access to such formal loans. Moreover, the marketers had problems of; scarcity of animals during festivals, diseases and pests, risks of buying unhealthy animals, theft insecurity and as well as low educational level. Other market facilities such as clean environment, good sheds, veterinary services, fire services, banks, security, water supply, and good toilets etc. which contribute to efficient marketing were also lacking.

Table 2: Constraints to sheep marketing in Katagum Local Government Area of Bauchi State

	Constraints	*Frequency	Percentage	Ranking
1.	Non-remunerative prices	118	98.33	1st
2.	Lack of credit access	114	95.00	2nd

Source: Field survey, 2019

CONCLUSION

The results obtained from this study concluded that the marketing of sheep enterprise is profitable. The total returns recorded by the study implied that all the participants were able to cover the total costs incurred in sheep marketing in the study area. This is a clear indication that the business is efficient and has the potentials of increasing the marketers' income; which can induce and attracts new entrants into the market.

RECOMMENDATIONS

However, based on the findings of the study, the following recommendations were made for improving the performance of sheep marketing in Katagum Local Government Area of Bauchi State, Nigeria;

a) Individuals and government should focus in this sector of sheep enterprise so that production and marketing of sheep will become a focal and highly commercial business away from its present subsistence status.

b) Governments and other stakeholders should provide favourable and functional market regulating framework that can eliminate illegal fees or taxes charged along marketing channels for small ruminants.

c) Governments should improve policies on security measures; to help reduce the rate of insecurities like armed robbery on the highways.

ABSTRACT

This paper examines some of the socio-economic factor determining an income of small ruminant farmers in Bauchi State. Data were collected with the aid of 500 structured questionnaires and the collected data were analysed using simple descriptive statistics and regression analysis. The result revealed that majority of sheep and goat farmers falls within the age bracket of 31-60 years (72.4%) while distribution of respondents by marital status reveals that more than half are married (53.8 percent). Educational distribution of respondents indicates that only about one-third (32.4 percent) are educated up to the tertiary level. While about 45.8 percent did not receive formal education, the rest received either primary or secondary education. However, age,educationalstatus(P<0.01),householdsize(P<0.00),povertystatus(P<0.01)extensioncontact,membership ofcooperatives(P<0.10)andsizeofflock(P<0.00)areimportantdeterminants of income realized from small ruminants farming. The coefficient of educational level, extension contact, membership of cooperatives and flock size are positively related to income realised from small ruminants farming. On the other hand, the coefficients of age of household size and poverty status are negatively related to it. In conclusion, the importance of small of small ruminants in meeting social and economic need of rural farmers in Bauchi Statecannotbeoverempha- sised. This has to do with the different roles that these animals played in providing a sigh of relief in production shortfalls and unexpected ill health. Based on the findings from the study, it is recommended that government should intensify efforts at building capacity of small ruminant farmer in Bauchi State through education which can enhance their productivity as education is empowerment which can translate to better adoption of technology that will invariably enhance output and increase revenue.

Keywords: Analysis, Descriptive, Ruminant, Status, Structured

INTRODUCTION

Small ruminants have a number of advantages for being an integral component of the pastoral production system. Sheep and goats are kept for a variety of economic reasons including savings and investment, security and insurance, stability, and social functions. Sheep and goats appear to withstand drought better than cattle, and their short reproductive cycle allows them to quickly recover from rapid resumption of breeding following drought or devastating disease infestation. The small size of sheep and goats has distinct economic, managerial, and biological advantages. Economically, low individual values mean a small initial investment and correspondingly small risk of loss by individual deaths. The role of sheep and goats as a continuous source of protein during and immediately following a period of drought is one major reason for making them the most important component of livestock in pastoral and agro-pastoral production system (Wilson, 1991). Managerially, they are conveniently cared for by women and children, occupy little housing space, lower feed requirements, and supply both meat and milk in quantities suitable for immediate family consumption.

In contrast to large ruminants like cattle which are normally concentrated and remain in the hands of a restricted number of producers (high income rural households), small ruminants are dominant in almost every low income rural household. In the dry areas of Northern Nigeria, fewer than 20 percent of farmers own cattle (ILCA, 1980). In Côte d'Ivoire, Barry (1985) reported that, on average, fewer than four cattle are found on farms where there are ten sheep/goats. Small ruminants are a source of food and financial security for the rural poor. According to FAO (1983), more than 50 percent of milk

produced for human consumption is from sheep and goats in Niger and Somalia. This ownership pattern characterises the legacy of sub-Saharan Africa's rural economy as capital constraints limit access to cattle among poor households whilst small ruminants are well suited for their financial and labor resource capabilities. It is generally more suitable to slaughter a sheep or a goat than a large animal such as a cow to feed community members en- gaged in communally private fieldwork. Small ruminants also provide cultural and economic benefits for households. In the same vein, while a 10 to 15 kg small ruminant carcass is easily handled by a rural household for either home consumption or sale without means of preservation, slaughtering even a steer (when it is available) for the same purposes is generally impracticable and uneconomical and is therefore a rare event.

The study was carried out in Bauchi State in which 500 small ruminants farmers were randomly selected in the 20 Local Government Areas of the State.
Descriptive statistics and regression analysis were used to analysed the data collected from the structured questionnaires.

RESULT AND DISCUSSION

Socioeconomic Characteristics of Respondents

Table 1 revealed that majority of sheep and goat farmers falls within the age bracket of 31-60 years (72.4%) and had an average age of respondents in the study area is 46 years old, implying that they are young and able to work. Distribution of respondents by marital status reveals that more than half are married (53.8 percent), while only about 21.6 percent are single. The rest are either divorced or widowed (24.6 percent). Educational distribution of respondents indicates that only about one-third (32.4 percent) are educated up to the tertiary level. While about 45.8 percent did not receive formal education, the rest received either primary or secondary education. Average household size of respondents is six, and this large household size decreases respondents' per capita income, further lowering their poverty status. Respondents distribution by membership of social group/association (especially cooperative societies) indicates that over three-quarter (74.4 percent) belong to one association or another. Such association is very important in creating a platform to showcase what they have to sell thereby enhancing the ease of converting small ruminants into credit facility or ready - made cash. Occupational distribution of respondents shows the relatively high importance of farming (agriculture–crop/animal husbandry) compared to other occupations available in the study area. Thus, while about 57.8 percent of the respondents indicate armingastheirmainsourceoflivelihood,overtwo-thirdsindicatefarmingasanalternativesourceofincome. Next to this are artisans (18 percent). Only about 12.2 percent are engaged as civil servants in the government parastatals or ministries.

Determinants of Income from Small Ruminants Farmers in Bauchi State

In explaining the determinants of income realized from small ruminants' rearing (Table 5) among women in the study area, the ordinary least squares regression model was employed and the result shows that:

Table 2 revealed that age, educational status (P<0.01), household size (P<0.00), poverty status (P<0.01) extension contact, membership of cooperatives (P<0.10) and size of flock (P<0.00) are important determinants of income realized from small ruminants farming. The coefficients of educational level, extension contact, membership of cooperatives and flock size are positively related to income realized from small ruminants farming. On the other hand, the coefficients of age, household size and poverty status are negatively related to it. For example, the higher the educational status and the higher the flock size of respondents, the higher the income to be realized from small ruminants farming. This is because education enhances adoption of better management practices that can boost productivity and sales of farm produce especially among farmers. Thus, increased/enhanced income is assumed to be a determining factor of being able to meet household financial obligations.

Table 2: Regression result showing how small ruminants assisted respondents in meeting financial obligations

CONCLUSION

The importance of small ruminants in meeting social and economic needs of rural farmers in Bauchi State cannot be over emphasized. This has to do with the different roles that these animals played in providing a sigh of relief in production shortfalls and unexpected ill health.

RECOMMENDATIONS

Based on the findings from the study, it is recommended that:

1. Government should intensify efforts at building capacity of small ruminant farmer in Bauchi State through education which can enhance their productivity as education is empowerment which can translate to better adoption of technology that will invariably enhance output and

increase revenue.

2. Governments should intervene to encourage small ruminant farmers to engage in cooperative activities by providing the initial take-off capital needed and fostering an enabling environment for cooperative activities to thrive.
3. Householdsizeofrespondentsinthestudyareashouldbeputundercheckthroughsensitisationtofamilypl anningtechniques as increased household size reduces income per head (per-capita income) which invariably leads to increased poverty.

MARKETING CHAINS OF COW-MILK BY FULANI WOMEN IN BAUCHI METROPOLIS

Abashi, J. T; Paul, Y. S and Rabo, E.K
Department of Agricultural Economics and Extension, Abubakar Tafawa Balewa University, Bauchi
ephraimrabo@yahoo.com/paulsulim99@gamil.com; 07036973263

ABSTRACT
The study assessed marketing chains and channels of cow-milk by fulani women in Bauchi metropolis**.** The data was collected using questionnaires administered to 100 respondents and were analyzed using descriptive statistics. The respondents were selected using simple random sampling techniques. The results showed that 60% of the respondents were within the age range of 31-40 years and 75% were married. The results also revealed that 58% and 55% had Qur'anic education with 11-15 years of market experience respectively in the study area. Furthermore, majority (60%) of the respondents were retailers consisting of 70% of the respondents who processed dairy products themselves. It was observed that 95% of the respondents sale the products during raining season when the market have the highest supply (90%). The major constraints to cow-milk marketing included poor storage facility (60%), low patronage (25%), seasonal supply (10%) and poor transportation (5%). It can therefore be recommended that basic infrastructure especially electricity, roads and permanent shops may be improved upon while dams and other sources of water should be provided by the government. Grassing areas should be reserved or protected against farming activities and cow milk marketers should be encouraged to form association.
Keynotes: marketing, chains, cow, milk, Fulani

INTRODUCTION

Milk is a white liquid production by the mammary gland of mammals. It is the primary source of nutrition for the young mammals before they are able to digest other types of food. Milk consists of many nutrients such as protein, Vitamin A, calcium, thiamin and riboflavin. Milk with many its products (butter, cheese, un-skimmed milk and skimmed) are important diets required for healthy human growth and development (Blasko, 2011). Milk have medical, cultural and cosmetic value and this might explain why since the early stages of civilization, man has domesticated mammalian animals such as cattle, goat, sheep and camels and utilized them along with other uses, for the production of these vital products for his consumption. Overtime, concern for the improvement and development of the production of milk and its products has been stressed in the agricultural development policies of most countries United Nation Industrial Development Organization (UNIDO, 2004), while in the developed countries of the world, appropriate technologies have been invented to improve on the production, preservation and marketing of these products (Agra Center for Euro-Atlantic Studies, CEAS, 2006). Although in most of African countries, the livestock sub-sector is dominated by traditional system of production, however, processing and marketing seem to be inadequate in meeting the demand for dairy products in the ever increasing population of the developing countries. This demand pressure is especially high in African cities that are experiencing rapid and sustained population growth due to high rate of rural-urban migration.

MATERIALS AND METHODS

The study was conducted in Bauchi, Bauchi State. Bauchi State is located on latitude $10^{0}17^{1}$N and longitude 9^{0} 45^{1}E. Sample size of one hundred (100) Fulani Cow-milk marketers were used in the study, purposive sampling was adopted because it was only Fulani women that are engaged in cow-milk marketing .One (01) *Fulani* woman out of every three (03) marketers was selected. A total number of five (05) markets were selected and the criteria for selection of the markets included spatial spread within the metropolis and the presence of designated areas of sales deports for local dairy products by *Fulani* women. Random sampling techniques was utilized in selecting five (05) markets which included MudaLawan, Wunti, Tashan mass, Kofarwambai and SabuwarKasuwa. In each of the market units, twenty (20) respondents were selected which gave a total sample of one hundred (100) respondents. The data for this study were collected using questionnaires/interview schedule distributed to respondents with the help of an interpreter. The data collected was analyzed using simple descriptive statistics such as frequency tables and percentages.

RESULTS AND DISCUSSION

Table 1: Distribution of respondents according to age of the respondents

Age ranges (years)	**Frequency**	**Percentage**
21-30	22	22

Source: Field Survey, 2014

The result in Table 1 showed that majority (60%) of the respondents fell within the age range of 31-40 years. Indicating that majority of the Fulani women milk sellers were in their active age hence they carry out marketing activities vigorously. This agrees with the finding of Oseni (2011) who asserted that it is logical to think that an individual's performance efficiency or productivity declines with increasing age. Majorities (75%) of the respondents were also married, suggesting that, the low participation of the unmarried may be attributed to the fact that they were mostly young and still dependent. Widows participation in low milk marketing was also low, probably as a result of no husband to supply milk. Marital status has significance on milk marketing. This result is in line with Kees (1995) who said that lactating cows are milked by men and then distributed among their women.
The study also revealed that 35% of the respondents have family sizes ranging from 1 to 5; 30% between 6 to 10; and 20% between 11 to 15 members, while 15% of the total respondents have family size of 16 and above members. This result agrees with the finding of Ibeauchi and Dalyop (1995), who found that quantity of milk that enters the traditional market, depends on household and calf requirements.
The result from Table 1 also showed that 58% of the respondents had quaranic education, 32% never been to school and 10% only attended primary school. The result indicated that 32% of the respondents in the study area could not read or write but 68% of the total respondents are literate. This implies that majority of cow milk marketers had acquired one form of education ranging from formal to non-formal. This is a healthy situation because through education people could acquire skills and knowledge, which are important in obtaining and analyzing information about market situations, thereby increasing the social and economic wellbeing. It is also important in management of risk associated with marketing activities in the study area. This finding is in line with Njoku (1999) who observed that formal education has a positive influence on adoption of innovation.
Marketers generally handle for sale, one or combination of products at a time in the market; some commodities have derived demand especially agricultural products. Therefore they are sold together; the demand for dairy products, except that of industrially processed yoghurt is complementary in nature. They are consumed along with or in relation to other commodities such as sour milk with millet processed into local foods (*fura and youri*), tea, bread and cokes in some cases. The result in Table 2 showed that 70% of the total respondents sell sour milk and butter but there was no respondent on the sale of butter only, while 30% of the respondents were selling sour milk, *fura and youri* only.

The result in Table 3 indicated that 55% of the respondents between1 to 15 years experience in cow-milk marketing, while those with longer years of experience (11 years and above) accounted for 62% of the total number of respondents in the study area. This could be likened to their maturity in understanding the market situation as regard market intelligence, taking and managing risk and uncertainties in marketing activities in an attempt to generate more profit. And this could have contributed in maintaining them in the business, in agreement with, Haruna (2002), who stressed that knowledge and experience in marketing information has been shared among marketers since time immemorial and passed from one generation to another.
From Table 4, majority (60%) of the respondents complained of poor storage facilities This result is similar to the findings of UNDO (2004) who identified constraints of marketing of dairy products to include; poor infrastructure, electricity supply, road, inadequacy of storage facilities, etc. It agrees with Mohammed *et al*. (1990) who identified the problems of informal marketing as remoteness of production sites, high transaction cost and poor infrastructure among others.

CONCLUSION AND RECOMMENDATIONS

From the study conducted, it was concluded that, the major constraints to cow-milk marketing included poor storage facility, low patronage, seasonal supply and poor transportation. It can therefore be recommended that basic infrastructure especially electricity, roads and permanent shops may be improved upon while dams and other sources of water should be provided by the government. Grassing areas should be reserved or protected against farming activities and cow milk marketers should be encouraged to form association.

[2]National Veterinary Research Institute

ABSTRACT

A study on the information management on the availability, adoption and utilization of Non-conventional Feedstuffswas conducted. The study involved a survey of 253 poultry and 259 pig farmers from six States in Nigeria. Friends and neighbours (40.4% of poultry and 53.3% of pig farmers) were found to be the most important source of information on NCF followed by Extension Agents (36.5 % of poultry and 36.8% of pig farmers). Extension guides and bulletins were found to be more important sources of information on NCF than Radio or TV. The percentage of farmers who reported using guides and bulletins were 22.6% for poultry and 13.6% for pigs in contrast to only 3.2% for radio and 11.1% for TV amongst poultry farmers; 2.3% for radio and 1.1% for TV amongst pig farmers. The main source of NCF for farmers is the open market. This was reported by 44.7% of poultry and 68.8% of pig farmers. However, while oniy 26.1% of poultry farmers reported sourcing NCF from household wastes up to 57.1% of pig fanners did so. Similarly, only 14.1% of poultry farmers compared to 42.9% of pig farmers reported sourcing NCF from the industry. On farm sourcing was done by 10.7% of poultry in contrast to 36.7% of pig fanners. The difference between farmers who said they were satisfied with NCF use (39,2%) and those dissatisfied (34.5%) was marginal in the case of poultry farmers. Similarly, pig farmers that were satisfied with* NCF were 46.6% compared to 41.5% that were dissatisfied. Very few fanners said they were highly satisfied with NCF use: 2.6 % of poultry and 8.3% of pig farmers. Most of the farmers acknowledge that they share information on NCF with other farmers (56.9% of poultry and 82% of pig farmers). Some 28,3% of poultry farmers and 51.5% of pig farmers said they employ additional labour as a result of using NCF. For poultry farmers the number employed were 1-2 by 12.3%, 3-5 by 11.9% and >6 by 2.6%. For pig farmers, the number employed were 1-2 by 61.3%, 3-5 by 29.4% and >6 by 9.3%. This result shows the high potential that exists for employment generation through promoting the use of NCF. Given an average of 2 workers per farmer, the 259 pig farmers interviewed created additional 518 jobs. It is concluded that given the complex nature of most NCF, the use of well-trained Extension agents and contact farmers complemented with good Extension publications will greatly enhance the use of NCF by poultry and pig farmers.

INTRODUCTION

Nigeria is basically an agricultural country with a greater per cent of its people living in villages. Their livelihood is dependent mainly on agriculture and animal husbandry. Though we have a huge livestock population,the National Agricultural Sample Survey in 2011, indicated that Nigeria was endowed with an estimated 19.5 million cattle, 72.5 million goats, 41.3 million sheep, 7.1 million pigs and 28,000 camels, 145 million chickens, 11.6 million ducks, 1.2 million turkeys and 974, 499 donkeys, yet the production of livestock products is relatively low. It is evident that we are highly deficient in various livestock products. Oneof the main reasons for the low productivity of our livestock is malnutrition, under-nutrition or both, besides the low genetic potential of the animals.(Umesh*et al*., 2014). Likewise availability, vis-a-vis the requirement of green-fodder crops and concentrates, there is a huge gap between demand and supply of all kinds of feeds and fodders. The formation of a Presidential Task Force on Alternative Formulation of Livestock Feeds by the Federal Government of Nigeria in 1989 was the climax of that recognition in this Country (Babatunde, 1999). The purpose of this study was to identify the channels by which farmers get information on NCF and the factors associated with their use.

Non-conventional feed resources (NCF):

The non-conventional feed (NCF) refer to all those feeds that have not been traditionally used in animal feeding and or are not normally used in commercially produced rations for livestock. NCF include commonly, a variety of feeds from perennial crops and feeds of animal and industrial origin. The term NCF has been frequently used to describe such new sources of feedstuffs as pallet oil mill effluent and palm press fiber (oil palm by-products), single cell proteins, and feed material derived from agro industrial by-products of plant and animal origin like mango fruit pulp, mango fruit peel and mango seed kernel(Rao *et al.* 2000; Soomro*et al.* 2013; Diara and Uaman 2008; Berardini*et al.* 2005; Palma *et al.* 2009). Poor-quality cellulosic roughages from farm residues such as stubbles, haulms, vines and from other agro-industrial by-products such as slaughter-house by-products and those from the processing of sugar, cereal grains (maize bran, rice bran, rice husk, the mustard seed

hulls), citrus fruits and vegetables from the processing of food for human consumption also comes under category of non-conventional feedstuffs. Many of these feed resources are yet to be incorporated into the feed bank for low cost of livestock production despite the fact that they could be gotten free or at a very low cost(Orayaga and Anugwa 2014).

Need of Non-conventional feed:

There are serious shortages in animal feeds of the conventional type,which alarms the livestock nutritionists to discover a new arena for endowing nutritional security on animals for optimum production. (Amandeep, 2016). The grains are required almost exclusively for human consumption. These feedstuffs can be put to use for animal feeding as they provide no competition from their human counterparts. Mostly these are the byproducts which are obtained after the removal of main product for human use. With increasing demand for livestock products as a result of rapid growth in the world economies and shrinking land area, future hopes of feeding the animals and safeguarding their food security will depend on the better utilization of unconventional feed resources which do not compete with human food. The availability of feed resources and their rational utilization for livestock represents possibly the most compelling task facing planners and animal scientists in the world. The situation is acute in numerous developing countries where chronic annual feed deficits and increasing animal populations are common, thus making the problem a continuing saga.(Umesh*et al*., 2014)

Thus non-conventional feeds could partly fill the gap in the feed supply, decrease competition for food between humans and animals, reduce feed cost which is said to account for up to 70% of the cost of production. Dried mango waste included in finishing pig diets at 10% as reported, had no deleterious effect on feed conversion ratio, animal performance and was cost effective and contribute to self-sufficiency in nutrients from locally available feed sources (Rao *et al.* 2000). It is therefore imperative to examine for cheaper non-conventional feed resources that can improve intake and digestibility of low quality forages. Feedstuffs such as fish offal and kitchen leftovers (i.e., potato peel, carrot peel, onion peel, and cabbage leftover), poultry litter, local brewery and distillery by-products are commonly used(Amandeep, 2016) and could be invaluable feed resources for small and medium size holders of livestock.More information is required on chemical composition, nutritive value and their utilization. Farmers are mostly not aware of the nutritive value of some feed sources and the way for their efficient integration in livestock feeding, a viable proposition could be the inclusion of non-conventional feed resources in livestock rations with suitable and complete feed technology that can utilize the feed sources with maximum efficiency.Over a period of time a wide range of new feed resources have been successfully evaluated and results of on-farm trials evaluating the use of several non conventional feed resources in broiler diets under small holder conditions Ravindran (1993) highlighted that the intention of those trials were to demonstrate the possible use of relatively cheaper, locally available by products by proportionately reducing the expensive concentrate feeds. The new technology helped to cut production cost drastically by improving the feed efficiency from 3.5 in 1980 to 2.2 in 1990 and reducing the growth span from 90 to 42 days. The involvement of local extension agencies and other means of communication in technology development for efficient use of NCF, assessment and transfer of the information is equally important and would provide first-hand knowledge of these feedstuffs from various livestock extension agencies, thus providing nutritional security to animals.

METHODOLOGY

A survey was conducted by NAERLS using a structured questionnaire through well trained enumerators which was complemented with the results of interview schedules and Rapid Rural Appraisal Techniques. A total of 253 poultry and 259 pig farmers were involved in the study from Abia, Adamawa, Akwalbom, Borno, Enugu and Lagos States about sources of information on Non-conventional Feedstuffs. A simple random sampling was used (Ikaniet al. 2001).

RESULTS AND DISCUSSION

The sources from which farmers get information are given in Table 1. Some 40.4% of poultry farmers and 53.3% of pig farmers said they got information about NCF from neighbours and friends. Extension agents were the source of information for 36.5% of poultry and 36.8% of pig farmers. The results obtained on the importance of neighbours/friends and Extension agents are in agreement with the results obtained by several other investigators. (Ikani, et al., 2001). Chikwendu*et al*., 1996, in an extensive study, on the effectiveness of communication channels for disseminating information on improved

farm practices to farmers involving about 950 farmers nationwide obtained similar results. However, in contrast to the results of that study, extension guides and bulletins were found to be more important sources of information on NCF than Radio. The percentage of farmers who reported using guides and bulletins were 22.6% for poultry and 13.6% for pigs in contrast to only 3.2% for radio and 11.1% for TV amongst poultry farmers; 2.3% for radio and 1.1% for TV amongst pig farmers. The market was a source of information to 5.2% of poultry and 10.7% of pig farmers. The main source of NCF for farmers is the open market. This was reported by 44.7% of poultry and 68,8% of pig farmers. However while only 26.1% of poultry farmers reported sourcing NCF from household wastes up to 57.1% of pig farmers did so. Similarly, only 14.1% of poultry farmers compared to 42.9% of pig farmers reported sourcing NCF from the industry. On-farm sourcing was done by 10.7% of poultry in contrast to 36.7% of pig farmers. These results indicate that pig farmers use more locally available NCF than poultry farmers. This is not surprising considering the fact that poultry depend more on refined feeds. Pigs have the capacity to effectively utilize many raw or semi-processed NCF directly whether wet or dry. From Table 2 it can be observed that a sizeable proportion of the farmers had used NCF for only 3 years or less. This was cited by 54.9% of poultry and 39.3% of pig farmers. About one third (31.4%) of poultry and a quarter of pig farmers had used NCF for more than six years. Inspite of the seemingly massive use of NCF, the difference between farmers who said they were satisfied (39.2%) with NCF use and those dissatisfied (34.5%)were marginal in the case of poultry farmers . Similarly, pig farmers that were satisfied with NCF were 46.6% compared to 41.5% that were dissatisfied. Very few farmers said they were highly satisfied with NCF use: 2.6 % of poultry and 8.3% of pig farmers. Most of the farmers acknowledged that they shared information on NCF with other farmers (56.9% of poultry and 82% of pig farmers). Some 28.3% of poultry farmers and 51.5% of pig farmers said they employ additional labour as a result of using NCF. For poultry farmers, the number employed were 1-2 by 12.3%, 3-5 by 11.9% and >6 by 2.6%. For pig farmers, the number employed were 1-2 by 61.3%, 3-5 by 29.4% and >6 by 9.3%. These results show the high potential that exists for employment generation through promoting the use of NCF. Given an average of 2 workers per farmer, the 259 pig farmers interviewed created an additional 518 jobs. The farmers were very conversant with the advantages associated with NCF use (Tables 3). Cheapness and availability were cited as the major advantages by 26.8% of poultry and 36.9% of pig farmers. Only 14.6% of poultry and 14.6% of pig farmers cited cost effectiveness / economical considerations as one of the benefits of NCF use.

CONCLUSION

The main reason for the poor animal production is the inadequate supply and low level of feeding due to serious shortage of feedstuffs. A major gap exists between the requirements and supplies of nutrients for feeding of animal, the non-conventional feeds could partly fill this gap. More information is required on chemical composition, nutritive value and their utilization. Farmers are not aware of the nutritive value of some feed sources and the way for their efficient integration in livestock feeding. The involvement of local extension agencies in technology development for efficient use of NCFR, assessment and transfer is equally important. Several factors may account for their limited use, among which is their low nutritive value, Seasonal availability, high cost of handling and transportation from the production site to the farm, presence of anti-nutritional factors. It is essential to increase feeds by growing more fodders, propagating agro and social forestry, improving the nutritive value of crop residues and utilising other NCFRs. Crop residues, Agro-industrial By-Products and browse foliage are certainly an increasingly important role as feeds in the future, as human and livestock populations expand and an intervention through training on feed treatment and supplementation is essential to improve the feeding value of crop residues and clear cut duration of time for how long a feed has been used as a feed for livestock should be put to distinguish it as conventional or non-conventional feed resource. The best information sources are those that involve visual aids and practical demonstrations. The use of well-trained Extension agents and contact farmers complimented with good extension publications are strongly recommended as ways of disseminating information and acquisition of the necessary skills required by farmers to adopt the use of NCF effectively.

ABSTRACT

Studies were conducted to determine the length-weight relationships and condition factor (k) of *Oreochromis niloticus* and *Clarias gariepinus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State Nigeria were evaluated for a period of four months, (September, October, November, and December, 2019). The following fish species where encountered and identified: *Oreochromis niliticus, Clarias gariepinus, Alestes nurse, Labeo senegalensis, Barillu senegalensis, Distinchodus engycephalus, Heminchromis faciatus* and *Schilbe mystus.* Atotal of three hundred and twenty two (322) *O. niloticus* and one hundred and twenty seven (127) *C. gariepinus* were collected in the dam by artisanal fishermen using drag net and traps. The length and weight of *Oreochromis niloticus* and *Clarias gariepinus* were measured using meter rule and electronic weighing scale (T500Y) respectively. Model equations of *O. niloticus* and *C.* gariepinus were $W = 0.0692 \times L^{2.3857}$ and $W = 0.0342 \times L^{2.5559}$. The fish species had negative allometric growth pattern (b<-3). The length-weight relationships of the fish species (*Oreochromis nilotiuss* and *Clarias gariepinus*) showed no significant difference $P > 0.05$. *Oreochromis niloticus* had a good condition factor with (k) value of 1.7525 while *Clarias gariepinus* had poor condition factor (K) with value of 0.7510. The condition factor (K) for dry season ranges from 1.7705 (*O. niloticus*) to 1.8474 (*C. gariepinus*) indicating that the fish species were in good nutrition condition. The condition factor (k) values for both species were (K >1) indicating the fishes in dam were in good condition except *C. gariepinus* obtained in wet season. Fishing regulations should be introduced in Gubi Dam.

Key Words: length-weight relationship, condition factor, *Oreochromis niloticus, Clarias gariepinus,* Gubi Dam.

INTRODUCTION

Length– weigh relationship studies of fishes are considered as an important tool for understanding the growth pattern of fish species. Length is a linear measure (in centimeter) and weight of a fish (in gram) is approximately equal to its volume (cubic centimeter). Hence weight of a fish is a function of length. The relationships can be expressed by the hypothetical law $W= aL^3$. The value of exponent may considerably deviate from the value 3, as most fishes change their form or shape when they grow (Martin, 1949). This variation form expected weights to the actual weight of individual fish is assessed by analyzing the length – weight relationships. Le Cren (1981) proposed the relative condition factor in preference to condition factors as the letter is influenced by many environmental and biological factors. Condition factor measures the deviation from a hypothetical ideal fish whereas relative condition factor measures the deviation from the average weight or length of fish. There is paucity of information on the length weight relationships and condition factor of fish species in Gubi Dam. This may not be unconnected with insufficient literature and research of all fish species in the dam.

MATERIAL AND METHODS

STUDY AREA

The study was carried out in Gubi dam Bauchi State. Bauchi State is located at longitude 10- 10°N arid altitude 9°40E, it is 69020cm above sea level. It cover an estimated area of about 3,354 kilometers with a population about 344750 people. The state experience two seasons in a year that is, rainy season and dry season. The annual rainfall is 905.3mm with temperature range of 11°c-4°c mean. Monthly hour of sunshine is 300.5 hour and decrease to 150 one hour in August experience minimum relative humidity of about 66.5% and February record lowest of 16.4%. The vegetation is open Savannah and with species of tin or more but the vegetation have been reduced to shrubs due to cultivation and burning effects. There are brown grasses of low nutritive value.

IDENTIFICATION OF FISH SPECIES

Fish species caught were identified by their local names. Fish identification key refer to monograph for their scientific names (Reed et al., 1907)

FISH SAMPLING TECHNIQUES

A total of 322 *Oreochromis niloticus* and 127 *Clarias gariepinus* were collected in the dry and wet seasons. Field visited was conducted once in a month in both dry and wet seasons in 2019. The local fishermen operating at the Dam deployed drag net and traps for their catches. The fish sample caught were immediately immersed in 10% formalin and transported to the laboratory for identification using the key provided by fish base (2013).

DATA COLLECTION AND ANALYSIS

The variations in the length weight represented by 'b' were recorded. The total length (TL) of each fish was measured from the tip of snout (mouth closed) to end of the caudal fin using meter ruleThe relationship between length and weight of the fish was examined by simple linear regression using WINKS software.. Body weight was measured using electronic digital balance (OHAUS). The parameter of length-weigh relationship of sampled fish species were evaluated using the equation.

$W = aL^b$ (Rickter, 1973) ….. equation 1

Where, W is weight of the fish (g), L is length of the fish (cm), a is the intercept

growth coefficient, and b is the slope growth coefficient. The value of constant 'a' and 'b' were estimated after logarithmic transformation as described by Zar (1984) to give

$Log_{10}{}^a + b\ Log_{10}L$ …….. equation 2.

The 95% confidence interval (CL) of 'b' was computed using the equation (Egbal*et al.*, 2011):

$CL = b \pm (1.96 \times SE)$ ….. equation 3

Where SE is the standard error of 'b'. The condition factor was calculated by the formula (Pauly, 1983):

Condition Factor (K) = $100W/L^3$

Where w is weight (g) and L is total length (cm).

RESULTS

Table 1: Length-weight Relationships Parameters of *Oreochromis niloticus*and *Clarias gariepinus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State (2019)

Species	Regression coefficient a	b	Correlation coefficient (r)	Model ($W=a \times L^b$)	±SE	N	Growth pattern
O. niloticus	0.0692	2.3857	0.7050	$W= 0.0692 \times L^{2.3857}$	0.38	322	NA
C. gariepinus	0.0342	2.5559	0.6618	$W= 0.0342 \times L^{2.5559}$	0.51	127	NA

N=number of Specimen used, **NA=** negative allometry, SE = Standard Error

Table 2: Condition Factor Values (k) of *Oreochromis niloticus*and *Clarias gariepinus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State for Wet season (2019)**.**

Species	Maximum (k) Value	Minimum (k) Value	Average (k) Value	N	Remark
O. niloticus	2.5451	0.1374	1.7525	161	Good condition
C. gariepinus	2.4303	0.1942	0.7510	74	Not in good condition

Table 3: Condition Factor Values (k) of *Oreochromis niloticus*and *Clarias gariepinus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State (Dry Season 2019)

Species	Maximum (k) Value	Minimum (k) Value	Average (k) Value	N	Remark
O. niloticus	2.5451	0.1521	1.7706	161	Good condition
C. gariepinus	2.7166	0.7140	1.8474	53	Good condition

DISCUSSION

The (b) value of the fish species from Gubi dam recorded during the period of study, fell within 2.3857 and 2.5559. this result contradicts the reports of Egbal*et al*, (2011) whose study showed that the 'b' value of the fish species from both Atbara and Khashm el-Girba reservoir in Sudan were within the range of 2.278 and 3.680, and Pauly (1983) who also recorded 'b' value range of 2.5 to 4.0 for many fish species. It is also reported that when b=3, the fish grows isometrically, resulting in ideal shape of fish (Olurin and Aderibigbe, 2006). When the values of b is less than 3.0 the fish experiences a negative allometric growth (Sudan, 1950). However, when the value of b is more than 3.0 the fish grows following the positive allometric growth pattern. Ibrahim (1984) reported that, the value of b then becomes greater than 3 as the fish is slimmer. Nevertheless, it was observed that the two sampled fish species in the study neither showed isometric nor positive allometric growth pattern but all suffered from negative allometric growth. All value observed for fish collected from the Dam during the study period indicates that, the two sampled fish species experienced this pattern of growth. The coefficient of determination r^2 for the length-weight relationship was high for *O. niloticus* (0.7050) and O.6618 for *C. gariepinus* indicating that the length increased with increased in weight of fish at

Dam. This is an agreement with previous findings (Laleye, 2006). The 95% interval of ranged from 0.0692-2.5451. lazima *et al*, (2007). However, reported a 95% CL of b value range between 2.329 and 3.919 of 12 fresh water fishe species in the Kenian River Basin and Pedu Lake.

The condition Factor (k) gives information on the physiological condition of Fish in relation its welfare, Perry *et al*, (1996) reported that fish with low condition index are presumably believed to have experience adverse physical environmental or insufficient nutrition. According to Maguire and Mace (1993), from a nutritional point of view, increase in k values indicates the accumulation of fat and sometimes general development. Angelscu*et al* (1958) reported that from a reproductive point of view, the highest k value are reached in species if the fish is fully mature and have higher reproductive potentiality. It was observed that the two fish species sampled in the study recorded inconsistent condition factors, with *O. niloticus* in wet season having 1.7252 and *C. gariepinus* having 0.7510. With *O. niloticus* falling within the normal range indicating good condition, while *C. gariepinus* falling below the normal range indicating not good condition. While in dry season all the fish species sampled in the study had condition Factor $\geq$ 1, and were within the normal ranges recommended by Ujjania*et al*, (2012) who stated that condition factor greater than or equal to one is good, indicating a good level of feeding, and proper environmental condition. Benegal and Tech (1978) recommended k value range (2.9-4.8) as suitable for matured fresh water fish. The condition factors of the two fish species sampled in the study revealed that the fish species had their k values outside and within the ranged recommended as suitable for matured fish in fresh water. This could be caused due to environmental factor such as damming the river. Abdullahi and Ahmad (2013) reported the predominance of cyanobacteria and spirogyra, phytoplankton species in Wudil Rivers, which suggest an indication of organic pollution, reflecting human interference to pollute the river. LWR Parameters (a and b) and the k value of the fish has been reported to be affected by factors such as feeding intensity, availability of food, fish size, age, sex, season, stage of maturation, fullness of the gut, degree of muscular development.

CONCLUSION

The following fish species were encountered and identified (*Oreochromisniloticus, Clariasgariepinus, Alestes nurse, Labeo senegalensis, Barillus senegalensis, Distinchodus engycephalus, Hemichromis faciatus, Schilbe mystus*) in the Dam.Length-weight relationships of the fish species indicated negative allometric growth pattern in the fish species. The lengh thas a close relationships with the weight. The fish species in the Dam were in better condition of wellbeing in the dry season.

ABSTRACT

The study assessed the adoption of innovation on improved fish feeding techniques among fish farmers in Urban and Rural communities in Obio/Akpor Local Government areas of Rivers State. Multistage sampling technique was used; the first stage fifteen (15) communities were purposively sampled and the next stage fish farmers were sampled randomly from the communities to obtain a sampled size of 100. Data were collected through structured questionnaire and interview scheduled. Descriptive statistics such as frequency, percentages and mean were used for data analysis. The results revealed that 22% farmers major source of information was through family and friends, while awareness rate was high 100% for the use of floating feed, about 85% of them used live food and most adopted innovation on improved fish feeding techniques were floating feed (X= 4.99) and use of live food (X= 4.23) constraints to adoption of innovations were high cost of improved fish farming techniques and technical knowhow. It was recommended that Government should provide funds in form of loan at a reduced interest rate to the fish farmers and extension agents should organize timely training for the fish farmers to enable them adopt innovations introduced to them.

Keywords: Awareness, adoption, fish farmers, fish, techniques

INTRODUCTION

The low domestic fish production was attributed to the fact that fish production in Nigeria is highly dependent on artisanal fishing, which is characterized by the use of crude fishing gear and equipment, low catch, lack of access to credit facilities and information on improved fishing technologies The fishermen, who rely on the use of small fishing gear, operate on creeks, lagoons, inland waters or rivers which extend beyond 5 nautical miles of seashore. Hence, increasing the domestic fish production in Nigeria would require among others the adoption and use of improved fishing technologies which consists of required equipment and practices for finding, handling, processing and distribution of fish resources and their products (Olaoye *et al,* 2018). Nigeria aquaculture development has been driven by social and economic objectives, such as nutrition, improvement of rural areas, generation of supplementary incomes, diversification of income activities and the creation of employment (Ozigbo *et al,* 2014).

There has been an increased effort at development of technologies for increased production. Agricultural Extension Agents are constantly engaged in the transfer of developed farming technologies to farmers for adoption (Olatunji, and Ogunremi *2016).* Adoption is a decision making process which involves a number of stages. Adoption as the integration of an innovation into farmers' normal farming activities is not a permanent behaviour (Ekong 2010).

The roles innovations are to simplify and make fish production more effective and efficient. It is therefore pertinent to investigate the extent to which fish farming technologies have been transferred to farmers and the extent to which the technology end-users have taken advantage of these technologies. Therefore, the study aimed at examining awareness and adoption of innovation on improved fish feeding among fish farmers in Obio-Akpor Local Government Area of Rivers State. The specific objectives of the study were to: (i) examine awareness of innovation on improved fish feeding technologies among the respondents, (ii) identify information sources of respondents on innovation (iii) determine adoption of innovations (iv) identify constraints to adoption of innovations by the respondents.

MATERIALS AND METHODS

AREA OF STUDY

The study was carried out in Obio/Akpor Local Government Area in the metropolis of Port Harcourt, one of the major cities of Niger Delta, located in Rivers State. The Local Government Area covers 260 km2 and had a population of 464,789 people at the 2006 census. Obio/Akpor is bounded by Port Harcourt (Local Government Area) to the south, Oyigbo to the east, Ikwerre to the North and Emuoha to the west. It is located between the latitude 4^0 45' N and 4^0N and longitude 6^0 5 ' E and 8^0 00' E. It is mainly made up by people of Ikwerre ethnic nationality. The major occupations of the people are arable crop farming, trading and fishing. Obio/Akpor has a total number of three kingdoms which are Apara, Evo and Akpor Kingdoms from which 54 communities are found (Obio/Akpor geographical location, 2017)

SAMPLING PROCEDURE

Multistage sampling technique was used to select respondents for the study. The first stage was a purposive sampling of fifteen (15) rural and urban communities that have more fish farmers than the others. The next stage involved random selection of one hundred (100) fish farmers in the selected fifteen communities. Thus, the total population size was 100 fish farmers.

DATA COLLECTION AND METHOD OF ANALYSIS

Questionnaire were used for data collection and supplemented with scheduled interview where respondents do not have formal education. Data collected were analyzed using descriptive statistics such as frequency percentage and mean.

RESULTS AND DISCUSSION

Table 1 showed that 22% of the fish farmers' main source of information on improved fish farming techniques was family and followed by other farmers which was 18%, internet source had 15% while extension agents had 2% respondents. The implication is that informal sources of information on improved fish farming were high. Reason for low level of information source from extension agents could be attributed to poor ratio of extension agents to fish farmers. In a similar study Ogunremi *et al*, (2018) reported low level of information dissemination by extension agents to fisher folks. However, Ifejika *et al.,* (2008) reported extension agents as the major source of information on fish technologies.

Table 1: Sources of information on improved fish farming techniques in Obio-Akpor Local Government Area of Rivers State

Variable	Frequency	Percentage
Extension agent	2	2
Internet	15	15
Private consultant	8	8
Family and friends	22	22
Fish buyer	4	4
Other farmers	18	18
Total	100	100

Source: field survey, 2019

Table 2 indicated that 100% of respondents were aware of floating feed, 85% were aware of use of live feed, 53% of respondents were aware of automatic feeder and only 12% were aware of pulse feeding. High level of awareness on floating feed was a function of dissemination sources, also

majority of floating feed available in the market were imported which could be attributed to the mentality that imported fish feed are superior to locally manufactured feed. Live feed such as maggot is also widely acceptable to fish farmers which prompted it level of awareness among fish farmers in the study area.

Table 2: Awareness about improved fish farming techniques in Obio-Akpor Local Government Area of Rivers State

Improved fish farming techniques	Frequency	Percentage
Automatic feeder	53	53
Pulse feeding	12	12
Alternative feed	26	26
Floating feed	100	100
Use of live feed	85	85

Source: field survey, 2019

Table 3 indicated that floating feed and use of live feed were adopted by fish farmers in the study area while automatic feeder, pulse feeding and alternative feed were not adopted. Ashley-dejo *et al,* (2013) in a similar study reported high level of fish farmers' awareness on use of live feed among fish farmers. The implication for the adoption of floating feed is because it enable fish farmers to monitor response of fish to feeding, also prevents feed wastage because feed floats on water unlike the local feed that sink and uneaten feed easily pollute the water. Live feed on the other hand like maggot when fed to fish helps in reduction of amount spent on feeding fish. Non adoption of automatic feeder could be attributed to high financial implication involved since most fish farmers could not afford it. Tosan (2008) reported that cheap technology will be adopted faster than an expensive one, because farmers are eager to make money.

Table 3: Adoption of innovation on improved fish feeding techniques in Obio-Akpor Local Government Area of Rivers State

S/N	Variables	Adoption	Mean	Remark
1	Automatic feeder	0	1.37	Not adopted
2	Pulse feeding	0	1.22	Not adopted
3	Alternative feed	2	1.43	Not adopted
4	Floating feed	99	4.99	Adopted
5	Use of live food	72	4.23	Adopted

Mean Criterion = 3

Table 4 showed lack of awareness of improved fish farming techniques, high cost of improved fish farming techniques, technical knowhow, limited or no access to credit facilities affected the adoption of innovation on improved fish feeding techniques. Innovations can be widely adopted when all channels of creating effective awareness are maximally utilized. Adoption of innovation is a function of credit facilities which can be finance or equipment. The services of experts on innovation utilization are paramount in training fish farmers who are willing to adopt innovations on fish feeding.

Table 4: Constraints to fish farmers' adoption of innovation on improved fish feeding techniques in Obio-Akpor Local Government Area of Rivers State

S/N	Constraints	VSC	SC	MC	NC	Total	Mean	Remark
1	Lack of awareness of improved fish farming techniques	93	5	2	0	359	3.59	Agree
2	The high cost of improved fish farming techniques	94	1	3	2	387	3.87	Agree
3	I don't know how to put the new techniques to use	57	11	16	16	309	3.09	Agree
4	Poor marketing structure is affecting the adoption of improved techniques	19	13	40	23	218	2.18	Disagree
5	Limited or no access to credit facilities affect the adoption of improved techniques	86	9	1	4	377	3.77	Agree

Mean criterion: 2.5

VSC= Very strong constraint, SC= Strong constraint, MC= Mild constraint. NCAA= Not constraint at all

CONCLUSION AND RECOMMENDATION

Fish farmers were aware of some innovations on improved fish feeding techniques and had adopted only a few of them which can be related to the constraints like high cost of the innovation, technical knowhow and limited or no access to credit facilities. It was recommended that Government should provide funds in form of loan at a reduced interest rate to the fish farmers and extension agents should organize timely training for the fish farmers to enable them adopt innovations introduced to them.

ACKNOWLEDGMENT:

The authors are grateful to Warmate, T. for the data collection during the study.

ABSTRACT
Feeding trial was conducted on One hundred and twenty (120) to evaluate the utilization of four different leaves used for feeding of African Giant Land Snail (*Achatina achatina*). Grower snails were used in a Completely Randomised Design with 4 treatments replicated 3 times with 10 snails per replicate. The treatments were *Spinach olaracea* Leaves, *Ipomoea asarifolia* leaves, *Cucurbita pepo* leaves and *Commiphora africana* leaves. Weight gain, Shell length, Shell breadth, Aperture breadth, and Feed intake were measured weekly. The result obtained showed significant difference ($p<0.005$) among the treatment means in final weight, weight gain, shell length, shell breadth, aperture breadth and feed intake. Feed conversion ratio was highest ($p<0.005$) for snails fed with *Spinach olaracea,* followed by *Ipomoea Asarifolia,* then *Cucurbita pepo* and *Commiphora africana* leaves. Therefore, the final Weight gain, Shell length, Shell width, Aperture width and Feed intake of the experimental Snail fed the selected edible leaves was represented in this descending order: *Ipomoea asarifolia* > *Spinach olaracea* > *Cucurbita pepo* > *Commiphora africana* leaves. The result of this study indicated that *Ipomoea asarifolia, spinach olaracea Cucurbita pepo* and *Commiphora africana* leaves can serve as feed for African Giant Land Snail (*Achatina achatina*).
Key words: *Ipomoea asarifolia, Curcubita pepo, Commiphora africana, Spinach olaracea, Achatina achatina*

INTRODUCTION
Snails dwell mostly in humid forest areas in West Africa from where they are gathered by villagers for consumption and other uses (Ademosu, Omidigi, 1999). In recent times, the wild snail population has declined considerably due mainly to the impact of man and other anthropogenic factors including deforestation, slash and burn agricultural practices and overexploitation of this animal resource stemming from the world teaming population hence the few remaining species are captured before they reach maturity. Usually, snails become scarce during the dry season hence expensive at this period (Amusan, 2002). The need to enhance the mass production of snails cannot be overestimated because snails can be reared both on small scale and large-scale production systems. Snail rearing can be seen as a veritable means of generating income and to achieve self sufficiency in hard times as presently experienced in Nigeria today. It is therefore necessary to domesticate snails in order to save the species from going in to extinction. To effectively do this, various plant materials need to be evaluated as feedstuff for snails. The present research is focused on evaluation of some selected leaves: (*Spinach oleracea, Ipomoea asarifolia, Commiphora africana, Curcubita pepo*) as feed resource for snails.

MATERIALS AND METHOD
A total of 120 (one hundred and twenty) average weight (0.538 g) grower snails were used for this research. This experiment was carried out in a local snail farm (Bayan Area Council) in Dutsinma Local Government, Katsina State, for the period of 6 weeks. The snails were weighed on arrival and randomly allotted to four treatments in a completely randomized design. Each treatment was in triplicate, having ten sails each. The snails were housed in a discarded car tire's and covered with mosquito net. The treatments were *Spinach olaracea* Leaf, *Ipomoea asarifolia* leaf, *Cucurbita pepo* leaf and *Commiphora Africana* leaf. Weight gain, shell length, shell breadth, aperture breadth, and feed intake were measured weekly. The thirty marked snails from each treatment were weighed and measured at the end of the experiment. Proximate analysis was carried out on the experimental diets and the fecal sample per replication using standard AOAC methods. Analysis of variance was carried out to determine the Growth performance of African Giant Land Snail (Achatina Achatina) on experimental diets using SAS (SAS 2001).

RESULTS AND DISCUSSION

The snails in all the treatments gained appreciable weight across all the treatments as can be seen in table (2). The highest weight gain was observed in treatment B (*Ipomoea asarifolia*) leaves, with a mean total weight gain of 2.510 grams/snail followed by treatment A (*Spinach olaracea*) leaves, with 1.587 grams/snail, treatment C (*Cucurbita pepo*) leaves, 1.507 grams/snail, while treatment D (*Commiphora Africana*) leaves recorded the lowest weight gain with 0.863 grams/snail. The result indicated that there were significant differences ($p<0.05$) in the treatments diets but no significant differences ($p>0.05$) were observed between treatment A (*Spinach olaracea*) and treatment C (*Cucurbita pepo*) leaves.

Significant differences ($p<0.05$) were observed in diet B (*Ipomoea asarifolia* leaves) with average mean shell increment of 0.078 mm/snail, this conformed with reports of Aribisala (1999) that there is direct correlation between shell length increment and growth of the snails, every factor that affects the growth rate would also affect the shell length increment. It also conformed with the reports of Eze *et al., (*2013) who indicated that when snails were fed herbages and poultry waste based diet, the gain in length was significantly higher ($P<0.05$) than gain in length as a result of feeding standard poultry diet and this indicate positive impacts of herbages/leaves in shell length increment of snails despite the availability of calcium in the standard poultry diets even though the shell of snail is made of calcium which is present in the Ash (Hamzat 2004; Omole *et al* 2008).Thus, no significant differences ($p>0.05$) were observed between treatment A (*Spinach* olaracea) 0.042 mm/snail and treatment C (*Cucurbita pepo*) 0.031 mm/snail while treatment D (*Commiphora africana*) recorded the lowest 0.019 mm/snail.

The analysis of variance shows that there were significant differences ($p<0.05$) between the treatments in terms of shell breadth increment. Treatment A (*Spinach olaracea*) had the highest breadth increment with 0.206 mm/snail followed by treatment B (*Ipomoea asarifolia*) 0.145 mm/snail while treatment C (*Cucurbita pepo*) had 0.090, treatment D (*Commiphora africana*) recorded the lowest 0.060 mm/snail, but no significant difference ($p>0.05$) were observed between treatment C and D 0.090, 0.060 mm/snail respectively.

The values across all the treatments showed that the snails did well on the four treatments in terms of shell aperture increment and there was significant difference ($p<0.05$) between the treatments diets. Highest increment was observed in treatment C (*Cucurbita pepo*) 0.097 mm/snail, there was also significant difference ($p<0.05$) between treatment B (*Ipomoea asarifolia*) 0.031 mm/snail and treatment A (*spinach olaracea*) 0.020 mm/snail, while treatment D (*Commiphora africana*) was the least having 0.019 mm/snail.

Highest feed intake was observed in treatment A (*Spinach olaracea*) 47.63 grams/snail followed by treatment B (*Ipomoea asarifolia*) 45.47 grams/snail While Treatments C and D (*Cucurbita pepo and Commiphora africana*) recorded 29.96 and 20.06 grams/snail respectively. The analysis of variance shows that significant difference exists between the treatments ($p<0.05$).

The highest feed conversion ratio as can be seen in (table 2) was observed in treatment A (*Spinach olaracea*) 26.980 followed by treatment B (*Ipomoea asarifolia*) 24.343 and treatment C (*Cucurbita pepo*) 23.905 while the lowest feed conversion ratio was recorded in treatment D (*Commiphora africana*) 20.790. The analysis of variance shows that there is significant difference ($p<0.05$). The zero mortality rate recorded could be due to proper management practices adhered to during the course of the feeding trial. Again it could be due to "hardy" nature of snail. This observation is in line with of (FAO 1986, Amusan and Omidiji 1998) that the snail is "hardy" in nature and can tolerate adverse environmental conditions better than other livestock.

CONCLUSION AND RECOMMENDATION

CONCLUSION

The results obtained in this study indicated that *Achatina achatina* respond positively to all treatment diets used in this study. Best performance in terms of growth response, feed intake and feed conversion ratio was obtained in *Achatina achatina* Snails fed with (*Ipomoea asarifolia*) leaves, followed by (*Spinach olaracea*) leaves and (*Cucurbita pepo*) leaves. Apart from the good performances of snails fed with these treatment diets, (*Ipomoea asarifolia*) leaves was available all the year round all over the country to the farmers since it can be obtained at little or no cost.

RECOMMENDATIONS

1. *Ipomoea asarifolia* plant and *Cucurbita pepo* leaves which has been hitherto been thought of as an undesirable plant material (weed) could be used in feeding of *Achatina achatina.*

2. Being able to use *Ipomoea asarifolia* plant and *Cucurbita pepo* leaf as feed stuff offers the opportunity of making the environment pollution free and farmers can be encouraged to raise snails to generate additional income.

3. *Ipomoea asarifolia* was considered easily accessible and available all the year round all over the country to the farmers and it can be obtained at little or no cost.

4. Utilization *Spinach olaracea* leaf, *Ipomoea asarifolia* plant and *Cucurbita pepo* leaf will effectively reduce the cost of snail production.

5. Future research should be conducted to determine the cost implication of utilizing the selected leaves.

ABSTRACT

The use of medicinal plants that can enhancement of immunity eases of stress through its richness in antioxidant and stimulating effects on appetite and performance is a well –known facts based on the diverse array of phytomolecules. The qualities and quantities of food products is now a serious concern to the consumers in term of its hygiene and safety, Therefore, the effect of graded levels of *Hibiscus sabdariffa* meal diets on the proximate and mineral composition of *Clarias gariepinus* were evaluated after feeding for 84days. The effect of *H. sabdariffa* on the carcass composition of *C. gariepinus* showed that the moisture, protein, lipid, ash and NFE did not vary significantly ($p<0.05$) within the tested groups and the control, but the crude fibre contents varied significantly as the increasing concentration of *H.sabdariffa*. The results revealed that the highest phosphorous and magnesium values (0.35±0.02; 2.78±0.05*) were from the fish carcasses fed HSM1 and HSM5 diets and the lowest values (2.50±0.08; 0.30±0.02) were from the carcass fed HSM2 and HSM1diets respectively. Carcass quality of African catfish fed *H. sabdariffa* was not compromised.

INTRODUCTION

Nutritional quality of a feed is influenced not only by nutrient contents but also by many other aspects such as feed presentation, hygiene, palatability and effect on intestinal health. Feed additives provide a mechanism by which such dietary deficiencies can be addressed, which benefits not only the nutrition and thus the growth rate of the animal concerned but also its health and welfare (Fefena, 2007) and higher profitability (Adewole**,** 2014). The qualities and quantities of food products is now a serious concern to the consumers in term of its hygiene and safety, in the process of meeting these demands, there is need for intensification of the husbandry processes which has the resultant effects of inducing stress. This has led to the use of antibiotics and other drugs that have been known to have untold consequences on the health of the animals and human respectively. Therefore, there is the need to seek for alternative non conventional resources that is as effective and with health proven benefits. *H. sabdariffa* (locally called Zobo) is very rich in its nutritional and medicinal profile and have been reported to be effective in blood pressure management, hepatoprotection, anti-cancer, anti-inflammation, antibacterial and improvement of digestion due to the presence of vitamins, minerals and flavonoids. Its utilization as dietary additive in fish production and economic advantages has been reported (Adewole, 2018). This study therefore seeks the effect of *H. sabdariffa* meal diets on the proximate and chemical composition of *C. gariepinus*.

MATERIALS AND METHODS:

STUDY LOCATION: The study was carried out at the Department of Aquaculture and Fisheries Management's Teaching and Research Laboratory, University of Ibadan, Ibadan, Nigeria.
EXPERIMENTAL PROCEDURES: Collection and identification of plant material, preparation and processing of Roselle Calyx (*H. sabdariffa)* and calculated dosage values were based on (Adewole, 2018; 2014).

FORMULATION OF EXPERIMENTAL DIETS AND EXPERIMENTAL DESIGN:

Six isonitrogenous diet (40% crude protein) were formulated using algebraic method along the least cost formulae and coded as HSM1 (Control), HSM2, HSM3, HSM4, HSM5 and HSM6 respectively. A Completely Randomized Block Design was used to the design of the experiment. Twenty juvenile *C. gariepinus* of initial mean weight and length: 10.94±0.02g and 10.28±0.04cm respectively were stocked in triplicates per treatments, fed twice daily at 5% body weight, for 12 weeks (Adewole, 2018; 2014).

PROXIMATE ANALYSIS AND MINERAL COMPOSITION:

Proximate composition of the fish were carried out according to AOAC (2005), while the mineral elements were determined using Atomic Absorption Spectrophotometer (AAS-Buck 205 model). Flame photometer was used for the determination of sodium and potassium ions (Sogbesan, 2007).

DATA ANALYSIS:

Analysis of Variance (ANOVA) at (α0.05) and significant treatment means compared using Duncan Multiple Range Test (SAS, 1999).

RESULTS

The final carcass moisture contents ranged from 73.40 ± 0.85 to 76.33 ± 0.26%. The highest final moisture value was from the fish fed the control (HSM1) diet and the lowest value was from the fish fed HSM2 diet. Within the treatments, there was no significant difference (P>0.05) in the moisture contents of fish fed the experimental diets (Table 1).The final carcass crude protein content varied from 65.26 ± 1.1 to 68.07 ± 2.00%. The highest final crude protein value was from the fish fed HSM5 diet and the lowest crude protein value was from the fish fed the control diet. Within the treatments, the flesh of the fish fed the control diet was insignificantly lower (p<0.05) in the crude protein contents compared to the flesh from fish fed other diets (Table 1). The final carcass crude lipid contents ranged from 9.63 ± 0.02 to 10.16 ± 0.36%. The highest crude lipid value was from fish flesh fed the HSM2 diet, while the lowest crude lipid was from the fish flesh fed HSM1 diet. Within the treatments, the fish flesh fed the control diet was insignificantly lower (P<0.05) in the final crude lipid contents compared to the fish flesh fed other diets (Table 1). The final carcass crude fiber contents varied from1.32 ± 0.02 to 1.64 ± 0.03%. The highest final carcass crude fiber was from the fish fed HSM6 diet and the lowest crude fiber content was from the fish flesh fed the control diet. Within the treatments, the fish flesh fed the control diet was significantly different (P<0.05) in the final crude fiber contents compared to the fish flesh fed the other diets (Table 1). The final crude ash contents ranged from 16.72 ± 0.24% to 17.30 ± 0.17%. The highest final carcass crude ash content was from the fish fed HSM4 diet, while the lowest final crude ash content was from the fish fed HSM6 diet. Within the treatments there was no significant difference (P>0.05) in the final carcass crude ash contents between the control diet and the other treatments (Table 1). All the final protein, fibre, and ash values were higher than initial.

The mineral element Sodium ((Na^+) ion concentrations ranged from 0.71 ± 0.06 to 0.80 ± 0.04 (units). The highest Na^+ ion concentration was from the carcass of fish fed HSM4 diet and the lowest concentration was from the carcass of fish fed HSM2 diet. The final Na^+ ion concentrations were higher than the initial. Within the treatments, the fish flesh fed the control diet was insignificantly lower (p<0.05) in final Na^+ ion concentration compared to the other treatments (Table 1).The Potassium (K^+) ion concentration varied from 1.33 ± 0.01 to 1.50 ± 0.05. The highest K^+ value was from the fish flesh fed the HSM1 diet and lowest from fish flesh fed HSM2 diet. The final potassium ion concentrations were higher than the initial. Within the treatments, the fish fed the control diet had insignificantly higher (p<0.05) final potassium compared to the others (Table1).The calcium (Ca^{2+}) ions concentration ranged from 2.78 ± 0.14 to 3.34 ± 0.20. The highest Ca^{2+} ion concentration was from the carcass of the fish fed HSM3 diet and the lowest was from the fish flesh fed HSM4 diet. All

the final Ca^{2+} ion concentrations were higher than the initial. The fish flesh fed HSM3 diet had significantly ($P<0.05$) higher Ca^{2+} ions concentration than the fish flesh fed HSM4 diet, but not significantly different from the other fish fleshes (Table1). The phosphorus ion concentration varied from 2.50 ± 0.08 to 2.78 ± 0.05. The highest was from the fish fed the HSM1 diet and the lowest was from the fish fed HSM2 diets. All the final phosphorus ion concentrations were higher than the initial. Within the treatments, the fish fed the HSM1 diet was significantly higher in the final phosphorus ion concentration compared to the fish fed HSM2 diet, but not significantly different from the others (Table1).The final carcass magnesium ion concentration ranged from 0.28 ± 0.02 to 0.35 ± 0.02. The highest was from the fish fed HSM5 diet and the lowest value was from the HSM1 diet. All the final magnesium contents were higher than the initial, but otherwise for the fish fed the control diet. Within the treatment, fish fed HSM5 diet had insignificantly higher ($p<0.05$) magnesium compared to the other treatments.

DISCUSSION

The result of the feeding of the different concentrations of HSM diets on the protein content of *C. gariepinus* obtained in the present study showed numerical increase as the concentration of HSM diets increase. This is similar to the observation of (Adeparusi *et al*, 2010) fed *Oreochromics niloticus* graded levels of ginger. The slight increase in the protein composition of *C. gariepinus* in this result when compared to the control at ($p<0.05$), may be due to the improvement in liver and other organs functions which synthesized plasma protein (Metwally; 2009).The moisture contents of *C. gariepinus* fed *H. sabdariffa* meal decreased insignificantly when compared to the control, but increase as the concentration of HSM diets inclusion levels increased. This is similar to a general decrease in percentage moisture contents which decrease inversely with increasing fat content of the fish carcasses (Olukunle, 2009) and were similar to 58.60 and 80.70% (Makanjuola, 2012).For the fat composition of *C. gariepinus* there was also slight increase as the concentration of *H.sabdariffa* meal's diet increases, this is similar to the results (Adeparusi *et al*, 2010) (9.38-10.11%) fed *O. niloticus*. This may be due to higher contents of the fat contents of the diets, which increased as the concentration of HS's diet increases, hence the higher fat deposit in the body of *C. gariepinus*. The mineral electrolytes/elemental composition of *C. gariepinus* fed HSM's diet showed that Na and Mg increased insignificantly within the tested groups when compared to the control, while elements like Ca and Phosphorus decreased significantly with the increase in HSM's diet levels, while K decreased insignificantly when compared to the control. The mineral element Na values obtained in the present study were similar to 0.73-0.80% reported for some selected species of fresh water, while the remaining mineral elements were higher than the values obtained by Fawole *et al*, (2007). Thus the study of mineral elements in living organisms is of biological importance, since many of such elements take part in some metabolic processes and are known to be indispensable to all living things. Conclusively, the use of *Hibiscus sabdariffa* at the different levels did not compromise the nutritional qualities of African catfish.

ABSTRACT

The dietary effects of raw and differently processed *Mucuna pruriens* seed diets on growth and haematology of *C. carpio* fingerlings was investigated. The Mucuna seeds were boiled with distilled water (DW), fresh tamarind pulp extract (TP) and maize cob ash solution (MCA) for 60 minutes. The raw (RM) and resulting meals from the differently processed Mucuna seeds were included at 20% substitution of soya bean meal in 4 (four) treatment diets designated RMD, DWD, TPD and MCD respectively, while a reference diet with no mucuna served as the control diet (NMD). The experimental set up consisted of 15 (fifteen) 40 x 30 x 25cm rectangular plastic tanks (15L capacity) in a static and aerated water system in an indoor hatchery. The treatment diets and control were fed in triplicate groups to *C. carpio* fingerlings (average weight, 15.40g) for 56 days in a completely randomized design. Data obtained was subjected to analysis of variance at $\alpha_{0.05}$. Results obtained showed that growth performance and feed utilization indices were lowest for fish fed RMD diet. The MCD diet gave the best growth indices thus considered the most appropriate processing method of *Mucuna pruriens* seeds for dietary inclusion in the feeding of *C. carpio* fingerlings.

Key words: Processed *Mucuna pruriens* Seed, Growth performance, *Cyprinus carpio* fingerlings, Fish and haematology

INTRODUCTION

Mucuna pruriens seeds like other legumes contains a high level of crude protein (28 to 35%), vitamins and minerals (Ukachukwu *et al*., 2002; Bressani *et al*., 2003) which makes it a suitable alternative plant protein source for fish feed. Previous studies have only focused on the improvement of the nutritional status of plant seeds as protein sources such as *Phaseolus lunatus* (Alegbeleye *et al*., 2005); *Mucuna utilis* (Akinmutimi and Okwu, 2006; Vadivel and Pugalethi, 2009); *Ricinus commnis* (Balogun *et al.*, 2008); *Vigna sinesis* (El-Saidy and Saad, 2008); *Vicia faba* (Azaza *et al*., 2009) and *Pisum sativum* (Davies and Gouveia, 2014).

The problem of biochemical components of plant protein sources which limit their utilization as potential alternative in fish diets has drawn much attention considering the fast growth of aquaculture industry (Bressani *et al*., 2003; Tacon and Metian, 2008). To enhance utilization of plant protein in aquaculture production, thermal processing and biochemical evaluation of feedstuff diets for fish are therefore essential (Davies and Gouveia, 2008; Tacon *et al*., 2009).

In this study, the dietary effects of inclusion of raw and differently processed *Mucuna pruriens* seeds by boiling the seed in distilled water, fresh tamarind pulp extract and maize cob ash solution were investigated on the growth response and digestibility indices of *C. carpio* fingerlings.

MATERIALS AND METHODS

The Mucuna seeds were boiled with distilled water (DW), fresh tamarind pulp extract (TP) and maize cob ash solution (MCA) for 60 minutes. The raw (RM) and resulting meals from the differently processed Mucuna seeds were included at 20% substitution of soya bean meal in 4 (four) treatment diets designated RMD, DWD, TPD and MCD respectively, while a reference diet with no mucuna

served as the control diet (NMD). The experimental set up consisted of 15 (fifteen) 40 x 30 x 25cm rectangular plastic tanks (15L capacity) in a static and aerated water system in an indoor hatchery. The treatment diets and control were fed in triplicate groups to *C. carpio* fingerlings (average weight, 15.40g) for 56 days.

EXPERIMENTAL DESIGN

Completely randomized design.

DETERMINATION OF GROWTH AND NUTRIENT UTILIZATION INDICES

At the end of the feeding trials, growth performance and digestibility parameters were calculated as follows: Mean Live Weight Gain (MWG), Food Conversion Ratio (FCR), Specific Growth Rate (SGR % day ¯1), Protein Efficiency Ratio (PER), Protein Productive Value (PPV), Apparent Protein Digestibility Coefficient (APDC).

STATISTICAL ANALYSES.

All experimental data obtained were subjected to One-way Analysis of Variance (ANOVA) and means were compared using Duncan's multiple-range test (DMRT) (Duncan, 1955). The PC software SPSS version 17 was used for the analyses.

RESULTS

Growth responses and nutrient utilization of *C. carpio* fingerlings fed the four experimental (RMD, DWD, TPD, MCD) and control (NMD) diets are as shown in Table 5 and Figure 1. The fish were observed to feed voraciously on all the diets at onset of feeding regime. Growth responses showed the mean live weight gain (MLWG) was highest (10.28g) for the NMD diet followed by the MCD diet (MLWG, 8.87g). Diets DWD and TPD gave MLWG of 6.93 and 5.66g respectively, while the RMD diet had the poorest MLWG of 3.34g. The differences were statistically significant ($P<0.05$). Similarly, there was significant difference ($p<0.05$) in the food conversion ratio (FCR) of the different diets which was least (1.61) in the NMD diet followed by MCD (2.18). Other processed diets (DWD and TPD) had FCR of 3.66 and 3.79 respectively, while the RMD diet had the highest (3.84) FCR. The protein utilization parameters such as protein efficiency ratio (PER), apparent net protein utilization (ANPU) and protein productive value (PPV) appeared to follow the same trend as the growth parameters which were significantly different ($p<0.05$) among all the experimental diets (Table 1).

TREATMENT DIETS

RMD = Raw Mucuna Diet,
DWD = Diet from *M. pruriens* seed boiled with distilled water
TPD = Diet from *M. pruriens* seed boiled with tamarind pulp extract
MCD = Diet from *M. pruriens* seed boiled with maize cob ash solution
NMD = Control diet
ANPU= Apparent net protein utilization
PPV = Protein productive value

DISCUSSION

From the results of this study, the differently processed mucuna diets (DWD, TPD and MCD) showed improved performance in the specific growth rate (SGR), food conversion ratio (FCR) and protein efficiency ratio (PER) of the *C. carpio* fingerlings as compared to the raw diet (RMD) suggesting an improvement in the nutritive values of the processed seeds which encouraged better utilization of the mucuna diets. In similar studies (Fagbenro *et al*., 2003; Siddhuraju and Becker, 2003) the authors reported that the improvement in the nutritive value of the processed seeds can be due to the detoxification and reduction on the quality and quantity of ANF in the raw seeds by various hydrothermal treatments. This study has shown that the lower level of residual anti-nutritional factors in the MCD diet made the Common carp fingerlings to better efficiently utilize the protein of MCD diet than protein of DWD and TPD diets. This is evident in the higher protein productive value (PPV), apparent net protein utilization (ANPU) and apparent protein digestibiblity coefficient (APDC) for *C.*

carpio fingerlings fed the treatment diets which showed higher values for MCD diet. Davies and Gouveia (2014) reported on the reduction of anti-nutrients in pea seed meals (*Pisum sativum*) with thermal processing, which subsequently made it more palatable and increased consumption resulting to higher growth performance of *Cyprinus carpio* fish. Similar observations were also reported by Alegbeleye *et al*. (2005) and Tiamiyu *et al*. (2006) in which anti-nutrients in lima bean and soybean respectively reduced significantly ($p<0.05$) with boiling, thus making the seed meals more palatable and acceptable when fed to fish.

CONCLUSION

The MCD diet gave the best growth indices thus considered the most appropriate processing method of *Mucuna pruriens* seeds for dietary inclusion in the feeding of *C. carpio* fingerlings.

ABSTRACT

A comparative nutritional evaluation of raw and differently processed *Mucuna pruriens* seeds. The processing methods adopted were boiling the Mucuna seed for 60 minutes with distilled water (DW), fresh tamarind pulp extract (TPS) and maize cob ash (MCA) solution. The raw and resulting meals from processed Mucuna seed were included at 20% substitution of soya bean meal in 5 treatment diets with the control diet (no Mucuna). Data obtained was subjected to analysis of variance at $\alpha_{0.05}$. There were significant different in the proximate composition. The result shows that MCA treatment as the best among other tested processing methods of *M. pruriens* seeds for inclusion in diet. Although the amino acid profile shown no significant different, but the MCA had the highest methionine and lysine compared to other treatment. In conclusion, this study has revealed that *M. pruriens* seeds processed with MCA has high feed promise and could be used as an alternative protein ingredient in fish diets.
Key Words: Processing Method, *Mucuna pruriens* seed meal proximate composition and amino acid profile.

INTRODUCTION

The use of plant-derived diets in animal feeding is technically limited by the presence of high levels of anti-nutritional factors, poor palatability, low protein content and digestibility, which at some levels result to lower growth (Francis *et al.,* 2001; Fagbenro *et al*., 2003). However, the utilization of potential plant protein material can be improved upon by adequate processing under controlled time and temperature which usually reduces or completely eliminates the effect of anti-nutrients, improves the protein quality and amino acid content of food grain legume (Makkar and Becker, 1999; Siddhuraju and Becker, 2001).

Soya bean has been the most commonly used feed ingredient for aquaculture feeds, however, it has become competitive for both human and animal uses (Tacon *et al*., 2009). Therefore, the need to source for alternative and cheaper plant protein sources has become imperative. *Mucuna pruriens* seed has not been intensively explored as a protein source for fish feed despite its good prospect. Previous study (Francis *et al*., 2001) on the analyzed chemical content of mucuna seed meal revealed crude protein content of between 25 to 32%, with approximately 3.5% lipid. The aim of this investigation therefore, is to determine potential nutritional value of processing Mucuna seeds in different solutions.

MATERIALS AND METHOD

PROCESSING OF *M.PRURIENS* SEEDS INTO FEEDSTUFF

A total weight of 2 kilograms of *M. pruriens* seeds was obtained from National Animal Production and Research Institute (NAPRI), Shika- Zaria in Kaduna State, Nigeria. The seeds were divided into four lots; three of which were subjected three indigenous processing methods in order to detoxify the seed materials viz: boiling at 105°C for 60 minutes in distilled water (DW), fresh tamarind pulp extract (TP) and maize cob ash (MCA) solution respectively, while the fourth was left raw (R). At the end of boiling duration, the processed seeds were washed with distilled water and screened-dried in open air under a shed for 3 days after which the raw and the processed dried samples were weighed, ground and preserved in air tight container and kept at 4^{0}C for analyses and diet preparation.

Chemical Evaluation of Raw and Processed *M. pruriens* Seeds

The *M. pruriens* seed samples were analyzed for percentage proximate compositions of moisture, crude protein, lipid, ash fibre and mineral contents which were determined using validated analytical method of Association of Analytical Chemists International (AOAC, 2005). Amino acids profiling was done for all the five treatments using the Technician Sequential Multi-sample Amino Acids analyser (TSM) (Spackman *et al*., 1958).

RESULTS AND DISCUSSIONS

The analysed proximate and amino acid profile of the experimental diets are shown in Table 1and 2 respectively. There are significant different in the proximate composition. The control with contains the fish meal had the highest total proximate values. Next to the control is the maize cob ash (MCA) solution soaked mucuna which shows a closely proximate values to the control. Although the amino acid profile shown no significant different but the MCA had the highest methionine and lysine compared to other treatment.

Although the differently processed mucuna seeds appeared to be at par statistically, but subjectively, MCA processed enhanced better results. The RMD caused reduced food utilization and severe effect on nutritional status which showed direct involvement of unprocessed antinutritional factors in the raw samples. Thus boiling mucuna seeds with maize cob ash solution for 60 minutes as a locally adaptable processing method was considered most suitable for nutritional improvement of *M. pruriens* seeds for dietary inclusion to enhance growth and nutrient utilization.

CONCLUSION

In conclusion, this study has revealed that *M. pruriens* seeds processed with MCA has higher nutritional content and could be used as an alternative protein ingredient in fish diets.

ABSTRACT

Searching for cheaper and less tedious methods of producing maggot with good nutritional value will be a pragmatic approach to address issues of livestock feed insecurities thereby increasing farmer's income. Several attempts have been made to find inexpensive and relatively abundant nutrient substrates to partially or, even completely, replace expensive components among are fruits residues, brewery by-products, feather, abattoir wastes product, hatcheries and dairy waste although the sustainability of these requires skills, labour, capital and accessibility to companies producing such by-products. This paper highlights simple techniques of producing qualitative and quantitative maggots from readily available materials without elaborated maggotry building and equipment. Techniques involved from site selection for maggotry, substrate tanks (by uses of 200 litter capacity drum), choice of available substrate and flies attractant, harvesting techniques, processing and preservation. Photograph 1 - 6 provide practical demonstrations of techniques involved. Simple techniques of maggot production will save cost, labour and minimized threat of livestock waste product that imposes serious pollution problems to the incumbent environment and human health.

Keywords: Techniques, Maggot and Production**.**

INTRODUCTION

In developing nation like Nigeria, the cost of commercial livestock farming and fish feeds have become very expensive (John, 2015) account for over 60% of the recurrent overhead costs of livestock farming and about 70% of a fish farming venture (Sogbesen *at al.,* 2005). This is due mainly to the fact that most of the protein ingredients such as fishmeal are imported while locally available alternatives like soyabeans and groundnut also serve as food for humans. Maggot meal have been used extensively to replaced conventional expensive feed ingredient with better utilization by various classes of livestock such as Broiler chickens (Adeniji, 2007; Hwangbo *et al.,* 2009), Layers (Agunbiade *et al.,* 2007), rabbit (John, 2015), Pig (Adeniji, 2008), and Fish (Ebenso and Udo, 2003; Sogbesan *et al.,* 2006).

Sogbesan *et al.,* (2006) reported that about 932.5 tonnes of poultry manure is produced annually in Nigeria due to the well-established poultry and livestock industries which are expanding at 6-8% annually (Adejinmi, 2000). This large turn-out of poultry waste imposes threat of disposal to the poultry industries and as well serious pollution problems to the incumbent environment and man`s health. Therefore, recycling this waste will help to assumed significant role in livestock and aquaculture for the enhancement of detritus food chain and production of high quality protein. Maggot and other non-conventional insects have been explored to check their nutrient contents, relative abundance, use and conversion into processed meals, incorporation into formulated diets and subsequent development of technique(s) for on-farm mass production (Ugwumba and Ugwumba, 2003). The objective of this paper is to highlights simple techniques of maggot production.

MAGGOT PRODUCTION

Maggots: Are the larvae of the domestic fly (*Musca domestica*). Maggot serves as a solution to the high cost of feed in fish and livestock production especially poultry production.

ROLE OF MAGGOT PRODUCTION

1. As product for aquaculture: feeding of fresh maggots to tilapia and catfishes is can be done twice daily (late in the morning and later afternoon). It provides rich sources of nutrients.
2. Maggot provides a source of nutrient for chicken, quail, turkeys, guinea fowl, ducks etc.
3. It provides fertilizer for crop production; the spent substrates are used to fertilize directly plants in the field. The spent substrates are incorporated into the compost production.
4. It also helps to protect the environment as wastes are concentrated and decomposed.
5. The technology for maggot production is simple and cost effective for farmers.

POINT TO CONSIDER IN SITE SELECTION FOR MAGGOTRY

1. Maggotries should preferably be located away from human residence.
2. The place should be surrounded with trees and vegetation to absorb offensive odour from the maggotry and reduces the excessive high ambient temperature.
3. The housing should preferably be oriented in an East-West direction to reduce the effect of direct sunlight on the substrate.
4. The roof can be made up of corrugated iron sheets or thatch. The garble roof type of building with openings at the top and sides for ventilation is recommended.
5. In the absent of housing, maggotry can be sited under the trees.

MAGGOT CULTURE

To produce maggots, the following prerequisites must be satisfied:

1. Substrates: these can be fermented grain residue, maize bran, brewery spent grain.
2. The fly attractants: these include substances that arouse the attention and attract flies to enter substrate tanks. These include animal manure like pig and poultry waste; animal offal from the abattoir, slaughtered birds visceral, crack and spoiled eggs, dead lizards, birds, rats and other animals. Decaying fruits like mangoes; Fermented parkia seeds (*Daudawa*) and other good attractant.
3. Flies: preferably house fly (Musca domestica).

Photograph 1: substrate and flies attractant application in drum.

Photograph 2: covering the substrate after flies deposited eggs for 2 days.

Photograph 3: harvesting maggot using sedimentation technique

Photograph 4: washing maggot with clean water

Photograph 5: frying maggot for preservation

Photograph 6: sundrying method for maggot preservation

TECHNIQUES OF MAGGOT PRODUCTION

Maggot production is an aerobic fermentation process. Maggot can be produce in a clean substrate tank (plastic or metallic 200 liters drum) place 20kg full of fresh animal manure (poultry litres), 5kg full of fresh brewery spent grain or maize bran and 5 litters of water should be sprinkled on top and mix them together.

Cut the animal offal into small pieces (10cm length) or other flies attractant such as blood, cracked eggs and spread them in the middle on top of the substrate. The flies are attracted immediately to lay eggs. During dry weather, water the prepared tank (drum), using a watering can. Small maggots will be observed about 6 hours later (after first contact of flies with substrate), cover the drum with mosquito net to prevent coming out of maggot from the drum. Water the substrate daily. The drier the weather, the more frequent the watering. Avoid water logging of substrate.

At day 7 after flies contact with substrate the drum should be open and harvesting will be done by sedimentation process where about 15 litters of water should be added into drum to facilitated maggot floatation, floated maggot is then harvested using rubber sieve materials and maggot will then quickly empty into bucket containing clean water to reduce dirty and substrate from maggot. Maggot will later sieved again and fried in a fried pan for 5 minutes to reduce moisture content thereby sterilizing possible microorganisms and later sun dried for 1 hour. About 4 to 6 kg of maggot will be obtained from each drum. The processed maggot will be serve to animals or incorporated into other feed ingredient for fish, poultry, pig and rabbit or packaged in a bag and stored for more than 6 months.

CONCLUSION

Maggot, the larvae of the domestic fly (Musca domestica) has ability to grow on a large range of substrates and this can make them useful to turn wastes into a valuable biomass rich in protein and fat for livestock. Therefore, qualitative and quantitative maggot can be produce without elaborated building structures, equipment, and using available substrate and flies attractant in an area.

ACKNOWLEDGEMENT

The authors wish to thank the management of Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma, Katsina State, especially Micro-Livestock Unit in granting us the privilege to carry out this work.

ABSTRACT
Length-weight relationships and condition factor of *Oreochromis niloticus* in Gubi were conducted to determine the growth pattern and condition of well-being of the fish species in the dam. Four hundred and seventy two (472) fish species were obtained from fishers fishing with 1 inch cast nets between June - November, 2019. *Oreochromis niloticus* obtained in the dam had a total length range (5.5 - 24.5 cm) and weight range (3.1 - 234.45g). The fish species had allometric growth pattern (b = 2.9063). Condition factor range from 0.307502 - 4.38052 with average value of 1.831002 indicating that the fish species population was in good condition of well-being in the dam. Repeating similar research in the dam for other fish species and in other water bodies intermittently is recommended as part of eco-bio - monitoring strategies for developing and implementing conservation programmes.

Keywords: *Oreochromis niloticus*, Length-weight relationships, eco-biomonitoring strategies, conservation

INTRODUCTION

Length-weight relationships (LWR) are of great importance in fishery assessments (Ayoade and Ikulala, 2007). Length and weight measurements in conjunction with age data can give information on the fish stock, age at maturity, life span, mortality, growth and reproduction (Kumar *et al*, 2014). Length-weight relationships of fish is widely recognized as an important tool in fisheries science especially in ecology population dynamic and stock management (Abdoli and Rasooli, 2008).
Fish is said to exhibit isometric growth when length increases in equal proportion with body weight, the regression co-efficient for isometric growth is '3' and values greater than or less than '3' indicates allometric growth (Olurin and Aderibigbe, 2006).

Condition factor is good parameter that shows the wellbeing of fishes in their natural habitat or in aquaculture and it is represented as by the coefficient of body condition. It is an indicator of different biological and ecological factors in relation to fishes feeding habits.

Oreochromis niloticus is a species of tilapia, a cichlid fish native to Africa from Egypt; south to east and central Africa, and as far as west (Gambia). It is also native to Israel (Froese and Pauly, 2015). There is paucity of information on the length – weight relationships in Waya dam.

The effective management of any fishery requires considerable knowledge of population parameters such as length-weight relationships. This relationship is allow estimation of average weight of the fish of a given length group and stressed the importance in modelling aquatic ecosystems (Kulbicki *et al*,. 2005).

MATERIALS AND METHODS

STUDY AREA

The study area is Gubi Dam, Bauchi local government area, Bauchi state. The state is in the Sudan Savannah of the Northern Nigeria. Gubi Dam is located on latitude 10.4203N and longitude 9.8789E with two distinct seasons (dry and wet), with reservoir capacity of 38millions meters cube and with a height of 27m. The dam had total surface area of 179 km^2. It was created from the damming of four converging rivers (Gubi, Makaranta, Ran and Tagwaye) located at Piro, a village about 12 km North-East of Bauchi metropolis and 8 km off Bauchi - Maiduguri road for the primary purpose of providing potable and palatable water to Bauchi and its environs (Ezra and Nwankwo, 2001). The dam lies within

the boundary of longitude 10° 25'N to 10° 26'N and latitude 9° 51' E to 9° 52'E (Wufem *et al*., 2009).

DATA COLLECTION

Four hundred and seventy two (472) *Oreochromis niloticus* were randomly collected with 1 inch cast net from the fishers fishing in the Gubi dam in wet and dry seasons (2020). The fish species were identified using field guide by Olaosebikan and Raji (1998) and FAO (1992).

FISH MEASUREMENT

Total length (TL) and standard length (SL) were measured in centimetres with measuring tape to the nearest centimetre. The weight of the fish species were measured with a top loading weighing balance (model LP502.A) to the nearest 0.0lg.

STATISTICAL ANALYSIS

The length-weight relationships were determined using conventional formula described by Ekeng (1990).

$W = a \times L^b$ …1

Where: W = weight of fish in grams; L = standard length or total length of fish in cm; a = constant; b = an exponent.

The equation wasl therefore be transformed into lnW = lna + blnL Microsoft Excel 2007 was used for the analysis.

CONDITION FACTOR

The condition (k) was determined for each fish using the conventional formula described by Worthington and Richard (1931) as adopted by Afamdi (2009):

$K = 100W/L^3$ …2

Where: K = condition factor; W = weight in grams. **L** = standard length or total length in cm. Microsoft Excel 2007 was used for the analysis.

RESULT AND DISCUSSION

Table 1: Length-weight Relationships Parameters of *Oreochromis niloticus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State 2019.

Species	Range of Length (cm)	Range of Weight (g)	Regression coefficient A	b	Correlation coefficient (r)	Model (W= a x L^b)	±SE	N	Growth pattern
Total Length	5.5 - 24.5	3.1 - 234.45	0.0227	2.9063	0.9391	W= 0.0227X $L^{2.9063}$	0.16	472	A
Standard Length	4.1- 19.6	3.1 - 234.45	0.0757	2.6620	0.8409	W= 0.0757X $L^{2.6620}$	0.26	472	A

N=number of Specimen used, **A=** Allometric, SE = Standard Error

Table 1 shows that four hundred and seventy two (472) *Oreochromis niloticus* with total length range (5.5 - 24.5 ±SE 0.16) and weight range (3.1 - 234.45 ±SE 0.26) were obtained from the dam between June to November, 2019. The fish species had allometric growth pattern (2.9063). This may be due on set of early reproductive cycle of the fish in the dam. Bhatt (2004) reported that most fish attained maturity when they were approximately 10 cm long. Lagler *et al.* (1971) reported that for most fish

the b values are closer to 3. Model equation for length- weight relations of *O. niloticus* was W= $0.0227X\ L^{2.9063}$.

Table 2: Condition Factor Values of *Oreochromis niloticus* from Gubi Dam, Ganjuwa Local Government Area, Bauchi State

Minimum Value	Maximum Value	Average Value	N	Remark
0.307502	4.38052	1.831002	472	Good condition

Condition factor ranges from 0.307502 - 4.38052 with average value of 1.831002 indicating that the fish was in good condition of well-being. Ipinjolu *et al.* (1996) reported that individual condition factor of *Hyperopisus bebe ocindentalis* ranged from 0.69 to 1.10 (0.87$\pm$ 0.08SD) this suggests good nutrition and adaptation to habitat (Table 2). However, this is contrary to the suggestion of Nehemia *et al*.,(2012), who reported that K-values greater than 1 suggests the fish is in good condition and the mean K value found in this research for *O. niloticus* is greater than one.

CONCLUSION

Based on biological analysis *Oreochromis niloticus* had allometric growth pattern and in good condition of well-being in the dam. Model equation for LWR of the fish species: $W= 0.0227X\ L^{2.9063}$ is recommended for predicting weight from length of *O. niloticus*. Repeating similar research in the dam for other fish species and in other water bodies intermittently is recommended as part of eco-biomonitoring strategies for developing and implementing conservation programmes.

ABSTRACT
The study was conducted in Waya dam, Bauchi state, Nigeria to determine the concentrations of heavy metals in bones, gills and muscle tissues of *Oreochromis niloticus*. Nine *O. niloticus* were obtained from fishers fishing in the dam in May, 2018. Fish tissues collected were digested with concentrated HNO_3 and H_2SO_4 according to standard procedures. Heavy metals concentrations (Fe, Cd, Cu, Zn, Pb and Ni) after digestion were analyzed using 210 VGP atomic Absorption Spectrophotometer. The result shows that gills had highest concentrations (1.590±0.767 mg/kg) of Fe and lowest concentrations (0.004±0.001 mg/kg) of Ni. Gills tissues had highest mean heavy metal load than bones and muscle tissues. Mean concentrations of Zn was highest (0.228±0.076 mg/kg) in gills and lowest (0.077±0.076 mg/kg) in bones. Mean concentrations of the heavy metals in *O. niloticus* tissues studied were of the order: Fe>Zn>Cu>Cd >Pb>Ni. The mean heavy metal concentrations obtained in the study indicated that the fish species was safe for human consumption. It is recommended to periodically monitor the concentrations of heavy metals in Waya dam and in similar water bodies in order to prevent possible related health hazards.

INTRODUCTION
Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein of hundreds of millions of the populace (Ayo-olusi, 2014). The aquatic environment with its water quality is considered the main factor controlling the state of health and diseases in both cultured and wild species (Olusola and Festus, 2015). Malik *et al*.(2010) stated that, pollution of heavy metals in aquatic ecosystem is growing at an alarming rate and has become an important worldwide problem. This situation has arisen as a result of the rapid growth of population, increased urbanization and expansion of industrial activities, exploration and exploitation of natural resources, extension of irrigation and other modern agricultural practices as well as the lack of or poorly enforced environmental regulation (Idowu, 2004). An increase in agricultural and human activities in an area directly influences the quality of water. Fish in water bio-accumulate heavy metals through different gateways including intake of food and water, suspended particulate matter as well as metal ion exchange through gills and skin (Ibemenuga, *et al*., 2019). Heavy metals cause the mutation of fish inner organs, disturb immune reactions, change blood parameters, reduce an organism's adaptation qualities, vitality and resistance to diseases (Staniskiene, *et al*., 2006).

In Nigeria, the levels of toxic and non-biodegradable heavy metals in fish samples had been reported for some water bodies including River Niger, Onisha shelf, Anambra state (Ibemenuga, *et al.*, 2019), Njuwa Lake, Adamawa sate (Ibrahim *et al*.,2018), Coastal waters of Ondo state (Olusola and Festus, 2015). The target tissues of heavy metals in fish are metabolically active ones which accumulate high level of metals such as liver, kidney and gills, while muscles and skins accumulate less level of metals due to low metabolic activities (Ekpo *et al*., 2013).

The present study investigates the accumulation of iron (Fe), cadmium (Cd), lead (Pb), zinc (Zn), nickel (Ni) and cupper (Cu) in the gills, bones and muscles of *Oreochromis niloticus*, as well as levels of the temperature and pH of water in the dam.

MATERIALS AND METHODS

STUDY AREA

Waya dam is a medium sized earth dam located in Ganjuwa Local Government Area of Bauchi State, Nigeria. The dam is twenty five kilometers (25km) away from Bauchi town. It lies within latitude 10.30982^{o}N and longitude 9.84517^{o}E. It has a reservoir storage capacity of thirty million cubic meters (30cm^{3}). Its embankment has features which include width: 96m, crest width: 6m, crest length: 370m and elevation: 505m (Isma'ila, 2014). Subsistence and commercial fishing activities are carried out on the dam.

SAMPLING AND WATER QUALITY PARAMETERS

Samples of nine *O. niloticus* were obtained from fishers fishing in the dam in May, 2018. Temperature and pH were measured using Potable digital meter (Model: PH 009 (1) Pen type) within the sampling period.

PREPARATION AND ANALYSIS OF HEAVY METAL IN FISH TISSUES

The fish samples were washed and dissected to remove gills, bones and muscles. The tissues were thoroughly washed and placed in labeled plastic bottles rinsed with nitric acid. The tissues were oven dried at 105°C, until dry and constant weight was obtained after which they were separately grinded with laboratory mortar and pistil.

DIGESTIONS

Grinded fish tissues collected were digested with concentrated HNO_3 and H_2SO_4 according to procedures recommended by AOAC (2002).

Heavy metals concentrations(Fe, Cd, Cu, Zn, Pb and Ni) after digestion were analyzed using 210 VGP atomic Absorption Spectrophotometer at the Faculty of Engineering, Abubakar Tafawa Balewa University Bauchi.

STATISTICAL ANALYSIS

Data of fish samples were presented as mean ± standard error (SE) and analyzed with SPSS version 25 (SPSS, IBM.2017).

RESULTS

Table 1: Temperature and pH of Waya Dam (May, 2018).

Portions	Temperature	pH
Upper	36.9	6.5
Middle	35.3	6.0
Tail	37	5.9

Waya dam water temperature values recorded in the month of May, 2018 were Upper (35.3^{o}C), Middle (36.9^{0}C) and Tail (37^{0}C) (Table 1). The pH values were 6.5, 6.0 and 5.9 for Upper, Middle and Tail portions of the dam respectively.

Table 2: Mean ± SE of heavy metals concentration (mg/kg) in some tissues of *Oreochromis niloticus* from Waya dam, Bauchi (May, 2018).

Tissue	Fe	Cu	Zn	Pb	Cd	Ni
Bones	0.273±0.767	0.058±0.030	0.077±0.076	0.013±0.003	0.005±0.006	0.006±0.001
Gills	1.590±0.767	0.013±0.030	0.228±0.076	0.009±0.003	0.013±0.006	0.004±0.001
Muscles	0.250±0.767	0.001±0.030	0.170±0.076	0.007±0.003	0.018±0.006	0.005±0.001

Iron concentration ranged from 0.250±0.767 mg/kg in muscles to 1.590±0.767 mg/kg in gills. Copper concentration was from 0.001±0.030 mg/kg in muscles to 0.058±0.030 mg/kg in bones .Concentration of Zinc was from 0.077±0.076 mg/kg to 0.228±0.076 mg/kg in gills while Lead ranges from0.007±0.003 mg/kg in muscles to 0.013±0.003 mg/kg in bones. Cadmium ranged from 0.005±0.006mg/kg in bones to 0.018±0.006mg/kg in muscles and Nickel ranged from 0.004±0.001mg/kg in gills to 0.006±0.001mg/kg in bones. However, Iron was the most accumulated metal while the least was Nickel.

DISCUSSION

Waya dam water temperature values recorded in the month of May, 2018 were 35.3^{o}C, 36.9^{0}C and 37.0^{0}C for upper, middle and tail portions of the dam respectively (Table 1). The temperature recorded in the tail water may be suitable for fish growth and reproduction. Temperature affects the distribution, health, and survival of aquatic organisms (CWT, 2004). The water temperature range in Waya dam is within the range of 10°C - 50°C for river and dam water meant for domestic purposes and fish culture in tropical waters (WHO, 1984; Huett, 1977). The water pH values of Waya dam in May, 2018 were slightly acidic(5.94 - 6.5), This may be as a result of horticultural activities prominent around the dam that might have led to run off of fertilizers into the dam water. The lowest value of pH was recorded at the tail portion (5.94) of the dam. Aquatic organisms accumulate heavy metals from water and food either by absorption or ingestion (Ibemenuga *et al*. (2019). Fish bio-accumulate heavy metals, thus act as good bio-indicators of pollution (Ibemenuga, 2013). In the tissues of *O. niloticus* studied, the metals were bio-accumulated to varying levels. Iron was present in fish tissues in the highest concentration while Nickel in lowest quantity (Table 2). Ibrahim and Sa'id (2010) and Monday and Nsikak (2007) recorded highest concentration of Zinc in the muscles of Tilapia species they studied.

Gills tissues had higher mean metal load than bones and muscles tissues. Jobling (1995) attributed the high accumulation of heavy metals in gills tissues to the metallothionein proteins which are synthesized in liver and gills tissues when fishes are exposed to heavy metals and detoxify them. Cadmium and Lead are toxic non-essential heavy metals even at low concentrations and have no known biological functions (Bernad, 2008 and Tchounwou *et al*., 2012).

In this study mean concentration of Zinc was highest (0.228±0.076mg/kg) in gills and lowest (0.077±0.076mg/kg) in bones unlike Ibemenuga *et al*. (2019) who reported that mean concentration of Zinc was highest in the intestine and lowest in the muscle. Goel (2006) observed that fish and other organisms that respire through the gills can absorb metals through their respiratory surfaces. However, the mean metal concentrations obtained in the study indicated that the tissues are safe for human consumption as the heavy metals concentration in the tissues of *Oreochromis niloticus* studied were below the permissible limit according to FAO (2003).

CONCLUSION

The results obtained in the study, indicated that Waya dam was contaminated to varying levels of heavy metals. Gills were the highest metal accumulated tissue followed by bones and then muscles. Heavy metals concentration in the tissues of *Oreochromis niloticus* studied were below the permissible limits; therefore, the fish species is safe for human consumption.

RECOMMENDATIONS

It is recommended to be periodically monitoring the concentration of heavy metals in Waya dam and similar water bodies in order to prevent health hazards.

ABSTRACT
Macroinvertebrates of Gubi dam, Ganjuwa Local Government Area, Bauchi state, Nigeria was studied with the aim of understanding their diversity and abundance. Macrobenthic samples were randomly collected in the month of January, 2018 at three different locations: Head water (Tatumari station), Middle water (Polo station station) and Tail water (Spill way station) using standard method. The samples collected were identified with the aid of microscope in a well illuminated laboratory and later referred to monograph for comfirmation. The individual abundance was expressed in percentages and biodiversity indices were determined. The results showed that 105 individual benthic invertebrates belonging to 7 orders and 8 families were identified. Hemiptera had two families while Neotaenioglossa, Diptera, Plecoptera, Coleoptera, Odanata, and Ephemeroptera had one family each. *Aquarius remigis* (43) and *Goniobasis livescens* (29) were the most abundant benthic invertebrates caught in Gubi dam while the least abundant species were *Ranatra elongata* (2.86), *Dytiscus marginalis* (2.86) and *Tanytarsus sylvaticus* (0.95). Spillway had more individuals benthic fauna (40) than Tatumari (33) and Polo (32). The benthic invertebrates were evenly distributed (E=0.75). It is recommended that physicochemical parameters of the dam be studied. Also similar research should be carried out in more water bodies in Nigeria.

Keyworsds: Macrobenthic, Abundance, Biodiversity indices, Physicochemical, *Aquarius remigis*

INTRODUCTION
Macrobenthic invertebrates can be found in aquatic environment from small pond to large lakes. Within a water body, aquatic invertebrates inhibit a variety of habitats. In lotic they occur under stones or woody debris, buried in sand or sediment and crawling or sprawling on rocks, leaf packs and snags (Bouchard, 2004). Benthic invertebrates in freshwater can be used as indicators of changes in water quality. They also form an important part of the aquatic ecosystem food chain especially for larger animals (Uwadiae, 2010). They play a vital role in the circulation and recirculation of nutrients in aquatic environment.

According to Mooraki *et al*. (2009) rivers act as an important ecosystem that maintains the coastal biota and thus, is high in productivity and serve as nursery and breeding ground for many organism that occupies it. Pond fertilization enhances algae growth and produce macroinvertebrate suitable for larval fish. Several studies in Nigeria have investigated benthic invertebrate communities especially in some specific rivers: Anambra River (Eyo and Ekwonye, 1995), (Ogbeibu and Egborge, 1995) and Ogba River (Olumukoro and Okologume, 2008).

Invertebrate communities change in response to changes in physicochemical factors and available habitat. Chatzinikolaun *et al*. (2016) stated that human induced hydrological changes and other physical disturbances like habitat alteration, urban land use, chemical contamination, surface run-off, intensive agriculture and so on are examples of processes responsible for a broad scale deterioration of lotic ecosystems. The abundance of benthic fauna greatly depends on physical and chemical properties of the substratum.

Elias *et al*. (2014) stated that in tropical African regions, researches on the status and trends of freshwater macroinvertebrates in rivers have not been given much attention compared to non-tropical regions. It became necessary and important to study benthic invertebrates abundance and diversity because of the role they played as bioindicators of specific environment and habitat conditions. Increased anthropogenic activities increases pollution and causes varying degree of damage to the benthic ecosystem. Danladi *et al*. (2013) stated that highlighting the abundance of invertebrates in lotic and lenthic water bodies is paramount as they provide useful information on natural and anthropogenic disturbance gradients.

There is very scanty information on the composition and abundance of macro invertebrate in Gubi dam. Therefore, the goal of this research is to identify the macroinvertebrates present in the dam and to determine their composition and abundance as well as the diversity indices of macrobenthic invertebrate in the dam.

MATERIALS AND METHODS

STUDY AREA

The study was carried out in Gubi dam, Ganjuwa Local Government, Bauchi State, Nigeria. Gubi dam lies within 9° 5' 30" E and 10° 24' 32" N. The embankment of the dam have a length of 3.86 km. The area has two distinct seasons; a short (June-September) wet season and a long (October-May) dry season.

SAMPLING PROCEDURE

Macrobenthic samples were randomly collected in the month of January, 2018 at three different locations: Head water (Tatumari), middle water (Polo) and tail water (Spill way) in the dam, according to the method described by Andem*et al*. (2012). The collected samples were sorted into different groups and preserved in 10% formalin solution.

IDENTIFICATION OF FISH SPECIES

The samples collected were identified with the aid of microscope in a well illuminated laboratory using a magnifying glass and later referred to a combination of monographs (Batchellar, 2017; Danladi*et al.,* 2013 and 10WATER, 2005) for confirmation**.**

DATA ANALYSIS

The individual abundance of macrobenthic invertebrate was expressed in percentage composition of each order.

STATISTICAL ANALYSIS

The macrobenthic data obtained were subjected to diversity indices to determine: Shannon index (H`), Evenness (E), Simpson`s dominance index (D) and Margalef`s diversity index (d) using the following diversity indices formulas (Ogbeibu, 2005)

Shannon index (H') = $\sum (\frac{n}{N})\text{In } (\frac{n}{N})$ . . . i

Where n = number of abundance of each species in the sample

N = total number of all species in the sample.

Evenness index (E) = $\frac{H'}{InS}$ . . . ii

Where S = number of distinct order in all the samples

Simpson's species dominance (D) = $\frac{S}{\sqrt{N}}$ . . . iii

Margalef's diversity index (d) = $\frac{S-1}{In\ N}$ . . . iv

RESULTS

Composition and abundance of macrobenthic invertebrates collected in Gubi dam were showed in table 1. A total of 105 individuals benthic invertebrates belonging to 7 orders and 8 families were identified. Hemiptera had two families while Neotaenioglossa, Diptera, Plecoptera, Coleoptera, Odanata, and Ephemeroptera had one family each. *Aquarius remigis* (43) and *Goniobasis livescens* (29) were the most abundant benthic invertebrates caught in Gubi dam while the least abundant species were *Ranatra elongata* (2.86), *Dytiscus marginalis* (2.86) and *Tanytarsus sylvaticus* (0.95). Spillway had more individuals benthic fauna (40) than Tatumari (33) and Polo (32).

Diversity indices of benthic invertebrates in the study area were in Table 2. Simpson's, Shannon, Evenness and margalef's indices were 0.26, 1.56, 0.75 and 1.50 respectively.

Table 1: Composition and Abundance of Macrobenthic invertebrates in Gubi dam

Order	Family	Species	Location And Abundance			Total(%)
			Head water (Tatumari)	Middle water (Polo)	Tail water (Spillway)	
Hemiptera	Gerridae	*Aquarius remigis*	16	18	9	43(40.95)
	Nepidae	*Ranatra elongata*	2	0	1	3(2.86)
Neotaenioglossa	Pleuroceridae	*Goniobasis livescens*	4	7	18	29(27.62)
Diptera	Chironomidae	*Tanytarsus sylvaticus*	0	1	0	1(0.95)
Plecoptera	Perlidae	*Acroneuria carolinensis*	2	3	0	5(4.76)
Ephemeroptera	Baetidae	*Baetis bicaudatus*	4	1	1	6(5.71)
Odonata	Gomphidae	*Paragomphus genei*	4	0	11	15(14.29)
Coleoptera	Dytiscidae	*Dytiscus marginalis*	1	2	0	3(2.86)

Table 2: Diversity and Dominance Indices of Benthic invertebrates in Gubi Dam

Parameters	Values
Margalef's species richness (d)	1.50
Evenness index (E)	0.75
Shannon index (H')	1.56
Simpson's index (D)	0.26
Simpson's reciprocal index (D')	3.78

DISCUSSION

A total of 8 species comprising of 105 individuals shared within 7 orders and 8 families were recorded in this study. The species diversity of the macrobenthic organisms in the dam were less diverse compared to those reported by Asibor (2015) in Asijire reservoir, similarly, it also varied from a total of 19 species belonging to 4 phyla, 6 classes and 12 families identified by George *et al*. (2009) at Okpoka creek and 28 species identified by Ezekiel *et al*. (2011) at Sombreiro River, Niger Delta. These differences are attributable to difference in location, time, nutrient availability and prevailing physical and chemical characteristics of these aquatic bodies Iyagbaye*et al*. (2017).

Hemipterans were presence at all the 3 sampling stations and were the most abundant macrobenthic encountered. Diptera appeared only in Polo sampling station. Orders recorded at the tail water (Hemiptera, Neotaenioglossa , Ephemeroptera and Odonata) were fewer when compared with those at the head water (Hemiptera, Plecoptera, Ephemeroptera, Neotaenioglossa, Odonata and Coleoptera) and the middle water (Hemiptera, Diptera, Neotaenioglossa, Ephemeroptera, Odonata and Coleoptera), this could be as a result of great waste discharge in the tail water due to more intense human activities.

Higher diversity results when many species have equal or near-equal opportunity to co-exist. Mckintosh (2000), in support of this, observed that in the absence of disturbance, community composition may be strongly influenced by abiotic interactions such as competition and predation. Simpson's dominance index in this study was low (0.26). Evenness value was 0.75 indicating that the benthic invertebrates were evenly distributed. The high evenness and low dominance indices in this study indicates high diversity of benthic invertebrates in Gubi dam, since the higher the evenness the higher the diversity, and the lower the dominance index, the higher the diversity(Ogbeibu and Victor,1989). Shannon index was 1.56 and species richness was better (1.5).

CONCLUSION

A total of 105 macro benthic invertebrates represented by seven (7) orders and eight (8) families were recorded in Gubi dam. The benthic invertebrates were diverse with *Aquarius remigis* dominating the total catch. It is recommended that physicochemical parameters of the dam be studied. Also similar research should be carried out in more water bodies in Nigeria.

ABSTRACT

This review investigated the effect of feed form and feeding frequency of *Clarias gariepinus* fed floating and sinking pellet feeds, growth performance of *Clarias gariepinus* fed fish feeds, similarly to evaluate growth of *C. gariepinus* fed 5 difference commercial feeds. Fish fed with floating pellet had highest Final Weight Gain with the value of 9.50g than those fed with sinking pellet feed with the value of 8.98g. Final Weight Gain and Daily Feed Intake of *C. gariepinus* fed floating or sinking pellet feed fed twice a day and thrice a day were significantly higher than those fed once a day ($p < 0.05$). There were significant difference ($p < 0.05$) in Specific Growth Rate (SGR) with value of 2.79 and Protein Efficiency Ratio (PER) with value of 1.97 in *C. gariepinus* fed Aqua and Rana feeds. Furthermore, there were significant difference ($p < 0.05$) in the survival rate of the fish species fed Coppens (93.33%) while lowest (46.67%) in *C. gariepinus* fed with Aqua feed. *C. gariepinus* juvenile fed with Coppens, Multifeed and Eurogold with Final Mean Weight value of 181.54, 179.92, 0.95 and 139.92 respectively, while Final Mean Weight for Vital and Ajanla were 110.1 and 119.03respectively. Fish fed with Coppens had the highest SGR (3.19%) and lowest (2.71%) in those fed with Eurogold feed. *C. gariepinus* can be fed floating and sinking pellet feeds twice or thrice per day for optimum growth. *C. gariepinus* should be fed with feed that have macronutrient composition 7of 45% crude proteins, 12% crude fat, 1.5 crude fiber and 9.5% Ash in order to promote better growth.

INTRODUCTION

Catfish (*C. gariepinus*) are the major commercial culture species in Nigeria for good market reasons. Since 2000 there had been a rapid expansion in urban aquaculture and a significant increase in catfish culture (Anetekhai *et al., 2004*).

Optimal feeding for fish species especially African catfish was yet to be clearly defined and this had led to uncertainty in the feeding routines used by many farmers. Under feeding can be detrimental to the health of the fish and may cause reduction of weight and poor feed utilization. This will increased susceptibility to infection (Priestley *et al., 2006*). Specific growth rate (SGR) and the efficiency of feed conversion as have been observed to be directly related to feed ration and frequency of feeding (Dwyer *et al., 2002*). This study aimed to find the appropriate feeding frequency for optimum culture of *C. gariepinus* and to assess the impact of feed type/forms on the growth quality of fish seed production and assessment of *C. gariepinus*.

MATERIALS AND METHODS

EXPERIMENTAL FISH, REARING CONDITIONS AND FEEDING TRIAL

Two hundred and twenty five fish *Clarias gariepinus* were obtained from a local hatchery in Ibadan, with average weight of 3.12 ± 0.04g. They were stocked into 15 (60-liter) aquaria each holding 15 fish. Five feeds: Coppens (T1), Aqua (T2), Ranna (T3), Pira (T4) and Durante (T5) were used for this study.

Experimental trial was conducted at the laboratory of Bowen University, Iwo, Nigeria. A total of 360 *C. gariepinus* fingerlings were used. Three feeding frequencies were adapted, two different feed forms (floating and sinking pellets) were used, thus giving a total of 6 treatments.

Research on feeding trial were also carried out at the family testing unit of ARAC Nigerian limited. Some 500 nine week old *C. gariepinus* juveniles were purchased from Belem fish farm, Port Harcourt.
A completely randomized design was used with 5 treatments (commercial catfish feed): Coppens, Multifeed, Eurogold, vital and Ajanla feeds and 3 replicates per treatment.

GROWTH PARAMETERS
Growth performance of the fish was determined following the methods adapted by Ajani *et al.* (2011).

Measurement of weight and the survival of *C. gariepinus* Fingerlings/Juveniles
Weights of fingerlings were determined at the beginning of each treatment and subsequently at weekly intervals basis. Electronic digital weighing scale: ACCULAB model meter balance 2000 was used for measuring the weight of the fish species (Ajani *et al.* (2011).

STATISTICAL ANALYSIS
Data collected were subjected to analysis of variance (ANOVA). Significant difference means ($P< 0.05$) were separated using Duncan's New Multiple Range Test (Duncan). The statistical analysis was done using SPSS (Windows version 15.0).

RESULTS AND DISCUSSION
Table 1: Growth Performance and survival of *C. gariepinus* fish fed floating and sinking pellet once, twice and thrice/day

	Floating Pellet			**Sinking Pellet**		
	1x	2x	3x	1x	2x	3x
Mean Initial Wt(g)	3.03±0.05	3.10 ± 0.02	2.97±0.57	3.15 ±0.06	3.05±0.41	3.00 ±0.18

Mean values with different superscript along each row are significantly different from each other ($P<0.05$). Source: Ajani *et al.* (2011).

Table 1 revealed that the floating pellet feed fed thrice a day had the highest mean weight gain with the value of 12.44±2.31 while sinking pellet feed fed thrice per day had the lowest mean weight gain with value of 11.96±4.05. The highest final weight gain recorded in the fish species fed floating pellet feed fed to *Clarias gariepinus* had the highest with the value of 12.44±2.31 while The lowest final weight gain in fish species fed with sinking pellet feed fed thrice per day may be attributed to nature of feed types. Ajani *et al.* (2011) noted that floating pellets float on the water and doesn't disintegrate easily like sinking pellet feeds.

Table 2: Growth performance and survival rates of *C. gariepinus* fed different feed brand

	Treatments				
	Aqua	Coppens	Durate	Pira	Rana
Initial Weight	3.12 ±0.2	3.12 ±0.1	3.1 ±0.1	3.11± 0.2	3.10 ±0.2
Final Weight	57.18 ±4.05	33.38 ±33.2	39.28 ±3.64	42.93 ±3.72	24.82±2.57
Weight Gain	54.07 ±4.37	30.26 ±2.46	36.17 ±3.54	39.83±3.86	21.73±2.30
Percentage Weight Gain	1734.87±142.28	969.77^{bc}±100.32	1165.88^{b}±106.87	1282.07±110.09	704.01±80 a
Specific Growth rate	2.79^{a} ±0.76	2.25^{b} ±0.32	2.41^{b} ± 0.43	2.51^{b}±0.46	1.97^{a} ±0.21

Survival Rate	46.67^{c} ±2.46	93.33^{a} ±3.24	57.78^{c} ±3.76	91.11^{ab} ±2.55	62.22^{b}±3.65

Source: Ajayi *et al.* (2016).

The initial weight gain of *C. gariepinus* fed Aqua feed had the highest final weight gain with value of 57.18g while the fish species fed Rana feed had the lowest final weight gain with the value of24.82±2.57. No significant difference existed among Coppens, Dorante and Pira. The best feed was Aqua with feed conversion ratio and protein efficiency ratio values of 1.69 and 1.49 respectively.

There was no significant difference in FCR among Aqua, Durante and Pira. Feed fed with Coppens (table 2). Booth *et al.,* (2008) observed that different feeding regime doesn't not have a significant effect on weight gain.

Proximate composition *C. gariepinus* fed with Coppens, Multifeed, Eurogold, Vital and Ajanla and Multifeed had the highest percentage C.P with the value of 45% while vital had the lowest percentage C.P value of 38%. The crude lipid content of Coppens and Multifeeds had the highest with the percentage value of 12% while Ajanla had the lowest with the percentage value of 8%.A significant difference was observed in the percentage fat and ash content recorded from carcass of the fish fed different feed types feed brands. It may be due to losses due to volatisation between constituents (Micheal *et al.,* 1995).

Another feeding trial carried out indicated that Aqua had the highest final weight gain with the value 1734.87g while the Rana had the lowest final weight gain. There were no significant difference existed among Coppens, Dorantea and Pira. There were significant differences in the FCR among feed type with Rana feed brand. According to Haulihan *et al.* (2001) FCRs should never go above 2. According to the author opined that FRC vary with fish species, activity levels of fish and culture system.

Proximate composition in Coppens, Multifeed, Eurogold, Vital and Ajanla indicated that vital feed lowest C.P The crude lipid content of Coppens and Multifeeds had the highest value of 12% while Ajanta had the lowest value. According to Agokei (2011) significant highest growth performance of *C. gariepinus* was found in the diet that contained < 2% fibre content. This could be due to inability of the fish species to digest and utilized high content in the feed. Alam *et al.,* (2012) reported that ash content in the feed of *C. gariepinus* should not be less than 8%.

Growth performance of similar feeding trial indicated that Coppens feed fed to *C. gariepinus* had the highest final weight gain while the vital had the lowest final weight gain. Earlier worked of Fagbenro *et al.* (1992) ascertained that African cat fish tend to require at least 40% crude protein. Specific growth rate (SGR) was highest for fish fed Coppens but was not significantly different from SGR for fish fed Multifeed.

CONCLUSIONS

There was no significant difference in final weight gain in *C. gariepinus* fed floating and sinking pellet feeds although fish fed floating pellet feed exhibited higher final weight gain. It was also revealed that floating pellet feed can be fed to *C. gariepinus* three times a day for optimum growth while the best feeding frequency for sinking pellet feed in order to obtain optimum growth for *C. gariepinus* were twice and thrice per day.

Macronutrient combinations with 45% CP, crude fat, 12%, crude fibre 1.5% and Ash 9.5% will promote higher growth rates of *C.* gariepinus than other feed ingredients combination in the diets of the juvenile fish species.

ABSTRACT

This study was aimed at investigating some biological aspects of *Clarias gariepinus* Cought in River Gwallaga Bauchi state. The river was divided into four stations: head water (Jamaa), upper middle (Rafin Shaa), and lower middle (Maleka) and tail water (Jamjale) as stations A, B, C and D respectively. Ten (10) *Clarias gariepinus* were caught fortnightly from each station during the dry season (February - April 2019) and wet season (May – August 2019). A total of 480 fish were collected during the period of the research. Morphometric indices of the fish were measured. The fish were dissected, gut length and stomach weight were measured and stomach content were identified. The data obtained were used to determine morphometric relationships through correlation and regression analysis, using Microsoft Excel 2007 version. The stomach content analysis of *C. gariepinus* revealed Plant Parts had the highest importance index of 50.37 in the dry season and 28.81 in the Wet season out of the five feed items found in the stomach. Chi-square (X^2 =29.27; df = 12 P> 0.05) (X^2 18.20; df = 9; P> 0.05) showed that there was association between stomach repletion of the fish and the stations from which they were caught in wet and dry Seasons respectively. The average condition factor (K) of fish from station A (K = 0.6818), B (k = 0.5458), C (K = 0.8132) and D (k = 0.5510) for dry season and wet season: A (K = 0.526758), B (k = 0.589765), C (K = 0.738035) and D (k = 0.725151). All the K-value were less than 1; It can be concluded that *C. gariepinus* caught in River Gwallaga were not in good physiological condition and association between fish stomach repletion level and station from which they were caught; shows that feed items in the fish stomach was inadequate. Therefore, it is recommended that fertilization and some form of supplementary feeding practice should be carried out particularly in the dry season.

INTRODUCTION

Fisheries management and research often require the use of biometric relationship in order to transform data collected in the field into appropriate indices (Ecoutin and Albarel, 2003). Length and Weight Relationships (LWR) of fishes are important in fisheries and fish biology because they allow the estimation of the average weight of the fish of a given length group by establishing a mathematical relation between them (Sarka *et al*., 2008; and Mir *et al*., 2012). Length–weight relationship (LWR) is an important expression and plays paramount role in fishery biology as it serves several purposes. Like any other morphometric characteristics, the LWR can be used as character for differentiations of taxonomic unit on the relationship changes with various developmental events in life, such as metamorphosis at onset of maturity (Thomas *et al.,* 2003). Fishes exhibited growth in length and the increments in weight, both this developmental activities during it lifetime. It is very important to have information on the food and feeding habits of fish in fresh water bodies especially River Gwallaga that is located within Bauchi metropolis. The River is exposed to various sources of pollutants and effluence from residential areas surrounding it.

MATERIALS AND METHOD

SAMPLING TECHNIQUES AND STOMACH CONTENT ANALYSIS

Field visit were carried out fortnightly. Two (2) out of four station (4) (A, B, C and D) were randomly visited twice a week. Ten (10) *C. gariepinus* was collected with the help of local fishers using traditional fishing gear (Traps and Long Lines). A total of 480 *C. gariepinus* species were collected from the four stations within the period of wet and dry seasons during (Three months per seasons). Total Length of sample fish was measured to the nearest 0.1cm using measuring tape.

A total of ten (10) *Clarias gariepinus* were dissected from each station per visit. The gut were removed and measured, stomach content were placed in a petri dish and were assessed with hand magnifying lens, the feed items consumed by *Clarias gariepinus* were identified in dry season (February, 2019 to April, 2019) and wet season (May, 2019 August, 2019). Stomach repletion were indicated as 0% for empty, 1, 2, 3 and 4 for 25%, 50%, 75% and 100% respectively.

Volumetric index, Gravimetric index, Frequency of occurrence importance index and condition factor (K)

Mi = Σ [stomach score * (1/number of feed item in the stomach)/(total number of analysed stomach)

VI = 25 x M 01

Where Mi average point of each feed item identified

Gravimetric index formula:

GI = wi/w x 100 02

Where wi is cumulative weight of individual feed items and w is the total weight of all the feed items.

Wi = is cumulative weight of individual feed items.

W = is total weight of all the feed items.

Frequency of occurrence formula (F):

F = ni/n x100 03

Where ni is the number of stomach were each feed items is found and n is the total number of stomach where feed items were found.

Importance Index (AI):

AI = (F x VI x GI)/ 1000. 04

Condition Factor (K)

The condition factor will be calculated using the formula:

Condition factor (K) = $100W/L^3$ (Pauly, 1984)
..... 05
Where
W = Weight of fish (g)

L = Total body length of fish (cm)

Statistical Analysis

Correlation and regression analysis were carried out using Microsoft Excel 2007 version to determine the LWR of *Clarias gariepinus* in River Gwallaga.

Results and discussion

Table 1: Stomach content analysis of *C. gariepinus* in (Dry Season) (February – April, 2019)

Feed Items	Frequency of occurrence (F)	Volumetric index (V)	Gravimetric Index (GI)	Importance index (AI=(F,V,GI)/1000)	RANKING
Plant Parts	58.47	17.50	49.23	50.37	1
Insect/Insect Parts	33.98	7.75	19.23	5.06	2
Fish/Fish Parts	10.68	4.75	24.24	1.22	3
Water	6.31	1.50	3.32	0.03	4
Unidentified	3.88	1.25	3.95	0.01	5

Table 1 shows that Plant Part had the highest importance index with the value of (50.37) while unidentified had least importance index with the value of (0.01) foods items.

Table 2: Condition Factors of *C. gariepinus* in Dry Season (February – April, 2019)

S/No	Sampling Stations	Condition Factor (k) Values Minimum	Maximum	Average
1.	Jamaa (A)	0.2840	2.2263	0.6818
2.	Maleka (B)	0.2171	0.9985	0.5458
3.	Rafin Shaa (C)	0.2166	2.3900	0.8132
4.	Jamjale (D)	0.2462	1.1425	0.5510

Table 2 shows that *C. gariepinus* obtained in Rafin Shaa (C) had the highest value of (0.8132), followed by Jamaa (A) and the least value of (0.5458) was in Jamjale (D) dry season.

Stomach content analysis of *C. gariepinus* in River Gwallaga in dry and wet season indicated that the fish species feeds on Plant Part, Insect/Insect Part, Fish/Fish Part, Water and unidentified feed materials. Plant Part had the highest importance index with the value of (50.37) while unidentified had least importance index with the value of (0.01) foods items (table 1).

Condition factor (K) *C. gariepinus* obtained in Rafin Shaa (C) had the highest value of (0.8132), followed by Jamaa (A) and the least value of (0.5458) was in Jamjale (D) dry season (table 2). Reported that the study of condition factor is important for understanding the life cycle of fish species and it contribute adequately to management of species which will lead to achieving equilibrium in the ecosystem Lizama *et al.* (2002).

CONCLUSIONS

Based on the research the morphometric indices relationships shows a negative allometric growth pattern in the fish species. The food items consumed by *C. gariepinus* in River Gwallaga were identified as plant parts, insect/insect parts, fish/fish part, water and unidentified. The condition factor of the fish species in River Gwallaga being less than 1 indicated that they were in poor condition.

ABSTRACT

Wastes from poultry and fish processing plants whose disposal presently raises a major environmental concern may be a source of animal protein in fish diet, if properly processed. This study was carried out to determine the apparent digestibility coefficients (ADCs) of nutrients in differently processed poultry and fish offal for *Clarias gariepinus*. A reference diet (R) was formulated to contain 40% crude protein. Test diets contained 70% reference diets and 30% of test ingredients, with chromic oxide as the inert marker. The test diets were poultry offal paste with wheat offal as carrier (P1), oven-dried poultry offal (P2), autoclaved poultry offal (P3), autoclaved fish offal (F1), oven-dried fish offal (F2) and fish offal paste with wheat offal (F3). A total of 315 African catfish, *Clarias gariepinus* juveniles (average weight; 5.50±0.50 g) were randomly distributed into 21 plastic tanks of dimension 0.42m x 0.29 m x 0.25m at 15 fish per tank. Diets R, P1, P2, P3, F1, F2 and F3 were fed to triplicate groups of fish twice daily at 5% body weight for 8 weeks and excess feed siphoned out 30 minutes after each feeding. Faecal collection was done 8 hours after every feeding and pooled for each treatment for chemical analysis. Apparent Digestibility Coefficients of nutrients varied significantly across treatments ($p<0.05$). ADC of crude protein was highest in F3, fish offal paste/wheat offal (78.63%) and lowest in F1, Autoclaved fish offal (65.83%). ADC lipid was highest in F3 (81.37%) followed by F2, oven dried fish offal (80.54%) and F1 (73.94%). ADC of phosphorus was highest in F2 (97.27%) followed by F3 (86.71%) and least in F1 (81.27%). The result of this study reveals that fish offal subjected to oven drying and the one blended with wheat offal showed high nutrient digestibility and therefore, can be utilized as protein source in the diets of *Clarias gariepinus*.

Key Words: *Clarias gariepinus*, Poultry Offal, Fish Offal, Processing, Digestibility

INTRODUCTION

Nutrition plays a critical role in intensive aquaculture as it influences not only the production cost but also fish growth, health and waste production (Gatlin, 2002). For profitability and success in fish farming, ingredients for feed production must be readily available and cheap to produce diets that are cost-effective. Similarly, the bioavailability of nutrients in ingredients is very crucial for successful fish nutrition. The conventional feed ingredients for fish are mainly from plant and animal products especially by-products of processing plants. Some of these products are also used as human food (SRAC, 2010). Feed is the single most expensive factor in aquaculture production and the protein component of fish diet constitutes the highest cost, this is because the fishmeal that supplies the bulk of the protein is very expensive (Aniebo *et al.*, 2009). The proportion of protein in fish diets is higher than those of other cultured animals, thus making feeds very exorbitant (Aniebo *et al.*, 2009). Depending on the stage of growth, studies have shown that the African catfish requires between 35-50% crude protein in their diet, with resultant cost implication (Wilson and Moreau, 1996; Adebayo and Quadri, 2005). For sustainable and profitable fish farming, there is therefore a pressing need to reduce feed cost through the use of locally available, cheap and accessible materials.

Wastes generated from poultry and fish processing are potential protein source for cultured fish. In Nigeria, there is a rapid expansion of small and medium-scale poultry farms with huge amount of

waste generation. Similarly, the fish processing industry generates wastes consisting of discarded parts (internal organs such as liver, heart, kidney, eggs, gills, and gonads, bone and sometimes head) which are not fit for human consumption. The huge quantity of wastes has caused some serious environmental havoc such as vectors for insects, vermin, bacteria, and viruses, which may result in water contamination (leaching of nutrients and pathogenic microorganisms) and air pollution (FAO, 2011). However, instead of being wasted and dumped, they can be utilized to produce fish feed and indirectly helps towards a greener environment.

The utilization will however require some form of processing, as feeding of fresh fish offal to fish was reported to cause mycobacteriosis (Francis-Floyd, 2011). The reduction or elimination of pathogens is mostly achieved through heat treatment (Sauli *et al*., 2005), as it is simple and easy to adopt among local farmers. They however do have the potential to damage useful nutrients if appropriate processing technique is not applied (Papadopoulos, 1989). It is also of utmost importance that the nutrients present in feedstuffs are completely available to the animal body. Otherwise, large portions of the nutrients are excreted in the faeces because of not being digested in the alimentary tract. Digestibility study is thus very important in the selection of feed ingredients for feed formation. It is described it as one of the most important aspects in evaluating the potentials, efficiency of animal feedstuffs and basic requirements for formulating fish diets (Allan et al., 2000; Cho and Kaushik, 1990).

This study is aimed at determining the nutrient digestibility of differently heat treated poultry and fish offal meals by *Clarias gariepinus.*

MATERIALS AND METHODS

PROCESSING OF OFFAL

Offal of fish and poultry were procured from processing plants in Ile-Ife, Osun State. The fish and poultry offal were divided into three portions each.

Autoclaved Fish and Poultry offal meals: A portion of fish offal and poultry offal were seperately autoclaved at 15 psi for 20 minutes and then oven dried at 70°C for 24 hours, milled (Giri *et al.*, 2000) and designated as F1 and P1 respectively.

Oven-dried Fish and Poultry offal meals: A second portion of fish and poultry offal each were dried in hot air oven at 55^{0}C for 48 hours, milled (Giri *et al*., 2000) and designated as F2 and P2 respectively.

Offal in wheat meals: A third portion of fish and poultry offal were blended into paste (using an electric blender) and mixed with wheat offal at ratio 7:1 (Offal:Wheat), (slight modification of Makinde and Sonaiya, 2012) and oven dried at 50 ^{0}C for 48 hours, milled and designated as F3 and P3 respectively.

EXPERIMENTAL DIETS

A reference diet was formulated using Pearson square method to contain 40% crude protein (Table 1). Test ingredients for digestibility test were autoclaved fish offal (F1), autoclaved poultry offal (P1), oven-dried fish offal (F2), oven-dried poultry offal (P2), fish offal paste with wheat offal (F3) and poultry offal paste with wheat offal (P3). The test diets contained 70% reference diet and 30% of each of the test ingredients on a dry weight basis (Dong *et al.*, 2010; Luo *et al.*, 2009; Falaye *et al.*, 2014), with chromic oxide (Cr_2O_3) as inert marker (Cho and Slinger, 1979). Test ingredients were thoroughly mixed with other ingredients with cassava starch as binder. The mash was then pelletized with 2 mm

die hand-driven pelletizer to form pellets. The diets were then sundried at atmospheric temperature and humidity for 2 days and packed into well-labeled air-tight plastic containers until ready to use.

Table 1: Feed Formulation for Reference and Experimental Diets (g/100g)

Ingredient	Reference Diet	Experimental Diet
Fish meal	8.70	6.13
Soybean meal	43.75	30.63
Groundnut cake	17.50	12.25
Maize	24.49	17.14
Vitamin premix	1.00	0.70
Dicalcium phosphate	1.00	0.70
Lysine	0.50	0.35
Cr_2O_3	0.50	0.35
Salt	0.50	0.35
Starch	1.00	0.70
Palm Oil	1.00	0.70
Test Ingredient	----	30
Total (g)	100	100

EXPERIMENTAL DESIGN AND PROCEDURE

The experiments were carried out in rectangular plastic tanks of 0.42 m x 0.29 m x 0.25 m with water volume maintained at 20 L in each. After a 7-day acclimatization to laboratory conditions, a total of 315 African catfish, *Clarias gariepinus* juveniles with an average weight (5.50±0.50 g) were randomly allocated into 21 experimental plastic tanks at the rate of 15 juveniles per tank.

Diets were fed to triplicate groups of fish twice daily, between 7.00 - 8.00 am and 4.00-5.00 pm at 5% body weight throughout the experiment. The ration was adjusted every two weeks when new mean weights of fish for the various experimental units were determined. Leftover (uneaten) feed in each tank was siphoned 30 minutes after feeding to avoid leftover feed contaminating the faeces. Faeces in each tank were gently siphoned out using siphoning hose of 2 mm diameter every 8 hours after feeding. The faeces were pooled for each treatment and dried.

CHEMICAL ANALYSIS

The mineral and proximate composition of different diets and fecal samples were done as described by A.O.A.C (2005). Chromic oxide contents were determined as described by Farukawa and Tsukahara (1966).

APPARENT DIGESTIBILITY COEFFICIENT (ADC)

The apparent digestibility coefficients (ADCs) of protein, lipid and phosphorus for test and reference diets were calculated as follows (Cho and Slinger, 1979)

$$ADC\ nutrient = 100 - 100(\frac{Cr_2O_3\ in\ diets}{Cr_2O_3 in\ feaces} \times \frac{Nutrient\ in\ feaces}{Nutrient\ in\ diets})$$

Since the test ingredients substituted 30% of the reference diet, the ADC of the ingredients were calculated according to the following equation (De silva and Anderson, 1995):

$$\mathrm{ADCn} = \frac{\mathrm{ADCTD} - (\mathrm{Y\ x\ ADCRD})}{\mathrm{Z}}$$

ADCn: Apparent digestibility coefficient of nutrient in test ingredient, ADC_{TD}: Apparent digestibility coefficient in test diet and ADC_{RD}: Apparent digestibility coefficient in reference diet, Y is the reference diet proportion and Z is the test diet proportion.

STATISTICAL ANALYSIS

All data resulting from the experiment were subjected to one way analysis of variance (ANOVA) and subjected to Duncan's multiple range test at $p<0.05$. Analysis was carried out using SAS (statistical analysis software) system 2003 version.

RESULTS AND DISCUSSION

The proximate composition of test diets is presented in Table 2. The moisture in the diets ranged from 7.68% in F2 to 8.92% in P2. Ash content in diets varied significantly ($p<0.05$) ranging from 6.75% in P3 to 10.26% in F2. P3 and F3 groups with wheat offal meal had the least ash contents among the two. Crude fibre values were significantly lower ($p<0.05$) in the P2 and F2 groups, with the highest value recorded in P3 group. Similarly, crude protein was significantly lower in P2 and F2. The crude protein is significantly higher ($p<0.05$) in P1. The variation in proximate compositions of the test diets is attributed to the effect of the processing techniques used in this present study. Similar variations were reported for feedstuffs subjected to various heat treatments in Hueze *et al*, (2015).

Table 2: Proximate Composition of Experimental Diets

PARAMETER (%)	P1	P2	P3	F1	F2	F3	R	SEM
Moisture	8.64^{b}	8.92^{a}	7.82^{d}	8.29^{c}	7.68^{d}	8.76^{ab}	8.86^{a}	0.131
Ash	7.03^{f}	7.21^{e}	6.75^{g}	9.46^{b}	10.26^{a}	8.43^{c}	7.57^{d}	0.343
Crude Fibre	3.44^{bc}	2.73^{f}	3.70^{a}	3.57^{ab}	2.99^{e}	3.29^{cd}	3.12^{de}	0.089
Crude Protein	39.81^{a}	38.50^{d}	39.38^{b}	38.94^{c}	37.63^{e}	38.94^{c}	38.50^{d}	0.180
Lipid	21.53^{a}	21.84^{a}	17.86^{b}	14.34^{d}	16.41^{c}	13.50^{e}	7.31^{f}	1.296
NFE	19.55^{f}	20.80^{e}	24.49^{d}	25.40^{c}	25.03^{cd}	27.58^{b}	34.64^{a}	1.270

Means with the same superscripts along rows are not significantly different (P>0.05)

P1: Autoclaved Poultry offal diet, P2: Oven-dried Poultry offal diet, P3: Poultry offal paste + Wheat offal diet, F1: Autoclaved Fish offal diet, F2: Oven-dried Fish offal diet, F3: Fish offal paste + Wheat offal diet, R: Reference Diet

Result of the apparent digestibility coefficients (ADCs) of nutrients is presented in Table 3. Apparent digestibility of protein varied significantly as a result of heat treatment. Protein digestibility was significantly highest in P2 (83.36%) and least in P1 (56.06%). The apparent digestibility for crude protein in this study was lower than that reported by Hossain and Jauncey (1989), where observed apparent digestibility coefficient for crude protein of fish meal in carp was 88.9%. Also higher value of fish meal digestibility for *Labeo rohita* was also reported by Salim *et al.*, (2004). The ADCs for protein obtained in P2, F3 and F2 are in agreement with the range of protein digestibility values of 75 to 95% reported for freshwater fish fed selected diets (Koprucu and Ozdemir, 2005), while the ADCs of protein in F1, P3 and P1 are significantly lower than the range. It is important to note that protein content can be affected by heat treatment (Falaye *et al.*, 2014), and subsequently, the digestibility, as observed in F1 and P1 in this study. Part of the variation in the ADC of protein in different ingredients may also be explained by differences in the chemical composition resulting from processing techniques used for various feed ingredients (Koprucu and Ozdemir, 2005; Watson, 2006). Excessive heat as demonstrated in autoclaved meals denatures protein and thus negatively affects digestibility as affirmed by Falaye *et al.* (2014).

The apparent crude fat digestibility coefficients varied significantly ($p<0.05$) across treatments, with the highest recorded also in P3 (96.30%) followed by P1 (95.37%), P2 (91.74%) and the least in F1 (73.94%). The apparent digestibility coefficients of crude fat in F1, F2 and F3 in this study were lower than the values reported for fishmeal by NRC (1993), while the values of ADCs of lipid in P1, P2 and P3 are in line with reported values of 85-95% for fish meal. Crude fat digestibility in F2 and F3 groups are similar to 81.35% reported by Jalal *et al*., (2000). However, the apparent fat

digestibility coefficients obtained in this study were higher than the 68% reported by Gaylord and Gatlin (1996).

The apparent phosphorus digestibility increased from 74.31% in P3, 81.27% in F1, 85.37% in P2 86.71% in F3, 97.27% in F2 to 99.57% in P1. Phosphorus is a very important factor in aquaculture. Its utilization in fed diets is critical in aquaculture effluent as it affects eutrophication (Falaye *et al.*, 2014).

Table 3: Apparent Digestibility Coefficients of Protein, Lipid and Phosphorus of Experimental Diets

PARAMETER (%)	**P1**	**P2**	**P3**	**F1**	**F2**	**F3**	**SEM**	**P-VALUE**
ADC Protein	56.06^{f}	83.36^{a}	57.09^{e}	65.83^{d}	76.96^{c}	78.63^{b}	3.20768	<0.0001
ADC Lipid	95.37^{b}	91.74^{c}	96.30^{a}	73.94^{f}	80.54^{e}	81.37^{d}	2.52817	<0.0001
ADC Phosphorus	99.57^{a}	85.37^{d}	74.31^{f}	81.27^{e}	97.27^{b}	86.71^{c}	2.63729	<0.0001

Means with the same superscripts along rows are not significantly different (P>0.05)

The result of this study reveals that autoclaving reduced crude protein digestibility as observed in P1 and F1, thus reducing the nutritive value of these ingredients. It can be concluded that oven-dried meals were better digested by *Clarias gariepinus* when ADC protein, lipid and phosphorus are considered and therefore should be explored in growth experiment for this species.

ASSESSING RISKS MANAGEMENT STRATEGIES AMONG BACKYARD SNAIL FARMERS IN OWO METROPOLIS, ONDO STATE, NIGERIA

P. T. Owombo[1], I. Ibidapo[2] R. E. Mbossoh[3]

[1]Department of Agricultural Economics and Extension, Ondo State University of Science and Technology, Okitipupa, Nigeria
[2]Department of Agricultural Science, Adeyemi College of Education, Ondo, Nigeria
Department of Agricultural Economics, Obafemi Awolowo University, Ile-Ife, Nigeria

Abstract

just like any other farming enterprise is faced by a number of production militating risk factors, ranging from production through to marketing. Risk is a condition that relates to the possibility that yield or output levels will be lower than projected (Ibekwe & Andopara, 2016). Etchu *et al*. (2008) itemized snail production limiting risk factors to include climate change, pests and diseases as well as lack of good quality stock. In addressing production limiting factors called risk, farmers adopt risks management techniques for the purpose of ensuring optimum production. Risk management in agriculture is an essential tool employed by farmers to guide against production shock (OECD, 2011). Risks threatens output, returns and the overall performance of a farm business (Hamid & Chiaman, 2010). Hamid & Chiaman (2010), added that selecting appropriate risk The study was conducted to assess risk sources and management strategies employed in backyard snail farming in the study area. The study employed a snowball sampling procedure to select 29 respondents for the study. Data were collected with the aid of structured questionnaire. Data collected were analysed with the aid of descriptive statistics such as frequency count, simple percentage and standard deviation. Results of analysis showed that the mean age of the respondents was 50.55±5.1 years. Results also showed that 40.3% of respondents had no formal education while the mean year of production experience was 4.97±3.1. Results further showed that 100, 89.7 and 79.3% of respondents indicated climate change/drought, poor quality foundation stock and theft as major sources of risk in backyard snail farming while watering and building mini fence were the major risks management strategies employed in the study area. Snail producers should be encouraged to adopt right risk management strategies for efficient performance.

Keywords: Assessing, management, strategies, backyard, snail

INTRODUCTION

Snail farming is a micro-livestock enterprise that creates supporting source of livelihood for both rural, semi-urban and urban dwellers. Snail farming is now a popular micro livestock enterprise in Africa, Nigeria, inclusive owing to high protein demand, biodiversity conservation and livelihood option (Rekha *et al*., 2015). The spread of the non-conventional farming system is on the increase probably due to awareness of its nutritional, therapeutic, cosmetic and industrial properties (Ezeano, 2016). Snail farming management techniques is a right decision in the right time as a guide against production failure. The study therefore, investigate the sources of risks and risks management strategies employed by snail farmers in the area.

RESEARCH METHODOLOGY

The study was conducted in Owo metropolis in Owo Local Government Area (LGA) of Ondo State. The town is selected in the LGA for the study based on household's involvement in backyard snail farming. Ondo State is located in the western part of Nigeria. The state falls on longitude 4^0 $45^{1`}$ and $6^0$00 east of the Greenwich meridian and latitude $4^0$ $45^{1`}$ north of the equator. The inhabitants of the metropolis are mainly civil servants and artisans who engage in secondary occupation mainly backyard farming among which is snail keeping. Snowball sampling procedure was used for the study. A backyard snail producer was located who helped identify other snail keepers in the study area. A total of 29 backyard snail keepers were identify for data collection. Data were collected on socio-economic characteristics of snail producers, risk sources and risk management strategies employed in the study area. Data collected were analysed with descriptive statistics such frequency counts, simple percentage, mean and standard deviation.

RESULTS AND DISCUSSION

SOCIO-ECONOMIC CHARACTERISTICS OF THE RESPONDENTS

Table 1 shows socioeconomic characteristics of respondents. The results in the table show that 72.41% of the respondents were male while just 27.59% of them were female. This implies that backyard snail farming in the

area is dominated by male farmers. The results also show that majority (34.4%) of respondents fell in the age range of 41-50 years while 20%, 25%, 9.4% and 10.6% fell in the age ranges of ≥40 years, 51-60 years. 61-70 years and ≥71 years, respectively. This implies that active men were in the enterprise. The results further show that 45% of the respondents were widowed while 6.9%, 31.4%, and 16.1% were single, married and divorced, respectively. Majority (43.9%) of the respondents had household size range of 8-9 while 18.9%, 19.4% and 16.1% percent had household size ranges of ≤2, 3-4 and 5-7, respectively. The mean household size in the area was 5.01±2.4. Majority (40.3%) of the respondents had no formal education while 35.6%, 14.5% and 9.1% of respondents had primary, secondary and tertiary education, respectively. Also, 43.9% of respondents had snail production experience range of 4-5 years while 17.5%, 19.7% and 16.7% of respondents had snail farming experience ranges of ≤1 year, 2-3 years and 6-7 years, respectively. Majority (65.52%) of the respondents owned the building they live in while 34.48% of them indicated otherwise. Building ownership might be the reason for involvement in the enterprise.

Table 1: Socio-economic characteristics of the respondents

Variable	Frequency	Percentage	Mean ± Std. Dev.
Sex			
Male	21	72.41	
Female	8	27.59	
Age of respondents			
≤40	6	20	
41-50	10	34.4	50.55±5.1
51-60	7	25	
61-70	3	9.4	
≥71	3	10.6	
Marital status			
Single	2	6.9	
Married	9	31.4	
Divorced	5	16.1	
Widowed	13	45	
Household size			
≤2	5	18.9	
3-4	6	19.4	5.01±2.4
5-7	5	16.1	
8-9	13	43.9	
Level of education			
No education	12	40.3	
Primary education	10	35.6	
Secondary education	4	14.5	
Tertiary education	3	9.1	
Year of snail keeping			
≤1	5	17.5	
2-3	6	19.7	
4-5	13	43.9	4.97±3.1
6-7	5	16.7	
Ownership of building			
Owned	19	65.52	
Otherwise	10	34.48	

Std. Dev = Standard deviation

Risk sources in snail farming

Table 2 showed the risk sources in backyard snail farming in the study area. The result showed that all respondents (100%) indicated climate change/drought as major source of risk in backyard snail production. This was ranked 1st source of risk in backyard snail farming in the study area. The table further showed that 89.7% indicated poor quality foundation stock as major source of risk in the study area. This was ranked 2nd major source of risk in the area. Also, 79.3% and 37.9% indicated theft and pest/disease as major sources of risk in backyard snail farming. Theft and pest/disease were ranked 3rd and 4th major sources of risk in the study area. This implied that backyard snail farming in the area is faced with several risk factors.

Table 2: Risk sources in snail farming

Item	Frequency	Percentage	Rank
Climate change/drought	29	100	1st
Poor quality foundation stock	26	89.7	2nd
Theft	23	79.3	3rd
Pest/disease	11	37.9	4th

MULTIPLE RESPONSES

RISK MANAGEMENT STRATEGIES

Table 3 showed the risks management strategies in backyard snail farming in the study area. The result showed that 93.1% managed climate change/drought by periodic watering of snailry. The result also showed that just 48.3% of respondents sought experts' advice before stocking while 82.8% and 31% managed theft and pest/diseases risks by building mini fence round the snailry and checking snailry for pest picking. This implied that backyard snail farmers in the area managed risk factors for efficient performance of snailry.

Table 3: Risk management strategies

Management strategies	Frequency	Percentage
I carryout periodic watering	27	93.1
I seek expert's advice before stocking	14	48.3
I build mini fence round my snailry	24	82.8
I check snailry for pest picking	9	31.0

CONCLUSION

The study concluded that the backyard snail farmers in the area were still in their active ages. The major production risks faced in backyard snail farming in order of severity were climate change/drought, poor quality foundation stock, theft and pest/disease. The major risks management strategies employed by snail farmers were periodic watering and building mini fence round snailry. Small scale snail farmers should be encouraged to manage drought and theft risks by watering the snailry as well as building mini fence round the snailry.

ANALYSIS OF PROFITABILITY IN CATFISH PRODUCTION A CASE STUDY OF LOKOJA LGA KOGI STATE

Saliu H.O, & Ayegba F.I

Department of Agricultural Education, Kogi State College of Education(Technical), Kabba, Kogi State, Nigeria.

ABSTRACT

This study examined the profitability of catfish farming in lokoja local government area of Kogi State, Nigeria. A multi-stage random sampling procedure was used to collect primary data for the study. The first stage involved a purposive selection of lokoja local government areas based on predominance of catfish production. The second stage involved a random selection of 4 villages. The final stage involved the random selection of catfish-producing households from the villages selected. Data were analysed using descriptive statistics and gross margin analysis. The result of the analysis shows that the mean age of the respondents was 38 years; the majority of the farmers do not have formal education. The mean household size was 6, farming experience had the mean of 5 years and mean for the amount of credit obtained was ₦6000. The average rate of returns on investment (return per naira invested) was 1.91, indicating that for every ₦1 invested in catfish production in the study area; a profit of 91 kobo was made. Thus, it could be concluded that catfish production in the study area though on a small scale, was economically viable.

INTRODUCTION

Aquaculture refers to the cultivation of aquatic organisms under controlled or semi-controlled conditions for economic and social benefits. Aquaculture has been the world's fastest growing food production system over the past decade (Fourier, 2006). In Nigeria, fishery in the agricultural sector is important (Kudi *et al*., 2008). It serves as a source of income and job creation for a good number of people, most especially in the rural areas where agriculture is their major source of livelihood. Also, fish is a source of protein, minerals and vitamins in the diet of Nigerians (Kingdom and Alfred-Ockiya, 2009). Despite the importance of fish in the diet of Nigerians, supply is far below that required to meet the dietary needs of the teeming populace, thereby exposing them to dangers of malnutrition and other resulting health implications (Oyakhilomen and Zibah, 2013). This shortage in supply is seen in the importation and consumption rates of animal protein in Nigeria. Animal protein consumption is 8grams per caput per day (Ugwumba, and Chukwuji, 2010), a far cry from the Food and Agriculture Organization (FAO, 1991), minimum recommendation of 35 grams of animal protein per caput per day for sustainable growth and development, The raising of fish in Nigeria cuts across both the extensive and intensive system of farming and the rearing of different species. However, catfish is among the most commonly cultured species of fish (Issa *et al*., 2014). Catfish commands very good commercial value in the market (Ugwumba, 2011).

Materials and Methods

The study was conducted in Lokoja Local Government Areas of Kogi State of Nigeria. Kogi State is located between latitudes 60 33'and 80 44'North and longitudes 50 22' and 70 49' East of the Equator (Kogi State Government, 2007). The state has a total population of about 3,278,000, with an average of about 228,964 farm families (NPC, 2007). Based on 3.2 percent annual growth rate, the projected population of Kogi State as at 2019 was 4,417,000. About 70% of the people live in rural areas and are engaged in agricultural production. The average farm family is made up of 7 people, with an average farm size of about 2 hectares per farmer (Kogi State Government, 2007).

The two largest rivers in Nigeria (Niger and Benue) flow through the state with all their tributaries. In addition to farming as the major occupation, some of the citizens are civil servants while others are engaged in buying and selling of goods and services.

A multi-stage sampling technique was used for the selection of respondents. The first stage was purposive selection of Lokoja Local Government Areas in Kogi State, based on the predominance catfish production in the area. Secondly, four villages were randomly selected from the Local Government Areas, Thirdly, random sampling method was used to select ten percent of the catfish farmers from the villages through the use of random numbers from the list of the sample frame.

For this study, only primary data were used. The primary data were collected for the 2018 season with the aid of structured questionnaire. The information collected includes:

The socio-economic characteristics of the respondents such as age, catfish farming experience, household size, educational level, extension contact, amount of credit obtained and membership of farmers' group/associationsnand the cost(Naira) of inputs; output of cat fish (Kilogramme) and the sales (Naira), and the constraints associated with catfish production in the study area.

The analytical tools that were used to achieve the objectives of this study include descriptive statistics and gross margin analysis.

RESULTS AND DISCUSSION

RETURNS TO INVESTMENT IN CATFISH PRODUCTION

Results presented in Table indicate that the total revenue (TR) was ₦63,354.08 while the total variable cost (TVC) was ₦33,155. The gross margin was therefore ₦30,199.08. The average rate of returns on investment (return per naira invested) was 1.91, indicating that for every ₦1 invested in catfish production in the study area; a profit of 91 kobo was made. Thus, it could be concluded that catfish production in the study area though on a small scale, was economically viable.

Average costs and returns of catfish production

Variables	Values (₦)	% Contribution
A. Variable cost		
i fingerlings (kg)	3,020	9.1
ii feeds (kg)	9,047	27.3
iii labour (man-days)	19,344	58.3
iv agrochemical (litres)	1,744	5.3
B. Total variable cost	33,155	100
C. Total Revenue	63,354.08	
D. Gross Margin (C -B)	30,199.08	
F Return per Naira Invested (C/B)	1.91	

CONCLUSION

Based on the findings of this study, it could be concluded that catfish production in the study area was profitable by returning 91 kobo to every ₦1.00 spent.

ABSTRACT
The study was conducted to determine the effect of replacing soyabean meal with different levels of African Yam Bean meal (AYB) in the diet of growing snails. A total of one hundred and twenty growing snails (*Archachatina margi*nata) of mean weight 73.42 ± 2.5g of about 3 months of age were used for the feeding trial. Four diets were formulated to contain African Yam beans (AYB) at 0% (AYB_1) Control, 50% (AYB_2), 75% (AYB_3) and 100% (AYB_4) as replacement for maize fraction in the diet of growing snails. Completely randomized design was used for the trial and each treatment was replicated thrice with 10 snails per replicate. The mean feed intake in 0% and 75% replacement of SBM with AYB were not significantly affected by the dietary treatments (P> 0.05). The mean weight gain in AYB_1, AYB_2 and AYB_3 were relatively the same (P>0.05). The feed conversion ratio (FCR) was relatively the same in all the treatments. The mean shell width increment was relatively the same across the treatments (P> 0.05). The lowest cost/weight gain was recorded in the diet containing 75% AYB as replacement for soybean meal while the highest cost/weight gain was recorded in the diet containing 100%SBM. African Yam Bean meal could be harnessed as alternative feed resource for snail production. It could be recommended that 75% of AYB could be used to replace soybean meal fraction of the diet in order to reduce feed cost

INTRODUCTION
Snail meat contains low fat and low cholesterol level which makes the meat a good antidote for fat related diseases. The cost of production in terms of housing and feed is relatively low compared to other conventional livestock (Odeyinka, 2014). One of the major limitations to the efficient snail rearing is the availability of quality feed at affordable price (Omole, *et.al*., 2016). Quality feed at affordable price has negative effects on livestock production in Nigeria and Africa in general. A lots of livestock farms have been closed down which has resulted in to high cost of livestock products such as meat, eggs and other products (Omole, *et.al*., 2016). Conventional feed ingredients such as soyabean meal, groundnut cake meal and fish meal which are major sources of protein in diet of livestock are expensive (Omole, *et.,al.,*2016; Odeyinka, 2014). The cost of groundnut cake meal and soya bean meal as of the time of conducting this study were ₦135 and ₦160 respectively hence there is need to look for alternative source of protein which is available and affordable **(**Agbulu *et al.,*2010). It has been established by authors that substituting conventional feed ingredients with unconventional ones has led to reduction of cost (Odeyinka, 2014). African yam beans is common in Nigeria but it is considered as underutilized legume (Adewale, *et al.,*2013). There is paucity of information in the use of African yam bean meal in the diet of snails hence the study was conducted to determine the effect of replacing soyabean meal with different levels of African yam bean meal in the diet of growing snails.

MATERIALS AND METHOD
A total of one hundred and twenty growing snails (*Archachatina margi*nata) of mean weight 73.42 ± 2.5g of about 3 months of age were used for the feeding trial. Four diets were formulated to contain African Yam beans (AYB) at 0% (AYB_1) Control, 50% (AYB_2), 75% (AYB_3) and 100% (AYB_4) as replacement for Soybean fraction in the diet of growing snails. Completely randomized design was used for the trial and each treatment was replicated thrice with 10 snails per replicate. The diets were formulated to contain about 24% crude protein and energy of 2400 kcal/kgME. (Table 1). The snails

were reared in a cage of 12 compartments and each compartment had a dimension of 0.5x 0.5m^2. All management practices were adhered to. African Yam beans (AYB) was purchased from a market in Ibadan, Oyo state, Nigeria. It was toasted and ground before incorporated with other feedstuffs. Feed intake and weight gain were measured on daily and weekly basis with the use of sensitive weighing balance. Feed intake was calculated by subtracting the left-over feed from the feed given while the weight gain was calculated by deducting the initial weight from the final weight. Shell length and width were measured on weekly basis with vernier caliper. Micrometer screw gauge was used to measure the shell thickness on weekly basis. Feed conversion ratio was calculated as the ratio of feed intake to weight gain. Feed cost and cost per weight gain were also calculated. The feeding trial lasted for 12 weeks. The chemical composition of the experimental diets and the foot were done according to the method of A.O.A.C. (1990). All data were subjected to statistical analysis using analysis of variance and the means were separated if they were significantly different using Duncan Multiple Range Test (SAS,2000).

RESULTS AND DISCUSSION

The results of growth performance of the snails fed varying levels of AYB in the diet is shown in Table 2.The mean total feed intake was significantly influenced by the varying inclusion of AYB in the diet ($P<0.05$) The highest feed intake was recorded in AYB_1.. The mean feed intake in 0% and 75% replacement of SBM with AYB were not significantly affected by the dietary treatments ($P> 0.05$). The values ranged between 930.39g to 928.35g for the twelve weeks. The mean weight gain was significantly influenced by the varying inclusion of AYB as substitute for SBM in the diets of growing snails ($P<0.05$). The mean weight gain in AYB_1, AYB_2 and AYB_3 were relatively the same ($P>0.05$). The highest mean weight gain was ($p<0.05$) was recorded in the control diet containing 0% AYB as replacement for soybean meal. The feed conversion ratio (FCR) which is the ratio of feed intake to weight gain was relatively the same in all the treatments as shown in Table 2. The relatively the same FCR reported in the study is an indication that AYB could be used to replace SBM in the diet of growing snails. The FCR reported in this study was in agreement with observation of several authors (Omole *et. al.,* 2016; Hamzat and Longe *et.al.,* 2014). The mean shell length increment was not significantly influenced by the dietary treatments ($P> 0.05$). The mean shell width increment was relatively the same across the treatments ($P> 0.05$). The shell thickness were not significantly influenced by the dietary treatments ($P>0.05$) as shown in table 2. This observation also buttressed the fact that AYB could be used as replacement for SBM. Also there was no case of shell deformity in all the treatments. The low mortality recorded in all the treatments could be due to proper management practice such as cleaning of the environment, regular washing of feeding and water troughs, proper shading and others as recommended by different authors (Omole *et al.,* 2016; Hamzat and Longe *et.al.,* 2014). The zero mortality reported could also be due to fact that the test ingredient used in this study was well processed and preserved and did not have any deleterious effect on the snails. **(**Agbulu *et al.,*2010). The report of zero mortality was an indication that AYB could be used as feed resource for snail. The lowest cost/weight gain was recorded in the diet containing 75% AYB as replacement for soybean meal while the highest cost/weight gain was recorded in the diet containing 100%SBM. The reduction in feed cost was due to low cost of AYB compared to soybean meal.. The prevailing market price of AYB and soybean meal during the course of the experiment was ₦135/kg and ₦160/kg respectively. This buttressed the reports of authors that replacing the conventional feedstuffs with unconventional ones led to reduction in the cost feed and total cost of production (Hamzat and Longe *et.al.,* 2014; Omole *et al.,* 2016). The lowest cost/weight gain reported in AYB_3 implies that AYB could replace soybean meal fraction of the diet of growing snails partially up to 75%.

CONCLUSION:

The lowest cost/weight gain was recorded in the diet containing 75% AYB as replacement for soybean meal while the highest cost/weight gain was recorded in the diet containing 100%SBM. African Yam Bean meal could be harnessed as alternative feed resource for snail production. It could be recommended that 75% of AYB could be used to replace soybean meal fraction of the diet in order to reduce feed cost.

ABSTRACT
An experiment was conducted to evaluate the response of broiler chickens to five different commercial diets. Two hundred and fifty day-old chicks were randomly allotted to five diets in replicates of three containing 16 birds each in a completely randomized design. Feed and water were supplied *ad libitum* and the feeding trial lasted for 42 days. Results for performance showed that at 4 weeks, birds on diet B had significantly (P<0.05) higher weight (2129.69g) than those on the other diets. Feed conversion ratio was also better (P<0.05) on birds fed diet B (1.35) than those fed other diets. A similar trend was observed for final weight, with birds on diet B recording the highest (P<0.05) mean weight of (2660.38g) compared to those on other diets (1792.37 – 2114.33g). Feed cost per kg was similar and higher on diets B and E (₦158.00). However, feed cost per kg body weight gain was lowest on diet B (₦306.01) and higheron dietE (₦441.63). It was therefore concluded that diet B gave better performance at reduced feed cost, hence recommended for broiler chicken producers.

Introduction

In addition to its ability to bridge the protein deficiency gap which exists among average Nigerian families, Poultry production can also provide job opportunities in the areas of commercial feed production and retail, hotel/restaurant industry, sales of roasted chickens carriage and transport of feed ingredients, finished feed, live and dressed birds (Afzal and Khan, 2019). However, the success of any poultry enterprise rests squarely on adequate and proper nutrition. Accordingly, poultry diets are formulated to provide specific levels of nutrients that are needed for optimum performance (Oluyemi and Roberts, 2013). Feed cost alone was reported to stand at about 75% of the total cost of broiler chicken production (Alagawany *et al.*, 2018). Against this background, a focus on efficient feed utilization in order to maximize profits and avoid loses becomes a necessity.

Due to inadequate knowledge of feed formulation techniques and weak capital base, several poultry farmers prefer to buy commercial feeds rather compounding their own. This has made the demand and cost for commercial feeds to be relatively high (Malebogo *et al.*, 2016). The demand factor, partly occasioned by the increasing number of people venturing into poultry business in Nigeria, has made some poultry feed manufacturers to produce sub-standard products, especially as the quality control agencies in Nigeria are not playing effectively their statutory roles (Okoli*et al*., 2009). Ordinarily, poultry feeds, based on type of birds, purpose and stage of growth, produced by different companies are supposed to be similar in composition in order to meet the birds' requirements. However, considering the selfish tendencies of some feed producers to maximize profit and that of some quality control agents to enrich themselves at the detriment of the poor farmer, sub-standard commercial feeds are bound to be found in the Nigerian markets (Jones, 2005). It is therefore the aim of this study to evaluate some of the commercial broiler feeds sold in Bauchi metropolis.

Materials and methods

The experiment was carried out at the Poultry Teaching and Research Farm, College of Agriculture, Bauchi, Bauchi State. Five selected commercial broiler starter and finisher feeds were purchased from feed vendors in Bauchi town. Two hundred and fifty day-old broiler chicks were randomly allotted to five different commercial diets, designated as A, B, C, D and E in replicates of 3 of containing 16

birds each in a completely randomized design. Recommended vaccinations were administered accordingly. Similarly, all routine sanitary operations were carried out during the study period lasted for 6 weeks of 4 and 2 weeks starter and finisher phases respectively. Data was collected for feed intake, weight gain and feed conversion ratio. Prices of feeds, total feed intake and total weight gain were the indices used in computing the economics of production. All data obtained was subjected to analysis of variance (Steel and Torrie, 1980). The statistical software employed was SPSS v. 23.0. mean seperation was according to Duncan Mutiple Range Test (Duncan, 1955).

Results and Discussion

Result of performance of broiler chickens fed different commercial diets during the starter phase is presented in Table 1. Initial weight of birds, which did not differ among diets ranged between 131.25 – 132.87g. Weight of broiler chickens at week 4 was significantly (P<0.05) influenced. Birds on diet B (2129.69g) had higher average weight than those on other diets (1480.38 – 1618.82g) which were similar. This agrees with Sogunle *et al.,* (2009). Daily feed intake (DFI) which ranged from 84.12 to 96.00g, was not significantly affected. However, daily weight gain (DWG) followed the same trend with week 4 weight. Birds on diet B (71.34g) gained higher (P<0.05) than those on other diets (48.12 – 53.10g) which did not differ. Feed conversion ratio (FCR) was also significantly (P<0.05) better on diet B (1.35) than on other diets (1.69 – 1.85).

The result of broiler chickens performance at the finisher phase is presented in Table 2. During the finisher segment, final weight of birds reveled that those on diet B (2660.38) outweighed (P<0.05) those fed other diets (1792.37 – 2114.33g) which were the same. Daily feed intake (124.08 – 139.20g) showed no significant influence of diet. However, DWG significantly (P<0.05) differed among treatments. Diet C (44.82g) which was higher, did not differ from diets A (38.91g), B (37.90) and diet D (43.54g). Birds on diet E (27.05g) had lower value of DWG which was comparable to diets A, B, and D. This concurs with the report of Uchegbu *et al* (2009) in finisher broiler. Feed conversion ratio was also better on diets A (3.52), C (3.15) and D (2.86) than diet E (4.98) which did not differ from diet B (3.95).

The overall phase (Table 3) indicated that total weight gain of birds fed diet B (2528.31g) was higher (P<0.05) than those on other diets (1659.50 – 1982.40g) which were similar. Daily feed intake (107.25 – 116.74g) did not show any significant influence of diet. However, daily weight gain was highest (P<0.05) on diet B (54.63g) and lowest on E (38.76g). Similarly, FCR was best (P<0.05) on diet B (2.14 and poorest (P<0.05) on diet E. This result is in conformity with findings of Sanusi *et al.,* (2015).

The economic analysis of broiler birds fed commercial diets is presented in Table 4. Birds on diet 2 consumed more feed (4.90 kg) than those on other diets (4.50 – 4.81 kg). Feed cost per kg was highest on diets 2 and 5 (₦158.00) which were the same, and lowest on diet 4 (₦150.00). Total feed cost was highest on diet 2 (₦774.20) and lowest on diet 4 (₦675.00). However, feed cost per kg gain was lowest on diet 2 (₦306.01) compared to other diets (₦364.86 – 441.63).

Table 4: Economic Analysis of Broiler Chickens Fed Five Different commercial Feeds

	Diets				
Parameters	**1**	**2**	**3**	**4**	**5**
Total feed intake (kg)	4.62	4.90	4.81	4.50	4.64
Feeed cost per kg (₦)	151.00	158.00	152.00	150.00	158.00
Total feed cost (₦)	697.62	774.20	731.12	675.00	733.12
Total weight gain (kg)	1.89	2.53	1.98	1.85	1.66
Feed cost per kg gain (₦)	369.11	306.01	369.25	364.86	441.63

Conclusion

Based on the results of this study, commercial broiler feed B was utilized better by the chickens which translated into higher total weight gain. Performance of birds on other diets was almost the same. Feed cost per kg weight gain was lower on diet B and therefore recommended for broiler producers.

ABSTRACT
An experiment was conducted to evaluate the performance of broiler chickens fed different commercial feeds available in Bauchi, Bauchi State, Nigeria. A total of 225-day old broiler chickens from Zartech Ltd were fed 5 different commercial feeds for duration of 35 days to compare the performance of broiler chickens. Feed intake of the dietary groups differed significantly (P<0.05). T4 dietary group showed high trend of feed consumption (75g) while the lowest feed intake was recorded in treatment 3 (48g).The body weight gain was highest (44.79g) in T5 dietary group (P<0.05) which was statistically similar with T2 and T4 groups and lowest body weight gain was observed in treatment 3 (20.91g). Higher FCR value (P<0.05) was observed in T3 dietary group which indicated low feed conversion efficiency. T3 showed high percent of survivability. Significant difference was obtained for meat yield parameters such as body weights, liver weight, abdominal fat, heart weight, dressed carcass and edible carcass weight. The result of the experiment from biological responses of birds gave an impression that commercial feeds of the feed mills T2, T4 and T5 were found to be better than those of T1 and T3 for the production of broiler chickens for the age duration of day old to 35 days.

Keywords: broiler chickens, performance, feed intake

INTRODUCTION
Poultry feeds are made up of many ingredients which are broadly grouped into providers of energy (fat and carbohydrates), protein (amino acids), vitamins, minerals and feed additives. Cereal grains such as maize, sorghum, wheat and millet provide energy while soya beans and groundnut provide protein. These ingredients are combined in such a way as to provide energy, protein, vitamins and minerals for poultry through the process of feed formulation.However, several factors may affect both feed quality and feed manufacturing parameters (Loar and Corzo, 2011). The nutritional value of grains used in poultry feed varies with the grain cultivars, its chemical characteristics and non-starch polysaccharide content, diet physical form, availability of energy and bird category (Gutierrez-Alamo *et al.,* 2008). These factors in addition to the choice of feedstuffs and quantity incorporated in the finished feed by different feed manufacturers has given to variation in the nutritive value of manufactured feeds and performance of birds fed different brands of feeds.
Poultry feeds are primarily produced to optimize the growth potentials of the target birds through a defined nutritional specification but more than 10% reduction in chicken growth rates has been observed when birds are offered different feed brands (Uchiegba*et al.,* 2009). It means there are variations in the compositions of different feed brands meant for the same class of birds. Knowledge of the nutritive value of feed brands is therefore imperative for the poultry industry.This research is aimed at determining the effect of differentcommercial feeds on growth performance of broiler chickens.

Materials and Methods
The experiment was conducted at the Poultry Unit of Bauchi State College of Agriculture Bauchi Teaching and Research farm. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East (BSD, 2009).
A total of two hundred and twenty-five (225) broiler chicks were used for the experiment. They were randomly divided into five treatment groups of 45 chicks per group in a completely randomized design (CRD) consisting of three replicates of 15 birds each. Birds were reared on a deep litter, with feed and water provided *ad libitum*. Left over feed and body weight of birds were monitored on a

weekly basis for the starter and finisher phases of the experiment and routine vaccines were given as recommended. All feed not consumed were removed, weighed and deducted from feed given daily to get the daily feed intake.

Five (5) broilers super starter, starter and finisher diets of different selected commercial brand were purchased and label as diet 1,2,3,4 and 5 which is given to treatment groups 1,2,3,4 and 5 respectively. All these feeds differ in composition of energy, crud protein, crud fibre, ether extract among others.

Results and Discussions

The daily feed intake values ranges from (48.93-75.25g) is similar to 53.00-75.55g as reported bySanusi, *et al.*, 2015, in comparative effect of self-formulated and four commercial diets on the growth performance, carcass and haematological parameters of broiler finishers in the tropics. This result is also similar to values obtained by Doma*et al* (2001) in broilers fed different commercial diets.The daily weight gain was significantly ($P<0.05$) influenced at the overall phase. The daily, the values obtained ranges from 20.91 to 44.79g were comparable to the report of Doma*et al* (2001) who reported that low protein diet lead to poor performance.Feed conversion ratio was significantly affected by the dietary treatment. The result is similar to what was obtained by Sanusi*et al* (2015). Birds on diet T5 were having better feed conversion ratio of 1.65 which is similar to 1.82 and 1.86 of treatments 4 and 2 respectively. Similarly, feed conversion ratio is obtained on birds in treatment 1 and 3 which is 2.11 and 2.36 respectively.

The average live weight ranged between 875.67 to 1738.33g on treatments 3 and 5 respectively, there was significant ($P>0.05$) difference among the treatments. Other parameters measured such as plucked weight, carcass weight, dressing percentage, lungs weights, head and legs weight, intestinal weight, liver weight, and abdominal fat weight showed significant ($P>0.05$) difference. But parameters such as heart weight, spleen weight, intestinal length, pancreas weight, caecal length and kidney weight showed no significant difference among the dietary treatment. This result is similar to similar to what was obtained by Hossain et al (2006) in his work titled performance of broiler chickens fed with different commercial compound feeds of Bangledesh.

The highest feed cost/kg is recorded in dietary treatments 3 and 5 while all the other dietary treatment had the same feed cost. The feed cost/gain ranged between 260.74 to N3377.70 it dietary groupps 5 and 3 respectively. This results differs with the range of 124.67 to N190.29 obtained by Sanusi et al (2015).

Conclusion and Recommendation

Birds on treatments 5, 4 and 2 performed better than those on treatments 1 and 3. And low feed cost/gain was recorded to be lowest in dietary treatment groups 2, 4 and 5 while dietary treatment groups 1 and 3 resulted highest feed cost/gain during the experiment. Diet 2, 4 and 5 are therefore recommended for production of 1.8 to 2.5kg broiler chickens for the period of day old to 42 days.

Abstract

A total of one hundred and fifty (150) four weeks old broiler birds were used to study the growth response to diets containing different levels of tigernut wastes meal (TNWM). The birds were randomly allotted to five dietary treatments of three replicates each containing 30 and 10 birds respectively. The treatment diets comprised 0, 25, 50, 75 and 100% of tiger nut waste meal (TNWM) as replacement for maize to form treatment diets 1 (control), 2, 3, 4 and 5 respectively. The control diet and Treatment 2 (25%TNWM) showed significantly (P<0.05) higher weight gain followed by treatment 3, 4 and 5 in that order. The feed intake showed a reversed trend as consumption significantly (P<0.05) increased with increasing dietary level of TNWM. The most favourable feed conversion ratio was obtained with birds in control and treatment 2 with values that were significantly (P<0.05) higher than birds in other treatment groups. The percentage reduction in feed cost per kilogram of diet showed a drastic reduction (P<0.05) as dietary TNWM increased in the diet. However, it did not correspond with percentage savings on feed cost which showed a negative trend as dietary as dietary TNWM increased. It is concluded that up to 25% level of maize could be replaced with TNWM without any adverse effect on performance but with favourable cost savings.

Key words: Tigernut waste, weight gain, feed conversion ratio, cost savings

Introduction

The search for lesser use and underutilized fedstufs, many of which are potentially valuable as animal feed has been intensified to maintain a balance between population growth and agricultural productivity, particularly in the tropical and sub-tropical areas of the world. In Nigeria, conventional feedstuffs especially energy sources like maize, wheat, millet and guinea corn are becoming increasingly costly. This has led to the search for alternative feedstuffs for use in animal production especially poultry species, which are the main sources of animal protein in Nigeria. Such alternative feed ingredients should of necessity be available all year round; easy to be procured and processed, if need be, into usable forms and must have a comparable cost advantage over the conventional feed stuffs (Oyebiyi *et al.*, 2007). Such feed stuffs must not be a staple item for human food (Okonkwo and Adikpe, 1988). At present in Nigeria, there are many agricultural and industrial by-products that have found their usefulness in livestock feeding (Togun and Oseni, 2005).

A species that can be exploited in this direction is *Cyperus esculentus* commonly called tigernut. It possesses as much agronomic and nutritional potential as the conventionally used energy sources. Tigernut is commonly known as earth almond, *chufa, chewfa* and *Zulu* nuts in Spain. It is known in Nigeria as *Aya* in Hausa, *Ofio* in Yoruba, Akihausa in Igbo and *Isip-Isong* in Efik where these varieties (black, brown and yellow) are cultivated. Among these, only two varieties, yellow and brown are readily available in the market. The yellow variety is preferred to all other varieties because of its inherent properties like bigger size, attractive colour and fleshier body. It also yields more milk upon extraction, contains lower fat, more protein and possesses less anti-nutritional factors especially polyphenols (Okafor *et al.,* 2003). Tigernut can be eaten raw, roasted, dried, baked or can be made into a refreshing beverage called *Horchata De Chufas* or tigernut milk. In Nigeria, it can be grown virtually everywhere. Residue after milk extraction is being discarded by the beverage industries as waste, even though it is said to have high energy content. The successful exploitation of this plant would add to the feed resources available to the livestock industry in Nigeria, and will contribute in solving the problem of scarcity and high cost of feed ingredients (maize, millet, guinea corn and so

on) in livestock feed industry. It will provide feed millers and poultry farmers with readily available high quality alternative feed ingredient that is relatively cheaper thereby reducing the cost of poultry production. This research therefore is to find out the actual level of replacement of maize with tigernut waste meal that can save cost without sacrificing growth performance parameters.

Materials and Methods

The study was carried out at the Poultry Unit of the Teaching and Research Farm of the University of Calabar, Nigeria. The tigernut waste was collected from Olam Agro- industry, which is located in Kaduna and Benue States, all in Nigeria. The waste was further sundried and preserved in jute bags for laboratory analyses and feed formulation. The dried tigernut waste and formulated diets were analysed for their proximate composition using AOAC, 2006 methods. The dried tigernut waste meal was used to replace maize in broiler chicken diets at 0, 25, 50, 75 and 100% levels, representing treatment diets 1, 2, 3, 4 and 5 respectively, The formulation was in line with the standard nutrient requirements as recommended by NRC (2013) for each phase of the poultry birds. One hundred and fifty (150) four weeks old broiler birds were distributed in a Completely Randomised Design to their respective experimental diets. Water and feed were administered *ad libitum* throughout the period of the experiment. Proper medication and vaccination were strictly followed. Feed intake was taken daily. Initial live weight was measured at the beginning of the study, thereafter done weekly. These help in computing their weight gain and feed gain ratio. All data collected was subjected to analysis of Variance (ANOVA) using SPSS, 2012.

Table 1: Ingredient composition of the experimental broiler finisher diets

	DIETS				
	1	2	3	4	5
Ingredient (%)	0%	25%	50%	75%	100%

Crude fibre (%)	5.32	6.54	6.69	6.82	7.31

* Vitamin/mineral premix containing the following per kg. Vitamin A, 8,000,000 IU; vitamin D3, 1,600000 IU; Vitamin E, 5,000 IU; Vitamin K, 2,000 mg; Thiamine, 1,500 mg; Riboflavin B2, 4,000 mg; Pyridoxine B6, 1,500 mg; Antioxidant, 125 g; Niacin, 1,500 mg; Vitamin B12, 10 mg; Pantothenic acids, 5,000 mg; Folic acid, 500 mg; Biotin, 20 mg; Choline chloride 200 g; Manganese, 80 g; Zinc, 50 g; Iron, 20 g; Copper, 5 g; Iodine 12 g' Selenium, 200 mg; Cobalt, 200 mg.

Results and Discussion

The results of the performance of finished broiler birds fed the experimental diets are presented in Table 2. The feed intake improves (P<0.05) significantly with the dietary levels of TNWM. This suggests the absence of odour and toxic factors in the TNWM. It also indicates reduction in the energy density of the diets as shown in Table 1. Monogastric animals are expected to consume more of low energy diets to meet their energy requirement (Nsa et al., 2010).

The daily weight gain values of the birds in control diet and treatment 2 were numerically similar but significantly (P<0.05) higher than that of birds in other treatment diets which tended to depress (P>0.05) as the level of dietary TNWM increases in the diets. The poor energy density of the diet as the dietary TNWM increases in the diets may have also attributed to the poor weight gain of birds on higher levels of TNW diets.

The feed conversion ratio was most favourable with birds in diets 1 and 2 with statistically similar values. Beyond this level (25% TNWM), Feed conversion ratio significantly (P>0.05) depreciated as the level of inclusion of TNWM increased in the diets. This might be an indication that broiler finisher birds have poor ability of utilising high level of TNWM in their diets. TNWM is high in fibre as indicated in Table 1. Archibong et al., 2018 reported that broiler birds have poor tendency of utilising feeds with high fibre levels. This is also reflected in the protein efficiency values as it tended to significantly (P<0.05) depressed as the level of dietary TNWM exceeded 25% of maize replacement. There was cost savings associated with the use of TNWM up to 25% but beyond this level it is unwise to use it in feeds as it shows negative returns to investments.

Conclusion

The results of this study have shown that replacing maize with 25% could save cost of investment without sacrificing growth performance of finished broiler birds.

Abstract

The study was conducted to investigate the response of broiler chicks to varying dietary levels of yeast and inorganic copper as growth promoters. A total of 120 day old Broiler birds were used for the study. The study lasted for eight weeks. The broiler chicks were randomly allocated to four treatment groups and fed diets containing four levels of copper and yeast been at constant level(0g Yeast + 0g Copper, 32.5g Yeast + 25.0g copper, 32.5g Yeast + 37.5g copper and 32.5g Yeast + 50g copper respectively per 25kg of diet.) Each group was replicated three times with 10birds per replicate in a Completely Randomized Design (CRD). The result showed that Significant (P<0.05) differences occurred among treatments in most of the parameters studied. Broiler birds fed 32.5g of yeast + 37.5g of inorganic copper per 25kg of feed performed better in the starter Phase with body weight gain (BWG) of 722.61g, feed conversion ratio(FCR) of 1.27g,cost© of ₦93.54, better CP and CF utilization when compared with other test groups. The result reveals that up to 32.5g of yeast + 37.5g of inorganic copper should be incorporated per 25kg of broiler diets as feed additive, to enhance growth and well-being of broiler birds.

Keywords: Broiler chicks, Yeast, inorganic copper

Introduction

Poultry is one of the most important sources of animal protein for human consumption. In Nigeria, the demand for poultry meat and egg has increased drastically, driven by the increase in population, income growth, and urbanization (Oladeebo *et al.,* 2007). For many years, antibiotic growth promoters (AGP) have been incorporated in the poultry diets due to their favorable effects on growth rate, feed consumption and feed efficiency (Goshen *et al.,* 2012). However, there are increasing concerns that the frequent feeding of AGP is leading to the rise of antibiotics resistance in many pathogenic and opportunistic bacteria (kana *et al.,* 2011). With the growing public concern about bacterial resistance, poultry scientists are researching on the AGP alternatives that can maintain intestinal health balance with antimicrobial properties as well as increased growth. Yeast (*Saccharomyces cerevisiae*) additives could be used as alternatives to the feed antibiotics due to their beneficial performance and health effects on monogastric animals (Dhama *et al.,* 2015). Copper is one of the most critical of the essential trace minerals required by poultry and can maintain proper body functions and obtain the optimal growth performance of poultry (Banks *et al.,* 2004). According to NRC (1994) the requirement for copper in broiler diets is 5-8mg/kg. Higher level of copper in broiler diet increases the intestinal lipase activity in young birds (Luo and Dove 1996) and also improves gut health by decreasing the intestinal crypt depth and lymphocytes leading to a better absorption of nutrients performance. Considering the importance of yeast and copper, the present study was designed to evaluate the potential effects of supplementation of yeast (*Saccharomyces cerevisiae*) and copper as a natural growth promoter on production performance of commercial broiler chicken.

Materials and Methods

The study was carried out at the Department of Animal Science Teaching and Research farm, University of Nigeria, Nsukka. One hundred and twenty (120) day old broilers (Anak strain) were randomly divided into four groups of thirty birds each. The groups were randomly assigned to four experimental diets containing 0g Yeast + 0g Copper, 32.5g Yeast + 25.0g copper, 37.5g Yeast + 25g copper and 50.0g Yeast + 25g copper respectively per 25kg of diet. The percentage of Starter and finisher feeds is shown in table 1. Each treatment was replicated three times with ten birds per replicate placed in a 2.6 x 3m deep litter pens with fresh wood shavings. Feed and water were offered *ad libitum* every morning from 7.00am -8.00am and the birds were properly vaccinated. The proximate analysis was carried out according to the procedure of AOAC (2006). Data collected were subjected to analysis of variance as described for Completely Randomized Design (Steel and Torrie, 1980) and differences between treatment means were separated using Duncan's New Multiple Range Test (Duncan, 1955).

Results and Discussion

Table 2 showed the growth performance of broiler birds fed diets containing yeast and inorganic Copper. Most of the parameters measured both at starter and finisher phase differed significantly ($p<0.05$) among the treatments on the (DWG), (FBW), (BWG), (FCR) and (PER). Birds fed diet 3 had a higher ($p<0.05$) Daily weight gain, Final body weight and Body weight gain compared to birds fed diets 2 and 4 but similar ($p>0.05$) to birds fed diet 1 (Control). Copper and yeast inclusion improved the FCR and reduced the feed cost per kg at 37.5g Yeast + 25g copper/ 25 kg diet. The results of Onwurah *et al.,* (2014) and Dat *et al*., (2010) agrees with the result of the present finding that yeast and substitution of inorganic copper improves body weight (BWG), and Feed conversion ratio (FCR). This indicates that yeast could be an alternative to antibiotic-growth promoter in feed for broiler chicken by maintaining normal intestinal micro-flora by competitive exclusion and antagonism altering metabolism by increasing digestive enzyme activity and decreasing bacterial enzyme activity and ammonia production.

Table 3 shows the nutrient digestibility of broiler birds fed diets containing yeast and inorganic copper. There is significantly ($p<0.05$) difference in most of the parameters measured among the treatments. The Crude Fibre, Crude Protein, Ash, of birds fed diet 3 was increased ($p<0.05$) significantly compared with birds fed treatment diets 2 and 4 which had similar ($p>0.05$) CF and CP. The observed positive effect in the nutrient retention is in agreement with the result of Raju *et al*., (2006) and this confirms yeast and copper dietary inclusion increased nutrient digestibility especially that of protein. Also the significant retention value of crude fibre confirms yeast and copper as possessing the ability to degrade fibrous material in poultry feed.

Conclusion

The result of the study showed that up to 37.5g Yeast + 25g copper/ 25kg feed can be included in the broiler diets without any deleterious effect on the growth performance and Nutrient intake and utilization.

Recommendation

It is therefore recommended that yeast and inorganic copper can be used as an effective growth promoter in broiler diets for the improvement of performance and Nutrient utilization.

ABSTRACT

An experiment was conducted to for eight (8) weeks to determine the replacement effect of yam and sweet potato peels meals for maize in broiler finisher diets on haematological and serum biochemical parameters.One hundred and eighty (180) birds were randomly allotted to five (5) treatment diets in a completely randomized design and raised separately in different pens. There were 36 birds in each treatment with three replicate and 12 birds per replicate. Feed and water were provided adlibitum. Five experimental diets were formulated and designated as T_1 (control) containing 0% yam and sweet potato peels (Maize – based), while diets T_2, T_3, T_4 and T_5 contained 2.5%, 5%, 7.5%, and 10% each of yam and sweet potato peel meals respectively . Data were collected on haematologicaland biochemical profile of the birds at the end of the feeding period (29-56 days). The data collected were subjected to analysis of variance (ANONA) using SAS (2010) Software. Differences between treatment means were separated using Duncan's New Multiple Range Test of the same software.The result of hematological parameters revealed that there was no malnourishment and anemic condition in the experimental birds.The serum biochemical parameters obtained fall within the normal range of birds, indicating good nutritional and physiological quality of the test ingredients.

KEYWORDS: Haematology, serum Biochemistry, yam and sweet potato peel

INTRODUCTION

High cost of feeds and scarcity of essential raw materials have necessitated poultry farmers to look out for alternative sources which could help to identify feed ingredients of lower cost and sound biological values that can partly supplement the conventional protein and energy sources in broiler diets. Cost of feed from the total estimated price of production in poultry is about 75% in Nigeria (Atteh, 2002, George & Wariboko 2015).

The combination of yam peel meal and sweet potato is good because the Yam peel meal good protein source while the sweet potato peel meal is good .Although some researchers have been used singly to replace part of dietary maize, replacement (Eka, 1985; Ekenyen*et al*, 2006; Aladoku, *et al*, 2007 ; Akinmutimi and Onen, 2008) and some have used it as a combination (Etela and Ironkwe, 2008; Diarra*et al*, 2012)

There is paucity of information available on literature of the Hematological and Serum Biochemical Parametersof Broiler finisher Chickens fed yam and Sweet Potato Peel Meals as Replacement for Maize. This study investigates the effect of feeding yam-sweet potato peels combination on Hematological and Serum Biochemical Parametersof Broiler finisher Chickens

MATERIALSAND METHODS

Location and duration of the experiment

This study was conducted with one hundred and eighty (180) day-old Anak broiler at the Poultry Unit of Teaching and Research Farm of Archdeacon Brown Education Centre, Woji, Port Harcourt Rivers State and it lasted for 8 weeks.

Processing of Yam, Sweet Potato Peels and Experimental Diets

The yam and sweet potato peels were washed, sun dried and milled immediate after obtaining it from the school kitchen of Archdeacon Brown Education Centre in Woji, Port-Harcourt. Five experimental diets were formulated and designated as T_1(control) containing 0% yam and sweet potato peels (Maize – based), while diets T_2, T_3, T_4 and T_5 contained 2.5%, 5%, 7.5%, and 10% each of yam and sweet potato peel meals respectively (Table 1).

Experimental Birds and Management

They were brooded using kerosene stoves under metal hooves and electric bulbs as source of light in a deep –litter house. The house was a tropical one with dwarf walls. Both sides were open covered with wire gauze. All drugs and vaccines were given to the animal.

The one hundred and eighty (180) birds were randomly allotted to five (5) treatment diets in a completely randomized design and raised separately in different pens. There were 36 birds in each treatment with three replicate and 12 birds per replicate. Feed and water were provided *adlibitum*.

Data Collection

Blood Collection and Analysis

Blood samples were drawn from punctured wing vein to aspirate about 5ml of blood. About 2.5ml of the sample was collected in ethylene diamine tetra acetic acid (ETDA) for haematological analysis. The other 2.5ml was allowed to coagulate to produce serum for blood chemistry analysis. The blood samples were analyzed within 2 hours for packed cell volume, (PCV), haemoglobin, (Hb), red blood cell (RBC), white blood cell (WBC), Mean corpuscular haemoglobin concentration (MCHC), bilirubin, creatinine, SGOT and SGPT as described by Schalm (1965), while the coagulated blood was subjected to standard methods of serum separation and analysis while haematological indices were calculated.

Data Analysis

The data collected were subjected to analysis of variance (ANONA) using SAS (2010) Software. Differences between treatment means were separated using Duncan's New Multiple Range Test of the same software.

RESULTS AND DISCUSSION

Table 2 showed that the Hematological indices of broiler finishers fed yam and sweet potato peels. The result did not follow any definite pattern that may be attributed to the test ingredients. Among the

measured parameter which included PCV%, HB, RBC, WBC, MCH and MCHC% there were significant difference($p<0.05$) among all the treatments. However there was no significant difference between treatment T_1 and T_4 in terms of HB%. Also, no significant difference ($p>0.05$) between treatment T_1, T_4 and T_5. There is also, no significant difference between treatment 2 and 4 in terms of WBC.

Table 3 showed that the serum biochemical parameters of broilers fed yam and sweet potato peel meal diets. The result obtained revealed significant difference ($p<0.05$) among the treatments in all the parameters measured which included bilirubin, creatinine, SGOT and SPGT. However, it did not follow any definite pattern that may be attributed to the test ingredients. Also, there were no significant difference ($P>0.05$) between treatment 1 and 2 in terms of SGOT. Similarly, there was no significant difference between treatment 1 and 4 and treatment 2 and 5 in terms of SPGT. The values of the hematological parameters of broiler finishers fed yam and sweet potato peels showed significant differences ($p<0.05$). The result of the investigation revealed that there were no malnourishment and anemic condition in the experimental birds since the values obtained fall within the normal range of measured hematological parameters. In a recent study with 15% inclusion level of yam peel by Akinmutimi and Onen (2008) observed that, there were significant difference for albumin, alkaline phosphate and urea. Also in a recent study on the combination of sweet potato and yam peel diets to broiler finisher by Ilo*et a*l., (2010), the result also revealed that among the parameters, measured only the WBC showed significant ($p<0.05$) difference between the treatments with T_2 (10%>PM) having the least value of (19.00) than others; the highest value of (27.36) was obtained from T_1(control).

The serum biochemicals in broilers fed yam and sweet potato peel meal diets showed significant differences ($p<0.05$).Among the treatments the value obtained from SGOT and SGPT fall within the normal range value of chicken as reported by Baerjee (1998). This indicated no toxicity in the experimental feed (Ologhobo, 1992). Increase creatinine value in blood among other things signifies poor protein utilization by the animals Fasina *et al*.,l999).

Conclusion and Application

The result of hematological parameters revealed that there was no malnourishment and anemic condition in the experimental birds.

The serum biochemical parameters obtained fall within the normal range of birds, indicating good nutritional and physiological quality of the test ingredients.

ABSTRACT

This study was conducted to evaluate the effect of replacing maize with processed mango seed kernel meal (PMSKM) in the diets of weaner rabbit on performance and carcass characteristics. A total of thirty two (32) mongrel rabbits (8 rabbits per treatment, 2 per replicate) were randomly allotted to four experimental diets in which processed mango seed kernel meal replaced maize at 0, 20, 40 and 60% level designed as diets 1, 2, 3 and 4 respectively. The experiment lasted for eight weeks. The result showed that the Average initial weight (500.00-518.75), average final weight (1393.75-1412.50), average daily feed intake (52.98 55.05), average daily weight gain (15.74-16.19) and feed conversion ratio (3.29-3.48) obtained were not significantly (P<0.05) affected by the dietary levels of processed mango seed kernel meal. Most of the carcass traits showed no significant difference (P<0.05) among the treatment except for carcass weight, dressing %, Intestine and loin weight. Diet 2, 3 and 4 (20, 40 and 60% PMSKM) gave highest values for carcass weight, dressing% and intestine while also diet 1, 2 and 3 (0, 20 and 40%) gave higher value for loin weight. It was therefore concluded that processed mango seed kernel meal can replace maize at 60% level in the diet of weaner rabbit as an energy source without any negative effect on their performance and carcass parameters.

Introduction

There is a continuous rise in the cost of production of cattle, sheep, goats and poultry which has prompted people to explore other less common but potential sources of animal protein like rabbits. Taiwo *et al*., (2005) indicated several advantages of rabbits over other livestock species in the tropics and advocated for its increased production in Nigeria. However, cost of feeding rabbits is high and accounted for about 65.7% of the total cost of rabbit production in Nigeria. Therefore, there is a need for researchers to find cheap and readily available sources of rabbit feed in Nigeria.

The potential of rabbit meat as a quality or nutritious food stemmed from its higher protein content, lower fat, lower sodium and cholesterol content compared with other meat source such as beef, pork, mutton and chicken. The World Health Organization recommended 76g protein intake of which 34.0g should be of animal origin (Akintola *et al*., 1999). This has been difficult to achieve in most developing countries due to insufficient availability, high cost of conventional feed stuffs resulting from stiff competition between man and animal for the few available feedstuffs especially cereal and legume grains. Tewe (1988) observed that under the prevailing circumstances, it is unlikely that there will be surplus from conventional cereals and pulses upon which livestock production can develop: thus his suggestion of waste-to-wealth approach to solve the animal feed crisis.

Mango seed kernel meal (MSKM) has been reported to be a good non conventional ingredient. Faniyi (1997) reported its importance in poultry production while Arogba (1997) provided the physical, chemical and functional properties of Nigerian mango *(Mangifera indica)* kernel and it processed flour. Chemical analysis and metabolizable energy of mango seed kernel meal as determined by Arogba (1997) revealed that it contains Tannin an astringent compound, thus necessitate processing the seed before it could be safely fed to animals. The nutrient composition of Mango seed kernel on dry matter basis was estimated in Nigeria to be 6.16% crude protein, 13.63% ether extract, 2.23% ash and 73.35% nitrogen free extract (Farinu *et al.* 1999) while EI-Alaily *et al.* (1996) reported that the gross energy is 4.7Kcal/g. This study was designed to evaluate the growth performance and carcass characteristics of weaner rabbits fed diets containing processed mango seed kernel meal.

Materials and Methods

Experimental Site:

The experiment was conducted at the Rabbitery Unit of Bauchi State College of Agriculture Teaching and Research farm, Bauchi State. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East.

Collection and Processing of Mango Seed into Mango Seed Kernel Meal

Mango seeds were collected from various dumping sites of major markets within Bauchi town. They are readily available in the area of study. The collection was done during the months of April and May which represents the peak of the mango season in Bauchi town. The kernel were obtained by cutting the seed coat using a knife or crushed with a stone. The Mango Seed Kernel (MSK) obtained was then processed through soaking and boiling.

Mango Seed Kernel was soaked in water for 24 hours at the rate of 100g per liter of water in containers. The water was changed at regular intervals of 8 hours for a day. The Mango Seed Kernels were thereafter boiled for 30 minutes, drained and sundried. Thereafter milled before incorporation into the diets.

Experimental Design and Management of Rabbits

A total of thirty two weaner rabbits were used for the experiment. They were randomly assigned into four dietary treatment groups of 8 rabbits per group in a completely randomized design (CRD) consisting of four replicates of 2 rabbits each. Feed and water were provided *ad libitum*.

Experimental Diets

Four diets were compounded manually. The diets contain 0, 20, 40, and 60% replacement level of proceed mango seed kernel meal for maize coded diets 1, 2. 3 and 4 respectively. The feed were prepared by mixing the various ingredient together at Abubakar Tafawa Balewa University feed mill.

Carcass Characteristics

At the end of the experiment four rabbits (one per replicate, were randomly selected from each treatment and slaughtered for carcass analysis, carcass and internal organ's weight were measured using a sensitive balance.

Determination of the Proximate Composition of Mango Seed Kernel

The proximate composition (Table 2) was obtained by analyzing the different samples of Mango seeds kernel according to the methods described by AOAC(1990).

Results and Discussions

The proximate composition of the test ingredients is presented in Table 2. The PMSKM used in the study contained 89.61, 2.23, 5.39, 9.62 and 3.87% for dry matter, ash, crude protein, ether extract and crude fibre respectively. These values were lower compared to the values reported by Faniyi (1997) and El-Alail *et al*. (1996). It could be due the varietal differences.

The results of performance of weaner rabbits fed processed mango seed kernel meal (PMSKM) as replacement for maize were presented in table 3. The performance characteristics in this experiment revealed that the replacement of maize by processed mango seed kernel meal at 0, 20, 40 and 60% recorded on average daily feed consumption of 52.98, 53.06, 54.45 and 55.05 (g) for treatment 1, 2, 3 and 4 respectively. There was no significant different amongst the treatment means. This agrees with the finding of Saleh *et al*., (2015) and Shitu *et al*., (2013). They reported that the average daily feed intake were not significantly different ($P<0.05$) for weaner rabbit fed mango seed kernel meal and for growing crossbreed rabbit fed PMSK meal respectively. The result also revealed that there was no significant different ($P>0.05$) in the average daily weight gain of rabbits fed PMSKM as replacement for maize. The values ranged from 15.74-16.19g obtained in this study is higher than 10.1g reported by Adama and Nma (2002) when groundnut leaves were fed to rabbits. This also confirms the report of (Saleh *et. al*., 2015) and (Fayeye and Joseph, 2004). Shitu *et.al*; (2013) reported no significant effect on growing crossbreed rabbits fed processed mango seed kernel meal. The non significant effect of processed mango seed kernel meal based diets on feed conversion ratio among the treatments means contradicts the findings of Diarra *et.al*; (2004) but similar to the finding of Saleh *et al*., (2015).

Table 4 showed the result for carcass analysis of weaner rabbits fed PMSKM base diets. For carcass analysis it also revealed that there was no significant ($P<0.05$) difference in the live weight, heart,

lung, kidney, stomach and liver which agrees with the findings of Shitu *et.al*; (2013) they reported non significant different between the control diet and the mango seed kernel meal based diet in rabbits. There was a significant difference in the carcass weight and dressing percentage among the treatment means, the significant effects of mango seed kernel meal based diet on carcass weight and dressing percentage among the treatment means contradict the finding of Fayeye and Joseph (2004) who reported non significant difference across the dietary treatments. The weight of stomach also shows significant difference between the control diet and the mango seed kernel meal based diet in rabbits. The weight of head, skin, tail, shoulder and thigh also did not show significant different across the dietary treatments.

Conclusion and Recommendation

It can be concluded that processed mango seed kernel meal can be use to replace maize in the diet of weaner rabbits as an energy source without any negative effect on their performance and carcass values, thereby reducing competition and improving consumer access to animal protein. Thus the use of mango seed kernel meal is there by advocated at up to 60% replacement.

Abstract
An experiment was conducted to determine the performance of broiler chickens fed diets with acha offal (AO) replacing maize. A total of two hundred and forty (240) day-old broilers were randomly allotted into six dietary treatments with AO at 0%, 5%, 7.5%, 10%, 12.5% and 15% with forty birds per treatment. Each treatment had four replicates with 10 birds each in a completely randomized design. Feed and drinking water were served ad libitum throughout the experiment which lasted for 42 days. The results showed that at the starter phase only feed conversion ratio (FCR) was significantly (p<0.05) affected by treatment while others parameters were not significantly different from each other. Chicks fed 12.5% AO had best FCR (1.59) while those fed 0%, 5%, 7.5%, 10% and 15% AO had poor (2.05, 2.08, 2.03 and 2.02, respectively). At finisher phase, final weight (FW), total weight change (TWC), daily weight gain (DWG) and FCR were significantly (p<0.05) affected by treatment. Chickens fed 7.5% - 15% AO had higher FW, TWC and ADG than 0% AO while birds fed 5% AO had lower compared with those fed 0% AO. However, those fed 15% AO had best FCR (2.26) while those fed 0% and 5% had poor (2.46 and 2.33, respectively). It can be concluded that AO can replace maize in broilers' diets by 12.5% at starter phase and 15.0% at finisher phase without adverse effect on performance.

Introduction

Globally, the aim of any poultry farmer is to have flock with efficient feed utilization, uniform growth rate, and low cost of production. This can be achieved in parts through the use of standard feed produced from low cost ingredients (NRC, 1994). In developing countries, where competition on conventional feedstuff between man and livestock exist, a careful selection of agro industrial by-products stand as means of reducing cost of feed (Makinde *et al*., 2014). Many agro industrial by-products including brewers dried grains, broken rice, cottonseed cake, groundnut cake, maize bran, millet hulls, oat hulls, palm kernel cake, peanut hulls, rapeseed hulls, sunflower meal, rice bran, rice hulls, sesame hulls, soybean hull, wheat bran have been well reported as alternative ingredients (Mottet *et al*., 2017). However, many others are yet to be exploited, one of which is acha offals.

Acha (also called white fonio) is a small annual, herbaceous plant that belongs to the family *Poaceae* and the genus *Digitaria* (Cruz *et al*., 2016). It grows to the height of 30-80 cm (Cruz *et al*., 2016). It is grown in the Central Zone of Nigeria and many West African countries as staple food (Cruz *et al*., 2016). Acha offal (AO) is a by-product obtained from dehulling acha grains by pounding with a pestle in a mortar to crack the hulls or using machines (NRC, 1996). A 100g of AO contains 5.74% total ash, 10.16% crude protein, 4.70% crude fat, 7.82% crude fibre, 2.65g/16N methionine and 2.89g/16N lysine (Sudik, 2016). By implication AO is rich in essential nutrients. The objective of this study is to determine the effect of partial replacement of maize with acha (*Digitaria exilis)* offal on performance of broiler chickens.

Materials and Methods

The experiment was conducted at the Teaching and Research Farm Federal University of Technology Akure, Nigeria. Akure lies on latitude 7^0 15' N and longitude 5^0 12' 0" E and within the rainforest zone of Nigeria. Its annual average rainfall is usually1524 mm, average atmospheric temperatures ranges between 28^0C and 31^0C, and mean annual relative humidity is usually about 80% (Ajibefun, 2011).

The acha (*Digitaria exilis*) offal was purchased in Bokkos local Government Area of Plateau State, Nigeria. Maize grains and other ingredients were purchased from a feed miller in Akure town, Ondo

State, Nigeria. A basal diet (0% AO) that meets nutrient requirements of broiler chickens (NRC, 1994) was formulated. Thereafter, 5 other diets with 23% CP (Starter) and 20% CP (Finisher) were formulated with AO replacing maize at 5%, 7.5%, 10.0%, 12.5% and 15% (Table 1 and 2).

AO = Acha offal

Two hundred and forty (240) day-old Abor-Acre broiler chicks were purchased from Chi Farm, Ibadan, Nigeria. They were randomly allotted to six dietary treatments. Each treatment had forty birds and four replicates with ten birds per replicate in a completely randomized design (CRD). The birds were raised on deep litter and heat was provided by charcoal and electricity. Feed and water were provided *ad libitum* throughout the 42 days of the experiment. Gumboro disease vaccine 1st and 2nd dose was administered on day 7th and 21st, respectively while Newcastle disease vaccine on day 14th and 28th and routine management practices were strictly adhered to.

At the start of the experiment, the birds were weighed to determine initial weight thereafter, on weekly basis to determine the body weight chance (BWC) and daily weight gain (DWG) was calculated by dividing the cumulative weights by number of days considered. The left over feed of each diet was subtracted from supply to determine the feed consumed. Dividing the cumulative total feed intake (TFI) by number of day under consideration gave daily feed intake (DFI). Feed conversion ratio (FCR) was calculated as feed intake/weight gain.

AO = Acha offal

Data generated were subjected to Analysis of Variance (ANOVA) using the computer software SAS (2010). Significant means were separated with Duncan multiple range test at 5% level of probability.

Results

Feed conversion ratio (FCR) was only significantly ($p<0.05$) affected at 21-day (Table 3). Birds fed 12.5% AO had better FCR (1.59) than those on 0% AO (2.05) while birds fed 5%-10% and 15% AO had poor FCR (2.08, 2.03, 2.03 and 2.02, respectively) comparable to those fed 0% AO. At the finisher phase FW, BWC, DWG and FCR were significantly ($p<0.05$) affected (Table 4). Birds fed 7.5% - 15% had higher FW (2057.50 g, 2070.00 g, 2093.75 g and 2132.50 g, respectively), BWC (2016.25 g, 2028.50 g, 2052.00 g, and 2091.25 g, respectively) and DWG (48.01 g, 48.30 g, 48.86 g and 49.79 g, respectively) than those fed 0% AO (FW (1906.76 g), BWC (1865.26 g) and DWG (44.41 g)) while those fed 5% AO had lower (FW (1863.75 g), BWC (1822.25 g) and DWG (43.39 g)) compared with 0% AO. The birds fed 15% had better FCR (2.26) while those fed 0% and 5% AO had poor (2.46 and 2.33, respectively).

Discussion

The better FCR observed in birds fed 12.5% AO indicates that the optimum level to use AO for younger birds is at 12.5% and their high performance over those fed control means that the diet might have contained nutrients probably deficient in the control. The decline in FCR at 15% AO demonstrates that the birds could not tolerate AO beyond 12.5% probably due to high fibre because high fibre in diet interferes with the nutrients availability. This observation confirms the results of Makinde *et al*. (2014) that high fibre content in diet limit nutrients available for birds to grow.

At the finisher stage the higher gain and better FCR in birds fed diets with 7.5% -15% AO means that AO can be tolerated by older birds up to 15% which probably might have not interfered with the nutrients availability. This finding confirms the results of Ezieshi *et al*. (2011) that older birds tolerate fibre diet at certain levels than young ones.

In comparison with other offals the optimum level recorded for AO in this experiment is in agreement with 15% rice offal reported by Maikano (2007) for broilers. However, Makinde *et al*. (2014) reported that higher levels of 20-30% rice offal could be used with enzyme supplementation.

Table 3: Performance of broiler chickens fed diets with acha offal (21 days of age)

Parameters	Diet 1 0%AO	Diet 2 5%AO	Diet 3 7.5%AO	Diet 4 10%AO	Diet 5 12.5%AO	Diet 6 15%AO	±SEM
Initial weight	41.50	41.50	41.25	41.50	41.75	41.25	0.03
Final weight	765.00	758.75	778.75	785.00	790.25	799.00	8.84

Feed conversion ratio	2.05[a]	2.08[a]	2.03[a]	2.03[a]	1.59[b]	2.02[a]	0.05

Values are average of 40 birds, AO = Acha offal, ±SEM = Standard Error of Mean,
Means with differing superscripts in the same columns are significantly ($p<0.05$) different.

Table 4: Performance of broiler chickens fed diets with acha (42 days of age)

Parameters	Diet 1 0%AO	Diet 2 5%AO	Diet 3 7.5%AO	Diet 4 10%AO	Diet 5 12.5%AO	Diet 6 15%AO	±SEM
Initial weight	41.50	41.50	41.25	41.50	41.75	41.25	0.03
Final weight	1906.76[b]	1863.75[b]	2057.50[a]	2070.00[a]	2093.75[a]	2132.50[a]	22.85
Body weight change	1865.26[b]	1822.25[b]	2016.25[a]	2028.50[a]	2052.00[a]	2091.25[a]	23.00
Daily weight gain	44.41[b]	43.39[b]	48.01[a]	48.30[a]	48.86[a]	49.79[a]	0.55
Total feed intake	4584.72	4638.30	4683.32	4697.26	4701.00	4729.66	89.19
Daily feed intake	109.16	110.44	111.51	111.84	111.93	112.61	4.50
Feed conversion ratio	2.46[a]	2.55[a]	2.32[b]	2.32[b]	2.29[c]	2.26[c]	0.13

Values are average of 40 birds, AO = Acha offal ±SEM = Standard Error of Mean,
Means with differing superscripts in the same columns are significantly ($p<0.05$) different.

Conclusion and Recommendation

It can be concluded that birds fed 12.5% AO at the starter phase and 15.0% AO at the finisher phase had outstanding performance over those fed 0% AO. Therefore, 12.5% AO and 15.0% AO are recommended for starter and finisher broiler chickens, respectively.

EFFECT OF REPLACING WHEAT OFFAL WITH RICE BRAN ON GROWTH PERFORMANCE OF BROILER CHICKENS

[1]Usman, Y., [2]Egbo, L.M., [2]Abdulkarim, M.,[2]Doma, U.D.
[1]Department of Animal Health Technology, College of Agriculture Bauchi, Nigeria

Abstract
A feeding trial was carried out to evaluate the effect of replacing wheat offal with rice bran on growth performance of broiler chickens. Five (5) diets were formulated in which rice bran replaced wheat offal at 0, 25, 50, 75 and 100% levels, designated as diets 1, 2, 3, 4 and 5 respectively. Two hundred (200) day-old broiler chicks weighing between 158.98 – 169.02 g were randomly allotted to five diets in replicates of three containing 13 birds each in a completely randomized design. Feed and water were providedad libitum and the experiment lasted for eight (8) weeks. Results showed that there was no significant influence of diet on all performance parameters during the starter, finisher and overall phases. It was therefore concluded that rice bran can completely replace wheat offal in broiler chicken diets without compromising growth performance.

Introduction
The growth of Nigerian poultry industry is constrained by persistent scarcity and high cost of conventional feed ingredients such as maize and soya bean. To stem this problem and ensure that the sector expresses its full potentials of making animal protein available at affordable rate, the need for use of relatively cheap and readily available unconventional feedstuff becomes necessary. This will also reduce feed cost which stands at about 75 - 80 % of the total cost of broiler chicken production (Ani *et al.*, 2012). Previous research findings have shown that diets formulated with some alternative fibre sources such as rice offal can replace wheat offal in broiler diets (Amaefule *et al.*, 2006). Rice offal has a CP content of 5.09% and 30.39% crude fibre. The inclusion of rice offal at up to 15% level in broiler chicken diets, did not negatively affect performance and carcass yield (Makinde *et al.*, 2014). Okpanachi *et al.*, (2015) reported that, when treated with urea, rice offal can be included in broiler diets at up to 15 and 10% levels respectively without reduction in performance. This study was therefore aimed at investigating the performance of broiler chickens fed graded levels of rice bran as replacement of wheat offal in the study area.

Materials and methods
The experiment was carried out at the Poultry Teaching and Research Farm, College of Agriculture, Bauchi, Bauchi State. Five experimental diets were formulated in which rice bran replaced wheat offal at 0, 25, 50, 75 and 100% levels, designated as diets 1, 2, 3, 4 and 5 respectively. The percentage composition and calculated analysis of experimental diets for both the starter and finisher phases are presented in Tables 1 and 2. A total of 200 day-old chicks were allotted to five experimental diets in three replicates of 13 birds each in a completely randomized design. The study lasted for 56 days. Data was collected for feed intake, weight gain, feed conversion ratio and mortality. All data collected were subjected to ANOVA.L.S.D. was used for mean separation.

Results and discussion

Results for growth performance of broiler chickens (Table 3) revealed that no parameter was significantly influenced by diet during study phases. During the starter phase, birds at 4th week weighed between 606.32g on diet 5 and 714.10g on diet 3, daily feed intake, 43.29g (diet 3) to 50.44g (diet 1), daily weight gain, 15.89g (diet 5) to 20.10g (diet 2) while feed conversion ranged from 2.22 (diet 3) to 2.73 (diet 1). This agrees with Onuh *et al.* (2015), Similar performance was recorded during the finisher phase. Final weight of birds ranged from 1322.70g (diet 3) to 1564.70g (diet 2), daily feed intake, 91.69g (diet 3) to 101.10g (diet 1), daily weight gain, 31.74g (diet 3) to 42.33g (diet 2) and feed conversion ratio from 2.29 to 2.89 on diets 2 and 3 respectively. This contradicts Akpet and Ibekwe (2018). The overall phase showed that total feed intake of birds ranged from 3779.64 to 4243.12g, total weight gain, 1400.08 – 1747.96g, daily feed intake, 67.49 – 75.77g, daily weight gain, 25.00 – 31.21g and feed conversion ratio from 2.27 to 2.83.

Mortality (%)	2	1	1	2	2	-

SEM = Standard error of the mean, NS = Not significant

Conclusion

Rice bran can completely (100%) replace wheat offal in broiler chicken diets without compromising growth performance.

Abstract
144 day-old Arbor Acre chicks were used to investigate the effect of feeding diets containing cowpea milling waste and plantain peel meal mixture (CMWPPM) on the growth performance and economy of feed conversion of broiler chickens. The birds were randomly allotted to four dietary treatments in a completely randomized design model, and consisted of 0, 10, 20 and 30 % dietary inclusion levels of CMWPPM. Each treatment was replicated three times with 12 chicks per replicate, making a total of 36 chicks per treatment. The experiment lasted for eight weeks. Results showed that at the starter phase, birds on CMWPPM 0 % had significantly (P<0.05) higher feed intake, while birds on CMMPPM 20 % had significantly (P<0.05) lower feed intake than birds on the other treatments. The cost of feed and total cost of feed intake were significantly (P<0.05) higher for CMWPPM 30 % and significantly lower for CMWPPM 20 % than for the other treatments; while feed cost per kg weight gain had no significant difference across the treatments. At the finisher phase, there were no significant differences in all the growth performance parameters measured across the treatment groups. However, total cost of feed intake was significantly (P<0.05) higher for CMWPPM 10 % and significantly (P<0.05) lower for CMWPPM 20 %. The feed cost per kg weight gain was significantly (P<0.05) higher for CMWPPM 10 % and significantly (P<0.05) lower for CMWPPM 20 % and 30 % diets. Therefore, it is concluded that the inclusion level of CMWPPM in the diet of broiler chickens should not exceed 20 % for optimum economy of feed conversion at the starter phase; whereas birds can be fed diets containing 30 % dietary inclusion level of CMWPPM with good economy of feed conversion at the finisher phase.

Introduction

The poultry industry has not been a very lucrative enterprise because of high cost of conventional feedstuffs, which most times are competed for by both human beings and the livestock industry (Ironkwe and Oruwari, 2012). Nigeria, like many other developing countries of the world, is currently faced with shortage and high cost of conventional feedstuffs for poultry production (Duwa *et al*., 2014). This high cost and low availability of conventional poultry feedstuffs frequently demand consideration of by-products, even if efficiency of utilization is low, for poultry feeding (Negesse *et al*., 2009). It is important to utilize inexpensive materials not only to sustain the market of animal products but also to search for new sources of animal feed by recycling underutilized wastes (Ulloa *et al*., 2004). It is therefore necessary now for animal nutritionists to look for non-conventional feedstuffs that are readily available and cheaper in order to cut down on the feed cost, which constitute about 65-70 % of the total cost of production. Reports have shown that there are large numbers of feedstuffs with enormous potentials in Nigeria and one of such is plantain peel meal and cowpea milling waste.

Plantain peels are mostly regarded as wastes which constitute environmental pollution especially in urban areas where goats and sheep are not allowed to roam about (Ajasin *et al*., 2004; Ighodaro, 2012). Plantain peel is reported to have some nutritional values. It is a source of energy which compares favourably with maize, except for its crude fibre and ether extract content. Plantain peel is a good source of energy containing 12 % crude protein, 6 % crude fibre and 2700 Kcal/kg metabolizable energy on dry matter basis (Omole *et al*., 2008). It also contains higher levels of minerals such as calcium, iron and phosphorous (Nsa *et al*., 2010). Cowpea milling waste is a by-product obtained from cowpea. It contains 24 % crude protein and its nutrients can easily be utilized by livestock (Maidala and Bello, 2016). Research have shown that cowpea milling waste meal can be

fed to cockerel chicks up to 40 % inclusion level with no adverse effect on their growth performance (Raheem, 2016); while plantain peel meal can replace maize in broiler diets up to 75 % (Agubosi *et al*., 2019) or constitute as much as 50 % of a broiler diet (Nsa *et al,* .2010).
Although, cowpea (*Vigna unguiculata*) milling waste and plantain (*Musa paradisiaca*) peel meal have been used individually for feeding livestock, however, there are no reports on the use of cowpea milling waste and plantain peel mixture for feeding broiler chickens in Nigeria. Hence, this research study was designed to evaluate the growth performance and economy of feed conversion of broiler chickens fed diets containing cowpea milling waste and plantain peel meal mixture.

Materials and Methods

This research study was carried out at the Poultry Unit of the Department of Animal Production Teaching and Research Farm, Federal University of Technology, Minna, Niger State. This lies within the Guinea Savannah zone of Nigeria (latitude 9°37' North and longitude 6°33' East). Cowpea milling waste and plantain peel meal mixture were obtained from Kitchen Friendly, an agro–industrial company located in Gurara area of Minna. It was obtained as a by-product of cowpea and plantain processing, and used to compound four treatment diets as follows: T1 (without cowpea milling waste and plantain peel meal), T2 (with 10 % cowpea milling waste and plantain peel meal), T3 (with 20 % cowpea milling waste and plantain peel meal) and T4 (with 30 % cowpea milling waste and plantain peel meal) for the starter and finisher phases respectively (Tables 1). A total of one hundred and forty-four (144) day-old Arbor Acre broiler chicks were purchased from Damas Farm, Ibadan, Oyo State, Nigeria. Before the arrivals of the birds, the walls and floors of the pens were sanitized using Germicide (Izal®) solution, after thoroughly washing with detergent and water. The pens were then allowed to dry completely and litter materials made of wood shavings were spread on the floor of the pen. Newspapers were spread on the floor for the first one week of the experiment. Germ free feeders and drinkers were also made available with proper label of treatment and replicates for easy identification. Local pots and charcoal were made available during the brooding process to produce warmth for the chicks. The day old chicks upon arrival were made to acclimatize for one week after which the experimental diets were introduced to them. The birds were randomly allotted to four treatments in a completely randomized design (CRD) lay-out. Each of the treatment had three replicates made up of 12 birds per replicate. The experiment was carried out under an intensive management system with feed and water supplied *ad-libitum,* and it lasted for eight weeks. Vaccines were administered to the birds based on the recommendations of the Nigerian Institute of Animal Science (NIAS) for the region. Data were collected on feed intake, weekly weight gain and feed conversion ratio. Efficiency of feed conversion was determined based on the following parameters: feed cost per kg (₦), total cost of feed intake per bird (₦), and feed cost per kg body weight gain (₦/kg). Data collected were subjected to one-way analysis of variance using SPSS (2007) version 16.00. Where means were significantly different ($P<0.05$), they were separated using the Duncan Multiple Range Test as contained in the Package.

CMWPPM = Cowpea milling waste and plantain peel meal mixture ME = Metabolizable energy

Results and Discussion

The proximate composition of cowpea milling waste and plantain peel meal mixture (CMWPPM) is presented in Table 2. Dry matter, crude protein, ether extract, ash, crude fibre, and nitrogen free extract content were 83.40, 19.25, 9.50, 6.00, 9.00, 39.65 % respectively. This result shows that cowpea (*Vigna unguiculata*) milling waste and plantain (*Musa paradisiaca*) peel meal mixture has high crude protein and low crude fibre content, hence, the mixture can serve as a non-conventional protein feedstuff for broiler chicken.

Table 2: Proximate composition of cowpea milling waste and plantain peel meal mixture

Parameters (%)	Percentage composition (%)
Dry matter	83.40
Crude protein	19.25
Crude fibre	9.00
Ash	6.00
Ether extract	9.50
Nitrogen free extract	39.65

At the starter phase, birds on CMWPPM 0 % had significantly ($P<0.05$) higher feed intake, while birds on CMMPPM 20 % had significantly ($P<0.05$) lower feed intake than birds on the other treatments (Table 3). This result contradicts the findings of Abdon *et al* (2013) who reported that different dietary levels of cowpea seed had no significant ($P>0.05$) effect on feed intake in broiler chicken. The observed difference in feed intake in this study might be due to plantain peel meal inclusion in the diets which affected feed palatability and acceptability, and hence feed intake. There were no significant differences in all the growth performance parameters of the birds fed different dietary levels of CMWPPM at the finisher phase. This differs from the findings of Akanji *et al.* (2015) who reported that cowpea based diets had effect on broiler performance because feed consumed and growth response were extremely ($P<0.05$) declined in chicks fed unprocessed cowpea and dehulled cowpea diets respectively.

The results of the economy of feed conversion at the starter phase showed that as the level of cowpea milling waste and plantain peel meal mixture increased, cost of feed per kg decreased (which was not the case at the finisher phase). This is similar to the findings of Adama *et al.* (2007) when they fed sorghum dried brewers' grain to broiler chicken and reported that feed cost was significantly ($P<0.05$) lower when fed at 40 % dietary inclusion level. At the finisher phase, feed cost per kg weight gain was significantly ($P<0.05$) higher for CMWPPM 10 % and significantly ($P<0.05$) lower for CMWPPM 20 % and 30 % diets; whereas, there were no significant differences in feed cost per kg weight gain among the birds fed the different dietary treatments at the starter phase.

Conclusion and Recommendations

From the results of this research study, it is concluded that the inclusion of CMWPPM in the diets of broiler chickens should not exceed 20 % for optimum economy of feed conversion at the starter phase; whereas birds can be fed diets containing 30 % dietary inclusion level of CMWPPM with good economy of feed conversion at the finisher phase.

Abstract
An experiment was conducted to investigate the carcass yield and the economics of rabbit production. Rabbit were fed different types and levels of rumen content. Forty-eight (48) mongrel rabbits were randomly allotted to six diets containing rumen content of *caprine*, *ovine* and *bovine* each had 30 and 40% levels of inclusion in 3x2 factorial arrangements completely randomized design (CRD). Results showed that the interaction effect did not affect live weight (1075.00-1487.50g), carcass weight (456.25-775.00g) and dressed weight (38.36-52.86%). There were significant different (P>0.05) in the grow performance of rabbit fed different levels of rumen content. Most of the organs were not affected by the interaction effect (P<0.05) except the lungs (0.42-0.63%), head (7.72-9.25%) and small intestine (3.50-4.38%) which were affected by the interaction effects (P<0.05). Most of the parameters assessed were not affected by the main effect (P>0.05) of types of rumen contents except the kidney (0.15-0.64%), stomach (1.2-1.58%) and small intestine (0.93-1.19%) which were affected (P<0.05). The economics of production showed that feed cost per kg decreased slightly at higher levels of inclusion for the three types of rumen content. The feed cost per kg gain also decreased as the level of rumen content increase. Therefore rumen content should be included at higher levels in the diet of rabbits for enhanced carcass yield and reduce cost of production

Keywords: Rumen content, Carcass yield, Caprine, Ovine, Bovine

Introduction

The dietary protein intake in Nigeria is 4.5g grossly short of the recommended 35g of animal protein intake per person per day (FAO, 2001). This observed low animal protein intake may be attributed to the declining animal production occasioned by the high cost of feeds which usually accounts for 70-85% of total cost of production (Sanni and Ogundipe, 2005). Possible and most appropriate measure for shortage of animal protein for human consumption lies in the production of fast growing animals like rabbits. This is because livestock like cattle, camels, sheep, goats and pigs take longer time to mature. Rabbits as potential animal with short generation interval, high prolificacy, easy management strategy, ability to utilize waste and other unconventional feed sources for maximum weight gain (efficient feed conversion) to good high quality and quantity animal protein and the ability to thrive on forage with little concentrate will reduced the shortage of protein from animal sources. Rabbit meat is also known to be low in sodium, cholesterol and higher proportion of polyunsaturated linoleic and linolenic fatty acids. All these attributes in addition to less fed cost of production, make rabbit desirable livestock that can help increase and improve protein intake of an average income earning in Nigeria (Mohammed, *et al.,* 2011)

There is an urgent need for low cost feed ingredient especially locally available and cheap agro-industrial products particularly those that do not attract competition in consumption between humans and livestock or have no direct relevance in human food channel. Rumen digesta is one of these wastes that pose a problem to the environment. It is an abattoir by-product obtained from cattle, sheep and goat as well as camel (Maigandi *et al*., 2004). Magaindi and Tukur (2002) reported the proximate analysis of rumen content for camel, cattle sheep and goat slaughtered at the Sokoto abattoir. In their studies, camel rumen content was reported to have 8.39% crude protein (CP), 11.98% ether extract (EE), and 36.74% (CF) while 8.18% CP, 2.68 EE and 33.31% CF were documented for cattle. Sheep rumen digesta had 9.18% CP, 5.57% EE and 33.31% CF while 8.03 % CP, 5.57% EE and 30.83% CF were values for goat. Sun-dried rumen content of various ruminants animal by-product which is found mostly in abattoirs when the rumen of the animals is cut open after slaughter. The rumen is a unique organ. Its content (rumen content or digesta) is very heterogeneous. It is made up of digested feed at different stages of degradation, saliva (making up the rumen liquor) micro-organisms and the products of their metabolic activities such as proteins, peptides, amino acids, lipids, vitamins and Volatile Fatty Acids (VFA). The aim of this research work is to ascertain higher inclusion levels of rumen content of cattle, sheep and goats on carcass characteristics and economics of production of rabbits.

Materials and Methods

Experimental Site

The experiment was conducted in Katagum Local Government Area of Bauchi State, Nigeria. It is located between latitudes 11^0 42' and 11^0 40^0 and longitude 10^0 31' and 10^0 11' east (Anon, 2009). It shares common boundary with Itas/Gadau local government in north-west, Jama'are to the west, Dambam to the east, Misau to the south-west, Giade to the south and Shira to the southwest (Azare, 2013). It has a landmass of 1,120 square kilometres (NPC, 2009). The climate of the study area is controlled by the intertropical convergent zone (ITCZ) which is marked by the rainy and dry season. The major climate elements that influence the weathe of the study area and affecting the farming system were temperature and precipitation (rainfall), the annual temperature ranged between 22-33^{0}C from April to May (Bashir *et al*., 2001). The mean annual rainfall ranged between 615.6-985mm with peak between July-Augusts.

Sources and feed Processed

Different rumen contents inclusion from caprin, ovine and bovine were obtained from Azare Abattoir and suns dried by constant raking at an intervals of 2hours until dry materials were obtained. Other feed ingredients were procured at Azare main market. The rabbits used in this study were mongrels obtained from the rabbit farmers in Azare. The three types of rumen content were used for formulation of six diets each at 30 and 40% levels. The percentage composition of the experimental diet was shown in table 2. Forty-eight mongrel rabbits were randomly allotted to the six experimental diets. There were eight rabbits per treatment and replicated 4 times (two rabbits per replicate) in a completely randomized design (CRD) using 3x2 factorial arrangements.

Proximate composition of different types of rumen content

The samples of different types of rumen content were taken to biochemistry laboratory, School of Agriculture and Agricultural Technology of Abubakar Tafawa Balewa University Bauchi for proximate analysis. Samples were analyzed for crude protein (CP), crude fibre (CF), ash, crude fat (ether extract) and nitrogen free extract (NFE) accurate to the procedures of AOAC (1990).

Carcass evaluation

At the end of the feeding trial, 4 rabbits were randomly sampled from each treatment, weighed, starved overnight and slaughtered by severing the jugular vein. During evisceration, the internal organs and other gut contents were removed and weight, the dressed carcass and internal organs were weight and expressed as percentage of the live weight.

$$\text{Dressing \%} = \frac{\text{Dressed carcass weight}}{\text{Live weight}} \times 100$$

The economics of production was based on the prevailing market price at Azare as of the time of the experiment. The experiment lasted for six weeks and both the interaction effects as well as main effects were tested. The data set generated was analyzed according to Steel and Torrie 1980 using the Minitab Statistical software. LSD was used to separate the means.

Results and Discussion

Table1 showed the percentage composition of the different types of rumen content fed to rabbits. The crude protein, crude fibre and ash content ranged of 16.00%-16.06%, 8.34%-17.83% and 3.56%-7.93% were adequate for growing rabbits in the tropics (Aduku, 2004). The proximate composition of different types of rumen content shown in table 2, results showed variation in different types of rumen content for caprine, ovine and bovine CP 15.93%, 12.29% and 11.23%, CF 32.58%, 33.56% and 34.61%, EE 0.86%, 1.15% and 1.23%, Ash 11.21%, 13.42% and 12.54% and NFE 40.85%, 34.42% and 35.59% respectively. The results were similar to those reported by Abubakar (1998), and Dairo (2005). The high CP in caprine rumen content can be attributed to grazing habits of goat which prepare to browse of young shoot, twigs and flowers which are more nutritious than the mature plant. Similarly Mohammed *et al*. (2008) showed a wide variation between rumen content of cattle, camel, sheep and Goat. The effect of interaction of carcass of rabbits fed rumen content is shown in Table 3, results showed that final live weight, carcass weight and dressed weight were not affected by the types and levels of rumen content ($P>0.05$), and this findings partly concord with the findings of Ani *et al*. (2015) who reported non-significant difference in rabbits fed dehydrated rumen content. Most of the gut content of different rumen content fed to rabbits were not affected by the types and levels of rumen content except the head, and small intestine which were affected by interaction effect ($P<0.05$). Olabanji *et al*., (2007) reported a significant difference in small intestine of rabbits fed rumen content. Similarly Esonu *et a*l., (2006) reported that there were no significant differences in organs of rabbits fed rumen content. The main effects of different types of rumen content are shown in Table 4. Results showed that most of the carcass parameters were not affected by the types of rumen content ($P>0.05$), this results partly agrees with the findings of Okpanchi *et al*., (2010) who reported that there was no significant difference between carcass yield and organs of rabbits fed sun dried rumen content. The economics of production of rabbits fed different rumen content is shown in table 5. Results showed that the feed cost per kg steadily declines from 30-40% level. Similarly the feed cost per kg gain decreased from 30-40% for the three types of rumen content and this is in line with the earlier reports of Mohammed *et al*., (2011) who reported decline in cost per kg gain of rabbits fed bovine rumen content. The highest fed cost per kg gain was observed in caprine rumen content (₦181.60) while the lowest fed cost was observed in 40% rumen content of bovine (₦137.75)

Conclusion

Rumen content of cattle sheep and goat can be included up to 40% level in the diet of growing rabbits without adverse effect on carcass characteristics with reduction in cost of production.

Abstract
Twenty-five (25) Crossbred grower rabbits were used to assess the effects of Rumen Epithelial Scrapings (RES) inclusion in the diets for rabbits. The five treatment groups consisting of five replicates of one rabbit per replicate in a Completely Randomized Design (CRD). The dietary treatments comprised graded levels of RES at 0, 2.5, 5, 7.5 and 10% in T_1, T_2, T_3, T_4 and T_5 diets respectively. Total feed offered was 100g/rabbit/day. Feed intakes were similar ($P<0.05$) across the dietary treatments, 1, 2, 3, and 4. Daily weight gain and feed to gain ratio were not affected ($P<0.05$) by increasing rumen epithelial scrapings except in T5 (10% RES) that recorded (10.01) and (8.51) respectively. Lower feed cost/kg significantly reduced ($P<0.05$) the cost/kg gain (₦) in diets 2 (₦444.4), 3 (₦447.7) and 4 (₦449.5) compared with the control diet 1(₦450). Conclusively, grower rabbits can utilize up to 7.5% rumen epithelial scrapings based diets without any adverse effect on performance.

Keywords: Grower rabbits, rumen epithelial scrapings, feed to gain ratio, cost/kg gain, inclusion

Introduction
There is an increasing interest in rabbit production in the developing countries, as a means of producing meat from forages and agricultural by-products in the tropics (Babayemi *et al.,* 2014; Adedoyin and Bamimore, 2018). Rabbits are especially well adapted to backyard rearing systems, with little capital and fodder resources which are usually limiting factors in animal production. Rabbits reared according to the techniques appropriate to the environment can do much to improve the family diet of many of the neediest rural families, while at the sametime supplying them with a source of income. With more advance bio-technology rabbit production can also help to supply big City meat markets. It has infact been stated that hindgut digestion which takes place in the rabbit is a superior adaption for dealing with wide varieties of feed staffs (Iyeghe-Erakpotobor and Esiero, 2010). However, to ensure sustainability in livestock production there is a need to optimize usage of the by-products of the abattoir as sources of nutrients for farm animals (Abubakar, 1998). A number of slaughterhouse byproducts are presently being wasted, such as rumen epithelial scrapings, blood, meat scraps, etc. Rumen contents can be prepared as a few material either by sun-drying involves spreading the material on any heat absorbing surface and constantly raking it to facilitate uniform drying. Ensiling involves mixing rumen contents with other ingredients such as molasses and packing the mixture tightly in silos or other suitable containers under anaerobic conditions (Adedoyin *et al.,* 2013). Abubakar (1998) opined that rumen contents are a good source of vitamins, especially the B vitamins. And that the dried material contains 15.43% crude protein, 1.91% ether extract, 39.08% crude fibre, and 31.71 Nitrogen free extract (NFE). Thus, the objectives of this study is to evaluate the nutritional values of rumen epithelial scrapings based diets for grower rabbits.

Materials and Methods
A total of twenty-five, four to five weeks old crossbred rabbits of mixed breeds (New Zealand white and Chinchinlla) and sexes, obtained from I.A.R.T, Ibadan, Oyo State were randomly assigned to treatment (n = 5 rabbits per treatment). The rabbits of average initial weight of 450g were individually housed and maintained in battery cages in an open sided house. Rumen Epithetical Scrapings (RES) were obtained from Bodija market abattoir, Ibadan. The RES are then dried and grounded separately to a fine powder and replaced with groundnut meal at 0, 2.5, 5, 7.5, and 10% w/w in treatment 1(control), 2, 3, 4 and 5 respectively (Table 2). Body weight and feed intakes were determined weekly

while feed to gain ratio was estimated as outlined by Olomu (2011). Feeding was done in the morning at 08:00 hours in earthen flat bottom pots. The concentrate and forage were offered to give a total of 100g feed/rabbit/day. Feed wastage and/left over were measured daily before the morning feeding so as to determined the total feed intake for eight weeks, water was provided ad libitum in plastic drinkers (Iyeghe-Erakpotobor, 2012). Mortality ratio were also calculated as percentage of total Number of rabbits per group. Data collected were subjected to the analysis of variance test, (2007). Means of significant result was compared by Duncan's. Proximate analysis of the rumen epithelial scrapings were analyzed according to the procedures described by AOAC (1990).

RESULTS AND DISCUSSION

Performance of grower rabbits fed different levels of rumen epithelial scrapings (RES) is shown in Table 3. Feed intakes were similar with a slight increase with an increasing levels of Rumen Epithelial Scrapings (RES) from 2.5 to 7.5% in the diets 2, 3, and 4. Similar intakes observed in the diets 2 (78.01), 3 (79.11) and 4 (81.8) for grower rabbits fed 2.5 to 7.5% RES could indicate a threshold of intake which might have been approached as the forage level increased. This could probably also suggests, an inability of the rabbits to further increase their gastrointestinal tract capacity to accommodate any further increase in feed intake as RES level increased from 2.5 to 7.5% level as also suggested (Iyeghe-Evakpotobor *et al.,* 2012). Daily weight gain and feed to gain ratio were not affected (P>0.05) by increasing RES except in T5 (10% RES) that recorded (10.01) and (8.51) respectively. A significant lower weight gains of grower rabbits fed diet 5 (10% RES) in this study compared to others (diets 1, 2, 3, and 4) could be as a result of the depressing effect of increasing rumen epithelial scrapings (RES) in the diet. Also, that possibly an increased level of RES brought about on rich bacteria protein a drastic changes in the biological functions of grower rabbits, poor feed efficiency and utilization, disturbances in metabolism of energy, mineral and vitamin balances, and enzymatic reactions with an impaired fermentative mechanisms in the cecum (NAP, 1991; Nwagu and Iyeghe-Erakpotobor, 2012; Adedoyin *et al.,* 2013) Lower feed cost/kg gain obtained with increasing level of RES up to 7.5% in the diet indicates the potential of reducing cost of producing rabbits by increasing the level of rumen epithelial scrapings in the diet of grower rabbits.

CONCLUSION

It is concluded from this study that grower rabbits can utilize up to 7.5% rumen epithelial scrapings diet based without any adverse effect on performance. Also, that lower feed cost and cost/kg weight gain were obtained.

Abstract
One hundred (100) Anak strain day-old broiler chicks were used to evaluate the replacement value of Sesame Seed Meal (SSM) (Sesamum indicum) for soybean meal (SBM) on growth response of broilers starter. Chicks were randomly allotted to four treatment groups consisting of five replicates of five chicks per replicate in a completely randomized design. The dietary treatments were sesame seed meal (SSM) replaced for soybean meal at 0, 5, 10 and 15% w/w in T_1 (control), T2, T3, and T4 diets respectively. For four weeks, data were collected on feed intake, weight gain, feed to gain ratio and mortality. Results revealed that all the parameters were similar ($P<0.05$) across the dietary treatments except feed to gain ratio which was significantly ($P<0.05$) better in T_2 (5% SSM replacement) (1.60) compared to control T1 (0% SSM replacement) (1.61) respectively. It can be concluded that sesame seed meal (SSM) has a potential to replace at least 5% soybean meal (SBM) without any negative effect

Key words: Replacement value, growth response, feed to gain ratio, potential, mortality.

Introduction

Nigeria still remains among the least animal protein consumers in Africa. For instance, the average animal protein intake for Africa is 11g/head/day while the average value for Nigeria is 7.5g/head/day. This has been attributed to high and rising cost of some feedstocks which are not always accessible to rural farmers' accounts for 60 – 75% cost of raising commercial poultry (Adedoyin, 2014), Similarly, with the insufficient production of soybean meal (SBM) in Nigeria has led to permission being given for an import of this product from other countries such as Brazil, Austria etc. However, today the price is considerably still high due to government policy which also on the other hand has to encourage soybean growers in Nigeria. Searching for alternative vegetable protein sources, which are cheap and locally available, has become increasingly urgent subject to poultry nutritionists in the country. One of the vegetable plant sources that can replace soybean is sesame seed. Sesame (*Sesamum indicum-L*) seed is a drought, tolerant crop adapted to many soil types (Rahimian *et al*., 2013). Sesame meal is the by-product of oil extraction from sesame seed. It has a crude protein content of about 46% and medium energy value (Olomu, 2011). Full fat sesame seed and the meal after oil extraction are not only excellent sources of edible nutrients (45 to 50% lipid, 15 to 20% protein, and 10 to 15% carbohydrate and 47.1 to 52.9% crude protein respectively (Deyab *et al*., 2007). The amino acid composition of the protein is similar to that of soybean meal with the exception of lower lysine and higher methionine in sesame. The fiber content of the seed ranges from 2.7 to 6.7% (Ralf and Knoietzny, 2016). Sesame seeds are also good sources of minerals and vitamins such as manganese, copper, calcium, vitamin B_1 and Vitame E and in addition to the highly absorbable spectrum of vitamin E, they increase its bioactivity in the body (Yakubu and Alfred, 2014) Many studies have showed sesame seed meal replacement of soybean meal at 25 – 75% in broilers diet. Therefore the objective of this preliminary study is to evaluate the replacement value of sesame meal for soybean meal based diets for broilers starter.

Materials and Methods

100 day old unsexed Anak strain broiler chicks were randomly allotted into four treatments groups in a completely randomized design. Each treatment group was replicated five times with five birds per replicate. Sesame seed meal purchased from Maya market in Ibarapa Area, Oyo State was dried and then grounded separately to a fine powder and replaced with soybean meal at 0, 5, 10, and 15% w/w

in treatments 1 (control), 2, 3 and 4 respectively (Table 2). Body weight and feed intakes were determined weekly while feed to gain ratio was estimated as outlined by Olomu (2011). The birds were fed the experimental diets and clean drinking water ad libitum for a period of 4 weeks. Mortality ratio were also calculated as percentage of total number of birds per group. All data collected were subjected to analysis of variance technique (SAS 2007). Means of significant result was compared by Duncan's. Proximate analysis of the sesame seed were analyzed according to the procedures described by AOAC (1990).

Table 1: Proximate Composition of Sesame Seed Meal and Soybean Meal

Results and Discussion

The nutrients composition of the test diets indicated an optimum crude protein value of approximately 23% as suggested by Olomu (2011). The growth performance of the starter broilers fed sesame seed meal (SSM) and soybean meal (SBM) based diets are presented in Table 3. At the starter phase, the results show that all parameters were similar (P> 0.05) across the dietary treatments. However, numerical higher values of 870. 8, 31.1 and 1.60 respectively were recorded for final body weight, daily weight gain and feed to gain ratio of birds fed T_2 (5% SSM) replacement of soybean meal. Also, there was a decrease in average final body weight and daily weight gain with increased level of sesame seed meal in the diets T_3 (10% SSM replacement) and T_4 (15% SSM replacement). This results is in agreement with the reports of Agbulu et al (2010) and Diarra and Usman (2008) that reported slight decrease in weight gain of broilers fed high graded levels of soaked sesame seed meal as a source of methionine in broiler chickens.This could be attributed to the presence of phytic and oxalic acid content of sesame seed meal and its subsequent inhibiting the nutrients utilization in the diet. Hossain and Jauncey (1998) suggested that the high phytic acid content of SSM is a possible reason for its lower apparent protein digestibility. Also, it was stated that being a lignanin plant which may interferes the absorption of minerals and vitamins in the diet and also led to poor feed to gain ratio observed as the level of sesame meal increased. Although, birds fed T_2 (5% SSM replacement) diet had better fed to gain ratio compared with the control. It agrees with Olomu (2011) that sesame

seed meal which has a higher content of methionine than most plant protein supplement when used in the right proportion together with soybean meal which also has a higher content of lysine, will result in balanced diet of lysine and methionine, which might play a crucial role in digestion as observed in this study.

Conclusion: It can be concluded that sesame seed meal has a potential as a feed resource to replace soybean meal at 5% in broiler diets without any negative effect. Also, its contents phytate and oxalate still possess some limitations to its use as a feed resource.

Abstract

The main objective of this study was to evaluate the effects of African walnut (Tetracarpidium conophorum) leaf and its extract on the growth performance of broiler chickens. Five experimental diets were formulated with the inclusion of Tetracarpidium conophorum Leaf Powder (TCLP) and its Extract (TCLE). The diets were made as followings: (T1) control and basal diet; (T2) T1 + 250mg TCLP kg/diet; (T3) T1 + 500mg TCLP kg/diet; (T4) T1 + 25mg TCLE kg/diet; (T5) T1 + 50mg TCLE kg/diet. This study was conducted from 7 to 49 days of age. A total of 135 seven days old, unsexed broiler chickens were used. They were individually weighed and randomly distributed into five dietary treatments; each treatment included three replicates each with a total of nine birds per replicate on the basis of their weight. Data were collected on growth performance and subjected to one way of analysis of variance in a Completely Randomized Design. At the starter phase, birds fed the control diet had significantly ($p<0.05$) greater average weight gain (420.55g), average feed intake (2201.45g) and lower feed conversion ratio (2.86) compared to other treatment groups. At the finisher phase, no significant ($p>0.05$) difference was observed on growth performance across the dietary treatments. Based on the results, it is therefore concluded that growth performance of the broiler chickens both at starter and finisher phases were not influenced by Tetracarpidium conophorum leaf powder and its extract.

Keywords: African Walnut leaf, broiler chickens, and growth performance

Introduction

Antibiotics have been utilized as growth promoters and to prevent outbreak of diseases (Phillips *et al.*, 2004). However, the benefit of the use of antibiotics as growth promoters has some disadvantages; these include drug toxicity, residual effects and development of bacteria resistance (Ogbe and John, 2012). These problems have led to the ban on the use of antibiotics as growth promoters by the European Union (Catalá-Gregori *et al.*, 2008). Thus, attention to safe and natural alternatives such as plants to replace antibiotics (phytobiotics) is on the increase. Therefore, for a long time antibiotics have been supplemented to animal diets to allow animals to cope better with these harsh conditions. This led to the ban of antibiotics in animal diets in the European Union in 2006. As a result, many substances belonging to the groups of prebiotics, probiotics, organic acids, enzymes, silicates and herbs and spices have been tested for their potential to replace AGPs in animal diets, also for poultry.

African walnut (*Tetracarpidium conophorum*), like many plants in Africa and other parts of the world has been proven to have nutritive, medicinal, agricultural and industrial values over the years. Phytochemical analysis of Africa walnut indicates that it contains bioactive compounds such as oxalates, phytates, tannins, saponins and alkaloids which partly show the use of the seeds, leaves and roots in herbal medicine (Ayoola *et al.* 2011. Studies have shown that *T. conophorum* possesses some properties that are required for wound healing like antibacterial and antioxidant activities (Amaeze *et al.*, 2011) and immuno stimulating activities (Animashaun *et al.* 1994).

Extracts of *T. conophorum* leaves have been shown to possess good antibacterial activities especially against Gram positive organisms. Results from a study conducted by Onwuli *et al.* (2014) suggested that *T. conophorum* nuts have antihyperglycaemic and antimicrobial activities. A research conducted by Okon *et al.* (2014) discovered that albino wistar rat fed with a standard, commercial diet (control group) or a diet *containing T. conophorum* seeds for 60 days reduced the level of cholesterol and triglyceride in the rats compared with the control group fed with standard diets.

Based on the aforementioned bioactive compounds and properties of (*Tetracarpidium conophorum*) the plant, there is need to know whether (*Tetracarpidium conophorum*) leaf and its extracts could be used as feed additives for broiler chickens in producing safe and cost effective meat. Therefore, the

objective of the present study is to evaluate the effects of African walnut (*Tetracarpidium conophorum*) leaf and its extracts on the growth performance of broiler chickens.

Materials and methods

Experimental Site

This experiment was carried out at the poultry unit, Federal College of Agriculture, Moor Plantation, Ibadan, Nigeria.

Sourcing and Processing of Test Ingredients

Tetracarpidium conophorum leaves were obtained from a farm in Omi adio, Ibadan. They were washed with clean water and allowed to air dry under shade and thereafter were ground into powder and stored in the dark in airtight plastic bags at ambient temperature. The Proximate analysis of the test ingredient was analyzed in the laboratory according to AOAC (1999). The *Tetracarpidium conophorum* leaf extract was obtained by soaking the *T. Conophorum* powder in ethanol (as an extracting solvent) for 48 hours. The ratio of ethanol volume (mL) and sample weight (g) was 40:1. Then, the extract solution was concentrated at a temperature of 50°C using a rotary evaporator. The leaf and seed extracts were stored in separate dark airtight plastic bags at ambient temperature.

Experimental Diet

Five experimental diets were formulated with the inclusion of *Tetracarpidium conophorum* Leaf Powder (TCLP) and *Tetracarpidium conophorum* Leaf Extracts (TCLE). The diets were made as followings:

(1) T1, control and basal diet; (2) T2, T1 + 250mg TCLP kg/diet, (3) T3, T1 + 500mg TCLP kg/diet (4) T4, T1 + 25mg TCLE kg/diet and (5) T5, T1 + 50mg TCLE kg/diet

Experimental Design and Management

This study was conducted from 7 to 49 days of age. A total of 135 day old, unsexed broiler chickens were purchased from a commercial hatchery in Oluyole, Ibadan, Nigeria. On arrival, all chickens were fed a commercial broiler starter for 7 days. Then, at 7 days of age, they were individually weighed and randomly distributed into five (5) dietary treatments; each treatment included three (3) replicates each with a total of nine (9) birds per replicate on the basis of their weight. Routine managements, vaccinations and medications were duly followed throughout the course of the study and the experiment lasted for six (6) weeks.

Data collection

Chemical Analysis: Proximate analysis of the test ingredient was carried out according to the method of AOAC. (1990).

Growth Performance Evaluation: Records of live weight (g), feed intake (g), weight gain (g) and feed conversion ratio (FCR) were determined on weekly basis.

Statistical analysis: All data were analyzed using one way analysis of variance (ANOVA) and means was compared by the Duncan's multiple range test when ANOVA analysis is significant (SPSS 16).

Results and Discussion

Table 2 shows the effect of varying levels of Africa walnut leaf Powder and its extract on growth performance of broiler chickens at starter phase. Birds fed the control diet (T1) had significantly ($p<0.05$) greater final weight, weight gain and feed intake than other treatment groups. The final weight (FW) values ranged between 503.89g and 555.78g with the highest value for the bird fed the control diet (T1) and least value for the bird fed 250mg TCLP kg/diet (T2). The inclusions did not increase the growth performance. Table 3 shows the effect of varying levels of African walnut leaf Powder and its extract on growth performance of broiler chickens at finisher phase. No significant ($p>0.05$) differences in final weight, average weight gain, average feed intake and feed conversion ratio observed in broilers fed *Tetracarphidium conophorum* leaf powder and its extract at finisher phase. These results are in accordance with the reports of Botsoglu *et al.,* (2002) and Lee *et al.,* (2004) who found that dietary supplementation of oregano essential oil (100 and 50 mg/kg, respectively) did not affect the broilers' performance. Likewise, supplemental PFA containing turmeric extract, citrus extract, grape seed extract, Chinese cinnamon essential oil, Chilean boldo leaves, and fenugreek seeds had no effect on growth performance of broilers (Fascina *et al.,* 2012).

Abstract
The study was conducted for six weeks to investigate the effect of Canarium schweinfurthii seed meal on performance and serum biochemistry of broiler chickens. One hundred and twenty arbo acre two weeks old broiler chicken were randomly allotted to four dietary treatments (T1 to T4) of 0%, 5%, 7.5% and 10% inclusion levels of Canarium schweinfurthii seed meal (CSSM) with three replicate of ten birds each in a completely randomized design. The parameters measured are performance (weight (g), average weight gain (g), feed intake (g), and feed conversion ratio (FCR) was calculated), serum biochemical indices (total protein (g/L), albumin (g/L), globulin (g/L), creatine (g/d) and cholesterol (mmol/L). The results showed significant variation ($p<0.05$) in average weight gain, average feed intake and final weight across the treatments while the FCR were not significantly different ($p>0.05$). The serum biochemical indices were significantly different ($p<0.05$) across the treatments. Therefore, Canarium schweinfurthii seed meal with phytase enzyme can be included in the diets of broiler chickens without having a negative effect on the growth performance and biochemical indices of the birds.

Key words: *Canarium schweinfurthii*, broiler chickens, performance, serum, phytase

Introduction
In developing countries like Nigeria, the supply of animal protein is grossly inadequate. It is established that an average Nigerian consumes only 8.6g of animal protein per day as against 53.3g by the inhabitants of developed countries (Ojo, 2003). Sanni and Ogundipe (2005) reported that poultry industry occupies a major position in livestock production as birds reproduce much quicker to produce meats and eggs for human consumption. According to FAO (2006) poultry is considered to be a means of livelihood and a way of achieving a certain level of economic independence. Nutrition is perhaps the most important consideration in livestock management. Therefore, the major interest of the farmer is to reduce the feed cost, which accounts for 60 to 70 % of the total cost of production (Igwebuike *et al*., 2001 and Ogundipe, *et al*; 2003). Research efforts are geared towards evaluating alternative feed ingredient that are less costly and yet efficient for poultry. In essence, to overcome the problem of feed shortage in the poultry industry, the recent trend is the usage of non-conventional feedstuff that is readily available, cheap and nutritionally safe in poultry feed formulation. One of such non-conventional feedstuffs with great potential is *Canarium schweinfurthii* seed. *Canarium schweinfurthii* is a suitable source of edible oil which can also serve as alternative source of energy with valuable minerals such as calcium, potassium, magnesium, sodium, phosphorous, iron, zinc and copper (Adelowo *et al*., 2019a). Adelowo *et al*., (2019b) in their findings reported that, the inclusion of roasted *Canarium schweinfurthii* seed meal up to 7.5% significantly improve the final weight, weight gain and feed intake of broiler chickens. Hence, this study evaluates the growth performance and serum biochemistry of broiler chickens fed graded level of *Canarium schweinfurthii* seed meal with phytase enzyme.

Materials and methods
The study was carried out at the Poultry Department of the National Veterinary Research Institute (N.V.R.I.), Vom, Plateau State. One hundred and twenty day-old broiler Arbo acre chicks were acquired from a local hatchery. The chicks were brooded for 14 days (at a density of 20 chicks/$m^{2)}$ using a commercial feed and thereafter the experimental diets were introduced. The chicks were weighed at the beginning of the experiment to obtain the initial weight. The 120 broiler chicks of fourteen days old were randomly allotted in a completely randomized design to 4 dietary treatments 0% (T1), 5% (T2), 7.5% (T3) and 10% (T4) inclusion levels of *Canarium schweinfurthii* seed meal (CSSM). Each dietary treatment had 30 chicks with 3 replicates of 10 birds. *Canarium schweinfurthii*

seeds were sourced in a local market from Pankshin L.G.A., Plateau state, dried, grounded and mixed with other ingredients in the experimental diets. Thirty grams of phytase enzyme was weighed and added to the dietary treatments; the composition and calculated analysis of the experimental diets are presented in Table 1. The diets were isonitrogenous and isocaloric to meet the recommended crude protein and Metabolisable energy requirements as stated by NRC (1994). Feeds and water were given *ad libitum.* The parameters were measured weekly: the performance data taken include feed intake, initial and final weight, body weight gain while the feed conversion ratio (FCR) was calculated weekly. Daily feed consumption was recorded as the difference between feed offered and the left over. The birds were raised on deep litter standard management and hygiene, the recommended vaccines for broilers were administered accordingly. The duration of the experiment was six weeks. At the end of the six weeks study, 2 birds from each treatment were randomly selected and blood samples were collected for serum biochemistry analysis. For each chicken, 2ml of blood was collected with a syringe via the wing vein and transferred into an anti-coagulant free bottle. Meanwhile, after centrifugation, blood free from anticoagulant, serum was collected and preserved at -20^{0}C for the evaluation of serum biochemical parameters (Total protein, Albumin, Globulin, Total cholesterol and Creatinine) using a colorimetric method as prescribed by the commercial kits (Chronolab® kits).

Statistical Analysis

Data obtained from the experiment were analysed using the statistical analysis of variance (ANOVA) procedure of SAS (2010) and significant level of p=0.05 was used. The treatment means were compared using the New Duncan Multiple Range test of the same software.

Table 1: Composition of the experimental diets

Ingredient	T1 (0%)	T2 (5%)	T3 (7.5%)	T4 (10%)

Results and Discussion

Table 3: Growth performances of broiler chickens fed *Canarium schweinfurthii* seed meal

Parameters	Treatments				
	T1 (0%)	T2 (5%)	T3 (7.5%)	T4 (10%)	SEM
Initial weight(g\bird)	235.00	235.00	232.00	230.00	0.12
Average Feed intake (g\bird)	970.00^{a}	893.50^{b}	842.50^{b}	768.00^{c}	14.8
Average weight gain (g\bird\week)	294.00^{b}	323.50^{a}	314.00^{a}	295.00^{b}	9.4
Final weight (g\bird)	1999.00^{b}	2271.00^{a}	2150.00^{ab}	2000.00^{ab}	65.0
FCR	3.29	2.76	2.68	2.90	0.37

abc Means along the same row with different superscripts are significantly different ($p<0.05$)
SEM =Standard Error of Mean

In Table 3, it was observed that final weight/bird, average weight gain/bird/week and average feed intake/bird increased significantly ($P<0.05$) across the treatments. The final weight/bird values ranges from highest 2271.00g (T2), to lowest 1999.00g (T1) respectively. The average weight gained/bird increases from 294g (T1), 295g (T4), 314g (T3) to 323.50g (T2) and the average feed intake/bird

decreases from 970g (T1), 893g (T2), and 842g (T3) to 768g (T4) respectively. The FCR values were not significantly different ($p>0.05$) across the treatments. The final weight value was higher in birds fed diet with 5% and 7.5% CSSM compared to those fed with the control diet (T1) this result agree with the findings of Adelowo *et al*., (2019) that broiler chickens can tolerate roasted *Canarium schweinfurthii* seed meal up to 7.5% without affecting their performance. The introduction of phytase enzyme in T2 to T4 had positive effect on the FCR which agree with the report in the findings of Agboola *et al*. (2015) that enzymes addition to diet had positive effect on broiler growth. The average weight gain and final weight of the broiler chickens were significantly different. Hence, CSSM can be included in broiler diet up to 10% because the seed contained appreciable amount of nutritionally valuable minerals such as calcium, potassium, magnesium, sodium, phosphorous, iron, zinc and copper while glutamic and aspartic acids dominated the amino acid profile also appreciable amount of essential amino acids which was more than fifty percent of total amino acid contents (Aigade *et, al.* (2017). Table 4 shows the effect of feeding different levels of *Canarium schweinfurthii* seed meal on serum biochemical indices of broiler chickens is shown in Table 3. The total protein levels were 52.50g/L, 58.50g/L , 47.00g/L, and 48.00g/L respectively. The albumin levels were 28.00g/L, 30.00g/L, 25.00g/L and 25.00g/L respectively. The globulin were 25.00g/L, 28.50g/L, 22.00g/L and 23.00g/L respectively, the creatinine levels were 1.95mg/dL, 1.65mg/dL, 2.15mg/dL and 1.55mg/dL respectively while the cholesterol levels were 2.80mmol/L, 1.75mmol/L, 2.30mmol/L and 2.25mmol/L from T1 to T4 respectively. There were significantly variations ($p<0.05$) in all the biochemical indices measured in this study across the treatments. Although, the total protein, albumin and globulin were not statistically different for treatments T1 and T2.

Table 4: The Serum biochemistry of broiler chickens fed *Canarium schweinfurthii* seed meal

Parameters	Treatments				
	T1 (0%)	T2 (5%)	T3 (7.5%)	T4 (10%)	SEM
Total protein (g/L)	52.50^{ab}	58.50^{a}	47.00^{b}	48.00^{b}	1.68
Albumin (g/L)	28.00^{ab}	30.00^{a}	25.00^{b}	25.00^{b}	0.78
Globulin (g/L)	25.00^{a}	28.50^{a}	22.00^{b}	23.00^{b}	1.12
Cholesterol (mmol/L)	2.80^{a}	1.75^{b}	2.30^{ab}	2.25^{ab}	0.15
Creatine (mg/dL)	1.95^{a}	1.65^{b}	2.15^{a}	1.55^{b}	0.08

abc Means along the same row with different superscripts are significantly different ($p<0.05$)

Conclusion and Recommendation

Canarium schweinfurthii seed is readily available with little or no economic value and its inclusion in diets of broiler chickens up to 10% without adverse effects on performance will reduce the cost of production of broiler chickens especially for farmers in the rural areas. It can also serve as cheap income for farmers who produces *Canarium schweinfurthii* olive oil from the fruits where the seeds serve as waste products.

Abstract
This study evaluate the growth performance of broiler chickens fed diet with graded levels of Vernonia amygdalina leaf meal. One hundred and twenty 2 weeks-old Arbo acre broiler chicks were weighed at the beginning of the experiment to obtain the initial weight and randomly allotted in a completely randomized design to 4 dietary treatments of 0% (T1), 5% (T2), 7.5% (T3) and 10% (T4) graded levels of Vernonia amygdalina leaf meal (VALM). Each dietary treatment had 30 chicks with 3 replicates of 10 birds. The duration of the experiment was six weeks. Data collected are initial weight, final weight, feed intake, weight gained and feed conversion ratio. Data obtained from the experiment were analysed using the statistical analysis of variance (ANOVA) procedure of SAS (2010) and significant level of p=0.05 was used. The treatment means were compared using the New Duncan multiple range test of the same software. The initial weight of the birds was significantly the same. Significant different was observed in final weight, feed intake, weight gained and feed conversion ratio. Treatment 4 containing 10% graded levels of Vernonia amygdalina leaf meal (VALM) was significantly higher in final weight compared to other treatments. Similar, trend was observed for feed intake and weight gained with least feed conversion ratio. In conclusion Vernonia amygdalina leaf meal (VALM) could be added to broiler chickens diet up to 10% inclusion level.

Keywords: *Vernonia amygdalina* leaf meal (VALM), growth performance, broiler chickens, feed conversion ratio.

Introduction

One of the profitable agro industries which can effectively tackle the problem of unemployment in the rural areas is the poultry sector (sings 2010). Poultry can be adopted under a wide range of climatic conditions and can generally combine conveniently with other farm enterprises. It is a common knowledge that feed constitute the greatest and most costly input in livestock production especially poultry. Thus, any significant reduction in the cost of feeds will definitely reduce the overall cost of production and increase the profit margin (Owen and Amakiri, 2011). Due to high cost of conventional protein ingredient like fish meal, groundnut cake and soya bean, the trust of nutritional research is toward identifying non-conventional sources that are locally available with low human demands (owen et al 2009). One of such non-conventional feed sources in livestock diet is bitter leaf (*Vernonia amygdalina*) meal. *Vernonia amygdalina* is a shrub or small tree that grows throughout tropical Africa. The leaves contain a considerable amount of anti-nutritive factors like tunic acid and saponin and according to Akwaowo *et al.,* (2000), the young leaves contain higher cyanide (60.1 mg 100^{-1}g DM) and tannin (40.6mg 100^{-1} g DM) than older ones. The Proximate composition of *Vernonia amygdalina* (V.A.) leaf showed a chemical composition of 527.83 ME Kcal/kg, 86.40% DM, 21.50%CP, 13.10% CF, 6.80% EE,11.05% Ash, and the result on mineral calcium, 0.40% magnesium, 0.03% phosphorus 0.06, 6% iron,0.33% potassium, and 0.05% sodium (Owen,2011). Furthermore, *Vernonia amygdalina* has also been fed to broilers, where it was able to replace 300g/kg^{-1} of maize-based diet without negative effect on feed intake, body weight gain and feed efficiency (Bonsi et al, 1995). Research also showed that *V. amygdalina* had some beneficial effects in disease management of poultry (Dakpogan, 2006) such as anti-coccidiosis, anti-bacterial and anti-parasitic (Gbolade, 2009; Tadesse et al,1993), anti- oxidant (Erasto et al, 2007) and as a growth promoter by enhancing the gastro intestinal enzymes thus increasing feed conversions efficiency (Huffman et al,1996; Olobatoke and Oloniruha,2009). This study therefore evaluate the growth performance of broiler chickens fed diet with graded levels of *Vernonia amygdalina* leaf meal.

Materials and Methods

The study was carried out at the Poultry Department of the National Veterinary Research Institute (N.V.R.I.), Vom, Plateau State. One hundred and twenty 2 weeks-old Arbo acre broiler chicks were weighed at the beginning of the experiment to obtain the initial weight and randomly allotted in a completely randomized design to 4 dietary treatments of 0% (T1), 5% (T2), 7.5% (T3) and 10% (T4) graded levels of *Vernonia amygdalina* leaf meal (VALM). Each dietary treatment had 30 chicks with 3 replicates of 10 birds. The composition and calculated analysis of the experimental diets are presented in Table 1. The diets were isonitrogenous and isocaloric to meet the recommended crude protein and Metabolisable energy requirements as stated by NRC (1994). Feeds were provided in the various troughs daily and water were given *ad libitum.* The parameters were measured weekly: the performance data taken include feed intake, initial and final weight, body weight gain while the feed conversion ratio (FCR) was calculated weekly. Daily feed consumption was recorded as the difference between feed offered and the left over. The birds were raised on deep litter standard management and hygiene, the recommended vaccines for broilers were administered accordingly. The duration of the experiment was six weeks.

Statistical Analysis

Data obtained from the experiment were analysed using the statistical analysis of variance (ANOVA) procedure of SAS (2010) and significant level of p=0.05 was used. The treatment means were compared using the New Duncan multiple range test of the same software.

(T3) =7.5% graded levels of *Vernonia amygdalina* leaf meal (VALM)

(T4) 10% graded levels of *Vernonia amygdalina* leaf meal (VALM)

Results and Discussion

The results of the initial weight and performance of the broiler chickens fed diets with *Vernonia amygdalina* leaf meal is shown in Figure 1 and Table 2. The initial weight of the birds was significantly the same. It was observed that the weight gain and the final weight of the birds fed with VALM increased significantly ($p<0.05$) across the treatments from 1924.50g (T1) to 2175.00g (T4) and 1924.50g (T1) to 2175.00g (T4) while the weight gains are 253.50g (T1), 254.00g (T2), 268.g (T3) and 319.50g (T4), respectively. The feed intake and the feed conversion ratio also increased significantly ($p<0.05$) across the treatments. The values for the feed intake are 949.5g (T1), 918.0g (T2), 962.5g (T3), and 979.0g (T4) while the FCR are 3.75 (T1), 3.70 (T2), 3.60 (T3), and 3.15 (T4), respectively.

(T4)= 10% graded levels of *Vernonia amygdalina* leaf meal (VALM)
SEM= Standard error mean

Similar result was obtained by Chiemela *et al.* (2016). The result for FCR in this study is in line with the findings of Olobotoke and Oloniruha (2009) who reported that inclusion of *VA* powder in cockerels feed significantly improved FCR. This could be associated with its effect on enhancing the gastro intestinal enzyme thereby improving digestion and assimilation of nutrients (Adaramoye *et al.*, 2008). The findings by Windisch (2007) also reported improved growth performance of animals fed *VA*. Furthermore, the report of Mohammed and Zakariya (2012) supported the observations made by Abubakar *et al*., (2010) that phytogenic feed additives are often associated to the improvement of flavor and palatability of feed, thus bitter leaf extract enhances production performance of birds. However, the observations made by Mohammed and Zakariya (2012) pertaining improvement of weight gain and FCR in broilers are in contrary with the present result.

Conclusion

In conclusion *Vernonia amygdalina* leaf meal (VALM) could be added to broiler chickens diet up to 10% inclusion level.

Abstract

Performance of weaned and growing pigs fed from concrete feeding trough, semi-automatic feeder and its combination was examined for eight weeks. Sixty weaned cross bred (Large white × Landrace) pigs of average initial weight of 9.04 ±0.31 kg were used for the weaner phase. The animals were distributed into three treatments (T1; concrete feeding trough, T2: concrete feeding trough and semi-automatic feeder and T3; semi-automatic feeder), with four replicates of five pigs per replicate. Ninety growing pigs with average initial weight of 18.19±0.31 kg were allocated to three experimental treatments with five replicates of six pigs per replicate. The experimental design was completely randomized design. Feed and water were supplied unrestrictedly. Weekly feed intake and weight were monitored. Performance and economic variables were evaluated. There was no significant (P>0.05) effect of different feeders on all the performance and economic variables across the treatments for the weaner phase. The total cost of feeding (₦) ranged from 7170.4 to 7687.80. During the growing phase, the average daily weight gain (g) ranged from 428.57 to 448.74. The highest and lowest average daily weight gain was observed in pigs fed from the combined feeders and the semi-automatic feeder respectively. The total cost of feeding (₦) and average cost of feed per day (₦) were significantly (P<0.05) different among the treatments. The pigs that fed from the combined feeders (T2) had highest total cost of feeding (₦) while the total cost of feeding for the pigs that fed from concrete feeding trough (T1) and semi-automatic feeder were comparable.

Introduction

The quest for strategies to address the issue of body weight variability among pigs of the same age has gained attention recently in pig industry. The use of strategies that are commercially relevant, easy to implement and acceptable, such as feeder space and feeding management are among those strategies (López-Vergé *et al.*, 2018). Feeder space and design has been considered to be one of the possible ways to reduce body weight variability experience in pig production. Feeder has been described as a tool used for pigs to correctly access the diets (Gonyou and Lou, 2000) and act as the interface used for pigs to potentially meet their maximum growth. Feed intake is essential for a correct performance. Limiting feed intake due to poor access to feed directly affects growth potential and affects metabolism and health status in pigs (Dong and Pluske, 2007). Therefore, a correct access to feed is fundamental to allow pigs to meet their nutrient requirements (Gonyou and Lou, 2000). Quite a number of feeders for pigs have been identified in the market, and all of them were designed for similar goals; to maximize feed intake and minimizing feed wastage in order to optimize pig performance. The feeder, then, may affect the performance, growth and homogeneity of pigs (López-Vergé *et al.*, 2018). Therefore, the objective of this study was to evaluate effect of different feeders on growth performance and economic analysis of weaned and growing pigs.

Materials and methods

The experiment was conducted at AK Research farms located at Eleyele, Ibadan, Oyo state, Nigeria and it lasted for 56 days. Two studies were run concurrently using weaner and grower pigs. Experimental diets (Table 1) were formulated using the nutrient requirement recommendations of National Research Council (1998) for weaned and growing pigs. Sixty weaned cross bred (Large white × Landrace) pigs of average initial weight of 9.04 ±0.31 kg were used. The animals were distributed into three treatments (T1; concrete feeding trough, T2: concrete feeding trough and semi-automatic feeder and T3; semi-automatic feeder as shown in Figures 1-3), with four replicates of five

pigs per replicate. Ninety growing pigs with average initial weight of of 18.19±0.31 kg were allocated to three experimental treatments (as in the weaner study) with five replicates of six pigs per replicate. The experimental design was completely randomized design. The pigs were kept in Pens (234cm L × 216cm W) which had concrete floors with no litter in groups (same sex) based on body weight. Each pen had a concrete feeder (97cm L × 33cm W) and a concrete drinker (97cm L × 33cm W)**.** Semi-automatic feeder used had a guard that prevents feed wastage by the animals and provided a total of 56.0cm. × 25.0cm. (length × width) of trough space per feeder. All pigs in weaner and grower phases were fed a common weaner and grower diets respectively. Pigs were allowed *ad libitum* access to the diets and water served in concrete watering trough. Data were collected on daily feed intake and body weight gain. Daily weight gain, feed conversion ratio and indices for economic analysis were evaluated. All the data were subjected to analysis of variance using General Linear Model of SAS (2002) and the means were separated using Duncan Multiple Range test.

Results and Discussion

The growth performance and economic analysis of both weaner and growing pigs fed from different feeding troughs are presented in Table 2. There was no significant (P>0.05) effect of different feeders on final weight, daily weight gain, average daily feed intake and feed conversion ratios across the treatments for the weaner phase. The final weight (kg) ranged from 27.32 to 29.35 with the pigs that fed from concrete feeding trough (T1) and the combined troughs (T2) having the lowest and highest respectively. The pigs fed from both feeders had improved daily weight gain (369.71 g) and best feed conversion ratio (2.99). The highest feed intake (1021.14 g) was also observed in pigs fed from the combined feeders (T2). The economic analysis showed no significant (P>0.05) difference among the variables measured. The total cost of feeding (₦) ranged from 7170.4 to 7687.80. The pigs that fed from the combined feeders (T2) had the highest total cost of feeding while the lowest was observed in pigs that fed from concrete feeding trough (T1). The feed cost/Kg live weight gain (₦/Kg) ranged from 401.99 to 444.14. The best feed cost/Kg live weight gain (401.99 ₦/Kg) was observed in pigs fed from combined feeders while the worst feed cost/Kg live weight gain (444.14 ₦/Kg) was observed in pigs fed from semi-automatic feeder. During the growing phase, no significant (P>0.05) difference was observed in all the performance parameters except average daily feed intake that was significantly (P<0.05) different across the treatments. The average daily weight (g) ranged from 428.57 to 448.74. The highest and lowest average daily weight gain was observed in pigs fed from the combined feeders and the semi-automatic feeder respectively. The average daily feed intake (1579.03 g) of pigs fed from concrete feeding trough (T1) and that (1558.61 g) of those fed from semi-automatic feeder (T3) were similar. However, the feed intake (1666.56 g) of the pigs fed from combined feeders (T2) was significantly (P<0.05) higher. The total cost of feeding (₦) and average cost of feed per day (₦) were significantly (P<0.05) different among the treatments. The pigs that fed from the combined feeders (T2) had highest total cost of feeding (165.95) while the total cost of feeding for the pigs that fed from concrete feeding trough (T1) and semi-automatic feeder were comparable. No significant (P>0.05) difference exists in feed cost/Kg live weight gain (₦/Kg) across the treatments. The values ranged from 380.89 to 407.34 with the pigs fed from concrete feeding trough and the combined feeders having the highest and the lowest value respectively. The results showed a better performance in terms of final body weight and daily weight gain for pigs allocated to both semi-automatic feeder and concrete feeding trough during the weaner and grower phases. This is in agreement with the earlier results of He *et al*. (2016), the authors suggested that more feeder spaces to pigs could lead to a better feeding motivation with a consequent increase in growth. The improved growth performance observed in pigs fed with combined feeders (T2) reinforced the claims by several authors that feeders affect performance of pigs. This probably explained by a higher feed intake and minimal feed wastage. This also corroborates the earlier findings of Bergstrom *et al*. (2009) who reported improved growth performance in pigs fed with wet-dry feeders compared with pigs fed with conventional dry feeders. However, Bergstrom *et al*. (2009) reported no difference in feed intake, which is in line with the findings of this study. Lack of significant difference in many of the parameters also supports the earlier findings of Brumm and Gonyou (2001) who reported no significant difference in growth performance but improved performance in pigs fed with wet-dry feeders when compared with conventional dry feeders.

Conclusions

It could be concluded from the studies that the combination of concrete feeding trough and semi-automatic feeders improved the average daily weight gain and average daily feed intake of weaner and grower pigs compared with the individual use of the feeders. However, the total cost of feeding of the pigs fed from the combination of the feeders increased for the grower pigs compared to the use of either the concrete feeding trough or the semi-automatic feeder.

Abstracts

Two hundred and seventy (270) pullet chicks were reared in a group for one week. At day 8, the chicks were randomly allotted into 3 treatments such that each treatment had three replicates of 30 chicks each. The chicks in experimental group R_0 were fed ad-libitum, R_1 were fed six days weekly while R_2 received full feeding for five days weekly. After the first 8 weeks, the three groups of birds used in the first experiment were each sub divided into three groups of ad libitum (r_0), one-day feed restriction (r_1) and two days feed restriction (r_2), resulting finally in nine experimental groups. Laying performance, internal and external qualities of eggs were determined. There were no significant difference ($p>0.05$) in the weights of first egg, egg weight and shell thickness across the treatments. However, R_0r_0 birds has the highest ($p<0.05$) value for henday (68.33%) and percentage yolk weight (23.56%) while R_2r_1 and R_2r_0 birds had the least ($p<0.05$) values; 53.41% and 21.26%, recorded for above parameters respectively. The albumen percentage is however significantly ($p<0.05$) higher in R_2r_0 birds than R_0r_0 birds. It could be concluded that starter-restricted Isa Brown layers (R_2) had poor laying performance and egg quality with the exception of the albumen percentage. Mild starter-restriction (R_1) is recommended as it gave effects similar to ad libitum feeding.

Keywords: feed restriction, laying performance, egg quality

Introduction

Poultry products has been recognized as the cheapest source of animal protein in the developing countries (Ajayi, 2010). Egg production is of great economic importance and the success of this enterprise hinges on the total number of eggs produced from management inputs (Ojepapo *et al*., 2009). The qualities of egg which include egg weight, shell thickness, and shell index are very important due to their economic importance in the egg production industry (Savegnago *et al*., 2011; Blanco *et al.*, 2014). The high cost of feed inputs in poultry farming means that feed management is the key profit index in poultry production (Achi *et al.*, 2007). Feed, according to Sanni and Ogundipe (2003) constitutes a major cost input in egg production enterprise. Any savings in feed consumption will increase the profit margin. Feed restriction is one major way of ensuring efficient utilization of feed and feed cost reduction.

Different methods of feed restriction programmes are applied in practice. These include: reduced nutrient intake by means of diet dilution (Camacho-Fernandez *et al.*, 2002), appetite suppressant (Oyawoye and Krueger, 1990), limiting the time of feed access as in skip-a-day feeding (Khajali *et al*., 2007), meal feeding (Susbilla *et al.*, 2003) and limiting the quantity of feed offered to the birds daily (Ocak and Sivri, 2008). This research is designed to determine the effect of restricted feeding at the chick and growing phases on laying performance and egg quality parameters of Isa Brown chickens.

Material and methods

The research was carried out in the Poultry Unit, Directorate of University Farms (DUFARMS), Federal University of Agriculture, Abeokuta, Ogun State. Two hundred and seventy (270) pullet chicks were purchased from a reputable hatchery. At day 8, the chicks were randomly allotted into 3 treatment groups such that each treatment had 3 replicates of 30 chicks each in dimensions of 2.5m x 3m. The chicks in experimental group R_0 were fed *ad-libitum* at chick phase and served as control. Groups R_1 and R_2 were restricted one-day and two-day per week respectively. After the first 8 weeks, the three groups of birds used in the first experiment were each sub divided into three groups of *ad libitum* (r_0), one-day,(r_1) and two days (r_2) weekly feed restriction, resulting finally in nine experimental groups. The birds were fed with chicks mash, grower mash and layers mash at chick, growing and laying phases respectively. At 20 weeks, the number of pullets per replicate was

reallocated in the battery cage to have equal number of eight birds per replicate. The production of egg and egg weights of all egg were measured daily and calculated periodically (every 30 days) from 20 to 68weeks of age. Haugh unit scores were calculated by the procedure of Haugh (1937) in the formula; $HU = 100\log(H + 7.5W^{0.37})$, Where H = Albumen height in mm; W = Egg weight in grams. Hen day egg production was the average of daily egg production of the 3 replicates (8 birds per replicate). Percentage albumen weight and Yolk weight were calculated as the percentage of the albumen weight and yolk weight to the egg weight respectively. Shell thickness: The thickness of individual air-dried shells was measured to the nearest 0.01mm using micrometer screw gauge. Albumen height: The eggs were gently broken and the maximum albumen height was measured with tripod micrometer. Egg shape Index (ESI) calculated using the formula ESI = $\text{Width of egg (mm)}/\text{Length of egg (mm)}$

Statistical Analysis

Data collected were subjected to analyses of variance for a Completely Randomised Design in 3x3 factorial arrangements of treatments. Duncan Multiple Range test was utilized to separate significant means (SAS Version, 2012).

Result

The effects of main restriction and sub-restriction on the laying performance and egg quality parameters are shown in Table 2. In the main restriction, there was significant difference ($p<0.05$) in the body weight at lay (BWL). Birds maintained on R_1 have the highest value (1419.75 g) of BWL which was not significantly different ($p>0.05$) from R_0 birds but significantly different ($p<0.05$) from birds in R_2. In the main restriction, R_0 birds have the highest values of henday and yolk weight percentage while R_2 birds have the least values of henday, albumin height, yolk weight, and Haugh unit. The interaction of main feed restriction and sub-restriction is presented in Table 3. The result showed that the age at first lay of birds maintained on R_0r_0 was earlier than other treatments, while birds in R_0r_2 has the highest (140 days) age at first lay. The birds maintained R_0r_1 has the highest body weight (1483.89g) at first lay while the least (1240.19g) was recorded in R_2r_0 birds. There was no significant ($p>0.05$) difference in the weight of first egg across the treatments. However, R_0r_1 birds has the highest egg weight value (43.67g) while R_1r_2 has the least value (38.77g). Layers on R_0r_0 has the highest value (68.33%) of hen day which was not significantly different ($p>0.05$) from other treatments except R_2r_1 birds with the least value (53.41). The highest values of egg length were recorded in R_1r_0 birds. R_2r_0 birds had the significantly ($p<0.05$) highest values of albumen percentage.

Discussion

The average age at first lay of Isa brown in this study ranges between 127.33 days and 140days. The birds on *ad libitum* feeding both at chick and growing phases (R_0r_0) came to lay earlier than all other groups. All restriction groups were delayed at least by 3 days or more when compared to the *ad-libitum* group. The range of age at first lay in this study is earlier than the observed age at lay by Roll *et al.*, (2008) who reported an onset of lay for Isa brown hens at 21 weeks. Lala *et al*., (2016) reported an age at first lay of 153 days (21.86 weeks) for same strain of birds. The difference might be due to methods of rearing which is an important factor in poultry production (Ojedapo, 2013). The body weight at sexual maturity was significantly higher in *ad-libitum* and one day restriction groups (with the exception R_0r_0 group) than the two days restriction groups. Sandoral and Gernat (1996) found 3-5 days delay in sexual maturity age and partially an increase in body weight due to fee restriction.

Restricted feeding effects were significantly found on the henday, albumen percentage, albumen height, yolk percentage and Haugh unit. The *ad libitum* (R_0) and mildly restricted (R_1) performed better in all parameters mentioned above than the severely restricted birds (R_2), with the exception of albumen percentage. This result may be due to severity and length of feed restriction programme for birds (Mahmood *et al.*, 2007). The performance of the bird group on more severe restriction (R_2) programme performed low compared with birds on *ad libitum* feeding and one day restriction programme. The lower values of egg length were recorded in R_0r_0 and R_1r_2 birds. The remaining groups recorded higher and similar values.

In conclusion, age at first lay may be delay and body weight at sexual maturity reduced due to severe starter restricted feeding. However, henday and most egg qualities parameters are negatively affected due to severe feed restriction.

Abstract
There has been increased interest in studying feed restriction in rabbits as a means of reducing the cost of production. This study evaluated the cost benefit of restrictive feeding on pregnant rabbit does reared in south-western Nigeria. A total of forty three (43) rabbits consisting of thirty six (36) 20 weeks old doe rabbits of mixed breeds with initial live weight of 1.7-2.0 kg and seven (7) mature bucks with live weight of 2.0-2.5 kg were used for the study. The does were divided into three groups of twelve rabbits each after balancing for weight. The does were placed on three levels of quantitative feed restriction (0, 15, 30 %) at three periods of gestation (15-19 days, 20-24 days and 25-29 days). Data collected were arranged in a 3 × 3 factorial layout. The interactive effect showed that there was no significant difference (p>0.05) in the cost of feed across the dietary treatments. Highest (p>0.05) feed cost was obtained for rabbit does on 30% restriction at 25-29days of gestation. However, 15% restriction at 25-29 days of gestation resulted into increased (p>0.05) average litter size at birth which competed favourably with the ad libitum groups. Therefore it can be concluded from the result obtained that feed restriction of pregnant does at 15% restriction at 25-29days is cost effective, as this period resulted in increase in average litter size at birth compared to others.

Keywords: Maternal restriction, restriction periods and Cost benefit

Introduction

Feed restriction could be exploited in the feeding regimen of rabbits, especially in periods of inadequate supply of concentrates and forages (Yakubu *et al.,* 2007). The cost of feeding rabbits is however very high, a condition that also prevails for other Nigerian livestock species (Adeyemi *et al*., 2008). Young rabbit does fed *ad libitum* diets often show parturition problems, (dystocia and abnormal presentation) with subsequent reduction of the number of kits per kindling, linked to excessive fat accumulation (Fortun-Lamothe and Lebas, 1996). In order to reduce the excessive fat in young does, restricted feeding during pregnancy is frequently applied to obtain uniformity in their body weights and to avoid high mortalities during kindling (Rommers *et al.,* 2001) and to allow a long productive life of these does (Partridge *et al.,* 1986).Therefore, feed restriction could be a useful tool to improve economic performance of rabbit does (Tůmová *et al.,* 2006b), which in turn consequently reduces the costs of production (Yakubu *et al.,* 2007). Several studies demonstrated that, after a restricted feeding, the appetite of rabbits improves and a sharp increase of voluntary feed intake occurs (Rommers *et al*., 1999). Moreover, rabbit can be used as an experimental model to elucidate the effects of anorexia during pregnancy on embryo-foetal development (Matsuoka *et al.,* 2006). Several studies have been done on cost of restrictive feeding in growing rabbits. However, details of the cost of restricted feeding on pregnant does are still obscure; hence, this study aims to examine the cost benefit analysis of restricted on pregnant rabbit does in south-western Nigeria.

Experimental Site

The experiment was carried out at the Rabbitary Unit of the Directorate of University Farms, Federal University of Agriculture, Abeokuta (FUNAAB), Ogun State. The site is located in the rain forest vegetation zone of South-Western Nigeria on latitude 7° 13' 49.46'' N, longitude 3° 26 11.98E and altitude 76m above the sea level (Google Earth, 2018).

Experimental Animals and Management

A total of forty three (43) rabbits consisting of thirty six (36) 20 weeks old doe rabbits of mixed breeds with initial live weight of 1.7-2.0 kg and seven (7) mature bucks with live weight of 2.0-2.5 kg were used for the study. The does were divided into three groups of twelve rabbits each after balancing for weight.

Experimental Design

Treatments consist of three (3) levels of concentrate feed restriction fed at three (3) different periods during the latter half of the pregnancy period after ascertaining pregnancy by palpation. Percentage composition of concentrate diet consist of Maize 47.50; Fish meal 2.00; Soyabean meal 3.00; Wheat offal 23.00; Groundnut cake 12.00; Rice husk 7.00; Bone meal 3.00; Oyster shell 2.00; Salt 0.25; Vitamin and Mineral premix 0.25. The feeding regimen included: 0% Restriction (control) was fed (100 g/rabbit/day), 15% Restriction was fed (85 g/rabbit/day), 30% Restriction was fed (70 g/rabbit/day). Experimental animals were offered forage (100grams of wilted *Tridax procumbens*) once in a week across the dietary treatment.

Statistical Analysis

Data obtained were arranged in a 3×3 factorial experimental layout using (SAS, 1999). Significantly ($p<0.05$) different means were separated using Duncan's Multiple Range Test of the same statistical package.

Results and Discussion

The main effect of level of feed restriction and period of feed restriction on cost benefit of raising gestating does is shown on Table 1. There were no significant ($p>0.05$) difference in the cost of feed/kg and total cost of feed consumed. Gestating does on 30% level of feed restriction recorded the highest cost (₦204.07) for feed consumed numerically, while gestating does on 0% level of feed restriction recorded the lowest cost (₦199.91) for feed consumed numerically. The highest feed cost recorded for rabbit does on 30% restriction can be attributed to highest feed intake compared to others during the period of realimentation. The results corroborates with the findings of Rommers *et al* (1999) who reported increase in voluntary intake of rabbits at the end of feed restriction.

The periods of feed restriction had no significant ($p>0.05$) effect on the total cost of feed consumed and cost of feed per weight gain. Gestating does between 25-29 days period of feed restriction had the highest (₦205.06) cost. Higher cost obtained for does on 25-29days of gestation could be attributed to longer periods of days before the restriction started while, gestating does between 20-24 days period of feed restriction had the lowest (₦196.89) cost.

Table 2 shows the interactive effect between level and periods of feed restriction on cost benefit of raising gestating does. There was no significant ($p>0.05$) difference on the total cost of feed consumed per gestating doe. Gestating does on 30% level of feed restriction between 25-29 days had the highest cost (₦218.98) while gestating does on 30% level of feed restriction between 20-24 days recorded the lowest cost of feed consumed (₦195.44). Highest cost obtained for does on 30% restriction corroborates with the findings of Rommers *et al*. (1999) who reported that after a restricted feeding, the appetite of rabbits improves and a sharp increase in voluntary feed intake occurs. Moreover, leptin a key hormone involved in the regulation of body weight either suppressing appetite or increasing metabolic rate can also be attributed to the increase in feed intake which will in turn increase feed cost (Friedman and Halaas, 1998).

Conclusion: Based on the results of this study it can be concluded that 15% level of feed restriction of pregnant does at 25-29 days of gestation is cost effective because it was at this level better cost of feed to weight was achieved likewise higher average litter size was obtained for the does compared to the control groups.

Abstract

This study evaluated the effects of wild sunflower and goat weed composite leaf meal mix (CLM) on the meat of 42-day old broiler chicken. Three hundred day-old Arbor-acre broiler chicks were used for the experiment. The chicks were randomly assigned into five experimental groups at sixty chicks per treatment and ten chicks per replicate. The experimental diets were supplemented with CLM at various inclusion levels: diet 1 (0%), diet 2 (0.11% Oxytetracycline supplementation), diet 3 (0.4% CLM supplementation), diet 4 (0.80% CLM supplementation), and diet 5 (1.20% CLM supplementation). Feed and water were giving ad-libitum and routine management strictly observed. The meat cholesterol level of the broiler chickens fed OXY supplemented diet (diet 2) was lower (P<0.05) to those that were fed the control diet. However, further significant (P<0.05) decrease were recorded in the birds fed the CLM supplemented diets (diets 3, 4 and 5) such that the least cholesterol content was recorded in 0.8 CLM supplemented-diet. The broiler meat glutathione peroxidase content recorded in the birds fed the 0.8% and 1.2% CLM supplemented diets were lower (P<0.05) compare to those birds fed the control diet; OXY and 0.4% CLM supplemented diets. However, the lipid oxidation of the broiler meat fed the OXY and CLM supplemented diets (diets 2, 3, 4 and 5) were (P<0.05) lower than those birds fed the control diet. In conclusion, 0.8% and 1.2% dietary supplementation of the broiler chicken diets reduced the meat cholesterol content and the glutathione. The phyto-additives reduced the meat lipid oxidation.

Keywords: Antioxidants, Cholesterol, Meat quality, Phyto-additives

Introduction

Phyto feed additives are plant-based feed additives or botanicals that are used in natural substances in poultry nutrition. They are derived from herbs, spices, other plants and their extracts, like essential oils. Phytogenics or phyto-additives are natural, less toxic, residue-free and ideal feed additives for poultry when compared to synthetic antibiotics. Phyto feed additives have antimicrobial, antifungal, antiviral, antioxygenic, antiparasitic and insecticidal properties. The benefits of using phyto- feed additives in poultry nutrition include increased feed intake, stimulation of digestion, increased growth performance, reduced incidence of disease, improved reproductive parameters, feed efficiency, profitability and reducing poultry house emissions (Windisch *et al*., 2008). The proximate composition (20.6% crude protein, 18.90 crude fibre, 4.00% ether extract, 42.5% carbohydrate and 14.00% ash) and Phyto-constituents (79.1 mg/100g phytin, 0.39 mg/100g tannin, 1.76 mg/100g oxalate, 2.36 mg/100g saponin, 1.23 mg/100g alkaloid and 0.87 mg/100g flavonoid) of wild sunflower leaf meal was reported by Fasuyi *et al*., (2010). The proximate analysis has shown that goat weed (*Ageratum conyzoides*) contains 11.93% crude protein (Gbolade, 1999). According to Okunade (2002), the extract of goat weed has anti-inflammatory, antipyretic and analgesic activities in mice and rats while the oil has antibacterial and antifungal activity. Verma *et al*., (2013) reported that the phytochemical investigation of the plant extract of goat weed shows a high concentration of phenolic compounds and flavonoids, for protection against disorders associated with an excess of free radicals or reactive oxygen species. The goat weed was reported to play a significant role in the eradication of Enteropathogenic microorganism causing inflammation of the intestine (Ram *et al*.,

2008). Little attention has been given to the effects of herbal mixture on poultry physiology when compared to other animals. There could be an interaction of the bioactive compounds in these botanicals (Oloruntola *et al*., 2018). Therefore, the study aimed at assessing the effects of dietary composite leaf meal mix of wild sunflower and goat weed leaf meals on broiler meat quality.

Materials and methods

The experiment was carried out at the Teaching and Research Farm of the Federal College of Agriculture (FECA), Akure, Nigeria. Fresh goat weed and wild sunflower leaves were plucked within the campus of FECA, Akure. The leaves were washed in running tap water, suspended on tray under shade for 20 minutes to ensure proper water drainage and chopped into small pieces with the sharp stainless knife, thereafter spread lightly on tarpaulin under the shed to air-drying for about 14 days and then after milled (100 µ size) to produce goat weed and sunflower leaves meals. Thereafter, equal portion of goat weed meal (GLM) and wild sunflower meal (WLM) were mixed to form wild sunflower and goat weed composite leaf mix (CLM) and analysed for proximate analysis, *terpenoid* (Ferguson, 1956), *saponin* (Shad *et al*, 2013), *flavonoid* (Shad *et al*, 2013), ferric reducing antioxidant property (FRAP) (Pulido *et al*, 2002) and 2,2-diphenyl-1- picrylhydrazyl hydrate (DPPH) (Gyamfi *et al*, 1999). Two basal diets were formulated for the starter (1 to 21 days) and finisher phase (days 22 to 42) (Table 1) to meet the minimum requirement of broiler chicken (NRC, 1994). At each phase, the basal diets were divided into five (5) equal portions and labeled diets 1 to 5. Diet 1 contained 0g/kg of CLM supplement, diet 2 was supplemented with 0.11% Oxytetracycline while Diets, 3, 4 and 5 were supplemented with 0.40%, 0.80% and 1.20% of g/kg CLM, respectively. Three hundred a-day old Arbor acre broiler chicks were distributed to five (5) dietary treatments (60 birds/treatments: 10 birds per replicate) in a complete randomize design. Feed and water were provided *ad-libitum* throughout the 42 days of the experiment.

Results and Discussion

Table 2 shows the proximate composition of phytochemical and antioxidant properties of WLM, GLM, and CLM. The crude protein and crude fibre contents of CLM was higher than the crude protein of WLM but lower than that of GLM. The phenol and flavonoid content of CLM was 6.07 mg/g and 9.56 mg/g, respectively. Saponin (68.91 mg/g) and terpenoid (56.02 mg/g) were also detected in CLM. The antioxidant properties determination shows that CLM has 65.59% DPPH and 1.70 mg/g FRAP. The CLM phytochemical and antioxidant parameter profiles recorded shows that the phyto-additive used in this study has phytochemicals of pharmacological importance. Earlier reports show that phytogenic feed additives usually possess phytochemicals that can be of benefits to the health (Maisarah *et al*., 2014, Oloruntola *et al*., 2018a,b). The effects of phyto-additives on meat analysis of broiler chickens are shown in table 3. The cholesterol content of the meat of the broiler chickens fed OXY supplemented diet (diet 2) was lower ($P<0.05$) to those that were fed the control diet. However, further significant ($P<0.05$) decrease were recorded in the birds fed the CLM supplemented diets (diets 3, 4 and 5) such that the least cholesterol content was recorded in 0.8 CLM supplemented-diet. This observed reduced meat cholesterol in the birds fed the phyto-additive supplemented diets in this study may be a result of activities of phytochemicals such as saponin in CLM which impaired and reduced the uptake of cholesterol in the gut (Oloruntola *et al*., 2019). The broiler meat glutathione peroxidase content recorded in the birds fed the 0.8% and 1.2% CLM supplemented diets were lower ($P<0.05$) compare to those birds fed the control diet; OXY and 0.4% CLM supplemented diets. However, the lipid oxidation of the broiler meat fed the OXY and CLM supplemented diets (diets 2, 3, 4 and 5) were ($P<0.05$) lower than those birds fed the control diet. In conclusion, 0.8% and 1.2% dietary supplementation of the broiler chicken diets reduced the meat cholesterol content and the glutathione. The phyto-additives reduced the meat lipid oxidation.

Table 1: Composition and Nutrient Contents of Experimental Basal Diets

Ingredients (g/kg)	Starter (1 to 21 days)	Finisher(22 to 42 days)

Abstract

This study was conducted to evaluate the efficacy of combined organic acids and their salts (Biotronic® Top Forte) as alternatives to the conventional antibiotics used in poultry production on the performance of growing pullets. Six hundred and nine (609) grower pullets were used for the study and were intensively managed. The pullets were randomly assigned into seven treatment groups in a complete randomized design and administered as 0,100,200,300,400,500g of Biotronic® Top Forte, oxytetracycline as positive control and defined as T1, T2, T3, T4, T5, T6 and T7 respectively. Results showed a significant ($p<0.05$) influence of Biotronic® Top Forte on weight gain, feed intake, feed/gain ratio, feed cost/kg gain age at 1st lay, weight of 1st egg and age at 10% lay. Birds on 500g inclusion of Biotronic® Top Forte had better weight gain (1359.83g), feed/gain ratio (3.71) and feed cost/Kg gain (₦364.92) when compared with birds on 0 inclusions, oxytetracycline and birds on other treatments. Haematological indices measured were within the normal range for healthy birds in all treatment groups. There was no mortality recorded in this study. It was concluded that Biotronic® Top Forte inclusion at 500g enhanced growth performance growing pullet from 9 weeks to 18weeks compared to birds on 0 inclusion diets, birds on oxytetracycline diets and birds on other treatments. Inclusion of of Biotronic® Top Forte at 100, 200, 300, 400 and 500g reduced the cost of production by 6.41, 8.36, 3.27, 0.00 and 12.45% respectively.

Keywords: organic acids, Biotronic® Top Forte, oxytetracycline, pullet and Haematological.

Introduction

High levels of production and efficient feed conversion are the need of the modern poultry industry, which to a certain extent could be achieved by the use of specific feed additives. Antibiotic feed additives as growth promoters have long been supplemented to poultry feed to stabilize the intestinal microbial flora, improve the general performances and prevent some specific intestinal pathology (Hassan *et al*., 2010). Young animals are highly susceptible to various stressors, including bacterial diseases, resulting in compromised growth performance and high mortality (Barton, 2000). Antibiotics have long been used at sub-therapeutical levels in swine, poultry, aquaculture and ruminant diets for better growth performance (Randrianarivelo *et al* 2010; Allen *et al.*, 2012). However, due to the emergence of microbes resistant to antibiotics which are used to treat human and animal infections, the European Commission (EC) decided to phase out, and ultimately ban (1 January 2006), the marketing and use of antibiotics as growth promoters in feed (EC Regulation No.1831/2003). There have been a significantly increased number of studies focused on searching for alternatives to antibiotics with similar antimicrobial and growth-promoting effects without inducing bacterial resistance and potential side effects to animals. Organic acids (Eckel *et al.*, 1992; De Lange *et al.*, 2010), enzymes (Bedford and Cowieson, 2012), prebiotics (Gibson *et al.*, 2004), probiotics (Musa *et al.*, 2009), antimicrobial peptide (Choi *et al*., 2013) and phytogenic compounds (Yang *et al.*, 2007; Windisch *et al.*, 2008; Randrianarivelo *et al.*, 2010; Gong *et al.*, 2014) have been widely recognized as potential alternatives to antibiotics in feed. Among these alternatives, dietary organic acids have gained greater attention because of their antimicrobial activity against pathogenic bacteria and the fact that these compounds can induce a pH reduction in the gastrointestinal tract (GIT), which can improve nutrient utilization in poultry diets (Eidelsburger *et al.*, 1992).

Organic acid treatments composed of individual acids and blends of several acids have been found to perform antimicrobial activities similar to those of antibiotics (Wang *et al*., 2009).

The European Union allowed the use of organic acids and their salts in poultry production because these are generally considered safe (Adil *et al*., 2010). The Biotronic® Top Forte combines selected organic acids and their salts with a phytochemical and the unique Biomin® Permeabilizing Complex fully utilizing a unique synergism in their mode of action. The Biomin® Permeabilizing

Complex boosts the activity of the active ingredients (the organic acids and the phytochemical) and facilitates their entry by permeating the outer membrane of Gram-negative bacteria (Biomin, 2018). Increasing worldwide concentration and growing competition in the poultry industry requires efficient pullets to satisfy specific market requirements. Lohmann Tierzucht offers a wide range of high quality pullet strain "bred in Germany" to meet these demand. Lohmann brown-classic is well known for their efficient production of quality brown eggs (Lohmann brown-lite management guide, 2018) Body weight and body conformation are the two important parameters for measuring growth in chickens, as growth and reproduction is the most important aspect of poultry production (Addisu, 2013).

The aim of this work therefore is to evaluate optimum inclusion levels of Biotronic® Top Forte (commercial blended organic acid) on grower pullets performance.

Materials and Methods

This study was carried out at the Poultry Unit, Teaching and Research Farm, Department of Animal Science, Faculty of Agriculture, Ahmadu Bello University, Zaria. Six hundred and nine (609) grower pullets were allocated to seven dietary treatments with 3 replicates of 29 birds each in a completely randomized design (CRD). The birds were housed in deep litter pens and managed with all necessary routine management practices. Feed and water were provided *ad libitum* for the 12 weeks period of the experiment. Left over feed was weighed to calculate feed intake. Birds were weighed at the beginning and end of experiment, to calculate weight gain. Birds were cared for according to guidelines established by the University Animal Care Committee. Seven diets were formulated. Table 1 shows the proximate composition of the common diet used. The Biotronic® Top Forte was added as non-inclusive part of the diets. Diet 1: (Control diet) – without Biotronic® Top Forte and oxytetracycline, Diet 2: 100g of Biotronic® Top Forte /100 Kg diet, Diet 3: 200g of Biotronic® Top Forte /100 Kg diet, Diet 4: 300g of Biotronic® Top Forte /100 Kg diet, Diet 5: 400g of Biotronic® Top Forte /100 Kg diet, Diet 6: 500g of Biotronic® Top Forte /100 Kg diet, Diet 7: Oxytetracycline at 0.8g/100Kg diet (as recommended by manufacturer). Recommended dosage for Biotronic® Top Forte is 1.85 – 4.50 kg/tonne of feed. Proximate analysis of the sample of experimental diets was done at the Biochemical Laboratory, Department of Animal Science, Faculty of Agriculture, Ahmadu Bello University Zaria according to methods described by A.O.A.C. (2005) At the end of 18 weeks of the feeding trial, 2mls of blood sample were collected from each of the three birds per treatment (that is one bird per replicate) via the wing veins into sterile tubes containing an anticoagulant (ethylene diamine tetra acetic acid, EDTA) for the determination of some haematological parameters. This was carried out at the Clinical Pathology Laboratory, Ahmadu Bello University Zaria. All data obtained were statistically analysed using the General Linear Model Procedure of Statistical Analysis Systems (SAS, 2002). Significant difference between treatments means were separated using Dunnett's test in the SAS package.

Results and Discussion

Table 2 shows the growth performance characteristics of grower pullet fed diets containing graded levels of Biotronic® Top Forte (9-18weeks) to replace antibiotic as growth promoter. There were significant ($P < 0.05$) differences in final weight, weight gain, feed intake and feed/gain ratio. No mortality was recorded. Significant ($P < 0.05$) difference in final weight, weight gain, feed intake, feed/gain ratio, feed cost/gain, age at 1st lay, weight of 1st egg and age at 10% lay was as a result of the organic acid (Biotronic® Top Forte) used to enhance effectiveness of nutrients and improved growth performance through establishment of low gastro intestinal tract (GIT) pH condition by supporting endogenous digestive enzymes, reducing undesired gut micro-organisms and exert their effects in the gut or on the gut wall cells of the bird. This is an indication that the birds effectively utilized their feed components. Acidifiers constitute an important component of modern feeding strategies without antibiotics. This result agrees with the report of Van Immerseel *et al.*, 2006 and Naseri *et al.*, 2012, that addition of organic acids in diet can have a beneficial effect on the performance of poultry by decreasing pathogenic bacteria. Higher organic acid inclusion resulted to lower feed intake, higher weight gain, better feed to gain ratio because the organic acids aid in the effective feed utilization in the gut which resulted in better growth performance thereby reducing amount of feed consumed and reduce cost of production. This agrees with the study of Patten and Waldroup, (1988) who reported reduction in feed intake and increased body weight due

to higher acid concentration. No mortality was recorded, is an indication that the birds effectively utilized the feed nutrient because of the organic acid included in the feed which help to lower the pH of the feed, gut and microbial cytoplasm thereby inhibiting the growth of pathogenic intestinal microflora. This agrees with the report of Avitech, 2004 that the inhibition of the growth of pathogenic intestinal microflora by the inclusion of organic acid reduces the microflora competing for the host nutrient and result in better growth and performance of the birds. Inclusion of Biotronic® Top Forte in the diets of grower pullets at 100, 200, 300, 400 and 500g reduced the cost of raising grower pullets by 6.41, 8.36, 3.27 and 12.45% respectively. The result of haematological indices of grower pullets (9-18 weeks) fed diets containing graded levels of Biotronic® Top Forte is shown in Table 3. Haematological indices are essential in monitoring feed toxicity especially with feed constituents that affect the formation of blood (Aro and Akinmoyegun,2012). Significant differences were observed on haematological values obtained among treatment groups, though significantly different, their values fell within the normal range of Pollack *et al.*(2005);Cray, (2000); Jain, 1986 and Simraks *et al* 2004 which defines that the birds were in complete normal state of health.

CONCLUSION AND RECOMMENDATION

Birds on 500g Biotronic® Top Forte inclusion significantly lowered the cost of production than the 0 inclusion and the AGPs treatments to 12.45%.

It can be finally concluded that the addition of the balanced acidifier product Biotronic® Top Forte, containing an organic acid blend of formic acid, propionic acid and its salts based on an inorganic carrier, increases in the absence of anti-biotic growth promoters the performance grower pullets chicken.

Farmers can use Biotronic® Top Forte feed additives as replacement for antibiotic in grower pullets production at 500g/100kg diets to improve growth, early laying performance and profitability

Abstract

Sixty-three Isa brown growing pullets of 11-weeks old with average weight of 849.44±2.16g were used in a completely randomized design to evaluate the growth response and blood profile of pullet fed diets supplemented with turmeric. Three experimental diets were formulated and supplemented with turmeric powder at 0g/Kg in diet 1(control), 10g/Kg in diet 2, and 20g/Kg in diet 3. Data were collected on weight gain, feed intake, haematological and serum biochemical indices. There was no significant (P>0.05) differences in the growth parameters except in feed intake. The highest significant feed intake of 88.57g/bird/day was observed in diet 1 followed by 81.61g/bird/day in diet 2 and least in diet 3 80.89g/bird/day. Pullets fed 20g/kg turmeric had the highest weight gain of 5.03g/bird/day. Mean values of haematological parameters measured differed significantly except the Packed Cell Volume (PCV). The haemoglobin (Hb), red blood cell (RBC) and white blood cell (WBC) of birds fed turmeric supplemented diets were significantly (P<0.05) higher than those fed the control diets. The serum biochemical indices were significantly (P<0.05) affected by the diets except for creatinine (CR mg/dl) but diet 1(control) was similar to diet 2 in all the parameters measured except for total protein (PRO) and cholesterol (CHOL). In conclusion, pullets' diet can be supplemented with turmeric up to 10g/Kg without adverse effect on their growth performance and blood profile.

Keywords: Turmeric powder, Pullets, Haematology and Serum biochemistry

Introduction

Medicinal plants, herbs and spices have prospect in livestock sector due to their bioactive compounds that have been in use in treating ailments (Labban, 2010) and also to improve performance when added to animal feed (Hussein, 2013). The focus on alternative to replace antibiotics in animal feed has gained significant interest and recently the use of herbs as feed additives has shown encouraging results. Adomeh and Eguaoje (2019) reported enhanced growth performance of birds fed ginger and garlic mixture at 2% while Olabode *et al.,* (2018) recommended 1.5% safe use of turmeric as a phyto-additive in starter broiler. Herbal feed additives like ginger, garlic and turmeric have received more attention due to their potential to improve nutritive value, boost immune system and enhance performance (Zhang *et al.*, 2009). Similarly, Lee *et al.*, (2004) reported that the antimicrobial activity of the phytochemical components in herbs may provide beneficial effects on poultry performance. Phytochemicals in turmeric are known to be natural, residual free and are thought to be ideal as feed additives in livestock diets (Wang *et al.*, 1998). Curcumin the main active compound furnishes turmeric with its characteristics yellow colour and is recognized as being responsible for most of it therapeutic effects such as antibacterial, antifungal, antiprotozoal, antiviral, antioxidant, anti-inflammatory and hypocholesterolemic activities (Chattopadhyay *et al.*, 2004). Supplementation of dietary turmeric reduced serum cholesterol in laying hens (Kermanshahi and Riasi, 2006), rabbits (Quiles *et al.*, 1998), and rats (Dixis *et al.*, 1998). The objective of this study was to determine the growth response and blood profile of pullet fed diets supplemented turmeric.

Materials and Methods

The study was conducted in the Poultry Unit of the Teaching and Research Farm of Lagos State Polytechnic, Ikorodu, Lagos State. Sixty-three (63) eleven-week old pullet chickens were randomly distributed into three groups with twenty-one chickens per group and each group was replicated thrice in a completely randomized design experiment. Turmeric rhizome were thoroughly washed with clean

water, sun dried for three days then oven dried for 30 minutes thereafter milled into powdery form and added as supplement into basal experimental diet comprising 42% maize, 22% PKC, 10% GNC, 20% wheat offal, 2%SBM, 2% bone meal, 1.5% limestone, 0.25% premix and 0.25% salt at the rate of 0g/Kg (control, T1), 10g/Kg T2 and 20g/Kg T3 turmeric supplementation. The determined crude proteins (g/Kg) are 185.5, 183.0 and 181.0 while gross energy (Kcal/Kg) are 3351.7, 3530.8 and 3477.9 for T1, T2 and T3 respectively. The pullets were raised in battery cage system during which feed and water were provided *ad libitum* for thirteen weeks. At the end of the trial about 2 mls of blood was collected from each bird using needle and syringe through the jugular vein from two birds per replicate into labeled heparin bottle and Ethylene-diaminetetraacetic acid (EDTA) bottle for analyses. Data were collected on weight gain, feed intake, haematological and serum biochemical indices. All data were subjected to analysis of variance using the Assistat-statistical Assistance 7.6 beta software developed by Silva and Azevedo, (2016) and differences between treatment means were separated using Duncan Multiple Range Test of the same software.

Results and Discussion

Growth performance of pullets fed diet supplemented with turmeric

The growth performances of growing pullets fed diet supplemented with turmeric are presented in Table 1. Statistical analysis showed that turmeric had no significant (P>0.05) influence on the growth parameters except for the feed intake (FI). The highest FI (88.57g/bird/day) was observed in T1 (control treatment) followed by T2 (81.61g/bird/day) and the lowest in T3 (80.89g/bird/day). The lowest feed intake might be attributed to the aroma in turmeric which probably affects the birds' appetite and also the level of inclusion of turmeric in the diet. Turmeric has been reported to reduced feed intake in bird (Durrani *et al.*, 2006; Olabode *et al.*, 2018). The weight gain, specific growth rate and feed conversion ratio of the experimental birds were similar (P> 0.05).

Table 1: Growth Performance of Pullets fed diet supplemented with turmeric

Variables	Levels of supplementation (g/kg feed)			SEM±
	T1 (0%)	T2 (1%)	T3 (2%)	
Average initial weight (g)	846.98	851.05	849.44	2.16
Weight gain (g/bird/day)	4.39	4.29	5.03	0.231
Feed intake (g/bird/day)	88.57[a]	81.61[b]	80.89[b]	2.448
Specific growth rate	1.13	1.24	1.25	0.038
Feed conversion ratio	20.18	19.02	16.08	1.22

[ab] mean with the same superscript on the same row are not significantly different (P>0.05),
SEM –Standard error of means

Haematological parameters of pullets fed diet supplemented with turmeric

Table 2 shows the haematological parameters of pullet fed different levels of turmeric based diets. The haematological parameters of growing pullets fed turmeric supplementation were significantly (P<0.05) higher than those on control diet except PCV. The haemoglobin observed ranged from 7.7 in T1 to 9 in T2. The Hb values were within the normal range of 7-14 reported by earlier workers (Mitruka and Rawnsley 1977; Esmail 2004; Sugiharto *et al.*, 2011; Iheukwumere and Herbert 2012; Campbell 2013). PCV values ranged from 27 in T3 to 29 in T2. The birds fed diets 10g/Kg of turmeric had the highest PCV of 29% though the values in all the treatments appeared to be within the normal range of 22.0-35.0% reported in literature (Jain 1986; Campbell 2013) The highest red blood cell (RBC) count ($3.77X10^{12}$/L) was recorded in T2 while the lowest value was observed in birds fed control diet (T1 $3.00X10^{12}$/L). The higher RBC counts of birds fed turmeric supplemented diets compared with the birds fed control diet might be attributed to the fact that turmeric in iron which probably resulted in increased production of haemoglobin and consequently increased RBC

concentration. Hence, turmeric positively influences blood formation and reduces anaemic condition (Sharma, 2003; Olabode *et al.,* 2018). Birds fed turmeric supplemented diets had significantly higher WBC values when compared to the control diet probably due to fact that the turmeric in the diets activates immune response and disease resistant (Zhang *et al.,* 2009). The improvement in haematological constituents in this study is in accordance with previous researchers' reports (Sugiharto *et al.,* 2011; Sodamola *et al.,* 2016; Olabode *et al.,* 2018).

Table 2: Haematological parameters of pullets fed diet supplemented with turmeric

Variables	Experimental diets			SEM±
	T1 (0%)	T2 (1%)	T3 (2%)	
Haemoglobin (g/d1)	7.7[b]	8.5[a]	9.0[a]	0.38
Packed cell volume (%)	28	29	27	0.58
Red Blood Cell ($X10^{12}$/L)	3.00[b]	3.77[a]	3.55[a]	0.23
White Blood Cell ($X10^{9}$/L)	4960[b]	7200[a]	7040[a]	721.48

[ab]mean with the same superscript on the same row are not

Serum biochemistry parameters of pullets fed diet supplemented with turmeric

Serum biochemistry parameter of pullet chickens fed turmeric-supplemented diet is shown in the Table 3. Statistical analysis revealed that serum biochemical parameters of pullets fed turmeric-supplemented diet differs significantly (P<0.05) except creatinine (CR mg/dl).

Table 3: Serum biochemistry parameters of pullets fed diet supplemented with turmeric

Variables	Experimental diets			SEM±
	T1 (0%)	T2 (1%)	T3 (2%)	
Protein (g/d1)	59.28[a]	48.59[b]	45.55[b]	12.49
Glucose (mg/dl)	141.90[a]	143.00[a]	126.50[b]	15.98
Cholesterol (mg/dl)	128.13[b]	171.23[a]	163.08[a]	39.67
Triglycerides (mg/dl)	74.64[a]	84.90[a]	70.91[b]	12.55
Albumin (g/dl)	1.26[a]	1.13[a]	1.08[b]	0.16
Alkaline phosphatase (u/l)	99.36[a]	118.68[a]	82.80[b]	31.1
Creatine (mg/dl)	0.82	1.1	0.64	0.4
Urea (mg/dl)	23.40[a]	34.22[a]	20.51[b]	12.52

[ab]mean with the same superscript on the same row are not significantly different (P>0.05)

The highest value of glucose was recorded in T2 (143.00mg/dl) while the lowest value was obtained in T3 (126.50mg/dl), the values of glucose recorded in this study is below the normal reference value (192-299mg/dl) reported by church *et al.,* (1984). Cheesebrought (1999) reported that high serum glucose indicates pancreatic or liver disease. The highest serum protein was recorded in T1 (59.28g/dl) while the lowest value was recorded in T3 (45.55g/dl). The protein value obtained from this study is above the normal reference value (3.0-4.9g/dl) reported by Church *et al.,* (1984) and also within the range of 39.45-55.53g/dl reported by Ochefu (2006). The highest value for Cholesterol was recorded in T2 (171.23mg/dl) and the lowest value was obtained from T1 (128.13mg/dl) the Cholesterol value of this study is within the normal reference value (129-297mg/dl) reported by Church *et al.,* (1984). The highest value of Triglycerides was obtained in T2 (84.90mg/dl) while the lowest value was recorded in T3 (70.91mg/dl). Numerically T2 had the highest value of Creatine while the lowest value was recorded in T3. Alkaline phosphatase and urea had their highest values in T2 and their lowest value was obtained in T3. T1 had the highest value for ALB while the lowest value was reported in T3.

Conclusions and Recommendation

The dietary inclusion of turmeric powder at 10g/kg and 20g/kg did not show significant difference except in the feed intake. However, chickens fed diet 2 (10g/kg) had the highest values for weight gain, feed intake, feed conversion ratio and specific growth rate except for protein efficiency ratio. The turmeric had no adverse effect on the haematological and serum biochemistry indices of the experimental birds. In conclusion, the results of the study indicated that up to 20g/kg dietary inclusion of turmeric could be recommended for beneficial effects on pullet chickens performance.

GROWTH PERFORMANCE, DIETARY SELECTIVITY AND NUTRIENTS PROFILE OF BROILER CHICKENS ON A CAFETERIA FEEDING REGIME

***AJETUNMOBI, A.W.; + OLOGHOBO, A.D. AND ++EGUAOJE, S.A.**
**Agric., Edu Dept. Adeniran Ogunsanya Coll. of Edu., Lagos.*
+ Dept. of Animal Science, University of Ibadan, Ibadan.
++ Dept. of Animal Science, University of Benin, Benin City.

Abstract
The study was conducted to determine growth performance, dietary selectivity of feed ingredients and nutrient profile of broiler chickens at 42 days of rearing. Two hundred and eighty-eight (288) unsexed day-old FUNAAB ALPHA Strain broiler chicks raised in battery cages were randomly distributed in a completely randomized design into 5 cafeteria dietary treatments and a basal dietary treatment groups of 6 replicate each containing 20% crude protein and 300kcal MC/kg. The results showed significant differences (P<0.01) among the treatment for all production variables except for feed: water radio. Weight gains were better (P>0.01) in broiler fed Red sorghum-soyabean meal-concentrate and Red sorghum-millet-soyabean meal-groundnut cake-concentrate. The feed conversion ratio showed similar trends with the weight gains and final body weights. The co-efficient of preference (%) indicated higher values (74g 5%) for millet in millet-soyabean concentrate diet compared to 67.43% for red sorghum in Red sorghum-soyabean meal- concentrate diet. Nutrient profile of the cafeteria dietary treatments showed similar trends with other measured variables. It was shown that Red sorghum and millet can nutritionally and suitably be used with soyabean meal for cafeteria-fed broilers that can select and consumed feedstuffs to meet energy, protein and mineral needs for growth and production.

Keywords: Cafeteria, coefficient of preference, dietary selectivity, nutrient profile, growth indices.

Introduction
Birds' performance and their products are affected by nutrition and feeding systems. Poultry can be managed under different feeding systems.Feed intake is influenced by the interface between nutrition, management and animal responses (Church and Pond, 1988; Leeson and Summer, 2005). About 86.2 percent of the poultry are managed under traditional husbandry systems (Tewe, 1998). Cafeteria system could be an option to *ad libitum* complete diet feeding. It allows the animals to select their own diet (Forbes and Shariatmadari, 1994; Forbes and Covasa, 1995). Cafeteria feeding has recently not received considerable research attention to meet the current needs of the poultry industry. Cafeteria study will serve as a basis for establishing semi intensive system for rural small-scale poultry production. The objective of the study was to evaluate the production response, dietary selectivity and nutrient profile of broiler chickens on a cafeteria feeding system.

Materials and Methods
The experiment was conducted at the poultry unit, Teaching and Research Farm, Agricultural Education Department, Adeniran Ogunsanya College of Education, Otto/Ijanikin, Lagos. Two Hundred and Eighty-eight unsexed day-old broiler chicks obtained from the hatchery of the Federal University of Agriculture, Abeokuta were randomly allotted to six experimental diets with six replicates of 48 broiler chicks each in a completely randomized design and raised in constructed cage system. The dietary treatments are presented in Table 1.

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

The feeds were presented in a mash form with 3 - compartment feeding troughs to separate the sources of energy, protein and concentrate with the exception of 5 - compartment feeder for treatment containing all the energies and protein sources.

The following parameters were measured; weight gain, feed intake, feed conversion ratio, feed/gain ratio, water consumption, feed to water ration co-efficient of preference and nutrient profile. The data obtained were subjected to analysis of variance using the General Linear model procedure (SAS Institute, 2012).

Result and Discussion

The results of the growth performance, co-efficient of preference and the nutrient profile of the broiler chicken at the finisher stage (22-42 days) are presented in Tables 2, 3 and 4 respectively.

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

There were significant differences (P<0.01) among the treatments for all variables except for feed to water ratio. Feed intake was greater in broilers on cafeteria feeding of red sorghum - soya bean meal - concentrate differing significantly (P<0.01) from birds on free-choice feeding of sorghum-GNC-concentrate and millet-GNC concentrate. Feed intake was not statistically different (P>0.01) among the treatments of red sorghum-soyabean meal concentrate, millet-soyabean meal- concentrate and millet- red sorghum-soyabean-GNC-concentrate.

SBM – Soya bean meal, GNC – Groundnut cake, Ma – Maize, S – Sorghum, Mi – Millet, C – Concentrate Supplement

The result indicated higher preferences for millet, red sorghum and soyabean meal as good sources of energy and protein for better performance. Birds consumed less groundnut cake probably due to its low protein quality, poor palatability and unattractiveness compared to soyabean meal.

The birds utilized the nutrient in feedstuffs according to their choice to meet their nutritional needs. Poultry has been reported to adjust voluntary intake of feeds with different energy and protein densities (*Cruz et al, 2005; Rose, 1997).*

Conclusion and Recommendations

Red sorghum and millet as energy sources can adequately be utilized in combination with soya bean meal as the broilers on the diets containing these ingredients presented better growth performance, dietary selectivity and nutrient profile than when groundnut cake was used. This therefore will provide a guide for the improvement of feeding and nutrition of the rural poultry system, which will ultimately improve smallholder poultry production in a sustainable and economic manner for higher animal protein intake.

GUT CHARACTERISTICS AND ILEA DIGESTIBILITY OF BROILERS FED PELLET AND MASH FEED FORMS

Akande T.O., Olakanmi O. F., Okunlola P.F. and Owolabi E.O.
Obafemi Awolowo University, Ile-Ife, Osun State
yakandetaiwo@yahoo.com

ABSTRACT
A study was conducted to evaluate performance, gut characteristics and nutrient digestibility of broilers fed pellet and mash feed forms. 100 Cobb-500 one-day old broilers used were randomly grouped into two treatments of five replicates and 10 birds per replicate in a deep litter system. The birds were fed with 2mm and 4mm die size pelletized feed at the starter and finisher phase respectively while commercial mash feed grade was applied at starter and finisher phase. The experiment lasted 7 weeks. Five days to the end of the experiment, two birds per replicate were separated into metabolic compartment for ilea digestibility trial and they were offered feed treated with chromic oxide at 0.2% for the five days. On the 6th day, the birds were slaughtered and the ilea content of the gut was collected for the proximate and chromic content determination. The morphometric measurement of the internal organs and intestinal components of the birds were taken and sample collected for histological assessment. The result showed significant difference (p<0.05) in the performance parameters measured with the birds fed pellet having higher feed intake, body weight gained and superior feed conversion ratio. There was no significant difference (p>0.05) in the length of the duodenum, jejunum and ileum and weight of the heart and liver between the two treatments while the gizzard weight was higher (P<0.05) in birds fed mash feed form. Ilea nutrient digestibility for ether extract was higher in birds on pellet. It was deduced from the result of the experiment that pellet feed form performed better than mash counterpart and with significant influence on the gut physiology and overall better nutrient utilization.
Key words: broilers, feed forms, ilea digestibility, gut morphology,

INTRODUCTION
Feed composition, feed structure and feed form are most important factors that determines the efficiency of feed utilization by animals particularly poultry because of the simple nature of their stomach (Choct *et al*., 2004; Ball *et al*., 2015). Modern meat type chicken have high appetite for feed which translate to increased live production costs claiming about 60-70% of total cost (Aliakbarpour *et al*.,2013; Willems *et al*., 2003). Therefore, broilers' feed consumption and utilization should be well studied to ensure optimum performance of the birds so as to offset maximum and substantial profit.

The growth and development of the gastrointestinal tract is equally vital for broiler chickens as it helps to effectively utilize nutrients in their diet (Jacobs *et al.,* 2010). Feeds fed to broiler can assume different forms such as pellets, mash and crumble due to difference in processing method during feed formulation. Mash is a form of a complete feed that is finely ground and mixed so that birds cannot easily separate out ingredients; crumble also is a type of feed prepared at the mill by pelleting of the mixed ingredients and then crushing the pellet to a consistency coarser than mash; while pellet is a feed form that is small (using different dies depending on the desired size) rounded and compressed in to a mass of substance. Ilea digestibility which collects digesta from part of the ileum is a more complex method of measuring digestibility but tactically eliminates some confounding factors such as urine and microbial contributions into the excreta which may produce overestimation of nutrient utilization. The objective of the study is to determine the comparative effect of two feed forms (i.e. mash and pellet) on the performance of broiler chicken, some gut characteristics and the ilea digestibility of the birds.

MATERIALS AND METHODOLOGY
Experimental station and Birds Management.
The experiment was conducted at Obafemi Awolowo Teaching and Research Farm, Ile-Ife, Osun State Nigeria. One hundred day old Cobb 500 were obtained from a reputable farm and were brooded in a floor litter system for two weeks but the birds were together for the first week after which they were distributed randomly to their various experimental pen at the beginning of the second week. The birds were offered a starter compounded ration 23%CP and 3000kcal/kg ME and

a finisher diet 21%CP, 3000kcal/kg at the onset of the fourth. Water and feed were offered *ad-libitum* while other routine management was performed as appropriate.

Experimental diets

The ingredients used for the feed formulation were purchased from a reputable commercial feed ingredient seller in Ile- Ife while the milling, mixing and pelleting were carried out at OAU Teaching and Research Farm. The gross compositions of the experimental diets are as shown in Table 1

Table1: Gross composition of the experimental diets

Feed Ingredients	Starter	Finisher
Maize	56.0	58.0
Soya bean meal	15.0	15.0
Groundnut cake	16.0	12.5
Palm kernel cake	4.50	8.00
Fish meal	4.0	2.0
*Other feed ingredients	4.5	4.5
Calculated analysis		
Crude Protein	23.1	20.30
Crude fibre	3.53	3.93
Metabolizable Energy	2993	2957

*Other feed ingredients: bone meal=2.5, 0yster shell=1.0, Methionine=0.3. Lysine=0.3, Pre.=0.2, salt=0.2

Data collections and Analysis

The initial weight of the birds was taken by end of first week using a digital scale while feed intake was obtained on weekly basis. At the end of the feeding trial which lasted 7 weeks, two birds from each replicate were randomly selected and transferred into metabolic cage. The birds were fed with chromic oxide supplemented diet at 0.2% concentration for 5 days and after which they were sacrificed to recover the ilea content. The sampling of the ilea segment of the intestine was standardized by collecting from the region between 30 mm before the ileo-cecal junction and 30 mm after Meckel's diverticulum, in order to avoid contamination of the cecal and jejunal flow, respectively. Contents from the ileum of each bird were collected by gentle finger-stripping directly into a jar, homogenized and oven dried (80 C) for 48 h, ground (0.5mm screen), and stored in air tight labelled bags for subsequent analysis. Sample of the diets and dried ilea content were taken to laboratory for determination of chromic oxide concentration and proximate contents according to the procedure of AOAC (2009).

The length of the duodenum, jejunum and ileum were taken using a measuring tape while small portion of the duodenum and jejunum were cut and preserved in 10% formalin. Samples were later prepared on slide for micrographs. The data generated were analyzed using student T-test of SAS 2009 statistical package.

RESULT AND DISCUSSION

Production performance of broiler fed mash and pellet feed forms

Data on performance indices are as presented in Table 2. The result shows that all performance parameters were significantly different ($p< 0.05$) across the treatments. The finding aligned with earlier reports on numerous advantages associated with pelleting which include enhancement of feed intake and growth of animals as a result of the reduction in feed wastage, decreasing of energy used

for consumption, improving palatability, and the reduction of dustiness of feed (Abdollahi *et al.*, 2013). However, a marginal increase in cost is expected with bird on pellet because of extra cost accrued from pelleting as indicated by Jahan *et al.* (2006).

Table 2: Performance characteristics of broiler chicken

Treatment	Control (mash)	Pellet	P value
Initial body weight (g)	152.52±0.8869	152.16±1.0348	0.80
Final body weight (g)	2473.7±29667[a]	2992.3±91.167[b]	0.01
Body weight gain (g)	2321.1±29.873[a]	2840.2±91.31[b]	0.03
Daily weight gain (g)	55.265±0.7113[a]	67.263±2.1743[b]	0.04
Total feed intake (g)	4964±70.62[a]	5533±102.8[b]	0.01

Gut morphology and Ilea digestibility of broiler fed mash and pellet feed form.

The result of the organ, intestinal and micrographs of the duodenum and jejunum are given in Table 3. Digestion and absorption of feed takes place majorly in the duodenum and the jejunum and partially in the ileum aided by the presence of the villus and crypt. Any changes observed in the villus and crypt may influence the rate of digestion and absorption as these components increase the surface area of the intestine and expose the feed to proper enzymatic reaction. The result in the Table 3 shows that the villus height of the duodenum and jejunum of birds fed pellet was significantly higher (P< 0.5) than birds on mash feed. The higher feed intake observed in birds fed pellet increased the activity of the villus in the intestine and may have resultant effect in their length being longer. The increased villus height may increase total luminal villus absorptive area and subsequently result in greater digestive enzyme action and enhanced transport of nutrients at the villus surface (Naderinejad *et al*., 2016). These higher value of the villus height of duodenum and jejunum and higher value of the crypt depth of jejunum observed in birds fed pellets may be responsible for the better performance observed. Although, there were marginal rise in nutrient digestibility of birds on pellet only ether extract was significantly different (P<0.05).

Table 3: Organ and intestinal measurement of broiler chickens

Treatment	**Control (mash)**	**Pellet**
Duodenum(cm)	36.00±3.03	46.00±6.02
Jejunum (cm)	85.50±6.364	80.50±3.500
Ileum(cm)	78.00±10	93.00±2.887
Gizzard (g)	57.00±2.000[a]	38.50±0.500[b]
Liver(g)	23.00±2.000	23.500±4.500
Heart(g)	12.00±2.000	14.00±100
Villus height duodenum(µm)	1829.30±78.760[b]	2349.9±65.539[a]
Villus height jejunum(µm)	664.56±46.709[b]	1443.50±27.839[a]
Crypt height duodenum (µm)	520.95±14.738[a]	304.95±16.689[b]
Crypt height jejunum (µm)	256.05±20.509[b]	441.77±18.333[a]

**ab means in the same column followed by different letter are significantly different. P<0.05

CONCLUSION

It was concluded that pellet feed form significantly improved feed conversion, influenced some gut changes and translated to better overall nutrient utilization in Cobb-500 broilers. Hence, farmers are advised to opt for pellet feed form for broiler chickens.

Abstract

This study was aimed to evaluate the effect of microbial degraded cassava peel-leaf blend on the growth performance and blood serum biochemistry of growing pigs. Eighteen intact male growing pigs (Landrace), weighing 44.6kg, were housed in a concrete cubicle with six pigs per treatment for six weeks. Pigs were fed ad libitum feed and water. Experimental diets were: control, microbial treated cassava peel and leaf blend and untreated cassava peel and leaf blend diets. The Cassava peel-leaf blend replaced maize at 100%. Cassava peel and leaf were mixed at ratio 5:1, allowed to ferment using Aspergilus tamari at 10.5 x 10^8 spurs/gram for five days, after which the mass was sundried to form microbial degraded cassava peel-leaf (MCPL). While the untreated cassava peel and leaf blend was tagged UCPL. Daily feed intake recorded and body weight was recorded for each treatment weekly. At the end of the experiment, blood samples were collected for serum biochemical indices. The results showed that pigs fed MCPL marginally gained more weight compared to pigs on the UCPL and control diets; and that the FCR of pig on MCPL was marginally better than those on other diets. The inclusion of cassava peel-leaf blend with or without microbial degradation had no significant (P>0.05) effect on the serum biochemical indices. It may be concluded that, feeding of microbial degraded cassava peel-leaf blend caused marginal improvement in the growth of pigs with no effect on blood serum biochemical indices.

Key Words: Pigs, microbial degraded, Growth performance, Serum metabolites, cassava peel-leaf blend

Introduction

The pig industry depends to a large extent on the availability of good quality pig feeds in sufficient quantity and at affordable price. In non-ruminant animals, such as pigs and poultry, greater proportion of cost is expended on feeding, feed representing 65-70% of total cost in intensive production system, in Nigeria and many developing countries (Apata and Babalola, 2012). As a result, alternate and cheap ingredients have been advocate, especially in the feeding of pigs. In general, the factors limiting the optimal use of alternate ingredients for monogastric animals include low palatability, often due to high levels of anti-nutritional factors (e.g. in cassava), low dry matter content (e.g. in duckweed) or high fibre content (e.g. in banana leaves and stem) and the low biological value of the protein (Khieu, 2014).

Cassava root is a rich source of energy but with low protein. Its by-products include: cassava peel, cassava leaf, cassava flour, cassava chaff and sievate. Major limitations in using cassava root is it low crude protein and presence of hydrocyanic acid (HCN). Several reports have shown that cassava leaf is high in protein, rich in lysine but low in some sulphur amino acids (Gomez and Valdivieso 1985).

Here in Nigeria, cassava peels and leaves are agricultural by product mostly discarded or fed to the local goat and sheep after the main content of the cassava product has been collected for further processing. However, their importance has not been discovered by both the local and commercial farmers in the Nigeria agro-industry (Aro *et al*., 2010; Adebayo, 2008). As such the combine use of

cassava peel and leaf in feeding of non-ruminant will assist in improving the utilization of these by-products and assist the farmer's economy.

Recent studies show that the biodegradation of by-products increase it nutritive content and reduces anti-nutritional content (Hawashi et al. 2019; Chebaibi et al. 2019). Augmenting cassava peel with other plant materials high in protein have been recommended to improve it use (Oni, 2010). Sun-drying and fermentation have been reported to reduce HCN or other anti-nutrients to tolerable level in diets (Ajagbonna et al., 1999). Therefore, this study is focused on evaluating the response of growing pig fed microbial degraded cassava peel and leaf blend diet.

Materials and Methods

The experiment was carried out at the piggery unit of the Directorate of University Farms, (DUFARMS) and at the College of Animal Science and Livestock Production Farm, Federal University of Agriculture, Abeokuta, Alabata, Ogun State, Nigeria. The site is situated in the derived savanna zone of the Southwestern Nigeria on Latitude $7^0$9' 39N and $3^0$20' 54E and 76m above sea level. The Mean Annual Rainfall is 1040mm and occurs from March to October, temperature average is 34.0C throughout the year.

Cassava root peels was collected from a reliable local cassava processing factory in Abeokuta and cassava leaves without petioles were sourced, sun dried. The two by-products were mixed at ratio 5:1 of cassava peel to leaves; degraded using microbial action *(Aspergilus tamari*) under anaerobic condition in a closed PVC nylon and container for 5 days; and then sun-dried. Table 1 show the gross composition of the experimental diet. Eighteen Male Land race pigs, weighing 44.6kgwere used Each treatment was allotted six pigs and given *ad libitum* feed and water six weeks. Daily feed intake and weekly weight of each pig, in each treatment, were recorded. Blood for serum biochemistry was collected at the end of the study and put in plane tube and analysed for Total protein, Albumin, Globulin, Cholesterol, Urea, Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), Alkaline Phosphatase (ALP) and Creatinine. Data were subjected to one-way analysis of variance in a completely randomized design using MINITAB 17. The difference among means was separated using Tukey krammer mean comparism procedure.

Results and Discussion

The effect of microbial degraded blend cassava peel-leaf meal on growth performance of growing pigs is shown (Table 2). The final weight gained of pigs fed MCPL was not significantly ($P>0.05$) improved compared to those on UCPL and the control diets. The feed conversion ratio of pigs on MCPL diet was not significantly ($P>0.05$) improved above those on other diets. Adeyemi et al. (2014) obtained similarity in values for all indices of performance for maize based diet and diet containing 50% replacement of maize with naturally fermented cassava peel and leaf meal for rabbit.

Table 1: Gross composition of experimental diet

Ingredients (g/kg)	Control	MCPLF	UCPLF
Maize	40.00	0.00	0.00
Microbial degraded Cassava Peel and leaf blend	00.00	40.00	0.00
Untreated Cassava Peel and leaf blend	00.00	0.00	40.00
Palm kernel Oil	1.00	4.50	3.50
Soyabean meal	17.00	18.00	19.00

Ether extract (%)	3.88	2.97	3.83
Fibre (%)	4.90	9.26	7.68

Microbial diet has 10.5 X 10^8 spurs/gram of *Aspergilus tamari* and untreated diet contains no inoculum culture.

Table 2: Growth performance of pigs fed microbial degraded cassava peel leaf meal diet.

Parameters	Control	MCPL	UCPL	SEM	P VALUE
Initial weight (kg)	44.00	43.50	45.00	3.970^{NS}	0.983
Final weight (kg)	65.83	67.17	66.83	1.890^{NS}	0.944
Weight gain per day(kg)	0.45	0.48	0.45	0.011^{NS}	0.274
Feed intake per day (kg)	2.18	2.14	2.20	0.118^{NS}	0.923
Feed Conversion Ratio	4.25	3.79	4.28	0.289^{NS}	0.408

SEM = Standard Error of mean; NS = Not Significant

Slight increase in final weight and weight gain observed with pigs fed diet containing MCPL. Solid state fermentation has been reported to enhance the nutrient content of foods through the biosynthesis of vitamins, essential amino acids and proteins by improving protein quality and fibre digestibility (Achinewhu et al., 1998). The slightly reduced feed intake can be explained by the higher water holding capacity of cassava peel-leaf by-product (Ngoc et al., 2013), which invariably increases the bulk density of the feed (Kyriazakis and Emmans, 1995). Fermented by-products may add some probiotic effects, which contributed to the improved FCR (Hong et al. 2016). Giang et al. (2010) reported that dietary supplementation of a lactic acid bacteria complex together with *Bacillus* and *Saccharomyces* to growing-finishing pigs improved FCR.

The effect of microbial degraded cassava peel, leaf meal on the serum biochemical parameters of growing pigs is shown on Table 3. The result revealed that there was no significant (P>0.05) effect of diets on the on serum biochemical parameters of pigs. Blood total protein ranged from 7.4 – 7.8 g/dl, Aspartate amino transferase (AST) value ranges from 36-38 U/L and Alanine amino transferase (ALT) 33-38 U/L.

Table 3: Effect of microbial degraded cassava peel leaf on the blood serum

Parameters	Control	MCPLF	UCPLF	SEM	P VALUE
Total protein (g/dl)	7.42	7.89	7.54	0.724^{NS}	0.897
Albumin (g/dl)	3.86	4.48	4.88	1.090^{NS}	0.809
Globulin (g/dl)	3.56	3.41	2.66	0.698^{NS}	0.642
Cholesterol (g/dl)	76.10	110.20	84.50	12.40^{NS}	0.207

ALT (U/L)	38.67	39.00	33.00	3.910^{NS}	0.514
ALP (U/L)	51.33	39.67	40.00	5.600^{NS}	0.316
Creatinine	0.65	0.75	0.57	0.495^{NS}	0.119

Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), Alkaline Phosphatase (ALP)

SEM= Standard Error of Mean; NS = Not Significant

The serum total protein and albumin of the growing pigs in this study were not affected by the diets in the three treatments. Gouache *et al.* (1991) reported albumin to be specifically influenced by protein shortage.

No significant (P>0.05) effect was observed in serum creatinine value with the imposed treatment. Ehebha and Eguaoje (2018) reported no significant difference in creatinine values of broiler fed varying dietary levels of sundried cassava peel meal supplemented with enzyme (Maxigrain). This indicate that no muscular wastage result from the use of cassava peel-leaf blend.

Conclusion and Recommendation

Microbial degradation caused marginal improvement of all growth performance parameter measured, except slight decrease in feed intake. All Serum indices measured indicated no adverse effect of microbial degraded cassava peel-leaf on the availability of nutrient for normal function of the growing pigs.

It is recommended that the utilization of cassava peel-leaf meal can be improve the adoption of microbial degradation.

Abstract

To evaluate the effect of Bambara nut offal (BNO) fed as a replacement for wheat offal (WO) on growth performance and carcass yield of weaner rabbits, a total of 24 mixed breed unsexed weaner rabbits were purchased, weighed and randomly grouped into four dietary treatments of 6 replicates each. The four dietary treatments were made up of varying ratios (in percentages) of BNO and WO at 0:100, 25:75, 50:50 and 75:25 respectively. Initial and final body weights, feed intake and feed conversion ratio (FCR) of the rabbits were taken on a weekly basis and the carcass yield was determined at the end of the study. The experiment was laid out in a completely randomized design and data obtained were subjected to one-way analysis of variance. The study showed that replacement of WO with BNO did not significantly influence ($p>0.05$) growth performance of rabbits across replacement ratios. Increasing the ratio of BNO to WO produced carcass yield closer to that of rabbits on 100% WO. Also, no significant differences ($p>0.05$) were recorded for carcass parts of commercial importance across treatments aside from tail where rabbits on 25%BNO recorded value (0.45g) significantly higher ($p<0.05$) than others on higher BNO levels but all are similar in weights to that of rabbits on 100%WO. Replacing WO with BNO in weaner rabbits' diets is therefore recommended as it produced similar results on growth performance and carcass yields.

Keywords: Weaner rabbits, Bambara nut offal, Wheat offal, Carcass yield, Growth performance

Introduction

Nigerians have been reported to be consuming about 7g of protein per day which is lower than 28g/head/day recommended by FAO (Uchegbu *et al.*, 2007). Rabbit is among the new livestock being explored to beef up the shortage in animal protein supply due to their short maturity period and overall acceptability when compared to major livestock such as cattle, sheep, goat and chickens (Yusuf *et al*., 2009). However, high cost of conventional feedstuffs which accounts up to 70% of the total production (Ijaiya, 2013) is a major challenge in animal production. Bambara nut offal is a cheap and commonly available fibrous waste gotten from processing of Bambara seed into flour used in preparing a delicacy called 'Okpa' in Southeastern part of Nigeria. Therefore, this study evaluated the effects of Bambara nut offal as a replacement for wheat offal on growth performance and carcass yield of weaner rabbits.

Materials and Methods

Preparation of the test ingredient

Bambara nut offal used for this experiment was sourced from Okpa processing centers in Igbo communities around Abeokuta, Ogun State. The offal was gotten after Bambara seed was washed, dried at 60°C for 8 hours, milled into flour and sieved. The dried Bambara nut offal collected was packed inside clean sacks, sundried to moisture content below 10% and taken to feed mill.

Experimental animals and management

A total number of 24 mixed breed unsexed weaner rabbits aged 6-7 weeks and weight range of 600-650g, were purchased from a reputable rabbit farm at Apata, Ibadan, Oyo state. On arrival, the initial weight of the rabbits were taken and randomly allotted into 4 experimental treatments of 6 replicates each. The animals were kept inside clean and disinfected wooden hutches and subjected to standard routine managements. Feed and water were provided to the animals *ad libitum* throughout the experimental period which lasted for eight weeks.

Experimental diets and design

Four different diets were formulated such that the control treatment groups were fed diet containing 0% inclusion of Bambara nut offal (BNO) as a replacement for wheat offal while experimental birds in the second, third and fourth treatment groups received diets containing 25%, 50% and 75% BNO as replacements for wheat offal. The experiment was laid out in a completely randomized design. The gross composition of the experimental diets is shown on Table 1.

Table 1: Gross composition (%) of the experimental diets for weaner rabbits.

Ingredients	**Control**	**25%BNO**	**50%BNO**	**75%BNO**
Maize	38.00	38.00	38.00	38.00
Soybean meal	17.00	17.00	17.00	17.00
Wheat offal	40.00	30.00	20.00	10.00
BNO	-	10.00	20.00	30.00

Crude fibre (%)	10.0	10.5	11.0	11.5

BNO- Bambara nut offal

Data collection

Growth performance

Weekly data was collected for growth parameter indices using the following formula:

$$\text{Weight gain per rabbit (g)} = \frac{\text{Final weight (g)} - \textit{Initial weight (g)}}{\text{Number of rabbits}}$$

$$\text{Feed intake per rabbit (g)} = \frac{\text{Feed supplied (g)} - \text{Feed leftover (g)}}{\text{Number of rabbits}}$$

$$\text{Feed conversion ratio} = \frac{\text{Amount of feed consumed (g)}}{\text{Weight gain (g)}}$$

Carcass yield

At the end of the experiment, 4 rabbits were randomly selected from each treatment, stunned with chloroform and slaughtered by cutting the jugular vein. The slaughtered rabbits were scalded with naked fire and eviscerated. Live weight, hot carcass weight, empty carcass weight and carcass dressing percentage were determined and recorded. The carcass was cut into retail parts and internal organs which were weighed using sensitive electronic scale and expressed as percentage of live weight.

$$Carcass\ dressing\ percentage = \frac{Empty\ carcass\ weight}{Live\ weight}\ X\ 100$$

Statistical Analysis

The data obtained were subjected into One-way Analysis of Variance (ANOVA) in a Completely Randomized Design using the GLM procedure of statistical analysis software SAS® version 2003. Significant ($p<0.05$) differences among treatment means were determined using Duncan Multiple Range Test (DMRT) as contained in the SAS® software.

Results and Discussion

The result of growth performance of weaner rabbits fed Bambara nut offal (BNO) as a replacement for wheat offal (WO) as shown on Table 2 below showed no significant difference ($p>0.05$) across the dietary treatments. However, the range of values recorded in this study for final weight gain (1433.30 – 1583.00g) is higher than the values (1200.00-1375.50g) reported by Igwebuike *et al*., (2013) who replaced wheat offal with sorghum offal but lower than values(1213.20-1690.70g) reported by Oni *et al*. (2015). Also, the values obtained for feed conversion ratio (FCR) (3.50-4.75) is lower than values (3.49-7.77) reported by by Igwebuike *et al*., (2013). This result suggests that Bambara nut offal is low in antinutritional factors such as tannin which has been reported to reduce feed utilization and growth (Helsper *et al*., 1993).

As also presented in Table 2, hot carcass weight, empty carcass weight and carcass length were not significantly affected ($p>0.05$) with the inclusion of BNO as a replacement for wheat offal aside from carcass dressing percentage which is relatively higher in rabbits fed 75%BNO (69.61%) and similar to the rabbits on control diet (66.71%). More so, carcass cut parts of economic importance and internal organs were not significantly different ($p>0.05$) in rabbits fed feed BNO containing diets and those fed 100%WO (control). The observation in this study is in conformity with what Igwebuike *et al*., (2013) reported when weaner rabbits were fed sorghum offal as a replacement for wheat offal. However, significant differences recorded for weight of tails could be attributed to the different breeds of rabbits used in the experiment.

Table 2: Growth performance and carcass yield of weaner rabbits fed Bambara nut offal as a replacement for wheat offal.

Conclusion and Recommendation

As observed from the results of this study, replacement of wheat offal with Bambara nut offal in weaner rabbits diets at levels of 25-75% produced results similar to that of rabbit fed 100% wheat offal for growth performance and carcass yield. Therefore, Bambara nut offal should be used as a replacement for wheat offal at up to 75% replacement level for proper growth, carcass yields and feeding cost saving.

Abstract

A total of ninety (90) day old broiler were used for the study to determine the carcass characteristics of broiler finisher fed acid soaked Cajanus cajan seed meal diet. The birds were randomly assigned into 3 dietary treatments of 30 birds consisting of 3 replicate of (10) birds per replicates in a completely randomized design experiment. The seeds used were purchased from Towobowo Market in Igboora. The raw pigeon pea seeds were pre-treated by soaking at the rate of 1kg/3L of water for 12 hours after which the soaked seeds were soaked at the rate of 1kg/3L of raw pap water filtrate for 24 hours, initial and final pH was taken. The sample was sundried for 3days, milled and then included in the diet accordingly. Birds on T1 received the control diet, T2 received 20% level of pigeon pea, while T3 received 40% level of pigeon pea. The experiment lasted for eight weeks. At the end of the 8 weeks three (3) birds per treatment were sacrificed for carcass analysis. Results showed that there were significant (P>0.05) difference in the live weight, dress weight, plucked weight, dress, neck, wing, shank, thigh muscle, drum stick, breast muscle, and back, while there was no significant (P<0.05) difference in the head. However, birds on T2 recorded the highest value of the live weight (2130.70g), dress weight (1924.30g), plucked weight (206.30g), neck (4.30g) and drum stick (11.34%) while T3 recorded the lowest value of live weight (1865.70g), dress weight (1682.30g), plucked weight (183.30g), dress % (90.20%), thigh muscle (10.67%), drum stick (10.61%), breast muscle % (24.67%), and back % (10.90%). Birds on T1 recorded the highest value of dress percentage (91.10%), shank (4.96%), thigh muscle (11.46%) and breast muscle (25.90%) however, bird on T1 recorded the lowest value of back (10.68%). It can be concluded that pigeon pea soaked in acidic medium can be fed to birds at 20% inclusion level without having any adverse effects on the birds.

Key word: Carcass, Broiler, Replicate, Pigeon pea.

Introduction

Poultry production is an important rapid growing money making industry. However, one of the major problems of poultry producers is the high cost of feed, which arises mainly from the competition between man and animal for conventional feedstuffs like maize, groundnut cake, soybean meal and fish meal (Amaefule and Obioha, 2005). Competition for these feed items (especially protein feeds such as soya bean) increases the price, leading to high cost of production and hence poultry products. Soya bean is an oil seed legume, high in protein (44-47% crude protein) and forms the major source of plant protein for non-ruminants mainly poultry, constituting 20-30% in poultry ration (Opara and Okorie, 2015). The over dependence on soyabean as major protein source for monogastric animal feeding and industrial purposes has increased its scarcity and consequent high cost of production. There is need to investigate into some other legume seeds that are rich in protein and have the potential to either partially or wholly replace soyabean in poultry ration

One of such unconventional legumes capable of substitution expensive soyabean is pigeon pea. Pigeon pea has a protein content of between 20- 29% however the seeds like other legume seeds contain Anti-Nutritional Factors (ANFs) such as protease trypsin and chymotrypsin inhibitors and haemaglutinins (Carlini and Udedibie, 1997). However several processing methods such as boiling,

toasting, roasting, soaking (Akintunde *et al*., 2010) had been used to inactivate these antinutritional factors

Materials and Methods

Experimental site: The experiment was carried out at the Teaching and Research farm, Oyo State College of Agriculture, Igboora in the derived Savannah zone of Nigeria. The college is located on $7^0$15N and 303^0E of the equator with average annual rain fall 1278mm and average temperature of 20C.

Collection of sample: Pigeon pea was purchased from Towobowo market in Igboora.

Pre-treatment of seed: Raw pigeon pea seeds were soaked at the rate of1kg/3L of water for 12 hours.

Treatment of sample: The soaked seeds were soaked at the rate of 1kg/3L of raw pap water filtrate for 24 hours, initial and final pH was taken. The sample was sundried for 3days, milled and then included in the diet accordingly.

pH range	CCSO
Initial pH	3.8
Final Ph	4.6

CCSO- *Cajanus canjan* soaked in ogi liquor

Experimental diets: A total of ninety birds were used for the study, they were randomly assigned into 3 dietary treatments of 30 birds consisting of 3 replicate often (10) birds per replicates in a completely randomized design experiment. Birds on T1 received the control diets; T2 received 20% level of pigeon pea, while T3 received 40% level of pigeon pea. The experiment lasted for eight weeks.

Table 1: Gross composition of experimental animal diets

Ingredient	T_1 (0%)	T_2 (20%)	T_3 (40%)
Maize	58.00	49.23	40.46
Soyabean	27.00	21.60	16.20
Cajanus cajan	0.00	14.17	28.34
Wheat offal	10.00	10.00	10.00

Lime stone	2.00	2.00	2.00
Lysine	0.25	0.25	0.25
Methionine	0.25	0.25	0.25
Salt	0.25	0.25	0.25
Broiler premix	0.25	0.25	0.25
TOTAL	100.00	100.00	100.00
M.E (Kcal/kg)	3005	3014.36	3023.32
Crude protein (%)	21.75	20.80	19.86

M. E- Metabolizable energy

Carcass Analysis: Three birds per treatment were selected and slaughtered. The carcass part were cut which include (live weight, dress weight, head, neck, wing, shank, thigh muscle, drum stick, breast muscle and back) and are weighed and express as percentage of live weight,

Statistical analysis: Following the experimental design, all data collected were subjected to statistical analysis of variance (ANOVA) using SPSS version 17 and means separated by Duncan Multiple Range Test.

Result and Discussion

Table 2: showed the carcass characteristics of broiler finisher fed acid soaked *Cajanus cajan* seed meal diet. There were significant (P>0.05) difference in the live weight, dress weight, plucked weight, dress, neck, wing, shank, thigh muscle, drum stick, breast muscle, and back, while there was no significant (P<0.05) difference in the head. However, birds on T2 recorded the highest value of the live weight (2130.70g), dress weight (1924.30g), plucked weight (206.30g), neck (4.30g), and drum stick% (11.34%). While T3 recorded the lowest value of live weight (1865.70g), dress weight (1682.30g), plucked weight (183.30g), dress % (90.2%), thigh muscle% (10.67%), drum stick % (10.61%), breast muscle % (24.67%), and back % (10.90%). Birds on T1 recorded the highest value of dress percentage (91.10%), shank (4.96%), thigh muscle (11.46%) and breast muscle (25.90%). However, bird on T1 recorded the lowest value of back % (10.68%).

Table 3: Anti-nutritional factor content of raw and processed pigeon pea

Anti-nutritional factors	Raw	Processed	Percentage reduction
Saponin	0.287	0.242	15.0
Tannin	0.026	0.014	46.15
Trypsin inhibitors	28.74	26.87	6.50
Oxalate	0.117	0.082	29.9

Discussion

There were significant ($P < 0.05$) difference in the values recorded for final live weight, dressed weight, Plucked weight and dressed percentage of broiler fed experimental diets across the treatment. The result of this study confirmed the findings of Fanimo *et al.* (2003) who reported heavier birds produced a greater eviscerated yield. The result of this study showed that highest dressed weight was observed in the broiler fed diet. The lowest back weight was obtained in diet 1 could be attributed to different abilities of the diets to differently induce tissue lay down for the said cut part. That the poorer back cavity for bird fed diet 1 could be attributed to different abilities of the diets to differently induce tissue lay down for the said cut part.

The decrease in the breast muscle, dress percentage, Drum stick and thigh muscle in treatment 3 was an indication that nutrient required for tissue synthesis were not sufficient. This could be attributed to poor utilization of protein due to presence of anti-nutritional factor such as Tannin. Tannin is reported to form complexes with dietary protein as well as endogenous protein including enzymes and this may inhibit the action of proteolitic enzymes from undergoing normal metabolism of proteins. Mathew *et al.* (2010) Reported that higher percentage of breast muscle indicated better protein utilization by birds

Conclusion

It could be concluded that pigeon pea soaked in pap water filtrate can be fed to birds at 20% level of inclusion without having any negative effect on the carcass characteristics of broiler fed experimental diet.

Recommendation

Feeding up to 40% level of inclusion showed fairly good result, however, there is need for adoption of other processing methods to further reduce the level of anti-nutritional factors in legumes seed

ABSTRACT
An experiment to determine the growth performance of starter broiler chickens fed raw Senna obtusifolia seed meal (SOSM) was conducted. A total of 150 Arbor-Acre broiler chickens were purchased and fed control diet for 6 days before randomly allotted to five experimental Treatments 1 to 5 (T1 to T5) of 30 birds each, replicated 3 times with 10 birds per replicate in a completely randomized design. The levels of the raw SOSM were 0, 2.5, 5.0, 7.5 and 10%. The experiment lasted for 4 weeks. Results showed that as the level of raw SOSM increased in the diet beyond 5%, the lower the final live weight and daily gain of starter broiler birds. It was concluded that raw SOSM could be included up to 5% in starter broiler diet.

INTRODUCTION
Feeding constitutes an important part of poultry production. Ukachukwu (2015) opined that in poultry and piggery, feed cost is put at about 70-80% of total cost of production because of expensive feed ingredients such as maize and soya bean. This according to the author, is made complex and complicated by competition among human, the industry and farm animals for the same food items as either food for man, feed for animals and raw materials for the industry. Reducing feed cost is a priority for every poultry farmer and animal nutritionist. One of the ways of getting round this problem of high feed cost is by looking for alternative feedstuffs, which have little or no dietary value for man and industry. The use of legume seeds in monogastric nutrition has attracted the attention of researchers worldwide. Several conventional legume seeds such as sword bean, pigeon pea, mucuna species and *Cajanus cajan*, to mention just a few, have been studied and evaluated for inclusion in non-ruminant diets in Nigeria (Udedibie and Nkwocha, 1990; Leon *et al.,* 1991; Ologhobo *et al*., 1993; Ukachukwu, 2000; Akinmutimi, 2004; Ekwe, 2014). There is, however some unconventional plants seeds that are still under-utilized, which little are known about their chemical composition and nutritional values, like sickle pod (*Senna obtusifolia)* seeds. There is, therefore, the need for continuous screening of minor legume seeds like *Senna obtusifolia* for use as unconventional alternative feed resource in monogastric diets. It was in view of the forgoing that this research was undertaken to determine the tolerance level of raw *Senna obtusifolia* seed meal on growth performance of starter broiler chickens.

MATERIALS AND METHODS
Senna obtusifolia seeds used were obtained from Bauchi State, Nigeria. The experiment was conducted at the Teaching and Research farm of University of Uyo, One hundred and fifty (150) day-old arbor acre broilers were purchased from a reputable supplier in Uyo metropolis, Akwa Ibom State, Nigeria. The poultry house was washed and disinfected. Prior to the arrival of the chicks, brooding room temperature was raised to 35^0C using kerosene stove and electric bulbs. The floor of the brooder was sprayed with wood shavings of 2cm thickness. Feeding and drinking troughs were provided. On arrival, the chicks were weighed and given anti-stress. The birds were brooded together for the first six days for acclimatization and fed the control diet. On day 7, the birds were weighed and randomly allotted to five experimental treatments with 30 birds per treatment. Each treatment was replicated thrice with 10 birds per replicate, in a Completely Randomized Design (CRD). Treatment 1 was control while raw *Senna obtusifolia seed* meal was included at 2.5, 5.0, 7.5 and 10% in treatments 2, 3, 4 and 5 respectively in the diet (Table 1). Feed and water were provided *ad libitum* throughout the experiment which lasted for 28 days. Feed intake was determined daily

and weight gain was determined weekly. Necessary vaccinations and medications were strictly adhered to. Data on performance parameters were evaluated and subjected to one-way Analysis of Variance (ANOVA) according to Steel and Torrie (1980) while differences between treatment means were separated using Duncan's Multiple Range Test using computer software IBM SPSS Statistic version 20.

RESULTS AND DISCUSSION

The growth performance of starter broiler chickens fed raw *Senna obtusifolia* seed meal is shown in Table 2. There were significant differences ($P<0.05$) among the treatment means for all the parameters considered, except for the initial weights. The result showed that the final live weight, daily feed intake and daily weight gain followed the same trend. The mean final weights were 921g for the control, 910g for T2 with 2.5% and 906g for T3 with 5.0%, 745g for T4 with 7.5% and 681g for T5 with 10%. Inclusion of 7.5 and 10% S. obtsusifolia affected final live weight negatively. The final live weight of control, 2.5 and 5.0% was similar. It was observed that above 5.0% inclusion live weight decreased with increased level of raw *Senna obtusifolia* seed meal. Daily weight gain followed similar trend as the final live weight. The feed intake of control, 2.5 and 5.0% were the same. It was also observed that feed intake was depressed by 7.5 and 10%. The result also showed no significant difference in feed conversion ratio and protein efficiency ratio up to 5.0% inclusion compared to the control diet.

The depression in feed intake and poor live weight could be as a result of presence of some anti-nutritional factors like saponins, tannin and phytate in the raw seeds. This agreed with Akinmutimi (2004), who reported poor palatability and consequently low feed intake in diets containing sword bean because of tannin content in raw sword bean. According to him, tannins could induce low feed intake due to its astringent property, as a result of its ability to bind with the protein of saliva and mucosa membrane. This he also opined was as a result of the effect of other anti-nutritional factors such as saponins, phytate, cyanogenic glycosides, trypsin inhibitors, canavanin and con-canavanin A

in the raw sword bean. According to Aletor and Fasuji (1997), cyanogenic glycoside, for instance, upon hydrolysis releases hydrogen cyanide, a substance which has the ability to cause marked weight reduction. The authors observed that cyanide detoxification route in man and animals is through cyanide thiocyanate sulphur transferase (rhodanase pathway), which generally requires organic sulphur donors in the form of methionine and cysteine, thereby precipitating methionine deficiency in an otherwise balanced diet. Akinmutimi (2004) reported that it is this methionine deficiency that resulted in poor growth. Feed conversion ratio (FCR) is an important index of performance which is a direct indication of how best feed offered to birds was utilized for meat production. The lower the FCR value, the better the feed utilization, thus birds with higher FCR value had suppressed growth. This result is in consonance with similar report by Tuleum *et al.* (2009), that broiler chicks on 10% raw *Mucuna pruriens* in balanced formulated ration had depressed growth, due to the limitation imposed on the birds by anti-nutritional factors present in the diet. Akinmutimi (2004) also reported that the poor weight gain by starter broiler birds fed raw sword bean may be due to poor nutrient utilization.

Table 2: Growth performance of starter broiler chickens fed raw *Senna obtusifolia* seed meal

Parameters	Levels of Inclusion of Raw *Senna obtusifolia* Seed Meal					
	T1 (0%)	T2 (2.5%)	T3 (5%)	T4 (7.5%)	T5 (10%)	SEM

Average Daily Feed Intake (g)	70.37[a]	69.98[a]	69.56[a]	61.34[b]	54.23[b]	1.34
Feed Conversion Ratio	2.23[c]	2.25[c]	2.24[c]	2.43[a]	2.36[b]	0.03
Protein Efficiency Ratio	1.95[a]	1.94[a]	1.94[a]	1.79[b]	1.84[b]	0.03

[a,b,c] Means with different superscripts in the same row are significantly different (P<0.05)

CONCLUSION

The growth performance of starter broiler chickens fed raw *Senna obtusifolia* seed meal reduced live weight and feed intake beyond 5% inclusion level. In view of the above, raw *Senna obtusifolia* could be included in the diet of starter broiler diet up to 5% without any deleterious effect on growth performance.

ACKNOWLEDGEMENT

The authors are grateful to Prof Demo Kalla of Abubakar Tafawa Balewa University, Bauchi, Nigeria for providing the seeds and to Tertiary Education Trust Fund (TETfund) for sponsoring the research.

ABSTRACT
Forty eight growing rabbits of mixed breeds and similar live weight were utilized in a 42 days experiment to evaluate the effect of feeding acha (fonio) offal meal-based diets supplemented with Maxigrain enzyme on their haematology and serum biochemistry. Six treatments diets namely T1, T2, T3, T4, T5 and T6 were compounded to be iso-caloric and iso-nitrogenous, the Acha Offal (AO) was included at 0, 15 and 30% while the enzyme was supplemented at 0 and 200ppm. The experiment was arranged in a 2x3 factorial fitted into Completely Randomized Design. Each treatment was replicated 4 times having two rabbits per replicate. Feed and water were provided to the animals daily and all standard routine management practices were strictly observed throughout the experiment. At the end of the feeding trial, blood samples were collected from each animal for blood analyses. Main effect of Acha offal was not significant (p>0.05)on the haematological parameters except on White Blood Cell(WBC) and Mean Cell Haemoglobin Concentration(MCHC). Effect of enzymes was not different (P>0.05)except on WBC{0ppm (5.75) and 200ppm (6.60)} and MCHC{0ppm (33.27) and 200ppm (33.20)}. Interactive effect of Acha offal and enzyme showed that T2 had the highest WBC (8.80) while T4 had the lowest MCHC (33.10). Serum biochemical parameters were not affected by Acha offalexcept phosphorus where there was a significant (P<0.05) reduction in 30%AO(1.35). Enzymes effect showed that animals on 0ppm had significantly (p<0.05) higher phosphorus (1.83) than 200ppm (1.38). Acha offal supplemented with Maxigrain enzyme can be included in the diets of grower rabbits without adverse effect on haematological and serum biochemical indices.

Keywords: Haematology, Biochemistry, Rabbits, Fonio, Enzymes

INTRODUCTION
The rapid growth of human population has brought the competition between man and livestock for these cereal grains adding to high cost of feeds and consequently high prices of Animal products(meat and egg) resulting to very low levels of protein intake in most developing nations. Therefore, leading to the increased in cost of production, research attention is now geared towards unconventional cereal by-product that will not affect the overall feed quality. One of such cereal grain by-products that could provide energy and fibre is acha offal. Feeding cereal grains (e.g. maize bran and rice bran) as replacement for maize-based diets to rabbits have been significantly reduced the cost of producing feed for livestock reported byUkim*et al*. (2012). It has been reported that many of the cereals by-product and grains contain some phytochemicals which can be reduced by enzymes supplementation Alu *et al*. (2012). Similarly, studies have reported increased feed breakdown especially of fibrous feed materials into easily digestible nutrients by exogenous enzyme supplementation in monogastric feeds Ogbe *et al.* (2013). It is on this background that a research with the objective of determining the haematological and biochemical indices of grower rabbits was conducted.

MATERIALS AND METHODS
Experimental Site
These experiments were conducted at the Teaching and Research Farm of Animal Science Department of the Faculty of Agriculture, Nasarawa State University Keffi, Shabu-Lafia Campus.
Feed Ingredients, Animals and Experimental Design
Acha offal was sourced from the local acha processors within Riyom Local Government Area of Plateau State and preserved under natural condition while other ingredients such as maize, maize bran, rice bran, groundnut cake, fish meal, bone meal lysine methionine were purchased from the suppliers in Lafia, Nasarawa State. Six experimentaldiets were formulated to be isonitrogenous (15% crude protein) and isocaloric of (2500kcal/kg) for the grower phase with three levels inclusion of the acha offal (0, 15 and 30%). The treatments were; T1 = 0% AO with 0ppm enzymes serves as control, T2 = 0% AO with 200ppm enzymes, T3 = 15% AO with 0ppm enzymes, T4 = 15% AO

with 200ppm enzymes, T5 = 30% AO with 0ppm enzymes and T6 =30% AO with 200ppm enzymes. Forty-eight (48) rabbits of similar live weight wererandomly assigned to a test diet in a 3x2 factorial. Each of the experimental treatment was replicated four times in each pen comprising of 2rabbits each.

Hematological and Serum Biochemical Indices Analysis

At the end of the experiment, two set of container was used to collect blood samples. One set contains anticoagulant while the other was anticoagulant free. The blood samples collected into bottles containing anti- coagulant: Ethylene Diaminetetraacetic Acid (EDTA) as reported by Jain (1987) were used for hematological indices {Packed Cell Volume (PCV), Hemoglobin Concentration (HB), mean cell haemoglobin concentratration (MCHC), Red Blood Cell (RBC), White Blood Cell (WBC)}. Serum biochemical indices such as cholesterol,total protein, albumin and globulin creatinine, Erythrocyte (calcium, magnesium and phosphorus) glyceraldhyde were analyzed using SIGMA kits (Feteris, 1965).

Statistical Analysis

Data collected were subjected to one or two analysis of variance (ANOVA) for factorial experiment using (SPSS, 2007) Model. Significantly different means were separated using Duncan's Multiple Range Test (Duncan, 1955). The following statistical model was used: $Y_{ijk}= U +A_I +B_J + (AB)_K+e_{ijk}$ where Y_{ijk}=individual observation, U= population mean, A_i = effect of factor A, B_j= effect of factor B, and AB_K = effect of interaction of factor A&B.

RESULTS AND DISCUSSION

The mainand treatment effect of acha offal and enzymes on haematological parameters of grower rabbits are presented in Table 2. The main effect of acha offal was not significant ($p>0.05$) except on White Blood Cell (WBC) and MCHC. The WBC value of control was significantly higher than 15% and 30% acha offal included diets. The result of MCHC was significantly ($p<0.05$) higher in control and 30% acha offal than in 15% acha offal fed rabbits.Thenon-variation in PCV between the control and other treatments indicates that the dietary treatments do not caused anaemic condition to the animals. This agreed with Ogundipe and Johnson (2012) who revealed that maize offal did not caused adverse effect on the haematological parameters of rabbits. Main effect of enzymes on haematological parameters of grower rabbits showed no significant ($p>0.05$) difference between the treatments (0ppm and 200ppm enzymes) except on the value of WBC and MCHC where the highest WBC and MCHC was recorded from animals fed 200ppm and 0ppm enzymes included diets respectively. The increased value of WBC due to inclusion of enzymes suggests an increased immunity in the animals.Thetreatment effect of acha offal and enzyme on haematological parameters of grower rabbit showed no significant ($p>0.05$) difference all the parameters except on WBC and MCHC values. The significantly ($p<0.05$) highest value of WBC (8.80) was recorded from T_2. Meanwhile T_1, T_3, T_4, T_5 and T_6 were not significantly ($p>0.05$) different from each other. MCHC (33.10) was significantly ($p<0.05$) lower in T4 than the rest of the treatments. The increased value of WBC due to inclusion of enzymes suggests an increased immunity in the animals.

ab means on the same column having different superscript differ significantly ($p<0.05$); NS = not significantly different ($p>0.05$); SEM = standard error of mean; LOS = level of significant; PCV = Packed cell volume; HBC = Haemoglobin count (g/dl); RBC = Red blood cell (×10^9/L); WBC = White blood cell(×10^9/L) ; MCV =mean cell volume(pg); MCH = Mean corpuscular haemoglobin (fl) = MCHC = Mean cellhaemoglobin concentration(×10^9/L)

The main and treatment effects of acha offal and enzyme on serum biochemical indices of grower rabbits are presented in Table 3. The main effect of acha offal does not significantly ($P>0.05$) affected the serum biochemical parameters except on phosphorus where there was significant ($P<0.05$) reduction in 30% than 0% and 15% acha offal fed rabbits. There was significant ($P<0.05$) effect of enzyme on phosphorus and calcium values. A significant ($p<0.05$) reduction in the value of Phosphorus was recorded and an increased calcium level of the animals was recorded when 200ppm enzymes was included in the diets. The treatment showed no significant ($P>0.05$) difference between the treatments except on the values of phosphorus, globulin and calcium where there was significant ($P<0.05$) difference. Phosphorus was significantly ($P<0.05$) higher in T_1 then in the rest of the treatments. While Globulin was significantly lower in animals fed T_6 diets although no difference

(P>0.05) from T_1 fed animals. This showed that the immunity of the animals is still maintained even when fed the diets. Rabbits fed T_1, T_2, T_3, T_4 and T_5 had no significant (P>0.05) calcium value. This showed that the needed calcium for bone formation in the animals is not affected by the dietary treatments.

ABSTRACT

A 42 day experiment was conducted to evaluate the response of grower rabbits fed cooked sunflower seed meal (SFSM) supplemented with enzyme on blood parameters using 72 growing rabbits. Nine diets namely T1, T2, T3, T4, T5, T6, T7, T8 and T9 were compounded to be isocaloric (2500 kcal/kg, ME) and isonitrogenous (15%) having treatments T1, T2 and T3with 0% inclusion rate of SFS meal and 0, 150 and 250PPM of the enzyme supplementation. Treatments T4 to T6 and T7 to T9 had 10 and 20% levels of SFS meal inclusion rate, respectively but maintaining same levels of enzyme supplementation as in T1 to T3. This arrangement translated to T1, T4 and T7 serving as the control diets for T2 and T3, T5 and T6 and T8 to T9, respectively. The rabbits were randomized and allotted to the 9 treatments and each treatment was replicated 4 times giving rise to a 3x3 factorial arrangement fitted into CRD. The results show that enzyme supplementation significantly (P<0.05) improved RBC, the values increased from 5.23 x10^{12}/l for non-enzyme supplementation to 5.38 -5.73 x10^{12}/l. Similarly, haemoglobin (11.42 vs. 11.37 and 12.01 g/dl), cholesterol (3.83 vs. 4.33 and 4.31mmol/l) and triglyceride (0.95 vs. 1.16 and 1.03mmol/l) were improved (P<0.05) as the level of enzyme supplementation increased in the diets. In view of the significant improvement in some of the blood parameters recorded, rabbit farmers can use the 150 PPM of the enzyme in SFS meal based diets without affecting the health of the rabbits.

INTRODUCTION

Conventional feed stuffs are very expensive and scarce. This high cost and scarcity according to Esonu*et al.*,(2004), are derived from crippling realities which are characteristics of the economics of developing countries, conventional feed ingredients are expensive since they suffer stiff competition with channels in the food chain which command higher priority and can pay higher prices than the compound feed industry (Esonu*et al.*, 2004). Therefore, the use of cereal based feeds in livestock nutrition may not be sustainable especially in developing countries where cereal grains form a major staple in human diets.

Again, the challenge of anti-nutritional factors and anti-nutrients in most non-conventional feedstuffs has remained a major hindrance to their use. Exogenous enzyme supplementation has been advocated (Alu *et al.*, 2012) as one of the ways or methods of alleviating the problems of anti-nutritional factors in feeds. One of such non-conventional protein sources is the sunflower seed, (*Helianthus annuus* L.) which is one of the few crop species that originated in North America. Sunflower was probably first introduced to Europe through Spain, and spread as a curiosity until it reached Russia where it was readily adapted.Commercially available sunflower varieties contain from 39 to 49% oil in the seed. The main object of this research was to evaluate the effect of enzyme supplementation on the blood parameters of grower rabbits fed SFS meal-based diets.

MATERIALS AND METHODS

The study was carried out at the research and teaching farm of Faculty of Agriculture Nasarawa State University Keffi, Shabu-Lafia Campus. It is located in the Guinea Savanna Zone of North Central. It is found in latitude 08 35N and longitude 08 33E. The mean monthly maximum and minimum temperatures were 35.06°C and 20.16°C respectively at the time of the experiment while the mean monthly relative humidity and rainfall were 74.67% and 168-190mm, respectively (NIMET, 2017).

Source of test ingredient

Sunflower seed (SFS) which is the test ingredient was purchased at Gambali Unique Gardens Jos, Plateau State,cooked, sun-dried, crushed and mixed with other feed ingredients to compound the experimental diets.

Chemical analysis

Proximate analysis of SFS was done at Animal Science Laboratory of Faculty of Agriculture, Nasarawa State University, Keffi, Shabu-Lafia Campus, using the standard procedure of AOAC (2000). Nitrogen Free Extract (NFE) was calculated using the formula: NFE (%) = 100 – CP + CF + EE + Moisture + Ash.

Experimental diets and design

Nine experimental diets namely T1, T2, T3, T4, T5, T6, T7, T8 and T9 were compounded to be isocaloric (2500 kcal/kg, ME) and isonitrogenous (15%) having treatments T1, T2 and T3with 0% inclusion rate of SFS meal and 0, 150 and 250PPM of the enzyme supplementation. Treatments T4 to T6 and T7 to T9 had 10 and 20% levels of SFS meal inclusion rate, respectively but maintaining same levels of enzyme supplementation as in T1 to T3. This arrangement means that T1, T4 and T7 serve as the control diets for T2 and T3, T5 and T6 and T8 to T9, respectively. Other ingredients were added to meet the nutrient requirements of grower rabbits as described by Olomu*et al.,* (2019). The gross composition of the experimental diets is presented in Table 1.

Management of rabbits and experimental design

Seventy-two cross-bred growing rabbits of about 6-7 weeks old with a mean weight of 567g were obtained from Dagwam Farms, National Veterinary Research Institute (NVRI) Vom, Jos, and PlateauState. The rabbits were fed *ad-libitum* and had access to drinking water at all times and were administered anti-stress vitamin/mineral premix orally at the recommended dosage after randomization before the commencement of the experiment. Other management practices were adopted as described by Aduku (2004). The rabbits were paired and allotted to the 9 treatments and each treatment was replicated 4 times giving rise to a 3x3 factorial arrangement fitted into a Completely Randomized Design.

Hematological and serological parameters

At the end of the experiment2-5ml of blood samples from 3 randomly selected rabbits per treatment were collected for haematological and biochemical analyses. The first set of blood samples were collected and emptied into labeled sterile universal bottles containing anti-coagulant, ethylene diamine tetra acetic acid (EDTA) for the determination of haematological components while the other set of blood labeled sterile bottles without EDTA for the determination of serum biochemical components. The packed cell volume (PCV) was determined using the micro-haematocrit technique, the red blood cells (RBC) and white blood cells (WBC) counts using the improved Neubauerhematocytometer method, and haemoglobin (Hb) using the Cyanomethemoglobin method as described by Kelly (1979). Serum total proteinwas determined using Biuret method as described by Kohn and Allen (1995). Albumin was determined using Bromoscresol Green (BCG) method as described by Peter *et al.,* (1982). The globulin concentration was obtained by subtracting albumin from the total protein while the albumin/globulin ratio wasobtained by dividing the albumin value by the calculated globulin value.

Data analysis

All data obtained from the experiment were subjected to Two Way Analysis of Variance (ANOVA) and where significant differences are observed the means were separated using Duncan's Multiple Range Test (DMRT) using the Statistical Package for Social Sciences (SPSS) software.

RESULTS AND DISCUSSION

The results of the effect of the ronoxymeHiPhos® supplementation on blood parameters of grower rabbits fed SFS meal (Table 2) show that enzyme supplementation significantly ($P<0.05$) improved RBC. The values increased from 5.23 $x10^{12}$/l for non-enzyme supplementation to 5.38 -5.73 $x10^{12}$/l for enzyme supplemented diets. Similarly, haemoglobin (11.42 vs. 11.37 and 12.01 g/dl), cholesterol (3.83 vs. 4.33 and 4.31mmol/l) and triglyceride (0.95 vs. 1.16 and 1.03mmol/l) were significantly ($P<0.05$) improved as the level of enzyme supplementation increased in the diets. These observations are in tandem to the earlier findings of Alu *et al.,* (2014) who reported significant improvement in some blood parameters such as, Pack cell volume (PCV), White blood cells (WBC), Haemoglobin (Hb), Mean corpuscular volume (MCV),of finisher quails fed enzyme supplemented diets. The values obtained in the present study fell within the normal range of PVC (30-50%),WBC (4-10X10^3/uL) for mature rabbits (Olomu *et al.,* 2019; Alu, 2018).

Table 2. Effect of ronoxymeHiPhos® supplementation on bloodparameters of grower rabbits fed sunflower seed meal diets

Parameters	0PPM	150 PPM	250 PPM	SEM	LOS
PCV (%)	33.83	34.58	35.75	0.52	NS
RBC ($X10^{12}$/l)	5.23^{b}	5.38^{b}	5.73^{a}	0.12	*
WBC ($X10^{9}$/l)	10.08	9.59	11.48	0.61	NS

Glucose (mmol/l)	9.19	8.23	8.80	0.49	NS

a,b = means on the same row having different superscript differ significantly (P<0.05), **NS** = not significantly different (P>0.05), **SEM** = standard error of means

CONCLUSION AND RECOMMENDATION

In view of the significant improvement in some of the blood parameters recorded in the present studies and the lack of difference in the 150 and 250 PPM of enzyme supplemented diets, rabbit farmers can use the 150 PPM of the ronoxyme HiPhos® in SFS meal based diets without affecting the health status of the rabbits.

Abstract
This study evaluates the effect of cassava peel meal supplemented with elemental Sulphur (ES) on the haematology of rabbits. Thirty six crossbreed weaner rabbits were allocated to six diets groups containing 0, 25, 50, 75, 100% of ES as replacement for methionine (diets 1-5) while diet 6 had 100% each of methionine and ES dietary concentration. Haemoglobin (Hb) concentration varied significantly ($p<0.05$) across the treatment groups while rabbits fed diet containing equal quantity of methionine and ES recorded least ($p<0.05$) Hb of 8.17g/dl. ES as replacement for methionine had no significant ($p>0.05$) effect on Mean corpuscular volume (MCV), Mean corpuscular haemoglobin (MCH) and Mean corpuscular haemoglobin concentration (MCHC) on rabbits fed cassava peel meal based diets. The study concluded that ES as replacement for methionine in the diets of rabbits containing cassava peel meal as basal ingredient had no negative effects on blood formation of rabbits. ES could be used at 50% replacement for methionine in rabbits fed cassava peel meal diets without detrimental effect on health while combination of methionine and ES each at 100% dietary content reduced rabbit haemoglobin.

Keywords: cassava peel, elemental suphur, haematology, methionine, rabbit

INTRODUCTION

The demand for protein of animal origin in Nigeria is greater than the supply (Akinmutimi and Onwukwe, 2002) thus the need to produce livestock such as rabbit that is efficient in feed utilization, strives on roughages, prolific and has good meat quality. Commercial rabbit production however, is faced with the challenge of high feed cost, a phenomenon that makes rabbit production and products expensive.

This challenge has consequently encouraged efforts in researches towards finding and using alternative feed resources that are readily available, less expensive and competed for by man (Osakwe and Nwose, 2008). Cassava peel, a by-product from cassava processing is one of such alternatives. It has high energy content but low crude protein. In order to effectively utilize cassava peel in rabbit feed, the protein content could be made up for by supplementing with yet another less competitive protein source, particularly the amino acids.

Methionine and cystine are among major sulphur-containing (Ostrakhovitch and Tabibzadeh, 2015) amino acids. Methionine has to be supplied in the diet as it forms a large number of key metabolic intermediates essential for life (Marcel *et al.*, 2007). However, methionine as feed ingredient amino acid is expensive. Elemental sulphur (ES) being a component of methionine could serve as an efficient protein supplement (Ehlers, 2018) and in cassava peel meal based diet. When protein is deficient in the animal's normal diet, supplementing its feed with sulfur can improve amino acid balance and also improve pH balance in the blood of animals (Lanka, 2014; Ehlers, 2018).

Blood profile is influenced by the quantity and quality of feed and also the anti-nutritional factors present in the feed (Akinmutimi, 2004). Blood elements can also be used to monitor the protein quality in feeds, especially with feed constituents that affect blood formation (Unigwe *et al*., 2016). Consequently, haematology could be explored to give assessment of rabbits fed cassava peel meal based diets supplemented with ES.

MATERIALS AND METHOD

This study was carried out at the rabbit unit of the Institute of Food Security, Environmental Resources and Agricultural Research (IFSERAR), Federal University of Agriculture Abeokuta (FUNAAB), Ogun State, Nigeria.

Cassava peel meal was obtained from the International Livestock Research Institute (ILRI), Ibadan, Oyo State, Nigeria while ES was purchased from open market within Abeokuta metropolis. Six diets (Table 1) were formulated containing ES at different levels (0, 25, 50, 75, 100 %) as replacement for methionine to form diets 1-5 while diet 6 had ES added as the same rate with methionine in control diet.

Table 1. Composition of experimental diets

Ingredient	ES inclusion levels as replacement for Methionine (ppm)					
	0	25	50	75	100	ES added as Methionine in control

Fat (%)	2.64	2.64	2.64	2.64	2.64	2.64
Crude Fibre (%)	7.64	7.64	7.64	7.64	7.64	7.64

Thirty-six (36) cross breed weaner rabbits of weight range between 700 and 800g were used. The animals were reared using dwarf concrete hutch with the base made of galvanized wire mesh of about 2cm sieve size and laid 30cm above the floor. The rabbits were apportioned into six experimental groups according to the diets. Each treatment was replicated six times. Concrete feeders and drinkers were used. Feed and water were given *ad libitum* for 56days.

Blood collection was done twice; the first at the beginning of the study (Day 1) as baseline data and the second at day 56. Blood sample (2.5 ml) was drawn from each animal according to treatment and replicate and emptied in EDTA bottle for haematological analysis. PCV, Hb and WBC were determined according to Mitruka and Rawnsley (1977) while RBC (Total Erythrocyte Count) was determined according to Baker and Silverton (1982). Mean corpuscular volume (MCV), Mean corpuscular haemoglobin (MCH) and Mean corpuscular haemoglobin concentration (MCHC) were estimated using a standard formula.

Data obtained were subjected to one way analysis of variance. Significant differences among treatment means were determined using LSD as contained in SAS (2002) package.

RESULTS

Result of haematology of rabbits fed cassava peel meal based diets with ES as replacement for methionine is shown in Table 2. Only Hb concentration varied significantly ($p<0.05$) across the treatment groups. The value ranged from 8.17 - 15.20g/dl. Rabbits fed diet containing equal quantity of methionine and ES recorded least ($p<0.05$) Hb of 8.17g/dl. Other haematological parameters (PCV, RBC and WBC) were similar ($p>0.05$) across the dietary groups. Also, ES as replacement for methionine had no significant ($p>0.05$) effect on MCV, MCH and MCHC of rabbits fed cassava peel meal based diets (Table 2).

DISCUSSION

Haematological values showed that PCV of rabbits across the treatment groups were within the range of 33 to 50% recommended for healthy rabbits (Hillyer, 1994). This suggested nutritional adequacy of the diets since PCV values did not indicate mal-or-under nutrition according to Church *et al*. (1984).

Haemoglobin functions in transporting oxygen to tissues of animals for oxidation of ingested food. Rabbits on diet containing methionine and ES at same level recorded the least value. Low values of haemoglobin concentration could be due to the harmful effects of high dietary content of ES. Haemoglobin of rabbits fed diets containing 0-100% replacement of methionine by ES were within the normal ranges (9.3 - 19.3g/dl) reported by Mitruka and Rawnsley (1977). According to Togun *et al*. (2007), this is an indication that the diets did not have any adverse effect on energy carrying capacity of the blood of the animals. However, low Hb concentration recorded in rabbits on diet containing same level of methionine and ES could suggest intolerable level and consequently may not be a viable combination level in diets of rabbits perhaps due to antagonistic or toxicity effect. Sulphur is an oxidizing agent and could portend oxidative stress when in excess. This view was supported by Rai *et al*. (2009) who reported that excessive methionine is associated with metabolic syndrome, oxidative and nitrosative endoplasmic reticulum stress in rabbits. According to Mecif *et al*. (2017), methionine is sulphur based protein, excess causes large plasma variations which is associated with the metabolic syndrome.

The RBC values recorded in this study were within the range of 3.07 to 7.50 x 106 /mm3. Similarly, WBC values were still within the normal ranges (2.5 – 12.5 x103/µl) reported by Canadian Council on Animal Care (2017). Riley and Rupert (2015) opined that normal range of values for WBC indicated that the animals were healthy because decrease WBC below the normal range is an indication of allergic conditions and certain parasitic infections.

The MCV, MCH and MCHC values were within the range of 50 - 75 fl, 18 - 24 pg and 34 - 37g/dl respectively, as reported by Gillet (1996) and they are important morphological characteristics used in detecting anaemia (Campbell, 2006).The results therefore indicated that the rabbits were not anaemic and the experimental diets support blood formation in rabbits.

CONCLUSION AND RECOMMENDATION

Based on the findings of this study, the following conclusion could be drawn:

1. ES as replacement for methionine in the diets of rabbits containing cassava peel meal as basal ingredient had no negative effects on blood formation of rabbits

2. ES could be used safely at 50% replacement for methionine in rabbits fed cassava peel meal diets.

3. Combination of each of methionine and ES at 100% dietary content in rabbits diets containing cassava peel meal as basal ingredient reduced haemoglobin content of blood.

ABSTRACT

The effect of replacing maize with millet was evaluated using one hundred and sixty-eight (168) day old Anak broiler chicks allocated to four (4) dietary treatments. Millet was used to replace maize at 0, 50, 75 and 100% levels coded as diets 1,2,3 and 4 respectively. The experimental design was completely randomized design with three (3) replicates per diet and fourteen (14) birds per replicate. Feed and water were supplied *ad libitum* and the experiment lasted for eight (8) weeks. The results showed that at the starter phase the daily feed intake values of 85.67 and 93.0g on diets 4 and 2 respectively were significantly different ($p<0.05$) while there was no significant difference in the body weight gain. The values ranged from 20.70-24.20g in birds fed diets 1 and 4 respectively. The FCR (3.53) of broilers fed diets 4 (100% millet) was significantly ($p<0.05$) better than the values on other diets. The performance at the finisher phase showed a non significant ($p>0.05$) treatment effect for all parameters. The pooled performance showed broilers fed diet 4 (100% millet) recorded significantly higher daily feed intake ($p<0.05$) and weight gain compared to the other diets. All the carcass characteristics measured were not influenced by the dietary levels of millet. The cost per kg gain was lowest on diet 4 (#30). These findings showed that millet can replace maize at 100% with better results and at reduced cost.

Keywords- Millet, Maize, Broiler, Economy, Performance.

INTRODUCTION

Maize is the most common feed stuff of choice as a major supplier of energy in monogastric animal diets. It is cultivated throughout the tropics where ever there is adequate rainfall. Conventional energy sources like maize have become very scarce and expensive due to multiple uses for human, animal feed and industries (Aduku, 2004). This competition has worsened the feed situation for monogastric animals. Maize alone accounts for about 50-70% of the total feed ingredients in broiler ration (Ojewola and Olugbemi 2011). The national demand for maize is estimated at 15.5 million metric tonnes, while current domestic production stands at 10.5 million tones annually. Several attempts have therefore been made to reduce the cost of feed production by replacing parts of the maize in diets with industrial by products and others (Akintola *et al* 2003, Okere and Akinseyiwa, 2011) such as millet. Millet is a cereal widely growth in drier areas of the tropics. It grows in areas not favourable to maize cultivation and it can be used in poultry diets. Millet resembles maize in composition and feeding value but is considerable higher in protein content. Banerjee (2013) reported CP of 8-12% and 10% for millet and maize respectively. According to Nnenna (1998) millet has a nutritive value comparable to other cereals with a CP of about 11% and sometimes up to 23%. It also has a higher fibre (8.6%) and carbohydrate with ash and fat similar to other cereals. Millet being an early maturing crop is more readily available and cheaper during the middle of the rainy season (July-August) when most other cereals are still in the field.

Abubakar *et al* (2006) fed graded levels of whole millet to broilers and reported cost reduction and no significant reduction in performance of broilers fed millet as a replacement for maize, this they attributed to higher level of crude fibre and anti nutritional factors like tannins present in millet. This study aimed to evaluate the effect of replacing maize with millet in the diet of broiler chickens.

MATERIALS AND METHODS.

Experimental site: the experiment was conducted at the Abubakar Tafawa Balewa University (ATBU) poultry research farm Bauchi. Bauchi is located within the Northern Guinea Savannah on latitude $10^{1}.17^{N}$ longitude 9^{0} 49^{1} E at an altitude of 690.2m above sea level. Bauchi has an annual rainfall of 600mm in the north and 130mm in the south.

Experimental Birds.

One hundred and sixty eight day old Anak broiler chicks were used for the experiments. The birds were brooded for one week there after were divided into four groups of 42 birds each. Each group of 42 birds were divided into 3 replicates of 14 birds per pen. They were weighed and randomly allocated to the 4 dietary treatments in a completely randomized design (CRD). Feed and water were provided *ad libitum.* Routine vaccinations were carried out as when due. The experiment lasted for eight (8) weeks.

Experimental Diets

Four (4) experimental diets were formulated arising from the replacement of maize with 0, 50, 75 and 100% of millet. The diets were isonitrogenous with 23 and 21% CP for the starter and finisher phases respectively (Table 1 and 2).

Gross Performance Analysis:-

The birds were weighed at the beginning of the experiment and thereafter on a weekly basis. Feed intake was measured daily, records of mortality were also taken as they occur. The cost of the four (4) diets were computed from the prevailing market prices of ingredient at time of the study. These were then used to calculate the cost of feed consumed per kg live weight gain of the experimental birds.

Carcass and Gut Characteristics:

Two birds per replicated were randomly selected at the end of the feeding trial. They were starved overnight, slaughtered, plucked and eviscerated. Live weight, dressing percentage and weight of cut parts and internal organs were recorded. Weight of cut parts relative to live weight were expressed as percentages.

Data Analysis:-

All empirical data generated were subjected to analysis of variance using SPSS (2012) and significant differences were separated using Duncan Multiple Range Test of the some package.

RESULTS AND DISCUSSIONS

The performance of the broilers fed millet as replacement for maize were as presented in Table 3. The birds on diet 4 (100% millet) recorded significantly ($P<0.05$) lower daily feed intake and FCR compared to the control and others during the starter phases. Values for the daily weight gain were however similar across the treatments. All the parameters measured also showed a non significant treatment effect during the finisher phases. The overall pooled performance of the broilers showed that those on millet based diet had significantly higher values of daily feed intake and weight gained compared to the control. This finding contradicts those of Ojewola and Olugbemi (2011) who reported significant reduction in performance when broilers were fed millet as a replacement for maize. The better feed efficiency for birds fed diet 4 (100% millet) agrees with the findings of Adamu *et al* (2001) who reported that the use of millet in broilers feeding was more rewarding than maize on account of feed utilization. The better results on the millet based diet compared to the control could be attributed to the higher protein quality of millet compared to maize.

The carcass characteristics and organ weight as replacement for maize showed a non significant treatment effect for all the parameters measured. The highest mortality recorded was 7.1% on diet 2 which perhaps is an indication that millet as source of energy in broilers diet may not be detrimental

The cost analysis (Table 4) showed decrease in feed cost with higher level of millet in diets from #121.88kg for diet 1 (0% millet) to #90.49 for diet 4 (100% millet). Total feed cost per kg weight gained followed the same trend. This is in agreement with the reports of Adamu *et al* (2001) and Abubakar *et al* (2006) who also observed cost reduction of broiler chickens fed millet as replacement for maize. This reduction in feed cost could be due to lower cost of pearl millet when compared to maize during the course of this study.

C0NCLUSION

Based on the result obtained, it can be deduced that millet can completely replace maize as source of energy in broiler chickens diets at both starter and finisher phases without any detrimental effect on performance and carcass quality. There was also a decrease in feed cost with increasing inclusion levels of millet. The use of millet is thereby advocated as an alternative energy source for maize to reduce competition especially during harvest period when it would be cheaper than maize.

ABSTRACT
The experiment was conducted to investigate the effect of turmeric (Curcuma longa) on haematological parameters of broiler chickens. A total of 108 day old arboacre broiler chicks were divided into three treatment groups in completely randomized design with a total of 12 experimental unit. The birds were assigned at the rate of 36 birds per treatment in 4 replicates of 9 chicks per replicate. Turmeric powder was supplemented to the feed at the rates of 0, 0.5 and 1% throughout the experiment (8weeks). Blood samples (3 birds per treatments) were collected through the jugular veins at the termination of the experiment. All data generated were subjected to analysis of variance (p=0.05). The samples were taken to medical laboratory to determine PCV, RBC, HB, MCV, MCH, MCHC, granulocyte, lymphocyte, monocyte and white blood cell. Result showed that turmeric supplementation positively affected the vital haematological constituents like Pcv, Hb and Rbc of birds fed 0.5 and 1.0% of turmeric but there was increased in monocytes values for birds on diets 2 and 3 which may be attributed to endogenous corticosteroid. It can be concluded that turmeric has the potential to improve immune response in broiler chickens and its use at 1.0% inclusion is hereby recommended for better results.
Keywords : Tumeric, haematology, feed additives, growth promoters and broiler chickens

Introduction
The ban of antibiotics growth promoters was problematics for growth performance and this has led to outbreak of diseases especially sub-clinical necrotic enteritis which led researcher to discover alternatives to synthetic antibiotics (Huyghebaert *et al*.,2011). Different natural growth promoters are used as an alternatives to replace antibiotic growth promoter e.g enzymes antioxidants, herbs and medicinal plants. Herbs, medicinal plants and their extracts are excellent alternatives due to the different beneficial activities (Das *et al*., 2012; Rana *et al*., 2014). Phytogenic feed additives are ideal for poultry because they are natural residue free. Phytogenic growth promoter showed antimicrobial, antiparasitic and antitoxic effects. They enhanced feed consumption, improved digestion and growth performance, minimized the incidence of disease and increased profitability (Yitbreak, 2015). Due to its antimicrobial, antiparasitic and antitoxic properties, the use of turmeric in poultry feed become extensive during the last decade (Khan *et al.*, 2012). The active ingredient present in turrneric root is curcumin. Turmeric contains 3 different analogues of curcumin which contains 5% bis-demethoxycurcumin, 18% demethoxycurcumin and 77% diferuloylmethane curcumin is insoluble in water and soluble in methylsulfoxide, ethanol, oils and acetone (Aggarwal, 2007). Turmeric has good pharmacological properties and can be a useful antimicrobial and antitoxic and safe alternative to antibiotics. The aim of the study was to investigate the effect of different levels of turmeric (*Curcuma longa*) on the haematological parameters of broiler chickens.

MATERIALS AND METHODS
The experiment was conducted at Teaching and Research farm in Federal Polytechnic, Ado-Ekiti. The poultry was thoroughly washed and disinfected. The house was allowed to stay for two weeks before the arrival of the experimental birds. A total number of one hundred and eight broiler chicks of arboacre commercial breed were obtained from a reputable hatchery. In the poultry house used for this study, enough provision was made for space, ventilation and protection against predators and extremes of weather. The birds were used to assess the different levels of turmeric on the haematological parameters of broiler chickens. Three experimental diets used for this study were formulated according to (NRC 1994) at the premises of Teaching and Research farm, The Federal Polytechnic, Ado-Ekiti. Diet 1 was the control diet with no turmeric supplementation, diet 2 contained 0.5% of turmeric supplementation and diet 3 contained 1% of turmeric supplementation. All diets were supplemented with methionine and lysine. The treatments were given to the birds for the period of the experiment (8weeks). There were three treatments with four replicates per treatment. Nine birds were allotted per replicate amounting to 36 birds per treatment. During the brooding exercise, the chicks were given all the recommended vaccination and medication. The turmeric used for this study

was purchased from a local market in Ado-Ekiti, the test ingredient was washed, sliced and sun dried and later ground with grinding machine.
On the last day of experiment (56day), blood samples collection was done in the morning after the birds were starved overnight in order to attain a stable haematological evaluation. Four birds were randomly selected from each experimental diet and blood samples were collected from the jugular vein of the birds. About 3ml of blood samples were collected from each bird in labeled ethylene diamine tetra-acetate (EDTA) bottles to determine the haematological indices. The tubes were immediately capped and the contents mixed gently for about 1minute by repeated inversion. The samples were taken immediately to the laboratory to determine packed cell volume (PCV), total red blood cell (RBC) count, haemoglobin concentration (Hb), mean corpuscular haemoglobin concentration (MCHC), mean cell haemoglobin (MCH), mean corpuscular volume (MCV) was calculated as described by Lamb (1981). The white blood cell, neutrophils (N), lymphocytes (L), monocytes (M) and Eosinophils were determined by the micro-haematocrit method (Dacic and Lewis, 1991).The experiment was completely randomized design (CRD) with a total of 12 experimental units. All data collected in these studies were subjected to analysis of variance. Duncan's Multiple Range Test of one way ANOVA (SPSS17.0 for windows was used to analyse the mean differences of the same parameter, significant differences were considered where necessary at a level of ($P<0.05$).
Composition of experimental diets (g/100g) for
Broiler starter/finisher diets.

RESULTS AND DISCUSSION

The effect of the turmeric supplementation on haematological parameters is presented in Table1. The mean RBC was significantly ($P<0.05$) increased in birds on diets 2 and 3 than birds on control diet suggesting that turmeric supplementation at 0.5 and 1% found to stimulate RBC production at a slightly increased level of supplementation. The mean monocyte was significantly ($P<0.05$) increased in birds on diets 2 and 3. The increased values of monocyte for birds on diets 2 and 3 may be attributed to endogenous corticosteroid which may be due to stress. The PCV, MCHC, MCV, MCH, HB, granulocyte, lymphocyte were not significantly ($P>0.05$) influenced by turmeric supplementation. There were increase in PCV, HB and RBC values which are comparable with the findings of Ajit *et al*. (2014) and Vivian *et al*. (2015) who opined that the increase in the vital constituents like PCV, HB and RBC in birds fed with herbal ingredients like turmeric, garlic, ginger is an indication of improven oxygen carrying capacity of the cells which translated to a better availability of nutrients for utilization by the birds consequently affecting their wellbeing with an active immune system. They were also no sign of anaemia as the degree of anaemia is determined by HB, PCV and RBC count which were in the normal range. Thus, this findings strongly agree with Nagalakshmi *et al*. (1996) and Gowda *et al*. (2008) who reported that bitter principles of medicinal plants possess a strong influence on haematological traits depending on their nutritional status.

Conclusion and Recommendation

It can be concluded that turmeric has the potential to improve immune response in broiler chickens and its use at 1.0% inclusion is hereby recommended for better results

ABSTRACT

The study was carried out to investigate the haematological and serum biochemical effect on starter broiler birds fed supplemented Niacin and yeast. Yeast and niacin were used as supplement in the feed, the level of yeast was constant in T_2 (32.5g), T_3 (32.5g), and T_4 (32.5g), while the level of Niacin varied in T_2 (1.5g), T_3 (3g), and T_4 (4.5g). T1 was the control (no niacin, no yeast included).The study was carried out in the Poultry Unit, Department of Animal Science Teaching and Research Farm, University of Nigeria Nsukka, and it lasted for 8 weeks. A total of one hundred and twenty (120) day old broiler birds were randomly allotted to four (4) dietary treatments with thirty (30) birds per treatment in each pen. The animals were further divided into three replicates with ten birds per replicate in a completely randomized design (CRD). The result of the study on the haematological parameters showed that the inclusion of niacin and yeast had significant effect ($P<0.05$) on the Haemoglobin concentration (Hb), Mean Corpuscular Haemoglobin(MCH), and corpuscular heamoglobin concentration(MCHC). The result of the study on the Serum profile of broiler starter phase showed that the inclusion of Niacin and yeast had significant effect ($P<0.05$) on the cholesterol, triglycerides and Low density lipoprotein (LDL). It is evident from this study that majority of the parameters measured or determined did not favor high inclusion of Niacin and yeast in broiler production. However, the research had established that inclusion of niacin and yeast in broiler production, small dosages have to be administered to avoid overdoes.

Key words: haematology, serum, diets, niacin and yeast

INTRODUCTION

In recent years, consumers' pressure and worries towards harmful effects of antibiotic use and the ban of antibiotics has prompted researchers to think about alternatives to antibiotics in poultry production (Diarra and Malouin, 2014). Probiotics are defined as "live micro-organisms, when administered in adequate amounts; confer a health benefit to the host" (WHO, 2001). Probiotic feed supplementation improves growth, feed efficiency and intestinal health (Giannenas *et al.*, 2012). Among the different probiotic organism, the Lactobacillus and Saccharomyces have most commonly been used. Saccharomyces cerevisiae (SC), one of the most widely commercialized types of yeast, rich in crude protein (40-45%) and its biological values were high and also rich in vitamin B complex, biotin, niacin, pentothenic acid and thiamin (Reed and Nagodawithana,1999) has long been fed to animals and poultry. Niacin is important in energy production and storage and tissue growth (El-Husseiny *et al*., 2008). The availability of niacin in grains and grain by-products is very low, therefore, the need to supplement it in the diet of the birds. Haematology refers to the study of the numbers and morphology of the cellular elements of the blood – the red cells (erythrocytes), white cells (leucocytes), and the platelets (thrombocytes) and the use of these results in the diagnosis and monitoring of disease (Merck Manual, 2012). However, the essence of this study was to investigate the effect of niacin and yeast on haematology and serum biochemical indices of starter broiler birds.

MATERIALS AND METHOD

Location and duration of study

The study was conducted in the poultry unit, Department of Animal Science Teaching and Research farm, University of Nigeria Nsukka. The study lasted for four (4) weeks.

Experimental materials

Niacin and yeast was used for the study. Niacin was gotten from Joechem Agrochemicals in Nsukka, Enugu state. Commercial yeast was also gotten from a reputable dealer in Ogige market in Nsukka.

Experimental animal and management

One hundred and twenty (120) broiler birds of a day old commercial broiler chicks of mixed sexes of the Anak strain were purchased from a reputable source in Nsukka, Enugu state and were used for the

study. The broiler birds were randomly allotted to four (4) dietary treatments with thirty (30) birds per treatment in each pen. The animals were further divided into three replicates with ten birds per replicate in a completely randomized design (CRD). Yeast and Niacin were included in the feed of the broiler birds. The treatments were as follows: T_1= Control (no Niacin, no Yeast included), T_2=32.5g of Yeast + 1.5g of Niacin, T_3=32.5g of Yeast + 3g of Niacin and T_4=32.5g of Yeast + 4.5g of Niacin. Feed and water were supplied ad *libitum* to the birds. Vaccinations and other management practices were strictly followed.

Feed composition table

Table 1: Percentage composition of the starter diets

INGREDIENTS (%)	**STARTER DIET**

Palm kernel cake	10.40
Wheat Offal	8.00
Bone meal	4.00
Fish meal	3.00
Salt	0.25
Premix*	0.25
Lysine	0.25
Methionine	0.25
TOTAL	**100**

Haematological and serum biochemical evaluation

At the end of the experiment, three birds per treatment were randomly selected and blood samples were collected from the wing veins of each bird using sterilized syringe and emptied into sterilized bottles containing EDTA (Ethylene diaminetetracetic acid) for haematological analysis, and into the bottles without EDTA for serum biochemical analysis. Haematological parameters that were determined included haemoglobin concentration (HbC), packed cell volume (PCV), white blood cell (WBC) count, and red blood cell (RBC) count. Serum metabolites (total protein (TP), glucose albumin, globulin, creatine, cholesterol and calcium) were also determined according to the methods described by Campbell and Coles (1986).

Statistical analyses

Data collected were subjected to analysis of variance (ANOVA) for completely randomized design (CRD) using a statistics package for social sciences. (SPSS 2015) model. Significantly different means were separated using Duncan's New Multiple Range Test (SPSS, 2015).

Result and discussion

Table 2: Proximate analysis for starter feed.

	MOISTURE	PROTEIN	ASH	FIBRE	FAT/OIL
T_1	16.00	23.05	14.00	5.00	1.50
T_2	17.50	23.11	12.00	5.05	1.32
T_3	14.90	24.10	13.94	4.98	1.09
T_4	16.80	23.92	14.00	5.08	1.21

Table 3: Effect of Yeast and Niacin on Haematological parameters of broiler starter phase.

TREATMENT	T_1	T_2	T_3	T_4	SIGNIFICANCE
PCV (%)	27.50 ± 1.44	24.50 ± 0.87	26.33±1.20	26.00 ± 1.73	N.S
RBC (mm^3)	2.76 ± 0.48	2.24 ±0.31	2.62 ±0.12	2.17 ± 0.14	N.S
HB (g/100ml)	9.06 ±0.51^{ab}	10.90 ±1.24^{a}	6.14 ± 1.06^{b}	7.82 ± 1.60^{ab}	*
MCH (%)	35.20 ± 7.02^{ab}	56.90±7.84^{a}	23.88± 5.07^{b}	37.17 ±9.42^{ab}	*
MCHC (%)	32.93 ±0.51^{ab}	44.10± 3.50^{a}	23.79±5.13^{b}	29.54 ±4.64^{b}	*

N.S= not significant, *= significant

The table above indicated that there was no significant difference on packed cell volume(PCV) and red blood cells(RBC), but there were significant effect (P<0.05) of treatments on heamoglobin concentration(Hb), mean corpuscular haemoglobin(MCH), and corpuscular heamoglobin concentration(MCHC). T2 was statistically higher in Hb(10.90 ±1.24),MCH(56.90±7.84) and MCHC(44.10± 3.50) values than Hb(6.14 ± 1.06), MCH(23.88± 5.07) and MCHC(23.79±5.13) values of T3 respectively. T_2 had similar values of Hb, MCH and MCHC with T_1 and T_4. Again T_3, T_1, and T_4 were statistically similar in HB, MCH and MCHC values. The haemoglobin concentration and packed cell volume in this study fell within the normal range of (6.0 – 13.0 g/100ml) and (29 – 38%) respectively according to (Nworgu, 2007). The mean corpuscular haemoglobin and mean corpuscular heamoglobin concentration also fell within the normal range of (32.30 – 60.10pg) and (27.35-45.51%) respectively as reported by Nowaczewski and Kontecka (2012). This suggested that inclusion of niacin and yeast did not constitute of any harmful effect to the broilers. This supports the findings of (Khan and Zafar, 2005) who stated that Haematological parameters are good indicators of the physiological status of animals.

Table 4: Effect of yeast and niacin on Serum profile of broiler starter phase.

TREATMENT	CONTROL	T_2	T_3	T_4	SIGNIFICANT
HDL (mg/dl)	80.08±7.02	69.99±4.02	75.82±5.66	79.14±1.94	N.S
CHOLESTEROL (mg/dl)	68.86±2.85^{c}	68.07±1.40^{c}	111.38±7.06^{b}	126.73±8.02^{a}	*
ALBUMIN(g/dl)	1.15±0.08	1.19±0.10	1.05±0.08	1.27±0.16	N.S
TRIGLYCERIDES(mg/dl)	120.64±14.35^{a}	51.88±7.54^{b}	60.94±23.02^{b}	74.21±9.06^{a}	*
TOTAL PROTEIN(g/dl)	4.73±0.69	3.97±0.43	3.27±0.32	3.50±0.43	N.S
LDL(g/dl)	-66.07±3.47^{c}	-26.73±7.81^{b}	7.87±6.17^{a}	13.22±2.04^{a}	*
GLOBULIN	3.52±0.68	2.78±0.34	2.22±0.30	2.22±0.36	N.S

N.S= not significant, *= significant

Table 4 indicated that there were significant (P<0.05) differences in cholesterol, triglycerides and LDL. T1 and T2 were significantly (P<0.05) lower in cholesterol values than the values of T3 and T 4. T4 was statistically higher in cholesterol value. T1 (120.64±14.35) was significantly (P<0.05) higher in triglycerides value than other treatments. The LDL values of T4 (13.22±2.04) and T3 (7.87±6.17) were significantly higer than other treatments. T1 (-66.07±3.47) had the least value of LDL. This study disagreed with the finding of Kamanna and Kashyap (2000) who reported that the typical effects of niacin causes decreased low density lipoprotein and cholesterol concentrations. And it is also in contrast with the findings of Kamanna and Kashyap (2000) who affirms that niacin is best used to reduce cholesterol serum. These differences could be due to the level of inclusion, environmental factor, climate and management practices. This result agreed with the findings of Djouvinov et al (2005) who reported no significant difference in the level of total proteins in a study with ducklings using a multi-strains probiotic. The result on the value of triglycerides level was in agreement with the findings of Hu *et al*. (2012) who reported that niacin effectively reduces plasma triglyceride levels.

CONCLUSION

This research established that in inclusion of niacin and yeast in broiler production, small dosages have to be administered to avoid overdoes. Notwithstanding, a right dosage of niacin and yeast can enhance the performance of broiler production in terms of haematological, serum biochemical and carcass and organ analysis.

EFFECT OF DIFFERENT INCLUSION LEVELS OF GINGER (*Zingiber officinale* Roscoe) MEAL ON THE PERFORMANCE OF STARTER BROILER CHICKENS

***Egenuka, F. C., Obi, H. N., Achi, J. C., Okere, P.C., Kadurumba, O. E. and Iwuji, T. C.**

Department of Animal Science and Technology, Federal University of Technology, Owerri, Nigeria.

ABSTRACT

One hundred and thirty-two (132) day old broiler chicks of Abor-acre strain were used in this study to investigate the effect of different inclusion levels of ginger meal on the performance of starter broilers. The birds were randomly divided into four treatment groups, each comprising of 33 broilers. Each group was further sub-divided into 3 replicates of 11 birds each, in a completely randomized design. Four dietary treatments were formulated. The control diet contained no ginger (0.0 % ginger diet). Diet 2 contained 0.5 % ginger; diet 3 contained 1.0 % ginger and diet 4 contained 1.5 % ginger. The experiment lasted for 30 days. Results from the experiment showed that differences in ginger levels did not affect weight gain and feed conversion ratio but feed intake of the ginger groups were similar but significantly higher ($P < 0.05$) than the control group. Cost of feed and cost/kg weight gain was higher in the ginger groups with diet 4 recording the highest values, though the differences were not significant. 0.5 % inclusion level of ginger meal in broiler starter diets could have positive effects on the birds since birds on this diet exhibited lower feed conversion ratio with minimal feed intake.

Key words: Ginger meal, starter broiler chickens, performance

Introduction

In-feed additives/growth promoters such as antibiotics have normally been used at sub-therapeutic doses to enhance growth in poultry. However, in January 1, 2006 the in-feed antibiotics were banned in European countries (Mansoub, 2010) due to their link to antimicrobial resistance among several pathogenic bacteria in animals and humans (Donogue, 2003). The ban necessitated the search for sustainable and economically viable alternative which was found in phytogenic feed additives (PFAs). PFAs called phytobiotics or botanicals are herbs or plant derived products which on addition to livestock feeds are able to enhance livestock performance trough the improvement of digestibility, nutrient absorption and elimination of pathogenic microbes resident in the animal gut (Balunas and Kinghorn, 2005; Athanasiadou *et al*., 2007). Spices such as ginger, garlic and turmeric and their essential oils have been extensively used as phytogenic feed additives and reported to posses the capacity to improve growth in broilers (Alcicek *et al*., 2003; Windish *et al*., 2007).

Ginger has for hundreds of years been consumed as a delicacy, medicine or spice. Arkan *et al*. (2012) reported that supplementing broilers ration with 0.2 % dried ginger meal increased body weight at six weeks of age. Ademola *et al*. (2009) and Onimisi *et al*. (2005) also reported that supplementation of ginger up to 2 % level in the diet of broilers increased body weight.

Materials and method

Experimental location

This research was conducted at the poultry unit of Teaching and Research Farm of Federal University of Technology, Owerri, Imo State, Nigeria. Owerri lies between latitudes $4^0$4' and $6^0$3' N and longitudes $6^0$15' and $7^0$28' E.

Experimental birds and treatment diets

A total of one hundred and thirty-two (132) day old broilers of Abor-acre strain were used in this experiment. They were weighed on arrival and grouped into four treatment diet groups, each comprising of thirty-three (33) broilers. Each group was divided into three replicates of 11 birds. Each replicate group was housed in a pen measuring 1 m x 1 m. Birds were offered experimental diets from

the first day until they were 30 days of age. Experimental diet 1 (control) contained no ginger. Experimental diets 2, 3 and 4 contained 0.5 %, 1.0 % and 1.5 % dry ginger meal, respectively. All diets were iso-proteinous and iso-caloric ranging from 23.07 – 23.09 % crude protein (CP) and 2870.93 – 2872.73 kcal/kg metabolizable energy. (ME). Table 1 shows the ingredient and calculated nutrient composition of the experimental diets.

Management of birds

The birds were managed on deep litter system and were offered feed and water *ad-libitum*. They were brooded using kerosene stoves, lanterns and electric bulbs. Necessary vaccinations and multivitamins were administered.

Source of experimental materials and processing of ginger

The broilers used in this research were procured from a reputable farm in Ibadan. The fresh ginger was bought from Relief market in Owerri while other feed ingredients were bought from a commercial feed dealer also in Owerri. The fresh ginger was washed, and water was allowed to drain. They were then sliced into small sizes of about 5 mm thickness to facilitate drying. They were sundried for 7 days and milled into fine powdery mass using a hammer mill fitted with 0.01 mm sieve. The powdery mass (ginger meal) was stored in plastic air-tight container and stored at room temperature until needed during feed formulation.

Data collection

The birds were weighed at the beginning of the experiment, weekly thereafter and on the 30th day to ascertain the weight gain. Feed intake was obtained daily by subtracting left-over feed from the feed fed the previous day. From the data collected averages were taken and recorded. Feed conversion ratio was obtained by dividing the average daily feed intake by the average daily weight gain. Cost of feed consumed per bird was calculated by multiplying the unit price of the feeds by the amount of feed consumed in kilogrammes. Cost of feed per kilogramme weight gain was calculated by dividing the cost of feed consumed per bird by kilogramme weight gain of the bird.

Experimental design and data analysis

All data collected from the experiment were subjected to analysis of variance (ANOVA) in a completely randomized design (CRD) at 5 % level of probability. Significantly different means were compared using Duncan's New Multiple Range Test as outlined by Obi (1990).

Results

The performance of the starter broilers fed different levels of ginger meal is shown in table 2. There were no significant differences in the final weight and weight gain of the birds, though values were higher in the ginger groups than the control group. The birds fed 1.0 % ginger diet had the highest weight gain followed by those on 1.5 % and 0.5 % ginger diets and then the control group. Feed intake of broilers on ginger diets were similar but significantly higher ($P < 0.05$) than the control group. Birds fed 0.5 % ginger diet had numerically better feed conversion ratio (FCR) though differences were not significant. Cost of feed consumed and cost/kg weight gain were similar though there were numerical increases with increasing inclusion level of ginger meal.

Discussion

In terms of weight gain, the results obtained in this study were similar to those of Zhang *et al* (2009) who reported that inclusion of ginger meal in broiler diets at 5g/kg did not affect daily gain of the broilers. However, Ademola *et al* (2009) and Onimisi *et al*. (2005) have reported that weight gain can be increased at 2 % level of ginger meal inclusion in broiler diets. Our result was in contrast to the findings of Dooley *et al*. (2009) who reported no differences in feed intake by broiler chickens fed ginger extract for a period of 6 weeks. The higher feed intake by birds on the ginger groups may be due to the sweet flavour and aroma of ginger. Similar to our results, Zomrawi *et al*. (2013) reported no significant differences in feed conversion ratio of broiler chickens fed ginger root powder at 1.0 %,

1.5 % and 2.0 % levels respectively. Mohammed *et al*. (2012) noted significant differences in body weight gain, feed intake and feed conversion ratio when broiler chickens were fed diets containing 0.1 % and 0.2 % ginger meal.

Conclusion

0.5 % inclusion level of ginger meal could have positive effects in starter broilers since it exhibited lower feed conversion ratio with minimal feed intake.

Abstract

The study determined the growth and feed cost benefits of broiler chickens fed graded levels of Morinda lucida leaf powder (MLP) using a total of 180 day-old broiler chicks (Arbor acre). They were weighed and randomly grouped into four dietary treatments of 3 replicates with 15 chicks each. The dietary treatments consisted of the control (basal diet), control+1g /kgMLP, control+2g/ kgMLP and control+3g/kgMLP diets. Body weights, feed intake and feed conversion ratio (FCR) of the birds were taken on a weekly basis and the feed cost benefits was calculated at the end of each experimental phase.The experiment was laid out in a completely randomized design and data obtained were subjected to one-way analysis of variance. Results obtained showed that inclusion of MLP at 1 and 2g/kg significantly increased ($p<0.05$) the final body weight at starter phase but had no effect ($p>0.05$) on finisher's final weight. Also, feed intake was significantly high ($p<0.05$) in birds on 1g/kgMLP (1528.43g) at starter phase but not significantly influenced ($p>0.05$) by MLP inclusion at finisher phase. FCR on the other hand was not significantly influenced ($p>0.05$) by MLP inclusion at the two phases of the experiment. Cost of feed per kg weight gain was significantly lowered ($p<0.05$) at the finishing phase in birds fed 1g/kg and 2g/kg MLP (₦364.50 and ₦353.48). Inclusion of MLP at 1 and 2g/kg improved feed cost benefit of broiler chickens at finishing phase with no deleterious effect on growth performance.

Keywords: Broilers, Performance, *Morinda lucida*, Starter, Finisher

Introduction

The use of phytogenic additives in poultry production has produced encouraging results that has helped researchers to discover various plant materials that perform various actions like growth stimulation, gut modulation, antibacterial and anti-inflammation. Researchers who reported improved growth performance and cost benefit of poultry birds to phytogenic additives attributed their findings to interaction of phytogenics with intestinal microflora (Lin, 2011), stimulatory effects of phytogenic substances on digestive secretions which result in increase in digestion efficiency (Platel and Srinivasan, 2004) as well as increased feed intake due to improvement in the dietary palatability resulting from the enhanced flavour or odour, emanating from the essential oils present in the plant materials used (Frankic *et al.*, 2009). However, major challenges being faced in the use of phytogenic additives is the determination of the exact quantity of the plant materials to be used to achieve the targeted objective. *Morinda lucida* is an important medicinal plant in African traditional medicine and has been reported to contain important phytochemicals that improve performance (Oduola *et al*., 2010).

The study investigated the growth performance and feed cost benefit of broiler chickens fed graded levels of Brimstone (*Morinda lucida* Benth) leaf powder as phytogenic additives in the diets.

Materials and Methods

Preparation of the test ingredient

Morinda lucida leaf sourced from Emere village, Camp, Abeokuta, Ogun State, Nigeria was properly identified at the Department of Forestry, Federal University of Agriculture, Abeokuta, Nigeria. The harvested leaves were washed, air dried under shade for 2 weeks until the moisture content was below

10% and greenish colour retained, milled into powdery form, sieved using 0.10 mm sieve and stored separately in air tight bag inside a refrigerator till time of use.

Experimental birds and management

The feeding trial was carried out at Federal University of Agriculture, Abeokuta, Ogun State, Nigeria. One hundred and eighty day-old chicks (Abor acre) were purchased from a reputable hatchery in Ibadan, Oyo State, Nigeria. On arrival, the initial weight of the birds were taken and randomly allotted into 4 experimental treatments of 45 birds each. Each treatment group was replicated thrice to have 15 chicks per replicate. The birds were all subjected to standard routine management during the brooding and rearing stages of the experiment. Feeds and water were provided to the birds *ad libitum*. The birds were raised in a standard deep litter poultry pen.

Experimental diets and design

Four different diets were formulated such that the control treatment groups were fed diet containing 0% inclusion level of *M. lucida* leaf powder (MLP) while experimental birds in the second, third and fourth treatment groups received diets containing 1, 2 and 3 g/kg feed *M. lucida* leaf powder (MLP) respectively. The experiment was laid out in a completely randomized design. The gross composition of the experimental diets was shown on Table 1.

Table 1: Gross composition (%) of the experimental diets for starter and finisher phases.

Ether Extract (EE) (%)	4.04	4.13
Crude Fibre (CF) (%)	3.48	3.43

Data collection

Growth performance

Weekly data was collected for growth parameter indices using the following formula:

$$\text{Weight gain per bird (g)} = \frac{\text{Final weight (g)} - \textit{Initial weight (g)}}{\text{Number of birds}}$$

$$\text{Feed intake per bird (g)} = \frac{\text{Feed suppl ied (g)} - \text{Feed leftover (g)}}{\text{Number of birds}}$$

$$\text{Feed conversion ratio} = \frac{\text{Amount of feed consumed (g)}}{\text{Weight gain (g)}}$$

Feed cost benefit

The feed cost benefit analysis was based on the methods of Anigbogu *et al.* (2010). The formula used for calculating cost benefit parameters includes;

$$\text{Cost of feed/kg (₦/kg)} = \frac{\text{Total cost of feed (₦)}}{\text{Quantity of feed (KG)}}$$

Cost of feed consumed/kg weight gain = feed conversion ratio X cost of feed per kg

Cost of feed intake = quantity of feed consumed (kg) X cost of feed per kg (₦)

Statistical Analysis

Data obtained from the study were subjected into One-way Analysis of Variance (ANOVA) in a Completely Randomized Design using the GLM procedure of statistical analysis software SAS® version 2013. Significant differences among treatment means were determined using Duncan Multiple Range Test (DMRT) as contained in the SAS® software.

Results and Discussion

As shown in Table 2, Feed intake of the birds at the starting phase of the experiment was significantly increased ($p<0.05$) in birds fed 1g/kg and 2g/kg MLP (1528.43 and 1421.40g) respectively and this manifested in the final body weight of the birds too as the birds on 1g/kg and 2g/kg MLP recorded the highest values (820.89 and 765.18g) for final body weight gain at the starting phase of the experiment. The increment in feed intake could be attributed to improved taste of the diet (Windisch *et al*., 2008) and low concentration of antinutritional content of the plant in the 2 inclusion levels. This observation corroborates the report of Muhammad et al. (2014). Also, the stimulatory effect of the phytogenic additives on the appetite and endogenous secretions in the digestive system of the birds which in turn improve the feed utilization (Wenk, 2002) could be related to the improved final body weight gain of the birds on 1g/kg and 2g/kg MLP at starting (820.89 and 765.18g) and finishing (2073.70 and 1990.80g) phases of the experiment. Similarity in feed intake recorded at the finishing phase corroborates the report of Amouzmehr *et al.* (2013), Bushra (2011) and Fadlalla *et al.* (2010).

Cost of feed consumed by birds on 1g/kg and 2g/kgMLP diets (₦233.70 and ₦217.76) were respectively high ($p<0.05$) at the starting phase but not significantly different at the finishing phase. Also, cost of feed per kg weight gain at finishing phase was lowest in birds on 1g/kg and 2g/kg MLP (₦364.50 and ₦353.48) when compared to other dietary treatments. This could be attributed to good feed utilization by the birds on 1g/kg and 2g/kg MLP diets.

Table 2: Growth performance and feed cost benefits of broiler chickens fed *Morinda lucida* leaf powder (MLP) at starting and finishing phases.

SEM- Standard error of mean; MLP – *Morinda lucida* leaf powder

Means on the same column having different superscript differ significantly at $P < 0.05$

Conclusion and Recommendation

It can be concluded that inclusion of MLP at 1g/kg and 2g/kg diet posed no deleterious effect but improved performance and cost benefits of broiler chickens at starting and finishing phases. The use of MLP at either 1g/kg or 2g/kg is therefore recommended for improved growth performance and feed cost effectiveness of broiler chickens.

Abstract
The experiment was carried out to investigate the inclusion levels of pearl millet in the diets of quails (Coturnix coturnix japonica). Four hundred and eighty (480) two weeks old quail birds were used for the study in an experimental diets that contained 10, 20, 40, 60, 80, and 100% Pearl millet (PM) with 24% CP& 2888kcal/kgME and 20% CP& 2778 kcal/kgME for growing and laying phases, respectively. The experiment lasted for 119 days and data were collected weekly; the parameters measured include feed intake (FI), total weight gain, water intake, egg weight, hen day egg production, and egg quality. At growing phase (2-6 weeks), the parameters measured were significantly different across the dietary levels of Pearl millet. At the laying phase (6-17 weeks) all the parameters measured were significantly (P<0.01) differences except in FI (26.70-30.60 g). It can be concluded that pearl millet can replace maize at 100% levels in diets of Japanese quails without adverse effects on growth performance and hen day egg production.
Key words: Pearl millet, Japanese quail, performance, layer, egg production,

Introduction
Cereal grains, especially maize which form the bulk of energy in poultry feeds are in short supply as a result of industrial and human needs (Nworgu *et al.,* 1999). In view of this, evaluation of pearl millet as alternative energy feedstuffs to maize becomes imperative in areas where their uses are less common. Millet is the most widely grown cereal that has been successfully cultivated in the semi-arid region of Africa and its production cost is relatively low. However, it has little industrial uses in Nigeria (Nyannor *et al.,* 2007). Pearl millet (*Pennisetum glaucum)* is considered as a staple food in Africa and India where it is used to make flour, bread, porridge and "couscous". As a feedstuff it is mainly grown to produce silage, hay (FAO, 2002).

Feeds are the most expensive production input which accounts for 65-75% of the cost of poultry production (Adelowo, *et al,*. 2018). Maize which is the best and major source of dietary energy for quail production has a high competition between human and animal. In view of this, it is highly necessary to search for suitable substitutes for maize in a developing country like Nigeria (Elangovan *et al.,* 2004). This study investigates the performance, carcass characteristics and egg quality of Japanese quails (*Coturnix coturnix japonica*) fed various inclusion levels of Pearl millet (*Pennisetum glaucum)* as energy source.

Materials and Methods
The experiment was conducted at the teaching and research farm of the Federal College of Animal Health and Production Technology, NVRI Vom, Plateau State. Four hundred and eighty (480) two weeks old Japanese quail were used for the study. Initial weight was recorded and the birds were randomly distributed into six treatments with four replicates of 20 chicks in a completely randomised design. Six experimental diets were formulated for the study (Tables 1 and 2). The diets contained 24% CP and 2800kcal/kg ME, and 20% CP and 2600kcal/kg ME for phase I and phase II respectively: the Treatments are; I. Contained 100% Maize as sole source of energy, II. Containing Maize 80%, Millet 20% energy source, III. Containing Maize 60%, Millet 40% energy source, IV. Containing Maize 40%, Millet 60% energy source, V. Containing Maize 20%, Millet 80% energy source, VI. Contained 100% Millet as sole energy source. The diets for both experiments were formulated to meet the nutrient standard of quail, (NRC, 1994) and water was given *ad-libitum* throughout the growing and laying period. Sample of formulated diets was analysed for proximate composition using the method described by AOAC (2006) at Biochemistry Laboratory Department of National Veterinary Research Institute, Vom, Nigeria. The quails were weighed weekly with digital

scale, the parameters measured include feed intake, weight gain, final weight and feed conversion ratio was calculated. Mortality was recorded as it occurred. All the chicks were subjected to same management practices throughout the experimental period. The brooding was done with100watt bulb as sources of heat.

Statistical Analysis: Data obtained from the experiment were analysed using the statistical analysis of variance (ANOVA) procedure of SAS (2010) and significant level of p=0.05, and p=0.01 were used. The treatment means were compared using the New Duncan multiple range test of the same software.

The result in this study shows the feed intake at the starter phase (FI) as 12.05-13.54g/day compared to the 10.52 to 11.04g/day reported by Abubakar *et al.* (2007) for quail chicks fed varying levels of rumen content in diets, but at variance with a study conducted at NVRI with observation in daily feed intake of 22.26g per quail at six weeks. Increased feed consumption on weekly basis as the quail grow older as reported by Edache *et al.* (2005). The FI at finisher phase 26.70-30.60 g/day were similar across the diets. This agrees with the observation of Café *et al.* (1999) in their study on feed intake of quails fed graded levels of millet diets. The results of water intake at the starter (20.19 – 23.40 ml/day) and finisher (31.68 – 50.52 ml/day) phase revealed that, the higher the feed intake the higher amount of water consumed. The results of weight gain (WG) recorded during starter phase ranged from 2.59 to 3.29 g/day while that of the finisher period ranged from 0.30 to 0.65 g/day. This is

similar to the reports of NVRI (1996) who evaluated the response of Japanese quails to diets containing three protein levels (20, 22 and 24% CP) and found that birds fed with high protein diet (24% CP) had best growth performance. This also agrees with the reports of Gheeisari *et al.* (2011) which indicated that increasing dietary protein in different stages of growth cause increase in body weight gain of Japanese quail. The result of feed conversion ratio in this study ranges from 4.09-4.90 and is similar to the observation of Al-Hanafy (2012) who reported that during the starting phase (1-6weeks) a significant improvement in feed conversion ratio was recorded.

Conclusion

The study revealed that quail birds fed with the highest inclusion (50%) of pearl millets in their diets were not different in the final weight, weight gain and feed conversion ratio of quails in the control diet and those in diets replaced with hundred percent pearl millet. Hence, pearl millet can replace maize in the diets of Japanese quails without adverse effects on performance and egg production.

PERFORMANCE OF BROILER STARTER BIRDS FED SORGHUM WITH DIFFERENT ENERGY LEVELS AS REPLACEMENT FOR MAIZE

H. B. USMAN, M. ANANDE AND M. N. SABO

Department of Animal Science, Federal University Dutsin-Ma

Abstract

The effect of substituting maize with sorghum using different energy levels was studied on broiler birds. Broiler chicks were assigned to one of the following experimental diets. T1: maize based diet containing 2,900kcal ME/Kg (control). T2, T3 and T4: were all sorghum based diets 2,900, 3,000 and 3,100 ME kcal/kg respectively. Feed intake, weight gain and feed conversion ratio were measured and determined. The results showed that final weight, weight gain, feed conversion ratio (FCR) and cost of feed per kg gain were similar (P>0.05) among the treatment means. Feed intake differ significantly (P<0.05) among the treatments with T1 having higher feed intake than T3. T2 and T4 have similar (P>0.05) feed intake to both T1 and T3. Total cost of feed consumed (₦/b) differ significantly (p<0.05) with T3 (209.37) having the lowest compared to T1 and T4 (251.76 and 236.71). T2 (215.71) had similar total feed cost to T3 and T4. was statistically similar with T4 having (177.89/kg) compared to the other treatments (213.91, 208.80 and 200.53 for T1,T2 and T3 respectively). In conclusion T4 was the most economical as it had lower FCR and cost per kg gain.

INTRODUCTION

Cereals are the most widely available and cheap source of high energy feed ingredients for the African farmer. Energy sources constitute the largest component of poultry diets. Globally, Maize is the most common energy source used in poultry feeds, constituting about 40-60% in poultry rations *(*Dayakar-Rao *et al*., 2003*).* This is mainly because their energy source is starch, which is highly digestible and palatable. The metabolizable energy value of maize is generally considered the standard with which other energy sources are compared (Oluyemi and Roberts 2000). The global maize requirement for poultry was estimated at 3.5 million tones at 2003 and was projected to rise to 31 million tons by 2020 (Dayakar-Rao, *et al*, 2003). Where available, other cereals could contribute to provide the seemingly ever increasing demand by the poultry industry.

In Nigeria, Maize production has never been sufficient to meet the needs of the growing human population, because it is a staple food crop for majority of the population (Iken and Amusa, 2004). Thus there is a continuing shortage of maize for use as feed, necessitating the exploration of other energy sources for livestock. To reduce the overdependence on maize, a number of researchers are exploring the use of cereals such as sorghum and millet as alternative energy sources. Sorghum grain is an interesting energy ingredient in poultry diets due to its nutritional composition, which is very similar to corn. (Louis *et al*, 1991).

Sorghum is grown in large quantity in the northern guinea and dry sub humid zones of Nigeria, where it is the second important cereal crop after maize. Its annual production was estimated at 11,700 million metric tons during the 2010 growing season (FAO 2011). The inclusion of sorghum in poultry diets is gaining interest due to favorable nutritional content of the grain. Sorghum can be used in commercial poultry diets to replace maize as an energy source, because they contain similar metabolizable energy (ME) (Kcal/kg) values (3,672 and 3, 667 for yellow and white maize; and 3, 669 and 3, 550 for yellow and red sorghum, respectively) (Tukur, 2011). Previous studies conducted with broiler chickens showed that feeding sorghum yielded similar and sometimes better results in terms of growth performance and carcass characteristics compared to maize (Cramer *et al*..' 2003; Nyamambi *et al.,* 2007). However, some varieties of sorghum have high tannin content, which lowers palatability and efficiency of feed utilization (Davies *et al., 2003,* Garcia and Dale, 2006*),* thus limiting its use in poultry feeds. Some varieties of sorghum can contain up to 6% tannin (Doka *et al., 2004;* Dicko *et al.,* 2015*),* which binds dietary protein making it unavailable for absorption. Owing to their astringent taste, tannins have negative effects on feed intake, palatability and digestibility of nutrients, with a consequent decrease in weight gain of birds (Hassan *et al.,* 2003; Makkar, 2003; Kim and Miller 2005). The objective of this research is to determine the performance of broiler birds fed with sorghum using different energy levels

MATERIALS AND METHOD

Location of the Study area

The study was conducted at the Poultry Unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma. Dutsin-Ma lies on latitude 12°26'N and longitude 07°29'E (Abaje *et al.*, 2014).

Experimental Materials and Animals

Ninety-six day old broiler chicks were sourced and kept for one week to acclimatize before randomly allotted to four treatment groups of 24 birds each. Each treatment was replicated thrice with 8 birds per replicate in a completely randomized design (CRD) the treatments were as follows: Diet 1 is maize based mash diet with the ME value of 2900 kcal/kg (T1) which is the control. Diet 2 is sorghum based mash diet with 2,900 kcal ME/kg (T2). Diet 3 is also sorghum based diet with 3000 kcal ME/kg (T3), and Diet 4 is sorghum with 3100 kcal ME/kg (T4). Birds in each replicate were weighed at the beginning of the experiment and subsequently on weekly basis to determine the weight gain of bird. Feed intake was also recorded daily. Feed conversion ratio, total feed cost and feed cost per kg gain were determined. Mortality was recorded. Routine management practices such as medication and vaccination were rightly observed. The birds were given feed and water *ad libitum*. The experiment lasted for four weeks. The composition of the experimental diets is shown in table 1 below. Data generated was subjected to analysis of variance in a completely randomized design using several linear program of the stat view statistical package (SAS, 2002).

Table 1: Composition of the starter experimental diet

Ingredients	T1 (2900kcalMe /kg)	T2 (2900kcalMe /kg)	T3 (3000kcalMe /kg)	T4 (3100kcalMe/kg)
Maize	57	-	-	-
Sorghum	-	55	54	53
Soybean meal	38.8	38.8	38.8	38.8
Limestone	0.5	0.5	0.5	0.5
Bone meal	3	3	3	3
Salt	0.25	0.25	0.25	0.25
Premix	0.25	0.25	0.25	0.25
Methionine	0.2	0.2	0.2	0.2
Palm oil	-	2	3	4
Total	100	100	100	100

RESULTS AND DISCUSSION

The proximate composition of the experimental diets is shown in table 2. Performance of broiler chicks fed with maize and sorghum-based diets containing varying energy levels is shown in table 3. Initial body weight did not differ between the treatments. Final weight and weight gain were similar ($P>0.05$) among the treatment means. Feed intake differ significantly ($P<0.05$) among the treatments with T1 having higher feed intake than T3. T2 and T4 have similar ($P>0.05$) feed intake to both T1 and T3. The feed intake observed in this study (1754.92-2016.39g/bird) was higher than that (1264-1415g/bird) observed by Bako J. M. (2018). Feed Conversion Ratio (FCR) was similar ($P>0.05$) amongst the treatments. (sorghum with the highest energy level have (1.44) compared to the other treatments (1.71, 1.80, and 1.68 for T1,T2 and T3, respectively)). The FCR value recorded for the maize and sorghum diets with the same energy density (T1 and T2) were statistically similar. The FCR recorded in this study is similar to the report of Bako J. M. (2018) because the birds in this research gained higher in body weight.

Table 2: Proximate Composition of the Starter phase of the Experimental Diet

Parameters	T1 (2900kcalMe /kg)	T2 (2900kcalMe /kg)	T3 (3000kcalMe /kg)	T4 (3100kcalMe/kg)
Dry matter (%)	86.17	88.38	87.66	87.12
Ash (%)	7.54	3.24	4.07	4.48
Ether extract (%)	16.41	6.27	8.18	10.16
Crude fiber (%)	5.23	6.71	4.64	5.10
Crude protein (%)	27.74	30.91	33.11	30.18
Nitrogen free extract (%)	29.25	41.25	37.66	36.85

Table 3: Performance of broiler birds fed with sorghum using different energy levels at the starter phase

Parameters	Maize control (2900Kcal ME)	Sorghum control(2900 Kcal ME)	Sorghum (3000Kcal ME)	Sorghum (3100Kcal ME)	SEM
Initial weight (kg/b)	0.104	0.104	0.104	0.104	0.000
Final weight (kg/b)	1.288	1.150	1.149	1.538	0.161
Total weight gain (kg/b)	1.18	1.046	1.045	1.434	0.161
Total feed intake (kg/b)	2016.39^{a}	1868.38^{ab}	1754.92^{b}	1922.08^{ab}	64.85
Feed conversion ratio	1.713	1.809	1.681	1.444	0.154
Total feed cost (₦/bird)	251.76^{a}	215.71^{bc}	209.37^{c}	236.71^{ab}	7.834
Feed cost per kg gain (₦)	213.91	208.80	200.53	177.89	18.650

Mean with different superscripts along rows are significantly different ($p > 0.05$) SEM -Standard error of mean

Total cost of feed consumed (₦/bird) differ significantly ($p<0.05$) with T3 (209.37) having the lowest compared to T1 and T4 (251.76 and 236.71). T2 (215.71) had similar total feed cost to T3 and T4. Cost of feed per kg gain was statistically similar with T4 having (177.89/kg) compared to the other treatments (213.91, 208.80 and 200.53 for T1,T2 and T3 respectively).which make T4 the best and recommended treatment for it is more economical and efficient to farmer.

Conclusion and Recommendation

From the results of this study, feeding sorghum using different energy levels as replacement for maize resulted in similar performance. Sorghum can therefore replace maize in the diet of broiler starter especially with palm oil inclusion.

PERFORMANCE OF WEANER RABBITS FED SELECTED FORAGES AS SUPPLEMENT

Ibrahim, H. and Mohammed, U.

Department of Animal Production, Faculty of Agriculture, Ibrahim Badamasi Babangida University, Lapai, Niger State, Nigeria. Correspondence: ihadiza080@gmail.com. 08036101761

Abstract

Feeding trial was conducted with 36 weaner rabbits of mixed sexes and breeds to evaluate the performance of rabbits fed selected forages with concentrate. The rabbits were randomely allocated in to four treatment groups in a complete randomized design. Each treatment was replicated three times with three rabbits per replicate. Four experiment diets were formulated. Diets one was supplemented Tridax procumbens with concentrate which served as control (TI), Amaranthus with concentrate, Fiscus carpensis leaves with concentrate and water melon peel with concentrate in diet 2, 3 and 4 respectively. The test materials were supplied at 100g per replicate. The trial lasted for 56 days. Data were generated on *growth performance (initial weight, final weight, total weight gain, daily weight gain, weekly weight gain, daily feed intake ad feed conversion ratio) and nutrient digestibility parameters were measured* . Results obtained revealed that the value of *there were no significant ((*P>0.05) *difference observed among the growth parameters and nutrient digestibility. It is concluded that T1 could be used for growing rabbit diets for optimum performance Therefore T1 can be recommended as best selected forages with concentrate*

Keywords: **Weaner, Rabbits, Forages, Supplement, Selected**

Introduction

One of the solutions to the problem of protein shortage in the diet of most Nigerians is the rearing of rabbits at both subsistence and commercial levels. Rabbits play an important role in the supply of animal protein to the Nigerian populace (*Amaefule et al., 2005*) and they possess a number of features that are of advantage which include high growth rate, high efficiency in converting forage to meat, short gestation period and high prolificacy, relatively low cost of production and high nutritional quality of rabbit meat (Biobaku and Oguntona, 1997). Forages such as *Panicum maximum* (Guinea grass), *Pennisetum purpureum* (Elephant grass), *Tridax procubens* are acceptable by rabbits (*Abu et al, 2008*). The use of non-conventional feed is gaining ground in Nigeria. Studies have shown that a 50:50 mixture of centorcema pubescens and a maize concentrate diet is optimal for maximum performance (*Nworgu et al, 1999).* One of the major problems of intensive rabbit production in Nigeria is feed because of the competition between man, industries and animals for conventional feed stuffs. This has led to the high cost of conventional feed resources and has account for about 70% of total cost of production (Akinmutimi, 2004). Therefore, this study is designed to estimate Comparative Evaluation of weaner rabbits fed forage as supplement.

Materials and Methods

Location of the Experiment; The research work was carried out at the Rabbit Section of the Teaching and Research Farm of Ibrahim Badamasi BabangidaL University Lapai , Niger state . Lapai lies between latitude 9.31˚and 9.45˚, east of the equator and is very close to Minna,the state capital (Usman, 2011).

Source of Rabbits, Test Ingredient , Experimental Diets and Management of Rabbits

The thirtysix weaned rabbits of mixed sexes and breeds were obtained from Sultan Veterinary Consult farm No 2, Samaru Street hayindogoSamaru Zaria, Kaduna state . Different forage wastes as Tridax procumbens, Ammaranthus waste, fig leaves, and water melon waste were collected from the surrounding environment in Lapai town, Lapai Local Government Area of Niger state, Nigeria. They were washed with salt solution prior to feeding the animals while premix, salt, lime stone and salt were obtained from Minna . Thirty six weaned rabbits mixed breeds and sexes, age between 5-6 weeks were randomly allocated to four treatment groups with nine

rabbits per treatment. Each treatment had three replicates of three rabbits per replicate. The same experimental diet was formulated with crude protein set at 23% for each. T1 was designated as concentrate with Amarathus, T2 concentrate and Tridax procumbens waste, T3 concentrate with fig leaves waste and T4 concentrate and water melon peels. using ivermecin Vitacox-plus and Neo-furaseryl-plus were adequately given as well. The cages were well clean disinfected with Dettol and equipped with drinkers and feeders. Prior to the experiment, the animals were fed concentrate and allowed the adjustment period of one week to enable the animals get used to their various cages and diets. Fresh clean water was provided ad-libitum and the forages were measured before giving throughout the research period. The experiment lasted for 8 weeks

Table:1 Proximate Composition of Experimental Diet

Ingradients	$T_{1:}$	$T_{2:}$	$T_{3:}$	$T_{4:}$
Maize	76.00	76.00	76.00	76.00
Fish meal	1.50	1.50	1.50	1.50
Groundnut cake	20.00	20.00	20.00	20.00
Limestone	1.00	1.00	1.00	1.00
Bone meal	1.00	1.00	1.00	1.00
Salt	0.25	0.25	0.25	0.25
Premix	0.25	0.25	0.25	0.25
Total	100	100	100	100

Key

T_1= Concentrate plus Ammarathus(100g) **T_2** = Concentrate plus Tridaxprocumbeans(100g)

T_3 = Concentrate plus Fig leaves (ficusCarpensis) (100g) **T_4** = Concentrate plus Water Melon Waste (100g)

Data collection

Performance Parameters

The parameters measured on the feeding traits were feed intake, Body weight gain and feed conversion ratio. The following formulae were used for growth performance parameter computation.

$$\text{Daily feed intake (g)} = \frac{\text{Quantity of feed offered-leftover}}{\text{Number of rabbits X Number of Days}}$$

$$\text{Weekly weight gain (g)} = \frac{\text{Final weight- Initial weight}}{\text{Number of Days}}$$

$$\text{Feed conversion ratio} = \frac{\text{Quantity of Feed Consumed}}{\text{Weight gzin}}$$

Nutrient Digestibility : Digestibility study was conducted using nine rabbits per treatment during the seventh week of feeding. Faecal sample were collected daily by placing of Aluminum zinc underneath each replicate for five. At the end of each collection period, the faecal samples were bulked, oven dried at 80°C for 12 hrs and grounded for proximate analysis according to package (SAS, 1998) procedures.

Data Analysis: Data generated were subjected to Analysis of Variance (ANOVA) Using Statistical Package (SA S, 1998).

Results and Discussion

The result of growth performance of weaner rabbits fed selected forages as supplementis presented (Table 2(showed there were no significant (P>0.05) differences in the values obtained for growth parameters measured across the treatment groups Although, higher values were recorded for final weight, treatment one had the highest value (3618g) while treatment four have the least value (3167g) , Also treatment three had highest value for total weight gain (1227g) while treatment four had the least value (950g). For the daily weight gain, treatment three had the highest value (21.90g) while treatment four has the least value (16.97g).feed conversion ratio, the result shows that treatment four had the highest value (12.63g) while treatment three had the lowest value (7.04g). However, treatment one had highest value for final body weight and daily feed intake. This implies that selected forages used as supplement in the diet with concentrate has no significant deleterious effect on the weight gains of the weaner rabbits. This also indicates an effective utilization of the forages by the rabbits.

Table 2:Growth Performance of Weaner Wabbits Fed Sselected Forages as Supplement.

Parameters	Treatments					
(g)	T_1	T_2	T_3	T_4	SEM	LSD
Initial weight (g)	2467	2383	2233	2217	62.92	NS
Final weight (g)	3618	3535	3460	3167	1.24	NS
Total weight gain(g)	1152	1168	1227	950.0	87.15	NS
Daily weight gain (g)	20.57	20.87	21.90	16.97	1.56	NS
Weekly weight gain (g)	144.06	146.11	153.32	118.77	10.89	NS
Daily feed intake (g)	160.40	144.58	150.62	135.96	5.69	NS
Feed conversion ratio	7.35	7.07	7.04	9.47	0.77	NS
Key						

NS: No Significant difference SEM: standard error of mean LSD: level of significant difference

The result of chemical composition of faecal sample as shown (Table 3) revealed that diet four (T_4) had the highest value percent dry matter, crude protein and crude fibre (91.00 %, 3.70% and 33.30%) . This probably could be as a result of increase fibre content. This particularly in consonant with Cheeke and Amberg; (1972) who reported that increase CF resulted in voluntary feed intake in growing rabbit as a means of compensating for feed. The observation also in line with the report of Esonu *et al*., (2003) who reported that inclusion of fibrous material had an energy dilution effect on feed and consequentially increases feed intake.

Table 3: ProximateAanalysis of Faecal Sample

Parameters (%)	Treatments			
	T_1	T_2	T_3	T_4
Dry matter	89.00	82.00	86.00	91.00
Crude protein	3.60	3.20	3.20	3.70
Crude fibre	32.70	33.20	32.20	33.30
Ash	2.50	2.60	2.60	2.60
Ether extract	4.10	4.00	3.60	4.30
Nitrogen free extract	43.20	38.00	35.00	31.00

Conclusion; There were no significant differences in all the parameters measured among the treatment group . However, rabbit fed diet one (T_1) had better performance in final body weight and daily feed intake.

Recommendation; Based on the conclusion from this trial (T_1) that recorded higher values for final body weight and daily feed intake can be recommended for optimum growth and performance.

ABSTRACT

The effects of replacing wheat offal with cowpea testa was investigated using one hundred and fifty one week-old broiler chickens for a period of 9 weeks. The chickens were randomly divided into 5 dietary treatments in groups of 30 chickens and replicated 3 times with 10 chickens per replicate in a Randomized Complete Block Design (RCBD). Broiler starter and finisher diets were compounded and cowpea testa was used to replace wheat offal at graded levels of 0%, 25%, 50%, 75% and 100%. Results obtained indicated no significant (P>0.05) difference in all the parameters. The economic analysis revealed that the feed cost (₦/kg) decreased with increasing levels of cowpea testa in the diets while, no significant (P>0.05) difference was recorded on the feed cost per weight gain (₦/kg gain). However, there was a corresponding improvement in savings in the overall cost of production at 25% cowpea testa diet. Cowpea testa could therefore replace wheat offal at 25% of the wheat offal in broiler diets and thus recommended in areas where the cost of wheat offal is high and supply inadequate.

Keywords: Wheat offal, cowpea testa, broiler chickens, performance, economic analysis

INTRODUCTION

Feed remains one of the most important single input in poultry enterprise, accounting for 60 – 70% of the total cost of commercial poultry production (Olajide, 2010). The utilization of un-conventional feed resources could be an alternative for expanding the feed resource base for poultry, because they are less expensive than the conventional ones. Agro-industrial by-products (AIBs) have in recent times formed the focus of research in animal nutrition especially for monogastrics and their use as un-conventional feed sources has offered opportunities in alleviating the problems associated with animal feed supply (Babatunde, 1989). However, there are limitations when some of the various products such as rice husk or bambara nut waste are fed to poultry. Problems associated with digestion and absorption of nutrients has been noted due to high fibre concentration (Ani, 2007).

Agro-industrial by-product such as wheat offal is in high demand, making the product expensive. There is therefore, a need to explore cheaper alternative such as cowpea testa. Cowpea testa contains 17% crude protein, 2.6% ether extract, 20.3% crude fibre and 1005 kcal/kg of metabolizable energy (Sonaiya, 1993). This implies that cowpea testa is comparable with other un-conventional feedstuff. Cowpea testa is cheap and available where cowpea production is abundant. The objective of this study was to investigate the productive and economic performance of broiler chickens fed cowpea testa as a replacement for wheat offal.

MATERIALS AND METHODS

Study Area. The study was carried out at the poultry unit of Livestock Teaching and Research Farm, Department of Animal Production, Adamawa State University, Mubi. Mubi is located between latitude 9°30' and 11°N of the equator and longititude 13° and 13°45'E of the Greenwich meridian and lies in Guinea savannah zone of Nigeria. The rainfall starts in April and ends in October. It has an annual rainfall of about 750 mm to 1100 mm per annum with temperature ranges between 15.2°C and 39°C (Adebayo and Tukur, 1999) .

Experimental Diets. The experimental diets contained cowpea testa which was dried and ground into meal. The cowpea testa meals (CTM) were used to replace wheat offal (WO) at 0%, 25%, 50%, 75% and 100% levels in the diets. Composition of the experimental diets is presented in Table 1.

Experimental Design. A total of one hundred and fifty (150) day-old chicks were randomly assigned to five (Adebayo and Tukur, 1999) treatment diets. Each treatment consists of three (Ani, 2007) replicates of ten (Akinfala *et al.*, 2013) chickens in a Randomized Complete Block Design (RCBD).
Experimental Stock and Management. The chicks were purchased from ECWA hatchery Jos, Plateau State and used for the study. The chicks were brooded for seven (Pauzenga, 1985) days and allotted to treatment group / diets. Standard management practices and vaccination schedule were carried out. Experimental diets and adequate drinking water were provided *ad libitum* throughout the experimental period. The experiment lasted for nine (Oluyemi and Roberts, 2000) weeks.

Chemical Analysis: Proximate composition of the feed ingredients was analyzed using AOAC (2004) methods. The energy values of the feeds were calculated using the formula of Pauzenga (1985) expressed as:
ME (kcal/kg) = 37 x %CP + 81 x % EE + 35.5 x % NFE.

Statistical Analysis: Data collected were analyzed using statistical package (Statistix 9.0 version). Least significant difference (LSD) was used to separate the means where significant differences ($p<0.05$) occurred.

Results and Discussion

The proximate composition of the experimental diet at starter and finisher phases were presented in Table 2. Result obtained showed that the dry matter ranged from 96.70% to 97.20% and 94.80% to 95.40% for starter and finisher diets, respectively. The crude protein levels of 20.10 to 23.00% and 17.20% to 20.50% for starter and finisher diets, respectively were obtained. The crude protein contents increased with increasing level of cowpea testa in the diets. Similarly, the ether extract levels increased with increasing level of cowpea testa. The ash followed similar trend and levels of nitrogen-free extract recorded in this study were 47.70% to 55.60% and 51.10% to 60.90% for starter and finisher diets, respectively. The values of crude protein obtained in this study were within the recommended values of 18 to 24% reported by (Olomu, 2011) for broiler chickens at nine (Oluyemi and Roberts, 2000) weeks of age.

Result of the growth and economic performance is presented in Table 3. There were no significant ($p>0.05$) difference in final weights, daily feed intake, and daily weight gain. Feed conversion ratio followed the same trend. The result of mortality showed that 6.67% of the chickens died during the experimental period which was within the recommended mortality rate for broiler chickens (Oluyemi and Roberts, 2000).

Result of economic analysis showed that, the total feed cost ranged from ₦1026.65 to ₦1974.42. The total weight (₦/kg) gain recorded were ₦1947.16 to ₦2017.26. The feed cost (₦/ kg) decreased from ₦168.55 to ₦176.55 as level of cowpea testa increased. The feed cost /kg gain was drastically reduced (₦518.47) at 25% level of cowpea testa inclusion. The analysis revealed that at 25% replacement level of wheat offal by cowpea testa, the feed cost decreased from ₦176.55 to ₦168.55/kg. If the total feed cost contributes 60 to 70% cost of poultry production according to (Olajide, 2010), 5% decrease is appreciable in order to boost the profitability of broiler enterprise when using non-conventional feed ingredients. The cost of total feed intake was relatively higher (₦1957.41) at 75% replacement level and lower (₦1026.55) at 25%. This was probably as a result of enhanced feed intake by the broiler chickens as the level of cowpea testa increases. The results of cost benefit analysis obtained in this study were in line with Akinfala *et al.* (2013) and Kwari *et al.* (2012) who used varied non-conventional fibre sources in poultry diets.

CONCLUSION AND RECOMMENDATIONS

Cowpea testa diets can favourably replace wheat offal in the diets of broiler chickens without adverse effects on performance. Cowpea testa was readily available and cheaper than wheat offal in the study area. The economy of poultry production using 25% level of cowpea testa to replace wheat offal was more rewarding in terms of financial benefits especially the feed cost per / kg gain. Farmers should be encouraged to use cowpea testa to replace wheat offal in areas where wheat offal is scarce and costly. More study should be carried out to explore other non-conventional feed resources for feeding poultry.

Abstract

A 28-day feeding trial was conducted to evaluate the growth performance and nutrient digestibility of broilers fed fermented shea butter cake meal (FSBCM) with cocktail of enzyme+probiotic (Nutrizyme®) supplementation. A total of 240, 4-week old broiler chickens were distributed into 4 treatments with 5 replications of 12 birds each using a completely randomized design. The 4 treatments comprised T_1 as control diet without FSBCM; T_2 contained 20% FSBCM replacing maize in control diet; T_3 and T_4 contained T_2diet with 0.05% and 0.1% supplemental Nutrizyme, respectively. Each 100g of Nutrizyme contains protease, xylanase, lipase and Lactobacillus acidophilus. Performance parameters measured were body weight, feed intake, weight gain, and feed:gain ratio. At the end of feeding trial, 3 birds per replicate were selected and placed in a metabolic cage for nutrient digestibility trial. Data collected were statistically analyzed using one way analysis of variance (ANOVA) of general linear model procedures of SAS (2012) software package and treatment means differences were separated using Turkey test.The result showed that higher ($P<0.05$) weight gain was obtained in birds fed control and T_3 diets and improved ($P<0.05$) feed:gain was obtained in T_3 diets group. Feed cost/kg gain was lowest ($P<0.05$) in T_3 and T_4 diet. Crude protein, crude fiber and crude fat digestibility were similar ($p>0.05$) among control, T_3 and T_4 groups but higher ($p<0.05$) than T_2 group. In conclusion, minimum inclusion of 0.05% supplemental Nutrizyme improved performance and digestibility of nutrients with lower feed cost/kg gain in broiler finisher chickens fed FSBCM based diets.

Introduction

The intensive competition between man and his livestock for scarce conventional feed ingredients has resulted to high cost of producing poultry birds and its products, hence calling for urgent utilization of potential agroforestry by-products such as shea butter cake (SBC). The SBC, as a by-product obtained during the processing of shea nuts to produce shea butter, has been identified to spare these conventional feed ingredients in livestock diets because of their low price, availability and high nutritional potential (Orogun *et al*., 2015). Currently, probiotics and enzymes have been used as a feed additive in diets of different classes of poultry to enhance productive performance and immune responses (Patil *et al*., 2015**).** In this regard, the effect of addition of feed additives such as enzymes and probiotics to poultry diets of different nutritive values has been investigated and resulted in positive effects on live body weight, feed:gain, carcass yield and serum profile of the birds, regardless if it was added to a nutritionally-adequate diet or a diet of diminished nutritive value (Zhang *et al*., 2014). Studies have shown that enzymes and probiotics exhibit the potential to maintaining beneficial microflora in the gastrointestinal tract by inhibiting the growth of pathogenic microorganisms and increase the efficiency of nutrient utilization through improving the intestinal health resulting in higher activities of endogenous enzymes (Angel *et al*., 2011; Chiang and Pan, 2012; Dida, 2016; Getachew, 2016).The use of probiotics and exogenous enzymes in poultry feeds to improve bird performance is not a new practice but has long been documented but the information on the synergy of the two feed additives has been scanty**.** Based on this information, this present study was conducted to evaluate the performance of broiler chickens fed fermented shea butter cake meal with Nutrizyme (cocktail of enzymes+probiotics) supplementation.

Results

The nutrient composition of the experimental diets as shown in Table 1 depicted that they were all isonitrogenous and isocaloric. Performance characteristics of broiler finisher chickens fed experimental diets are presented in Table 2. Average final body weight and body weight gain of the

birds fed control diet were higher (P<0.05) than other treatment diets, while those fed T3 and T4 were similar (P>0.05) but higher than those fed T2 diet which recorded the lowest (P<0.05) mean values. Birds fed T4 recorded the lowest (P<0.05) average feed intake followed by those fed T3 while those fed control and T2 diets have similar (P>0.05) higher average feed intake. The FCR of birds fed control diet did not differ (P>0.05) from those fed T3 and T4 but significantly (P<0.05) lower than those fed T2. The feed cost/kg gain of birds fed T3 and T4 diets were similar but significantly lower (P<0.05) than those fed control and T2 diets.The apparent nutrient digestibility of broiler finisher chickens fed experimental diets are presented in Table 3. Birds fed control diet had similar (P>0.05) crude protein digestibility with birds fed T3 and T4, but were higher (P<0.05) than those group fed T2. Birds fed T3 had the highest (P<0.05) crude fiber and fat digestibility and was similar to those fed control and T4, while those fed T2 recorded the lowest (P<0.05) mean values.

Discussion

Supplementation of Nutrizyme in FSBC based diets revealed significant improvement in live body weights, weight gain, feed intake and FCR as well as crude protein and fiber digestibility of birds compared to the group without supplemental Nutrizyme. Higher growth rate of birds in Nutrizyme group may be attributed to inhibition of growth of the enteropathogens in the gut by decreasing the intestinal pH and efficient utilization of nutrients by the beneficial microbes. Edwin *et al.* (2002), reported improved live weight due to multi-enzymes in diet. The increased weight gain observed in T3 and T4 may be due to the activities of the probiotic microbes. This is supported by the report of previous findings (Mansoub, 2010; Amer and Khan, 2012) that probiotic microbes elaborate digestive enzymes which help the host enzymes to increase digestibility and improve efficiency of feed utilization and weight gain. Also, it has been demonstrated that probiotics and enzymes have the potential to breakdown complex feed into smaller substances making their digestion and absorption by the host animal easier (Ghomi *et al*., 2012; Chuka, 2014). Moreover, birds receiving the diet with supplemental Nutrizyme had improved feed conversion ratio similar to control group than those on FSBC diet without supplemental Nutrizyme. This is attributed to enhancement of feed utilization efficiency and bioavailability of nutrients due to combined effect of supplemental enzymes and probiotics in the broiler's diet (Craig *et al*., 2008; Chiang and Pan, 2012; Dida, 2016). These findings are in accordance with Elongvan *et al*. (2004) who also reported better feed:gain on addition of probiotic and enzymes in diet of quails. In addition, earlier studies have shown that availability of better quality nutrients may increase the release of endogenous enzymes (Zhou *et al*., 2013); thus improving the nutrient digestibility and performance in broiler chicken (Tazi et al., 2014).

Conclusion and Recommendation

Supplementation of the fermented sheabutter cake meal based diet with Nutrizyme (cocktail of enzymes and probiotics) at a minimum inclusion of 0.05% showed an improved performance and nutrient digestibility in broiler finisher chickens. Therefore, utilization of agroforestry byproducts in poultry diets allows for the option of combined supplementation of enzymes and probiotics to enhance growth and feed:gain with lower net feed costs.

ABSTRACT

This study was carried out to determine the utilization of dietary levels of parkia pulp meal by weaner rabbits. A total of 16 weaner rabbits were usedand the Parkia pulp meal was included at 0, 33.3, 66.7 and 100% levels in a completely randomized design. The experiment was conducted in 4 replicates per treatment. Data were collected on daily feed intake, daily weight gain and carcass analysis. The daily feed intake ranged from 45.58-51.12g on diet 2 and 3 respectively while the daily weight gain ranged from 11.43-13.57 on diets 4 and 1 respectively. The best FCR of 3.23 was recorded on the control diet and this shows progressive decline with increasing inclusion levels of parkia pulp meal. However, the result of the experiment showed a non significant treatment effect on all the performance parameters. The carcass analysis also showed a non significant treatment effect on all the parameters except the liver and large intestine ($P<0.005$). The feed cost/kg also ranged from 4.31-90.02 on diet 4 and 1 respectively. The feed cost/kg weight gain also ranged from N290.70-355.73 on diets 1 and 4 respectively. The result shows that parkia pulp meal can only replace 33.3% of maize in weaner rabbits diets because at higher level the cost per kg is higher.

Key Words: Maize, parkia pulp, performance carcass, rabbits

INTRODUCTION

The high cost of grains caused by high demand by man, livestock and industries has necessitated the need to source for other viable alternative energy sources for the animals. One of such alternative is parkia pulp meal. Parkia pulp meal obtained from the African locust bean (ALBP) fruit (*parkia biglobosa)* after the husk and seed have been removed. The African locust bean tree is a perennial legume which belongs to the sub family *mimosoidea* and family *leguminosea i*n West African subregion. According to Abeke (2005) the seed represent 10% of the fruit while the pulp is 90% and it composition depends on the variety, climate and processing technique.

The parkia pulp which is a yellow powdery substance is used by natives in making gruel (Kunu). It is very rich in carbohydrate which makes it an excellent energy source. According to (Akoma 2001) parkia pulp is use in rural Africa during emergencies occassioned by grain scarcity which is an indication of its edibility and non toxicity. It has low level low level of anti nutritional factors which is an indication that parkia pulp meal is partially safe for incorporation into broiler chickens. The proximate composition of locust bean pulp reported by Afolayan *et al (*2014) indicated that it has a low CP content of 3.1%, NFE of 66.39% and apparent metabolizable energy value of 2344kcal/kg. Bot *et al* (2013) reported a CP of 11.52%, CF of 12.49%, EE of 3.09%, ash of 4.08 and Nitrogen Free Extract of 68 32%. The wide variation in CP (3.1-11.52%) could be attributed to geographical locations, varietal differences or method of processing.

In a feeding trial with locust bean pulp meal as an energy source in diet for egg type chickens, inclusion levels of 22.3 and 30% LBP were recommended for chicks and pullets diets respectively (Afolayan et al 2014). Bot *et al* (2013) used LBP as alternative energy source in broilers diet and concluded that broiler chickens can tolerate up to 25% of LBPM without a negative effect on performances. This research was conducted to evaluate the performance of weaner rabbits fed graded levels of ALBPM as replacement for maize.

MATERIALS AND METHODS

This study was conducted at the Rabbitry Unit, Teaching and Research Farm, Abubakar Tafawa Balewa University Bauchi. Bauchi is located within the Northern Guinea Savannah Ecological Zone at Latitude 10^1 17^N and Longitude 9^1 19^1E at altitude 6902m above sea level. The area is characterized by two distinct seasons (dry and rainy). The dry season begins in October and end in April with a

temperature range of 13.7^0-38^0C, while the rainy season is from April-September with a temperature range of 16-32^0C.

Experimental Design and Management of the Rabbits

Sixteen weaner rabbits of Mongrel breed were used for the study in a completely randomized design. The study was conducted over a period of five (5) weeks after an adjustment period of five (5) days. The rabbits were each housed in a metabolic cages. Feed and water were supplied *ad libitum.* Daily record of feed intake and weekly weight were taken.

There were Four experimental diets containing varying replacement levels of ALBPM: 0,33.33, 66.67 and 100% for maize designated as diets 1,2,3 and 4 respectively. The experimental diets were as shown in Table 1. The experiment was conducted in four (4) replicates of one rabbit per replicate.

Data Collection

Daily feed intake and weekly weight gain were recorded over the five weeks of the study, which form the performance parameters. The Cacass characteristics data were generated at the end of the feeding trial when all the rabbits were slaughtered, skinned, eviscerated and various organs weighted and values recorded as percentage of live weight

Statistical Analysis

The data generated above were analyzed using SPSS (2012) and means were separated using DMRT.

RESULTS AND DISCUSSION

The performance of rabbits fed graded levels of ALBPM were as shown in Table 2. The results of the daily feed intake, daily weight gain and feed conversion ratio showed a non significant dietary treatment effect. The daily feed intake ranged from 45.58-51.12g on diets 2 and 3. This finding contradicts the report of Bot (2013) on broiler chickens and Afolayan et al (2014) on layers fed ALBPM. The daily weight gain of rabbits though not significant showed progressive decrease with increase in inclusion level of ALBPM. This could be due to the higher energy value of maize compared to the experimental material. This is in agreement with Bot *et al* (2013) that also recorded significant decline in daily weight gain with increasing levels of ALBPM in broiler chickens diet which they attributed to low energy and higher levels of fibre and increase powdery nature of diets as the level of ALBPM increased. Similarly, the FCR also showed a non significant progressive increase with increase in ALBPM inclusion level where values of 3.23 -4.27 were obtained on control and diet 4 (100% ALBPM replacement) respectively. This agrees with Kwari and Igwebuike (2002) that also reported an increase in feed conversion ratio with increase in parkia pulp in broilers diet. Bot *et al* (2013) and Afolayan et al (2014) also reported a significant increase in FCR as the level of parkia pulp increase in broilers and layers diets respectively. The reduced feed efficiency on the test diets compared to the control diet could be due to reduced growth rate with inclusion of the experimental material. The cost analysis (Table 4) which was computed using the prices of the feed ingredients during the time of the research showed decrease in cost per kg of feed (₦ 84.31-90.30 on diet 4 and 1 respectively) with increase in parkia pulp meal inclusion level. The feed cost per kg weight gain however showed progressive increased with increasing level of test material inclusion. The cost ranged from ₦290.77-360.00 on control and diets 4 respectively. This finding contradicts the expectation that the use of unconventional feed ingredients in non-ruminant feed would result into cheaper cost of production (Abeke 2005). This is however related to the lower protein content of the experimental material and reduced performance recorded with its inclusion.

The carcass analysis of rabbits fed varying levels of ALBPM is shown on Table 3. Most of the parameters analyzed showed a non significant treatment effect. The weight of the liver and large intestine though were significantly ($p<0.05$) affected by dietary treatments, were not following any regular pattern. This finding shows that the inclusion of ALBPM in the diet of weaner rabbits has no negative effect on the carcass characteristics of rabbits.

CONCLUSION

From the results of this study, the following conclusions were drawn:

1. Replacing 33.3% of maize with parkia pulp meal has no negative effect on performance and feed cost of weaner rabbits

2. Higher inclusion level of parkia pulp meal in rabbits diets leds to reduced cost /kg of feed and increased feed cost per kg weight gained.

3. Inclusion of parkia pulp in weaner rabbits diet has no negative effect on their carcass characteristics

Abstract
This study evaluated the growth performance and cost benefits of broiler chickens fed diets containing garlic powder, ginger powder or their combination as additives at 0-4weeks of age. A total of 240 day old broiler chicks were randomly assigned to four dietary treatments formulated to meet nutrient requirements at the starter phase. Control diet contained neither garlic nor ginger powder. The second diet contained garlic powder at 5g/kg diet, the third diet contained ginger powder at 5g/kg diet while the fourth diet contained a combination of garlic and ginger powder each at 2.5g/kg diet. The birds were randomly allotted to the four dietary treatments in six replicates and fed ad libitum for four weeks. Data were collected on growth performance and cost estimations were made on diets and feeding. Higher (p<0.05) feed intake, cost per kilogramme diet, cost of feed per bird and cost per kilogramme weight gain were recorded among birds fed diets containing the feed additives. Feed conversion ratio was lowered (p<0.05) in birds fed the control diet. Mortality rate was reduced (p<0.05) with inclusion of garlic or ginger at a rate of 5g/kg or their combination at 2.5g each/kg in diet of starter broilers. The study concluded that garlic powder or ginger powder (5g/kg diet) or their combination (2.5g each/kg diet) could be explored as feed additives at the starter phase of broiler chickens production where organic growth as well as effective reduction in mortality is paramount.

Key words: garlic, ginger, additive, performance, livability.

Introduction
Modern production of poultry particularly the meat type requires very short and fast production cycles and hence fast growth rate of birds to meet increasing demands. It is an interesting fact that chicks grow fast and gain up to seven times their hatch weight in the first month while building healthy digestive tract and immune system will improve their growth (AAF, 2018). The gut and general health as well as performance of the poultry are greatly influenced by the intestinal microbial community and the complex interaction with the host birds (De Guseem, 2018). Gut health and immune support tools and strategies are therefore key requirements in a starter-grower nutrition. Antibiotic or antimicrobial growth promoters have hitherto been intensively used in broiler's rations to improve health, performance and productivity (Immerseel, 2019). However, they are now infamous because of the resultant bacterial resistance and their negative impacts on the consumers' health over time. The use of safer alternatives like phytogenic feed additives which offer with affordable costs, reduced risk of toxicity, minimum health hazard, and high suitability, positive consumer opinions and acceptance, and environmental friendliness (Rehman and Munir, 2015; Jones, 2018) have been gaining popularity over the years. Phytogenics including herbs and spices and their products have flavouring properties and exert effects on the gut environment or gut cell wall of animals and enhance the effectiveness of nutrient utilization for better health and productivity (Hanieh *et al*., 2010; Al-Shuwali *et al*., 2015; AAF, 2018; Jones, 2018). Hence, the use of phytogenic substances such as garlic and ginger. While garlic (*Allium sativum*) has been used as natural feed additives in poultry nutrition for broiler and growers due to its antibacterial and immune-modulatory properties (Rehman and Munir, 2015), inclusion of ginger in the diet of broilers have been reported to aid weight gain and feed conversion (Safa, 2014). Al-Shuwali *et al.* (2015) opined that garlic and ginger have strong stimulating effects on immune and digestive systems of birds. Recent research works on the combination of ginger and garlic as feed additives (Issa *et al*., 2012; Karangiya *et al*., 2016) have shown encouraging results with regards to weight gain, feed efficiency and lowered mortality in poultry. Confusion about choice of product, perceived lack of sufficient commercial and scientic data to support the efficicacy of products and whether they have real economic benefits may desuade animal producers and feed

manufacturers from using phytogenics (Jones, 2018). Therefore, according to De Guseem (2018), the next and best approach in use of alternative additives for improved gut health and animal performance is to list what has been achieved with the estimated cost per kilogramme bird produced. However, there is a dearth of report on the cost benefits of garlic and ginger as feed additive for broiler starter and this necessitated this study.

Materials and Methods

The study was carried out at the Poultry Unit of the Directorate of University Farms, Federal University of Agriculture, Abeokuta, Nigeria. The area is located in the derived savannah vegetation zone of Southwest Nigeria with altitude 76m above sea level; latidude (7.1475^0N and 3.3619^0E), and an average temperature of 34^0C (Google Earth, 2019).

The test ingredients, processed garlic and ginger powder were sourced from open market and incorporated into a basal starter diet formulated to contain 22% crude protein and metabolizable energy of 2873kcal/kg. The control diet had no garlic or ginger powder as additive. Diets 2 and 3 had garlic powder and ginger powder included respectively, at a rate of 5g/kg diet while diet 4 had each of garlic and ginger powder included at a rate of 2.5g/kg diet.

A total of two hundred and forty day old broiler chicks were obtained from a reputable hatchery and randomly allocated into the four dietary treatments in six replicates. The birds were reared under good animal production practices. The respective starter diet according to treatment as well as water was provided to the birds *ad libitum* for a period of four weeks. Performance parameters such as feed intake, weight gain and feed conversion ratio were recorded according to treatment and replicate. Prevailing market prices of feed and test ingredients were used to determine costs: per kilogramme diet, of feed consumed per bird and per kilogram body weight gain. All data collected were subjected to one way analysis of variance using the SAS statistical package (SAS, 2002) while significant means were separated using Duncan Multiple Range Test as contained in SAS.

Results and Discussion

Effect of inclusion of powdered garlic, ginger or their combination as feed additive on the growth performance of broiler chickens at the starter phase is presented in Table 1. Dietary inclusion of ground garlic, ginger or their combination had no influence ($p>0.05$) on final weight and daily weight gain of starter broiler chickens. Non-significant effects observed in the final weight and daily weight gain of 0-4weeks old broiler chickens in this study showed that the phytogenic additives used did not influence those parameters. This is in agreements with findings (Demir *et al.,* 2003; Issa *et al.,* 2012) that inclusion of garlic in diets for broiler chickens did not influence performance. However, daily feed intake (DFI), feed conversion ratio (FCR) and mortality of starting broiler chickens were significantly ($p<0.05$) influenced by dietary treatments. Birds fed the control diet recorded least DFI and FCR (57.88g/d and 1.56, respectively). These were higher and similar among additives treatment groups. High feed intake was observed among birds on phytogenics based diets. This is in line with findings (Mohammed *et al.,* 2012 and Karangiya *et al.,* 2016) that inclusion of ginger powder in the diets of broilers resulted in positive effect on feed intake. The report of Javandel *et al.* (2008) showed that higher levels of feed consumption was obtained when broiler chickens were fed diets with garlic inclusion. However, Oloyede *et al.* (2017) reported lower feed consumption of garlic based diets. This was not the case in the present study as the birds under this dietary treatment had higher feed intake.

Birds in all the treatment groups had similar final weight and daily weight gain, indicating that the stimulating effect of ground garlic, ginger or their combination on feed intake did not translate to higher weight gain in the birds. This probably explains why the feed conversion ratio was poor for the birds in the phytogenic treated groups. Disparity between the results obtained in this trial and those of other researchers could be due to variations in actual bioactive ingredient intake due to variations in composition of the phytogenic material which could be affected by climate, harvesting conditions among other factors as exposited by Maurin (2018).

No mortality was recorded for birds fed diets containing garlic, ginger or their combination. However, birds on the control diet recorded mortality rate of 0.83% indicating that the phytogenic feed additives impacted better immunity on the birds and hence higher livabilty. This suggests beneficial effects of phytogenics on the health of the birds. The report of Rehman and Munir (2015) and Karangiya *et al.* (2016) indicated that the use of these phytogenics improved immune system of birds give credence to the result obtained in this trial.

Table 1: Growth performance of broiler chickens fed diets containing garlic and ginger as additives at starter phase (0-4 weeks)

Parameters	Control (0g/kg)	Garlic (5g/kg)	Ginger (5g/kg)	Garlic (2.5g/kg) + Ginger (2.5g/kg)	P-value	SEM
Initial weight (g/b)	40.00	40.00	40.00	40.00	0.000	0.000
Final weight (g/b)	1082.00	1015.50	1063.50	1048.33	0.52	15.674
Daily weight gain (g/b)	37.21	34.84	36.55	36.01	0.52	0.55978
Daily feed intake (g/b)	57.88^{b}	62.64^{a}	62.59^{a}	62.76^{a}	0.01	0.661
Feed conversion ratio	1.56^{b}	1.80^{a}	1.71^{ab}	1.77^{a}	0.025	0.032
Mortality (%)	0.83^{a}	0.00^{b}	0.00^{b}	0.00^{b}	<0.001	0.085

^{ab} - means within same row having different subscript differ significantly ($p<0.05$, $p<0.01$, $p<0.001$))

All the feed cost parameters measured were significantly ($p<0.001$) influenced by the dietary treatments. Cost per kilogramme feed (CKF) increased ($p<0.001$) with inclusion of the phytogenic feed additives. Diet with garlic powder as additive had highest ($p<0.001$) CKF (₦190.15/kg) while the control diet had the least (₦174.90/kg). Values recorded for feed cost per bird (FCB) and feed cost per kilogramme weight gain (FCKWG) were similar across the phytogenic groups while birds in the control group recorded significantly ($p<0.001$) lower FCB (₦283.46) and FCKWG (₦272.70). Increased cost of feed as well as higher cost of feed consumed per bird with the inclusion of garlic and ginger in the diet is obviously due to additional cost of the garlic and ginger powder added to the diet. In the same vein, high feed cost per kilogramme weight gain obtained for birds fed diets containing garlic, ginger or their combination was due to the higher cost of feed coupled with their higher values of feed conversion ratio. As opined by Maurin (2018), costs of utilizing phytogenics like ginger and garlic are non-negligible while the expensive nature of their use may be due to low exploration and the need to use them in appreciable quantities.

Table 2: Cost benefits of broiler chickens fed diets containing garlic and ginger as additives at starter phase (0-4 weeks)

Parameters	Control (0g/kg)	Garlic (5g/kg)	Ginger (5g/kg)	Garlic (2.5g/kg) + Ginger (2.5g/kg)	P-value	SEM
Feed cost per kilogramme diet (₦/kg)	174.90^{d}	190.15^{a}	189.10^{c}	189.62^{b}	<0.001	1.332
Cost of feed consumed (₦)	283.46^{b}	333.51^{a}	331.40^{a}	333.20^{a}	<0.001	5.153
Feed cost per kilogramme weight gain (₦/kg)	272.70^{b}	342.05^{a}	324.02^{a}	334.77^{a}	<0.001	7.364

^{abcd} - means within same row having different subscript differ significantly ($p<0.001$)

Conclusion

Feed intake, cost per kilogramme diet, cost of feed per bird and cost per kilogramme weight gain were increased with inclusion of garlic or ginger at a rate of 5g/kg or their combination at 2.5g each/kg in diet of starter broiler chickens. Poor feed conversion ratio was obtained when garlic or ginger or their combination was included in the diets of starter broiler chickens. No mortality was recorded for the birds in the phytogenic fed groups. It is therefore recommended that garlic powder or ginger powder at inclusion rate of 5g/kg diet or their combination (2.5g each/kg diet) can be explored as feed additives at the starter phase of broiler chickens for improved livabilty of birds.

Abstract

An experiment was conducted to evaluate the effects of differently processed mango seed kernel meal (MSKM) on broiler chickens for eight weeks. The processing methods include: soaking for 24 and 72hours, boiling and soaking and boiling. The level of anti-nutritional factors and performance of broiler chickens were obtained. The results indicated that the different processing methods reduced the anti-nutritional factors: boiled and soaked has the best percentage reduction of tannin (84.31%), and oxalate (37.08%), Boiled mango seed kernel has the highest percentage reduction of saponin (35.68%) and flavonoid (34.15%), while Soaked for 24hours reduces alkaloid (47.43%) better compared to boiling (32.87%). Two hundred and twenty-five (225) day old broiler chicks were randomly allotted to five dietary treatments with three replicates of 15 birds each in completely randomized design. The experimental diets consisted of raw, soaked for 24hours, soaked for 72hours, boiled and soaked and boiled mango seed kernel meal included at 10% in both broiler starter and finisher diets designated as T1, T2, T3, T4 and T5. The performance results show that final weight at the finisher phase were significantly (P<0.05) higher in T2 (1583.33g) compared to all other treatments. The average water intake in the finisher was significantly (P<0.05) higher in birds fed soaked 72hours (T3) and soaked and boiled MSKM than the other treatments. There were no significant differences in the feed intake, weight gain, feed conversion ratio in both the starter and finisher phase. Treatment 5 recorded the lowest feed cost per kg weight gain (306.31₦/kg) in the starter phase while at the finisher phase it ranges from 231.46-297.54₦/kg in T5 and T4 respectively. From the experiment conducted, it is therefore concluded that different processing method can be used to reduce the effect of anti-nutritional factors and mango seed kernel can be used in broiler diet without adverse effects on the birds, although soaked for 24 hours' mango seed kernel gave the best result.

Keywords: mango seed kernel, anti-nutritional factors, broiler chickens, performance

Introduction

Mango seeds contain some anti-nutritional factors such as tannin, phytic acid, oxalic acid, trypsin inhibitors etc. Tannins are responsible for astringent taste, low digestibility of the feed, hence reduced feed intake due to reduction in palatability and /or acceptability (Rafiu *et al.,* 2014), which is in contrary to its good source of soluble carbohydrates (Diarra and Usman, 2008). Drying, soaking, leaching and fermentation have been reported to be simple means of detoxifying these feed sources to reduce the presence of anti-nutrients and toxic components (Aregheore, 1998). Boiling has been reported to be effective in reducing the tannin content of mango kernel (Diarra and Usman 2008). Similarly, boiling reduced the tannin content of the kernel from 9.89 to 1.26%, representing about 87.26% reduction (Diarra *et al*. 2011). Diarra *et al.* (2010) reported no adverse effect of boiling on the crude protein, crude fibre, ether extract and nitrogen free-extract of the kernel. This research is aimed at determining the effect of differently processed mango seed kernel on anti-nutritional factors content and growth performance

Materials and Methods

Experimental Site:

The experiment was conducted at the Poultry Unit of Bauchi State College of Agriculture Bauchi Teaching and Research farm. Bauchi State occupies a total land area of 49,119 km² representing about 5.3% of Nigeria's total land mass and is located between latitudes 9° 3' and 12° 3' North and longitudes 8° 50' and 11° East (BSD, 2009).

Experimental Design and Management of Birds

A total of two hundred and twenty-five (225) broiler chicks were used for the experiment. They were randomly divided into five treatment groups of 45 chicks per group in a completely randomized

design (CRD) consisting of three replicates of 15 birds each. Birds were reared on a deep litter, with feed and water provided *ad libitum*. Left over feed and body weight of birds were monitored on a weekly basis for the starter and finisher phases of the experiment and routine vaccines were given as recommended. All feed not consumed were removed, weighed and deducted from feed given daily to get the daily feed intake. Daily water consumption is obtained by subtracting left over water from the total volume of water supplied.

Collection and Processing of Mango seed into Mango Seed Kernel Meal

Mango Seed Kernel were collected from various locations in Sibire, Ardo kola LGA of Taraba State. The kernels were obtained by cutting the seed coat using a knife or crushed with a hammer. The Mango Seed Kernel (MSK) obtained were divided into five parts. The parts processed either by soaking for 24 and 72 hours, boiling and soaking for 24 hours and boiled.

Soaking of mango seed kernel for 24 hours

The Mango Seed Kernel were soaked in water for 24 hours at the rate of 100g per 1.5 litre of water in containers. The water was changed at regular intervals of 8 hours. The Mango Seed Kernels were then removed and sundried. The dried MSK were then milled before incorporation into the diets.

Soaking of mango seed kernel for 72 hours

The Mango Seed Kernel were soaked in water for 72 hours at the rate of 100g per 1.5 litre of water in containers. The water was changed at regular intervals of 8 hours for 3 days. The Mango Seed Kernels were then removed and sundried. The dried MSK were then milled before incorporation into the diets.

Boiling of mango seeds kernel

The Mango Seeds Kernel were put in boiling water at the rate of 100g per 1.5 litre of water at 100°C temperature for 30 minutes. The sample were removed, drained, sun dried, and milled before incorporation into the diets.

Soaking for 24 hours and boiling of mango seeds kernel

The Mango Seed Kernel were soaked in water for 24 hours at the rate of 100g per 1.5 litre of water in containers. The Mango Seeds Kernel was put in boiling water at the rate of 100g per litre and half of water at 100°C temperature for 30 minutes. The sample was removed, drained, sun dried, and milled before incorporation into the diets.

Experimental Diets

Five broiler starter and finisher diets were formulated. Diet 1 was the control 10% raw MSKM, diet 2, 3,4 and 5 contained soaked for 24 hours, soaked for 72 hours, soaked for 24 hours and boiled and boiled MSKM respectively all at 10% level of inclusion as replacement for maize.

Determination of anti-nutritional factors in mango seeds kernel

The anti-nutrient compositions of raw and differently processed samples of mango seed kernel were determined by the methods, Mega (1982) and Fasset (1966).

Results and Discussions

Effects of processing Methods on the Levels of Anti-Nutritional Factors in Mango Seed Kernel

The values obtained for anti-nutritional factors shows that the raw mango seed kernel were higher than those processed. The reduction of tannin content in this study (78.43%) for boiled MSKM is in agreement with the findings of Mbajunwa (1995) and Diarra and Usman (2008). These authors observed that cooking is an efficient method of reducing the tannin content of feeds. This level is however, higher than the 75% reduction obtained by Diarra and Usman (2008) under the same conditions of heat and time, probably due to differences in the solubility of the tannins in mango kernel varieties. The reduction in tannin level obtained with boiling mango seed kernel in this study, agrees with the report of Kaankuka *et al*., (1996) who observed that cooking was effective in reducing tannin content of soybean seeds. However, the percentage (78.43% and 84.31%) for both boiled and soaked and boiled were higher than 77.06% reported by Chia *et al*. (1997) after cooking *Phaseoulus angularis* and *D. lablab* for 60 minutes.

The percentage of saponin (raw mango kernel) 11.07% is higher than 2.96% reported by Orayaga *et al.,* (2018). Percentage reduction of Alkaloid, Oxalate and Flavonoid ranged from 32.87-47.43%, 12.92-37.08% and 16.58-34.15% respectively which agree with Dakare *et al.,* 2012) 22.6 -90.6%, 11.1 -65.1%, 16.4 -95.1% respectively. Processing methods was observed reduces the quantity of anti-nutritional factors in mango seed kernel.

Performance of Broiler Chickens Fed MSKM

The increased weight gains as well as final body weight during the finisher phase of broiler chickens fed differently processed mango seed kernel meal could be due to the fact that during boiling, some of the nutrients might have been denatured as reported by Parsons *et al*. (1992) and the leaching of soluble proteins in processing water. Mbajunwa (1995) also reported the leaching of soluble minerals in water. This could be the reason for the reduced weight gain and final weight of birds that were fed boiled mango seed kernel. The weight gain of the started phase ranged from 17.55-20.32g/b/d is similar to 14.40-20.42 g/b/d as reported by Diarra and Usman (2008). The average feed intake (94.93-105.64 g/b/d), average weight gain (33.97-47.68 g/b/d) and feed conversion ratio (2.25-2.96) of the finisher phase is similar to 104.15-109.06 g/b/d feed intake, 30.25-38.85g/b/d weight gain and 2.81-3.47 feed conversion ratio as reported by Orayaga *et al.,* (2015).

Conclusion and Recommendation

Different processing method can be used to reduce the effect of anti-nutritional factors. MSKM can be used in broiler diet without adverse effects on the birds, although soaked for 24 hours' mango seed kernel gave the best result. Other processing methods other than soaking and boiling that will help detoxify and improve the nutritive value of mango seed kernel should be investigated.

PERFORMANCE AND HAEMATOLOGICAL PARAMETERS OF LAYING HENS FED DIETS SUPPLEMENTED WITH SELENIUM AND VITAMIN E

Jemiseye, F. O., Ogunwole, O. A., Adedeji, B. S. and Mosuro, A. O.
Agricultural Biochemistry & Nutrition Unit, Department of Animal Science, University of Ibadan, Ibadan, Nigeria

Abstract
An experiment was conducted to assess the effect of supplemental selenium and vitamin E on performance and blood profile of laying hens. In a completely randomised design, ISA brown hens (n=192) at week 20 of age were assigned to six experimental diets: T1 (Basal diet), T2 (Basal diet + 0.5 mg selenium), T3 (Basal diet + 1.0 mg selenium), T4 (Basal diet + 1.5 mg selenium), T5 (Basal diet + 20 mg vitamin E), T6 (Basal diet + 40 mg vitamin E*). Each treatment was replicated four times with eight birds per replicate. Data were recorded daily for performance characteristics.* At week 26, blood was sampled from hens and analysed using standard procedures. Supplemental selenium and vitamin E had no significant effect ($p>0.05$) on hens' *p*erformance. However, dietary supplemental selenium and vitamin E had significant influence on eosinophils and monocytes. Eosinophils of hens on T1 (4.25) was similar to 4.00, 3.50, 4.33 and 3.75 recorded for hens on T2, T3, T4 and T5, respectively but higher than 1.33 obtained for hens on T6. Similarly, monocyte value in T1 (2.0) was similar ($p>0.05$) to T2 (3.25) and T3 (3.25) but lower than 4.00, 3.75 and 4.00 obtained in hens on T4, T5 and T6, respectively. It was therefore concluded that supplementation of vitamin E and selenium up to 40 mg/kg and 1.5 mg/kg, respectively had no significant effects on hen's performance.

Introduction
Stress exerts negative effects on the body such as disturbance of acid-base balance of the blood, various changes in metabolism and oxidative damage to the cells (Ertas and Sahik 2002). This often has resultant effect on egg production and quality, feed consumption, live weight and overall productivity in chickens.

When formulating feed for animals, nutritionists take into account several factors including stress management and immunity enhancement as very critical (Linge, 2005). The use of antioxidant nutrients in this respect cannot be overemphasized. Antioxidants are substances that can scavenge, suppress or reduce the formation of reactive oxygen species (Khan *et al*., 2011; Lu *et al*., 2010) that are constantly produced *in vivo* in the course of the physiological metabolism in tissues (Surai, 2015). Reactive oxygen species are detrimental to productive performance in laying birds (Assar *et al*., 2016). Antioxidants nutrients such as vitamin E and selenium *have been implicated in immune functions of domestic animals (Finch and Turner, 1996) and* with important roles in maintaining chicken health, productive and reproductive performance (Surai, 2002). However, there have been conflicting reports (Scheideler, 2010: Adebiyi *et al*., 2004) on the benefits of Selenium and vitamin E in poultry. *Therefore, t*he objective of this study was to evaluate the effect of dietary selenium and α-tocopherol supplementation on performance and haematological status of laying hens.

Materials and methods
Experimental Site and Animal Allotment
The experiment was carried out at the Poultry Unit of the Teaching and Research Farm, University of Ibadan, Ibadan, Nigeria. *A total of 192, ISA brown hens at the point of lay (20 weeks of age) were assigned to six experimental diets in an experiment that lasted twenty weeks. The experiment was a completely randomized design with each treatment replicated four times and with eight birds per replicate.*

Experimental Diets
Basal diet was supplemented with selenium and vitamin E as follows: T1=Basal diet, T2=Basal diet + 0.5mg selenium/kg, T3= Basal diet + 1.0mg selenium/kg, T4= Basal diet + 1.5mg selenium/kg, T5=Basal diet + 20mg vitamin E/kg, T6=Basal diet + 40mg vitamin E/kg*)* Feed and water were supplied *ad libitum*. (Jemiseye and Ogunwole 2019).

Data collection and analysis

During the period of the trial, pen temperature-humidity index was monitored three times daily, between the hours of 7:00-8:00, 12:00-13:00 and 17:00-18:00 using digital thermo-hygrotherms placed strategically at different locations within the pen house. Temperature Humidity Index (THI) was calculated from the average ambient temperature and relative humidity obtained using the formula: $THI = 0.6\ T_{db} + 0.4\ T_{wb}$, where, T_{db} = dry bulb temperature and T_{wb} = wet bulb temperature. Eggs were collected daily and recorded, hen day egg production was calculated by number of eggs laid divided by number of chicken at the period of data collection, feed intake was calculated by subtracting left over from feed offered to the chickens, egg were weighed with sensitive scale to obtain egg weight and egg mass was calculated from the percent hen day egg production and average egg weight. At week 26 of laying, blood was collected from two birds per replicate via the jugular vein into heparinized test tubes for haematology. Packed cell volume (PCV), haemoglobin (Hb), red blood cells (RBC), white blood cells (WBC) and differential counts were determined using standard procedures (Schalm *et al.*, 1975).

Statistical analysis

Data were subjected to analysis of variance using the SAS (1999) package. Means were separated using Duncan's multiple range test of the same package.

Results and Discussion

Temperature-humidity index of the experimental pen: Temperature-Humidity index of the experimental pen is shown in Figure 1. The maximum and minimum values were 30.40 and 25.10, respectively. The reported temperature and relative humidity were higher than thermoneutral temperature range (18-22 ^{o}C) of laying chicken reported by Charles (2002). Pen house temperatures beyond thermoneutrality have been reported to aggravate stress in chickens (Adedeji and Ogunwole, 2018) as higher ambient temperature and relative humidity have direct implications on feed consumption.

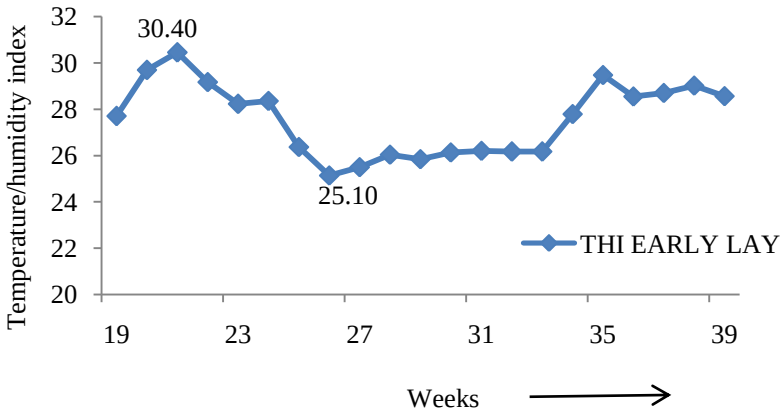

Figure 1: Temperature-humidity index of the experimental pen

Performance of laying chickens: Performance of laying chicken fed diet supplemented with selenium and vitamin E is shown in Table 1. **S**upplementation of layers' diet with selenium and vitamin E at the early laying phase did not have any significant effects ($p>0.05$) on the performance parameters measured. This observation corroborated earlier findings of Adebiyi *et al.* (2014) that neither vitamin E nor selenium and their combination increased hen day percentage and weight in turkeys. Also, Scheideler (2010) reported that there were no overall effect of vitamin E on egg production. Although, high temperatures have been reported to reduce production performance in laying hens (Deng *et al.*, 2012), this was not so as observed in this study. This may further emphasise the alleviating effect of antioxidants (Se and vitamin E) in stress management *(*Khan *et al*., 2011*)*.

Table 1. Performance of laying chicken fed diet supplemented with selenium and vitamin E

Parameters	T1	T2	T3	T4	T5	T6	SEM

Haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation. Table 2 shows the haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation. There were no significant differences (p> 0.05) across treatments for all haematological parameters measured except for monocytes and eosinophils. Eosinophils of hens on T1 (4.25) was similar to 4.00, 3.50, 4.33 and 3.75 recorded for hens on T2, T3, T4 and T5, respectively but higher than 1.33 obtained for hens on T6. Similarly, monocyte value in T1 (2.0) was similar (p>0.05) to T2 (3.25) and T3 (3.25) but lower than 4.00, 3.75 and 4.00 obtained in hens on T4, T5 and T6, respectively. Blood is significant in measuring the physiological, nutritional and pathological status of animals (Olorode *et al*., 2007). Elevated monocyte and eosinophil levels observed in this study was an indication that inclusion of the supplements improved the responsiveness of the immune cells to invading germs. This observation supports earlier position of *Finch and Turner (1996)* on the relevance of Se and vitamin E in immune function. Bush (1991) had earlier pointed out that low levels of WBC especially eosinophil and basophil in chickens could lead to poor immunity against diseases and may be an indication of poor health conditions due to parasitic disturbances. A slight deviation from this was observed in T6 for eosinophils. This however could imply that supplemental vitamin E beyond 20mg/kg of diet may lower eosinophil count in chicken.

Table 2: Haematological parameters of laying chickens fed levels of dietary selenium and vitamin E supplementation

Abstract

The experiment was conducted to evaluate the effect of feeding graded levels of sweet potato meal on performance and haematological indices of broiler chickens. A total of one hundred and eighty Anak strain day-old broiler chickens were fed varying levels of sweet potato meal at 0, 5, 10 and 15% dietary inclusion levels. The birds were randomly allotted to four dietary treatments which were replicated four times with fifteen birds per replicate in a completely randomized design. The compounded experimental diets (starter and finisher) were fed ad libitum. Fresh clean drinking water was given ad libitum throughout the days of the experiment. Routine medications and vaccinations were also observed. Results of haematological indices revealed no significant ($p>0.05$) differences in White Blood Cells (WBC), Haemoglobin (Hb), Mean Corpuscular Volume (MCV) Mean Corpuscular Haemoglobin (MCH), Mean Corpuscular Haemoglobin Concentration (MCHC) and Lymphocyte (LYM) across the treatments. However, significant ($p<0.05$) difference was observed in the concentration of Red Blood Cells (RBC). It was concluded that dietary inclusion of sweet potato meal up to 15% in the diet of broiler chickens at both starter and finisher phases had no negative effects on performance and haematological indices of the birds.

Key words: Sweet Potato, Haematology, Broiler Chickens

Introduction

The scarcity and prohibitive cost of commercial energy sources like maize and sorghum for poultry rations, has been the main cause of the high cost of poultry products especially in developing countries. To arrest this situation, poultry farmers all over the world and particularly those of the developing countries are forced to think of those plants that can be easily grown and yield more *per* unit area as compared to maize for inclusion in poultry rations. This will subsequently lead to a reduction of the cost of production of poultry products (meat and egg) Nazmus (2013). Sweet potato (*Ipomea batatas*) is produced in considerable quantities in Nigeria and form important energy source for human and livestock feeding. The sweet potato meal is readily available at cheap cost in many parts of the country, because it has limited value to some human and for industrial uses. Sweet potato is one of the world's most important food crops; its main nutritional importance has been its starch content. However, sweet potato can also be a source of other nutritionally important dietary factors such as Vitamin A, Ascorbic acid, Thiamin, Riboflavin and Niacin (Dominguez, 1990). The few available reports agree that sweet potato can be incorporated into diets of chickens but should not be made the sole source of energy (Lee, 1979 and Tewe, 1991) as cited by Afolayan (2010). Sweet potato meal (SPM) can be used with an energy value of more than 2830 ME kcal *per* kg. According to composition values, potato meal(PM) contains more than 65% starch, 6.74% ash, 12.72% CP, 23.48% CF, and 0.99% EE on a DM basis. SPM have been reported to be cheaper than maize and wheat (PAN, 1995). Thus, they reduced feed cost and maintain production effici. This study therefore, was designed to evaluate the effect of feeding graded levels of sweet potato meal on performance and haematological indices of broiler chickens.

Materials and Methods

The experiment was conducted at the Poultry Unit of the Teaching and Research farm of the Abubakar Tafawa Balewa University Bauchi. Bauchi State is one of the states in the northern part of Nigeria that span two distinctive vegetation zones, namely; Sudan savannah, and the Sahel savannah. The state is located between latitude 9° 3' and 12° 3' North and longitudes 8° 50' of the equator with a total land area of 49,119 km² representing about 5.3% of Nigeria′s total land mass. One hundred and eighty (180) day-old Anak strain broiler chicks were randomly allotted to four dietary treatments comprising forty-five (45) chicks *per* treatment which were replicated three times, with fifteen chicks *per* replicate in a completely randomized design. Four experimental diets were formulated and designated as A, B, C and D to contain sweet potato meal (SPM) at 0, 5, 10 and 15% levels of inclusion. Treatment one (A) did not contain the test ingredient, it served as control (Table 1). The

diets were formulated to meet the 23% and 20% crude protein requirements of broiler chickens for starter and finisher phases respectively. Fresh sweet potatoes were obtained from potato vendors in Ningi L.G.A of Bauchi State. The roots were washed, chopped using kitchen knife and sun dried for about three (3) days on concrete floor to reduce enzymatic and microbial reactions which may lead to spoilage. The dried sweet potato was milled and incorporated during feed mixing at different levels.Fresh clean drinking water with multivitamins (vitalyte) was given *ad libitum* throughout the days of the experiment. Routine medications and vaccinations were also observed. The experiment lasted for eight weeks.

Data Collection and Statistical Analysis

At the end of the feeding trial (8th week), two birds were selected on the bases of average pen weight from each replicate for collection of blood samples for haematological analysis and carcass measurements. The birds were fasted overnight and blood samples were collected early in the morning through the wing veins into sample tubes containing anti-coagulant. The direct measurement of erythrocytes values;{Haemoglobin (Hb), Packed Cell Volume (PCV), Red Blood Cells (RBC), White Blood Cells (WBC) Mean Corpuscular Haemoglobin (MCH). Absolute erythrocyte indices; {Mean Corpuscular Haemoglobin Concentration (MCHC), and Mean Corpuscular Volume (MCV) were determined using the methods described by Bush (1991). Data on haematological indices were subjected to analysis of variance using Steel and Torrie (1980) and DMRT was used to separate the means.

Table 1 Composition of Experimental Diets at Finisher Phase (20%Cp) (5-8 Weeks) of Age

	% Replacement of Sweet Potato with Maize (SPM)			
Ingredients	A (0)	B (5)	C (10)	D (15)
Maize		52.4	46.62	40.86	35.06

TP (%)		0.66	0.67	0.67	0.66

**Premix contained Vitamin A=12,500 IU; Vitamin D3=3,000 IU; Vitamin E=150mg; Vitamin K=3mg; Vitamin B2=8mg; Vitamin B6=5mg; VitaminB1=2mg; Vitamin B12=30mmg; Nicotinamide 50mg; Pantothenate 10mg; Folic acid 2mg; Biotin 150mmg; Vitamin C 35mg; Choline 300mg; Copper10mg; Manganese 80mg; Zinc 60mg; Iron 30mg; Iodine 2mg; Selenium 0.25mg; Molybdenum 0.2mg; Calcium ($CaCO_3$) limestone 70g/kg*

Results and Discussion

The result of haematological characteristics is presented in Table 2. The values ranged from 1.85 to 2.53% RBC. Birds fed diets C and D presented significantly ($p<0.05$) lower values compared to birds fed diet D (Fig.1). The values obtained for RBC of birds fed sweet potato meal based-diets were lower than the range of 3.07 - $7.05x10^6$/mm³ reported by Fudge (1999) and also lower than 5 - 8x10mm³ as reported by Anon (1980). Hackbath *et al.* (1983) reported that increased RBC values were associated with high quality dietary and disease free animals. RBC is responsible for the transportation of oxygen and carbon dioxide in the blood as well as manufacture of haemoglobin hence higher values

indicates a greater potential for this function and a better state of health (Olugbemi *et al*., 2010). Moreover, the result of RBC in this experiment corresponds with the findings of Onu *et al*. (2011) in their experiment on performance and blood chemistry of starter broilers. However, PCV, WBC, HGB, MCV, MCH, MCHC and LYM were statistically similar ($p>0.05$) among the treatment groups. The comparable values for WBC of birds suggests that the birds were healthy. The PCV count of diet A recorded the highest value of 34.43% followed by diets B and D with the values of 32.17 and 30.83% respectively.

Table 2: Haematological Characteristics of Broiler Birds Fed Different Inclusion Levels of Diets Containing Sweet Potato Meal

(SPM %) Parameters	A (0)	B (5)	C (10)	D (15)	SEM
RBC (%)	2.37^{bc}	1.88^{ab}	1.85^{a}	2.53^{c}	0.15*
WBC (10^{12}/ml)	121.43	105.87	90.07	132.93	12.99^{NS}
PVC (10^{9}/ml)	34.43	32.17	26.93	30.83	13.08^{NS}
HB (g/dl)	16.03	14.00	12.70	15.20	1.58^{NS}

*a,b,c mean within the same row bearing different superscripts differ significantly ($p<0.05$), NS = Not Significant, *= Significant ($p<0.05$), SEM= Standard Error of Mean, RBC= Red blood cell, WBC= White blood cell, PCV= Pack Cell Volume, HB= Haemoglobin, MCV=Mean Corpuscular Volume, MCH = Mean Corpuscular Haemoglobin, MCHC= Mean Corpuscular Haemoglobin Concentration, LYM = Lymphocyte.*

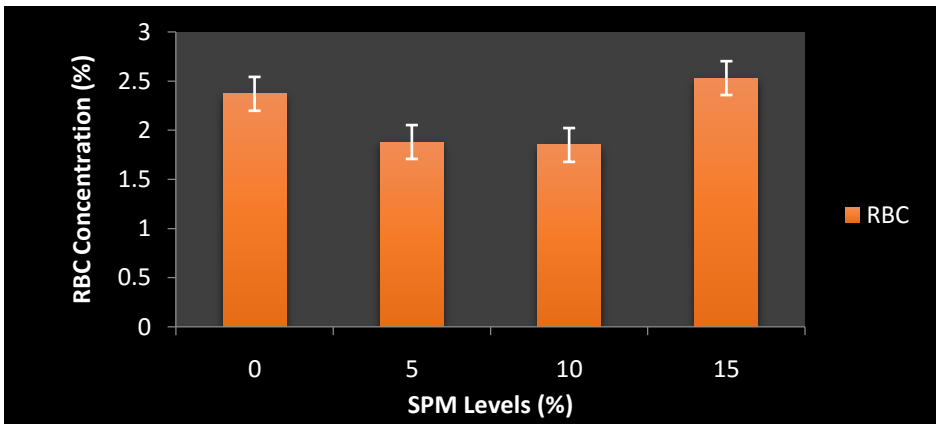

Figure 1: Effect of SPM level on concentration of RBC

Conclusion

The result of this study revealed that inclusion of sweet potato meal up to 15% dietary level of inclusion in broiler chickens diet at starter and finisher phases had no negative effects on performance and haematological indices of the birds.

ABSTRACT
This study was conducted to evaluate haematological response of broiler chickens fed garlic, ginger and garlic-ginger mixture. Four experimental broiler starter and finisher diets were formulated such that the diets contained 1.0% ginger (T_2),garlic (T_3) and garlic-ginger mixture (0.5 ginger + 0.5 garlic) (T_4), respectively. The control diet (T_1) contained no garlic or ginger or their mixture. The diets were fed to one hundred and twenty (120) day old Cobb broilers in a 56- day feeding trial. The diets were randomly assigned to four groups of 30 birds in a completely randomized design (CRD) replicated 3 times. Each replicate contained 10 birds. Broiler starter and finisher diets were fed for 0-28 and 29-56 day of age, respectively. The result obtained showed no significant differences in all the parameters measured on biochemical indices of broiler chickens. Birds on treatment group were slightly better than control group on biochemical indices of broiler fed diets containing ginger, garlic and their mixture. Ginger, garlic and their mixture should be considered an effective phytogenic feed additive in diets formulation for improved health and welfare of the birds.
Key Words: Garlic, Ginger, Mixture, Broiler, Biochemical Indices

INTRODUCTION
The ban on the use of antibiotic growth promoters in livestock and poultry nutrition by the European Union has generated interest in the search for an alternative. This has given rise to the use of different feed materials in poultry feed formulations to enhance growth rate, improve feed efficiency and utilization (Raeesi *et al.,* 2010; Oleforuh-Okoleh *et al.,* 2014; John and Emenalom 2018).Phytogenic feed additives are currently used in livestock and poultry production because of their positive properties including; anti-inflammatory, antiseptic, sedative, bactericidal, gut functions, fungicidal, antiviral, antioxidant, growth-promoting efficacy, dietary palatability, immune stimulating, stimulation of digestive enzyme and absorption of nutrients (Cross *et al.,* 2007; Steiner, 2009; Puvaca *et al.,* 2013).

These plant-derived compounds which include; herbs, spices and essential oils or oleoresins, are normally incorporated into diets for improved productivity in livestock and poultry. A variety of these phytogenic feed additives including ginger and garlic have been widely used as alternatives to synthetic antimicrobial growth promoters in livestock and poultry rations. Ginger,(*Zingiber officinale*) and garlic (*Allium sativum*) are widely used species in various foods and beverages and in medicine (Chrubasik *et al.,* 2005). Ginger contains; gingerol, gingerdiol and gingerdione which have the ability to stimulate digestive enzymes, affect microbial activity, anti-oxidative, anti-inflammatory, antiseptic, anti-parasitic and immune modulatory properties when used in poultry diet (Zhang *et al*., 2009; Mohamed *et al*., 2012; Akintobi *et al.,* 2013). On the other hand, garlic contains sulphur compounds; allin, diallysulphide, allyldisulphide and allicin (Chang and Cheong, 2008).

According to Shewita and Taha (2018), Ebegbulem (2018), Herve *et al.,* (2018) and Oleforuh-Okoleh *et al.,* (2015), George *et al.,* (2015), Ebrahimnezhad *et al* (2014) who reported role of ginger and garlic on biochemical indices of broiler chickens. The aim of this work therefore, is to determine the biochemical indices of broiler chickens fed diets containing 1% ginger or garlic and ginger-garlic mixture, respectively.

MATERIALS AND METHOD
Experimental site
This experiment was conducted at the Poultry Unit of the Teaching and Research Farm of the School of Agriculture and Agricultural Technology, Federal University of Technology, Owerri, Nigeria. Owerri is located in the South-East agro-ecological zone of Nigeria. It lies between latitude $4^0 4^1$ and

$6^0 3^1$Nand longitude $6^0 15^1$ and $8^0 15^1$E with mean annual rainfall, temperature and relative humidity of 2250mm, 26.5-27^{0}C and 70-80%, respectively (Adeyemi, 2011).

Processing of test materials and diets

Ginger and garlic used for the experiment were procured fresh from a market in Owerri. The light scaly leaves on garlic were removed and the bulb separated into cloves. Both ginger and garlic were then sliced into 3-4 slices, sun-dried for 5 - 7 days depending on the intensity of the sun, ground into meals using an attrition mill and stored for use in broiler diets. Four experimental broiler starter and finisher diets were formulated such that diet 1 (control) contained none of the test materials. Diets 2, 3 and 4 contained 1.0% ginger, garlic and mixture (0.5 ginger + 0.5 garlic), respectively. The ingredient composition of the experimental diet is shown in Table1.

Experimental birds and design

One hundred and twenty (120) day-old broiler chicks of Cobb strains were used for the trial. The birds were divided into 4 groups of 30 birds each. Each group was sub-divided into 3 replicates of 10 birds each and housed in a 1.4 x 1.4 m compartment in the cemented floor, covered with wood shavings as the litter material in an open-sided poultry building. The pens were covered with black polythene for the first two weeks to control wind and heat. Each pen contained a feeder, drinker and a stove (to supply heat) for the first two weeks. Three pens were randomly assigned to an experimental diet in a completely randomized design. Feed and water were provided *ad libitum.* The starter and finisher diets were fed for 0 – 28 day and 29 – 56 day of age, respectively. Routine medications and other routine poultry management practices were maintained. The blood samples were collected into heparinized tubes from the basilica wing vein of the birds between 07 – 08 am at 56 day of age from three birds *per* treatment for biochemical analysis. The samples were sent to Federal Medical Centre, Owerri for the blood analysis. Data collected were subjected to statistical analysis using the General Linear Models (GLM) procedure of SAS® and the Student Newman-Keul's test $P < 0.05$.

Results and Discussion

The inclusion of garlic, ginger and their mixture did not affect the biochemical indices of the bird measured. However, garlic, ginger and their mixture tended to be superior to control group which increase the biochemical indices of the birds as shown in table (2). This result is in line with the finding of Ebrahimnezhad *et al* (2014) documented no significant differences ($P>0.05$) in all the parameters except low density lipoprotein on blood chemistry of broilers fed different level of ginger root powder. Shewita and Taha (2018) documented non-significant effect on low density lipoprotein, globulin, albumin, alanine aminotransferase and aspartate aminotransferase. George *et al.,* (2015) also reported that, inclusion of graded levels of ginger on broilers diets has no significant effect on total protein, creatinine, urea, aspartate aminotransferase, alanine aminotransferase and alkaline phosphate. Ebegbulem (2018) observed significant effect on total protein, cholesterol, glucose, globulin, creatinine and urea of birds fed ginger supplemented diets.

This result is not in agreement with the findings of Herve *et al.,* (2018) that reported significant effect on total protein, cholesterol, triglyceride, globulin, aspartate aminotransferase and alanine aminotransferase of Japanese quail fed ginger essential oil. Oleforuh-Okoleh *et al.,* (2015) also reported significant difference on biochemical response of broiler chickens to aqueous extract of ginger and garlic. The slight increase in biochemical indices of birds may be due to bioactive compound in ginger such as gingerol, shogaols, gingerdiol, gingerdione, and some related phenolic ketone derivatives which have powerful antioxidant and immunostimulatory properties that allow them to improve immune responses.

EFFECT OF DIFFERENT HEAT TREA TMENT OF BAOBAB (*Adansonia digitata*) SEED AS AN ALTERNATIVE PLANT PROTEIN SOURCE ON HAEMATOLOGICAL AND BLOOD CHEMISTRY OF LOCAL TURKEY

L. A. SAULAWA, M. G. GARBA, M. N. SABO AND A. UMAR

Department of Animal Science, Federal University Dutsin-Ma

ABSTRACT
An experiment was conducted to evaluate the effect of boiling time of baobab (Adansonia digitata) seed meal as a partial replacement of soya beans meal on anti-nutritional factors, haematological and blood chemistry of local turkey. Raw baobab seeds were boiled for 30, 60, 90 and 120 minutes. The boiled baobab seed meals (BBSM) were used to replace 10% of soya beans meal. Seventy five poults were randomly selected and allocated to treatment diets with 15 poults per treatment and 5 poults per replicate. Proximate analysis of the experimental diets and anti-nutritional factors of the raw and boiled (30, 60, 90 and 120mins) BBSM were carried out. On the 9th week of the feeding trial, blood was collected from the poults for haematological and blood chemistry assays. The results obtained showed there was general reduction in the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) as a result of different boiling time of raw baobab seed. Monocyte count was different (P<0.05) among the treatment means with 30 mins BBSM having the highest count. The 30 mins BBSM recorded higher (P<0.05) creatinine compared the other treatments. Alkaline phosphate content was higher (P<0.05) for the control and 30 mins BBSM compared to 120 mins BBSM. It can be concluded that boiling reduces the content of anti-nutritional factors of raw baobab seeds and assisted the growing turkey in handling the anti-nutritional factors.
Keywords: Baobab, Local Turkey, Haematological, Blood chemistry, turkey

INTRODUCTION
Protein is a global index for measuring well-being of a country (Abdu, 2012). The basic sources of protein in Nigeria are the ruminant and the non-ruminant. The ruminant animals' production is seriously in dangerous stage due to insurgency in the north-east, cattle rustling in the north-west, and seasonal fluctuation of feed which resulted in reducing the supply of protein sources, the next alternative are poultry sources, but poultry is seriously affected by high cost of feed due to high competition between man, industries and poultry. Protein source is the major scarce and expensive ingredient in poultry production there by taking 75-80% of the total cost of production. Hence the need to source for alternative but promising feedstuffs. One of such alternative is baobab (*Adansonia digitata)* seed. Baobab (*Adansonia digitata*), locally called kuka (Hausa) and luru (Yoruba), which is another non-conventional feed stuff that is readily available in Nigeria particularly in the North. The use of legumes as a component of poultry feed has been limited by the content of anti-nutritional factors (ANF). Abdu (2012) and Saulawa *et al* (2014) reported that the inclusion of above 10% raw Baobab seed meal as plant proteins in diets of broilers leads to a significant impairment of growth and other undesirable physiological and biochemical alterations.

The examination of blood gives the opportunity to investigate the presence of several metabolites and other constituents in the body of animals and it plays a vital role in the physiological, nutrition and pathological status of an organism *(*Aderemi, 2004*). According to* Afolabi, *et al*, (2010), changes in haematological parameters are often used to determine various status of the body and to determine stresses due to environmental, nutritional and/or pathological factors. Hence, this study was conducted determine the effect of different time of hot water treatment on proximate composition and anti-nutritional factors of baobab and also its effect as a partial replacement for Soybeans on haematological and blood chemistry parameters of local turkey.

MATERIALS AND METHOD
Experimental Site
The study was conducted at the Poultry Unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma. Dutsin-Ma lies on latitude 12°26'N and longitude 07°29'E (Abaje *et al.*, 2014).

Processing of Baobab Seeds

The raw seeds of baobab were collected from Dutsin-ma market and were divided into five parts and boiled at different time interval. Boiling was carried-out according to the recommendation of Ukachukwu, *(*2000) for *Mucuna cochinchinensis*. The equal quantity seeds were boiled for 30mins, 60mins, 90mins and 120mins using equal vol. of water differently. Thereafter, they were brought down and a basket was used to drain the seeds and allowed them to sun dry.

Experimental Animal, their Management and Data Collection

One hundred (100) day old turkeys were housed and brooded in a deep litter. All routine management practices were strictly adhered to. At the end of the fifth (5) week (brooding period), 75 birds were allotted to five (5) experimental diets and replicated three times in a completely randomized experimental design. Diet was soybeans based (control), while 10% boiled baobab seeds boiled for 30, 60, 90 and 120 minutes were used to quantitatively replace equivalent weight of soya beans meal in diets 2, 3, 4 and 5 respectively. Feed and water were given *ad libitum* throughout the experimental period which lasted for nine (9) weeks.

On the 9th week of the feeding trial, 3 poults were randomly selected from each dietary replicate for blood collection. Blood was collected from the sub-clavicular vein of each poult using a scalp vein needle set. About 5ml of blood was collected into two (2) sets of three sterilized glass tubes/bottles containing Ethylene Diaminetetra-acetic Acid (EDTA) for Haematological studies. Blood samples for serum biochemical studies were collected into plain containers for serum separation.

Haematological parameters measured were red blood cell (RBC), haemoglobin (Hb), white blood cell counts (WBC), packed cell volume (PCV), mean corpuscular haemoglobin concentration (MCHC), mean corpuscular Haemoglobin (MCH) and mean corpuscular Volume (MCV) were all determined.

Serum biochemical parameters considered were total serum protein, serum albumin, glucose, cholesterol, creatinine, urea, serum glutamate oxaloacetate transfarase (SGOT), alkaline phosphate (ALP) and serum glutamate phosphate transfarase (SGTP). Data from the experiment are subjected to one way analysis of variance (ANOVA) using SAS software (SAS 1999).

RESULTS AND DISCUSSION

Table 2 shows the result of different anti-nutritional factors obtained in both raw and boiled baobab seeds. There was general reduction in the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) as a result of different boiling time of raw baobab seed though reduction varies in degree with different boiling period. The highest percentage reductions in trypsin is T5 (1.98), tannin T4 (1.08) and in phytate T4 (2.79) were observed when the raw baobab seed were boiled with different boiling period.

The haematology parameters of turkey fed boiled baobab seed meal for different duration is shown in table 3. The result shows that RBC, Hb, PCV, WBC, Neutrophills, Lymphocyte and MCHC were not affected (P<0.05) by the feeding baobab seed meal boiled for various duration a replacement for soyabean meal.

Eosinophil %	0.00^{b}	0.50^{ab}	2.00^{a}	0.33^{ab}	0.67^{ab}	0.57
Basophils %	-0.00	0.00	0.00	0.00	0.33	0.15

a,b,c,d means in the same row with different super scripts are significantly (P<0.05) different
SEM – Standard error of means

Monocyte count was different (P<0.05) among the treatment means with 30 mins BBSM having the highest count. 90 mins BBSM recorded the lowest which is statistically lower P<0.05) than the control and the 30mins BBSm but similar (P<0.05) with both 60 and 120 mins BBSM. Eosinophil count of the 60 mins BBSm was significantly higher (P<0.05) than that of the control but similar with the other treatments. The 30, 90, and 120 mins BBSM had similar Eosinophil count with the control. MCV was affected by the feeding of BBSM to growing turkey with 30 and 90 mins BBSM having hiher MCV than 60 mins BBSM.The control and 120 mins BBSM have similar MCV with the 30, 60, and 90 mins BBSM. Similar to MCV, MCH was higher than the 30 and 90 mins compared to 60 mins BBSM. The control and the 120 mins BBSM have similar MCH with the 30, 60, and 90 mins BBSM.

The result of the serum biochemistry of growing turkey fed BBSM is shown in table 4 all the parameters considered as shown in the table were not affected except for creatinine and alkailine

phosphate (ALP). The 30 mins BBSM recorded higher (P<0.05) creatinine compared the other treatments.The control, 60, 90, and 120 mins BBSM had similar (P>0.05) creatinine content. Alkaline phosphate content was higher (P<0.05) for the control and 30 mins BBSM compared to 120 mins BBSM. The 60 and 90mins BBSM had similar (P>0.05) alkaline phosphate with both the control and 30 mins BBSM and the 120 mins BBSM.

Conclusion and Recommendation

From the results of this study it can be concluded that boiling reduces the content of anti-nutritional factors (tannin, phytate and trypsin inhibitors) of raw baobab seeds. Boiling of raw baobab seeds for more than 30 mins assisted the growing turkey in handling the anti-nutritional factors. Hence, monocyte count and serum creatinine content decreased with increased boiling time. It is recommended that 10% raw baobab seeds boiled for a minimum of thirty minutes can be used to replace soyabean meal in diets of growing turkey.

Abstract
This study was carried out to determine the effects of cage location and tier-level on performance and egg quality characteristics of Isa Brown hens. One-hundred and eighty laying hens of similar body weights at 40 weeks of age were housed inside 3-tier cages denoted as Top (T), Middle (M) and Bottom (B) tiers in cages placed facing the Open side (OS) and the Corridor side (CS) of a battery cage pen. The 70-day long experiment was a Randomized Complete Block Design with a 2 x 3 factorial arrangement of treatments. Data on feed consumption and egg production were recorded daily and egg quality was determined at 5-weeks interval. Cage location had no effect on feed consumption and feed efficiency throughout the experimental period. However, the effects of cage location and tier level and their interaction were significant ($p<0.05$) on hen-day production throughout the experiment. Although cage location and tier level did not have any statistical influence on egg weight, other quality indices such as shape index, yolk index, albumen index and Haugh unit responded significantly ($p<0.05$) to the treatments. It is therefore recommended that poultry farmers should pay due attention to cage location and tier level as part of key determinants of egg production and quality.

Keywords: cage location, tier-level, performance, egg quality

Introduction
Egg production occupies a key position in the quest to meet the demand for the much-needed animal protein of the teeming population of most communities especially in the low-income food deficit countries. A lot of concerns have been raised by poultry scientists about the dynamics of egg production and its quality after oviposition.

Several factors have been identified to militate against the performance of laying hens housed in battery cages. Awoniyi (2003)) reported that, because there is an unavoidable variation in light intensity among multi-tier cage systems, a balance is needed between providing sufficient light at the bottom tier and avoiding excessive light intensity at the top tier. In another study, Yildiz *et al*., (2006) found that the lack of a homogenous light intensity in multi-tier system and each cage location in semi confined laying hen houses adversely affects egg production and quality. Karaman *et al*., (2013) reported that environmental conditions are not the same in every part of the caged layer house, and differences in micro-environments such as in ventilation,lighting and temperature might occur among cage tiers.

Cage location within the battery cage house and cage tier-level has been of serious research concern to poultry scientists. Poultry products and their quality are affected significantly by genetic and ecological conditions such as the indoor environment of the poultry house (Ahmed and Singh, 2007) Earlier researchers (Vovensy, 1990 and Sahin, 2012) investigated the effects of cage location and tier levels on performance of layers and reported great variability among the groups caged at different tier levels facing windows and located at corridor.External and internal quality of eggs are dependent on genotype and environmental factors such as housing system, oviposition time, age, ambient temperature and nutrition as well as their interactions (Tunova and Gous, 2012). Although diverse variations in performance and egg quality have been recorded among hens subjected to different housing coditions, more work is needed particularly considering the fact that existig reseaches on the subject were undertaken outside Nigeria and with no specific genotype in mind. Therefore, the present study was conceived to determine the effects of cage location and tier-level on performance and egg quality characteristics of Isa Brown hens reared in tropical Rain forest of Nigeria.

Materials and Methods

Birds and Management

This study was carried out at the Department of Agricultural Education Poultry Unit, Federal College of Education (Technical), Akoka, Lagos, Nigeria.The experiment was a randomized complete block design with a 2x3 factorial arrangement of treatments. A total of 180 Isa Brown layers of similar body weights at 40 weeks of age were blocked into location: Open side (OS) and Corridor side (CS) and cage (40 x 36 x 40cm, width x depth x height) as Top (T), Middle (M) and Bottom (B) tiers. Each treatment was replicated 5 times in 10 cells in each tier level of the 2 location types with each cell containing 3 hens. The experiment lasted 70 days aside from 14 days adaptation period (20 March to 29 May, 2017). Average daylight and darkness during the experimental period were 12.30 and 11.30h/d respectively, with no artificial lightening.

Data collection

Feed consumption and egg production were recorded daily and egg quality was determined at 5-weeks interval. Egg production was expressed as hen-day egg production; feed consumption was calculated as daily feed consumption. Feed efficiency was calculated as kilogram of feed consumed per kilogram of egg produced. A total of 60 eggs were randomly picked with 2 eggs per replicate at week 40 and subsequently at weeks 45 and 50 respectively for the determination of quality parameters such as shape index, shell thickness, albumen index, yolk index and Haugh unit. Apart from egg weight, formulas and methods as reported by Ergum *et al*., (1987) were used to determine other egg quality traits. Similarly, Haugh unit was calculated using the values recorded for the egg weight and albumen height as expressed by Haugh (1937) and enunciated by Asuquo *et al.* (1992) in the formula thus: $HU = 100 \log (H + 7.5 - 1.7W^{0.37})$ Where H = Albumen height in mm, W = Egg Weight in g. The data obtained were subjected to analysis of variance (ANOVA) according to SAS (1998) while differences between groups were determined by Duncan multiple –range test.

Results and Discussion

The results of performance indices from the experimental groups are presented in Table 1. The results of this study indicated that cage location had no effect on feed consumption and feed efficiency throughout the experimental period. However, hen day production was significantly ($p < 0.05$) influenced at 40th and 50th weeks old. A sharp contrast in HDP was observed as tier-level significantly ($p<0.05$) increased egg yield at 45th week old. Birds housed in the bottom tier produced more eggs ($p < 0.05$) than those in other tiers. The effects of cage location, tier level and cage location by tier level interaction on HDP were significant ($p < 0.05$) throughout the experimental period while such effects did not exist in other performance parameters investigated. This finding agrees with that of Sahin (2012) who reported that hens at location Facing Window had greater egg production than hens at Corridor side. The improved egg yield observed with birds on the open side of the pen at 40th and 50th weeks could be attributed to better exposure to light intensity as reported by earlier researchers (Awoniyi 2003; Yildiz *et al*., 2006; and Karaman *et al*., 2013). Vovensy (1990) and Ahmed and Singh (2007) also posited that environmental conditions are not the same in every part of the caged layer house, and differences in micro-environments such as ventilation, lighting and temperature might occur among cage tiers. Tier-level effect on egg yield at 45th week old contradicts the findings of Karaman *et al*., (2013) who reported that hens at the top-tier produced more eggs as a result of better exposure to lightning than those at the lower tiers. The significant interactive effects of cage location and tier level observed for HDP in the present study is consistent with the findings of Vowensy (1990) who reported great variability among the groups caged at different tier levels facing windows and located at corridor.

[a,b;] means on the same column with different superscripts are significantly different ($p<0.05$)

L = Cage location; T = Tier-level

The results of egg weight (g), egg shape index (%) and egg shell thickness (mm) are presented in Table 2. Cage location, tier level and cage location by tier level interaction did not have significant impact ($p > 0.05$) on egg weight throughout the experimental period. Tier level and cage location by tier level interaction ($p < 0.05$), but not cage location, affected egg shape index at 45th week of age. Hens caged in top tier recorded higher shape index (82.32%) than those in middle and bottom tiers with mean values of 78.59% and 78.59% respectively. This suggests that high light intensity prevalent at the top tier level might have resulted in superior shape index. However, this trend is at variance with the findings of Yildiz *et al.,* (2006) and Awoniyi (2003) who reported that neither cage location nor tier level affected shape index, yolk colour or yolk index. Moreover, cage location and cage location by tier level interaction had significant ($p < 0.05$) effect on shell thickness at 40th week of age. Hens in cages on open side produced eggs with thicker shells (0.31mm; Table 2) than those at corridor side (0.26mm). The effect of location and tier level on shell quality is largely unknown. However, Leeson and Lewis (2004) posited that egg shell quality was independent of light intensity or cage location and tier effect of cage level in other studies including hens.

Table 2: External quality parameters of Isa Brown hens' eggs at different cage locations and tier levels

Treatments		Egg weight (g)			Egg shape index (%)			Egg shell thickness (mm)		
Cage location	Tier level	40th week	45th week	50th week	40th week	45th week	50th week	40th week	45th week	50th week

Table 3 summarizes the effects of cage location and tier level on internal quality parameters of Isa Brown hens' eggs. Significant cage location and cage location by tier level interaction ($p < 0.05$) effects existed in yolk index at 50th week of age. Hens in cages on open side had superior yolk index (52.02%) to those on corridor side (47.39%). Conversely, Haugh unit responded ($p < 0.05$) to tier level and cage location by tier level interaction at 50th week of age. Mean value of 87.29 recorded for hens in top tier was higher than 81.28 and 81.20 obtained for those in bottom and middle tiers respectively. Furthermore, significant cage location by tier level interaction effects ($p < 0.05$; Table 3) occurred in all the internal parameters at different periods of the experiment. For instance, albumen index (45th week), yolk index (40, 45 and 50th weeks) and Haugh unit (50th week) all responded to cage location by tier level interaction effects. This implies that, while cage location and tier level did not significantly affect internal egg quality indices, cage location by tier level interaction did. This corroborates the findings of Yildiz *et al*., (2006) who reported that despite a lack of effect of tier level, there were significant cage location by tier level interaction effects on albumen index and Haugh unit. Since albumen index and Haugh unit are key determinants of inner egg quality, the outcome of the present study suggests that these parameters should not be ignored when considering environmental factors militating against egg production and quality.

Table 3: Internal quality parameters of Isa Brown hens' eggs at different cage locations and tier levels

Treatments		Albumen index (%)			Yolk index (%)			Haugh unit		
Cage location	Tier level	40th week	45th week	50th week	40th week	45th week	50th week	40th week	45th week	50th week

Conclusion and Recommendation

The findings of this study revealed that cage location and tier level as well as their interaction had significant effects on egg production with hens in cages facing the open side producing more eggs than those facing the corridor side at 40 and 50 weeks old. Generally, cage location and tier level did not have any statistical influence on egg weight but other quality indices such as shape index, yolk index, albumen index and Haugh unit responded significantly to the treatments. It is therefore recommended that poultry farmers should pay due attention to cage location and tier level as part of key determinants of egg production and quality.

Key words: Broiler Chicken, Garlic Powder, Performance and Serum Biochemistry

ABSTRACT

This experiment was carried out at the Research Unit of the Department of Animal Science, UsmanuDanfodiyo University Sokoto which is located at Veterinary Clinic, Aliyu Jodi Road, Sokoto.120 day old broiler chicks were studied in this research to determine the effect of garlic (Allium sativum) powder on the performance and serum biochemistry on the broiler chickens at starter phase. This experiment lasted for 4 weeks. Birds were randomly alloted to 5 treatments with 3 replicates each using CRD. Each treatment consisted of 24 birds and 8 birds per replicate. Treatment 1 was positive control with experimental diet only, treatment 2 was negative control with experimental diet with Neomycin antibiotic supplement and treatments 3, 4 and 5 were experimental diets with 1%, 2% and 3% garlic powder supplement.Results of the experiment showed significant ($P<0.05$) differences in average daily feed intake/bird, BWG and average daily weight gain/bird. There were no significant differences in initial body weight, final body weight, feed conversion ratio and mortality. There were also no significant difference in ALP, ALT, AST, Na, Cl and K.This experiment observed garlic had no effect on broiler growth performance and serum biochemistry at starter phase statistically. Although, numerically garlic supplemented treatments showed decreased liver enzyme activity in relation to antibiotic which indicated a healthy status. It was also concluded that these effects may not be observed due to the short duration of the experiment.

Introduction

Background of the Study

Broiler production has gained prominence in Nigeria since independence in order to meet the average daily protein requirement of Nigerians (Adene and Oguntade, 2006). Meat is an important composition of the diet for healthy living as it is a good source of essential amino acids. Broiler production involves the rearing of chicken for meat. The main requirements of broiler production are feed, housing and health management. The main concern of producers is to achieve growth of birds within a short period of time and prevent loss. In an attempt to achieve this, producers use substances that can improve growth and health status of the birds (Butaye*et al*., 2003).

Feed additives are added in poultry feed to improve nutritive value of ingredients, improve quality, improve feed conversion efficiency, increase growth rate and enhance performance (Brussels, 2005). Antibiotic growth promoters are feed additives which are primarily added in feeds to improve growth, improve feed utilisation and prevent diseases (Brussels, 2005). Antibiotics are chemical substances produced by a microorganism which can kill or inhibit the growth of another microorganism, most common of which are penicillin, oxytetracyline and tetracycline (Dantas*et al*., 2008). Antibiotics have been extensively used to prevent disease infections in poultry and to improve growth and carcass quality. However, the increased use of antibiotics leads to development of resistance in bacteria, residual drug effect and drug toxicity. Also, antibiotics have side effects on animals and humans consuming the animals' product due to drug residue (Sharma *et al.*, 2008).

Alternatives to antibiotics have gained interests in poultry production many of which are plants and their extracts. Recently, many countries have banned the use of antibiotics because of their harmful side effects and increased awareness about the alternatives of antibiotics such as herbs and medicinal plants to eliminate these threats (Manesh*et al.*, 2012).

Alternatives to antibiotics recognized include probiotics, phytogenics and organic acids growth enhancers (Borazjanizadeh*et al*., 2011). Many bio-active ingredients which include alkaloids, flavonoids, mucilage, saponin and tannin are new generation antibiotics (Wang *et al*., 1998; Wenk, 2000). Nutritionists are shifting their attention from the utilisation of chemical growth promoters to phytogenic growth promoters in recent years (Iji*et al*., 2001).

Common plants and herbs gaining interest as phytogenic growth promoters include; ginger, garlic, onion, turmeric, rosemary, oregano and thyme (Panda, 2009). These plants and their extracts have been used in human and animal medicine without knowledge of their exact effect and potency. Some growth promoters act as pro-nutrients because of the role they play in enhancing the physiology and microbiology of the animal. Many active ingredients from plant are considered as pro-nutrients and recently been tried in animal feed (Biovet, 2005). Active principles of the plant or plant chemicals present in certain parts of the plant confer therapeutic effect (Zhang *et al*., 2009).

Garlic (*Allium sativum*) has many beneficial uses in many regions worldwide. The use of garlic for its flavour is common across the world for a long time. It has been used as medicines for both humans and animals especially in the treatment of cold. Garlic plants have active ingredients and phenolic compounds that can reduce numbers of intestinal pathogens, minimize nutrient loss and improve performance; garlic also has pharmacological, antimicrobial and antioxidant effects (Al-amin*et al*., 2006; Tapsell*et al*., 2006; Ali *et al*., 2008). It acts on the appetite, intestinal micro flora and stimulate the pancreatic secretions to increase endogenous activity and immune system. Garlic can be used as good alternative for common artificial growth promoters like antibiotics (Demir*et al*., 2003).

One of the main concerns in poultry production in Nigeria is disease outbreak. Antibiotic growth promoters have been used to promote growth, prevent infection and control diseases. The use of antibiotic growth promoters is presently facing serious criticism and has raised global concerns as some reports revealed their ill effects among which is development of microbial resistance to the products and their potential harmful effects on human health (Rahmatnejad*et al*., 2009).

The use of antibiotic growth promoters can result in the development of drug-resistant bacteria (Alexander *et al*., 2008). Those resistant bacteria can infect humans through the food chain and thus it is a public health concern (Torres *et al*., 2010; Bekele and Ashenafi, 2010). Also, drug residues may be consumed by humans and this can lead to toxicity in humans. With all these side effects and harmful effects known there is need for decrease in the use of antibiotics but also there is need to find safer alternatives that can provide the benefits of antibiotic growth promoters.The major aim of this research is to determine the effect of garlic on the performance and serum biochemistry of broilers fed graded levels of Garlic powder as an additive from plant extract.

Materials and Methods

Study Area

The experiment was carried out at the Teaching and Research Unit of the Animal science Department, Faculty of Agriculture, UsmanuDanfodiyo University Sokoto located at the Veterinary Clinic, Aliyu Jodi road, Sokoto. Sokoto State is located at the extreme North –western part of Nigeria and lies at latitude 13.057^{o}N and longitude 5.2457^{o}E. It has an altitude of 350m (Mammam*et al*., 2000). The climate is dry and hot with temperature range of 16.3^{o}C – 40.6^{o}C, an average temperature of 28.4^{o}C and average humidity of 43%. Sokoto is a tropical area and has an annual average rainfall of 629 mm (Kowal and Knabe, 1972).

Experimental Materials

A Total of 120 day old broiler chicks were used for the experiment. They were grouped into 3 replicates and assigned to 5 treatments, with each treatment having 24 chicks and 8 chicks in each replicate using Complete Randomized Design. Garlic was purchased from the Sokoto central market, dried, ground into powder and added to the feed at graded levels (1%, 2% and 3%). Antibiotics (Neomycin) was purchased from veterinary drugs store and used according to manufacturer's instruction.

Experimental Diets

All ingredients for the experimental diets were purchased from the Sokoto central market, processed and properly mixed. Five treatments diet were formulated which include; the basal diet with no supplement labelled as treatment 1 (T1) served as positive control, the basal diet with antibiotic supplement as treatment 2 (T2) served as negative control, basal diet with 1% garlic powder supplement as treatment 3 (T3), basal diet with 2% garlic powder supplement as treatment 4 (T4) and basal diet with 3% garlic powder supplement as treatment 5 (T5). The antibiotic supplement was used according to label instruction.

Table 1. Gross Composition of the Experimental Diet

Ingredients	Starter phase
Maize	56.85
Soya bean meal	37.85
Soya bean oil	1.11
Calcium	1.00
Limestone	1.00
Salt	0.20
Methionine	0.41
Lysine	1.08
Premix	0.50
Total(kg)	100
Nutritional Composition	
Metabolisable energy (Kcal/kg)	2988
Crude protein (%)	21.00
Methionine (%)	0.46
Lysine (%)	1.20
Phosphorus	0.50

Management of Experimental Animals
Birds were reared for 4 weeks in a deep litter system pen. Birds were brood and allowed to acclimatize to the environment for seven days. Same basic management care of broiler production was given to all the birds. Feeds and water was provided *ad-libitum*.

Feed intake was calculated daily by measuring the weight of feed given and weight of any left over. Weight gain was taken on weekly basis and feed conversion ratio was calculated from it. All required vaccinations were administered. At the end of the experiment 2 birds were randomly selected from each treatment and blood samples were taken from the birds. Blood samples were taken from the jugular veins of the birds for serum biochemical analysis. 26 mortalities were recorded at the end of the experiment: 4 in treatment 1, 5 from treatment 2, 8 from treatment 3, 4 from treatment 4 and 6 from treatment 5.

Experimental Design
Complete Randomized Design (CRD) was used.

Data Collection
The parameters measured were growth performance parameters (feed intake, live weight gain and feed conversion ratio) and serum biochemical parameters (alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, sodium (Na), potassium (K) and chloride (Cl)).

Growth Performance
Weight of feed given and feed residue were measured daily and difference of the two was recorded as daily feed intake. Live weight gain was measured weekly and recorded. Weight gain was determined as the difference between the weight of birds at the end of the experiment and the initial weight at the beginning of the experiment. Feed conversion ratio was determined as the ratio of feed intake by weight gain (FI\BWG).

Serum Biochemical Analysis
Blood samples were collected in plain bottles at the end of the experiment from the using sterile syringe. The biochemical analysis was conducted at UsmanuDanfodiyo University Teaching Hospital (UDUTH). The blood ALT, AST, ALP, Na, K and CL were determined.

Data Analysis
The Data obtained from the experiment was subjected to analysis of variance (ANOVA) using SPSS. Least significant difference (LSD) was used to separate between the means.

RESULTS AND DISCUSSION

Growth Performance of the Broiler Chickens

Table 2. Growth Performance of the Broiler Chickens

	Treatments					
Parameter	**T1**	**T2**	**T3**	**T4**	**T5**	**SEM**
Average daily Intake (g)/ bird	41.5[a]	39.15[ab]	38.41[b]	37.35[b]	37.63[b]	0.69
Initial body weight (g)/ bird	109.63	104.17	120.55	108.92	110.13	5.92
Final body weight (g)/bird	428.57	503.97	411.43	423.81	389.29	42.91
Weight gain (g)/ bird	318.94[b]	399.8[a]	290.88[b]	314.89[b]	279.16[b]	16.71
Average daily weight gain (g/day)	11.39[ab]	14.28[a]	10.39[b]	11.25[ab]	9.97[b]	1.02
Mortality (%)	3.13	5.25	8.38	4.13	6.25	2.38
Feed conversion ratio (FCR)	3.6	2.74	3.70	3.32	3.77	0.48

There were significant (P<0.05) differences among the treatments in average daily intake (g)/bird, weight gain (g)/bird and average daily weight gain/bird. Birds in treatment 1 (positive control) with no supplement have similar value to treatment 2 (T2) with antibiotic supplement and show significantly (P<0.05) higher average daily feed intake compared to the other treatments. Birds in treatment 2 (negative control) supplemented with antibiotic were significantly (P<0.05) higher in weight gain/bird in comparison to the other treatments. Treatments 1, 3, 4 and 5 all have similar body weight gain (g)/bird. Treatment 2 showed relatively higher significance (P<0.05) in average daily weight gain (g/day). Treatment 1 (positive control) and treatment 4 (2% garlic supplementation) showed similar average daily weight gain statistically, while treatment 3 (1% garlic) and treatment 5 (3% garlic) were least significant (P<0.05) on average daily weight gain (g/day).

There were however non-significant differences among the treatments in feed conversion ratio, initial and final body weight (g)/bird and mortality.

Serum Biochemistry of the Broiler Chickens

Table 3. Results of Serum Biochemistry of the Broiler Chickens

Parameters	**Treatments**					
	T1	**T2**	**T3**	**T4**	**T5**	**SEM**
ALP (u/l)	317.5	226.5	328.5	347.5	200.5	0.621
AST (u/l)	93.5	88	127.5	101	108	0.132
ALT (u/l)	22	129	69.5	23.5	55.5	0.264
Na (mmol/l)	142	142	138	142.5	140	0.957
K (mmol/l)	5.15	4.0	4.65	5.85	5.1	0.466
CL (mmol/l)	106.5	116.5	100.5	102.5	101.5	0.827

There were non-significant differences among the treatments in ALP, AST, ALT. Na, Cl and K. ALP values of all the treatments were higher than the reference range values. Treatment 5 and treatment 4 recorded the lowest and highest values for ALP. AST values of all the treatments were within the reference range values. Although no significance between the treatments statistically, treatment 3 had the highest value numerically and treatment 2 had the lowest. ALT values of treatments 1and 4 were within the reference range while treatments 2, 3 and 5 had values higher than the reference range. Treatment 1 had the lowest value and treatment 2 had the highest.

Na values of the treatments were within the reference range. Treatment 1 and 2 recorded the same values. Treatment 4 and treatment 3 had the highest and lowest values respectively. K values of all the treatments were higher than the reference range except treatment 2 which was within the range. Cl values of all the treatments were within the reference range. Treatment 2 had the highest Cl value while treatment 3 had the lowest.

DISCUSSION

Growth Performance of the Broiler Chickens

Supplementation of garlic as feed additive did not have effect on feed intake of broiler chickens in this experiment. A significant (P<0.05) decreased feed intake was observed among the treatments fed garlic and this may be due to the strong odour of garlic as reported by Onu (2010). This result is in agreement with the result of Rahmanetjad*et al.* (2009) which reported that the inclusion of garlic as a feed additive at 1000 g/tonne did not have effect on the feed intake as well as on weight gain and feed conversion ratio in broiler chickens. Horton *et al.* (1991) also reported that inclusion of garlic in the diets of male broiler chickens did not improve performance of the chickens. The studies of Rahardja*et al*. (2010) is in contrast with this result as it observed an increase in feed intake of laying hens fed garlic at 1%, 2% and 4%.

Chickens fed with garlic supplemented diet had the least body weight gain in this experiment. Also, chickens fed with garlic had the highest FCR although not statistically significant (P>0.05) it is indicative of poor feed conversion efficiency. This maybe as a result of the short period of the experiment as some of the effect may take a longer time to manifest and may not be noticeable at the starter phase Antibiotic had more effect on body weight gain of broiler chickens in this research. This result correlates the reports of other studies that supplementation of garlic in the diets of broiler chickens had little or no influence on the performance of broiler chickens (Freitas et al., 2001; Demir et al., 2003). Fadlalla*et al*. (2010) reported non-significant effect on the body weight and feed conversion ratio of birds fed garlic powder. Aji*et al*. (2011) also reported non-significant effect of garlic on feed conversion ratio. Farhad*et al*. (2011) reported a significant decrease in the body weight and daily weight gain of birds fed with blends of medicinal herbs: garlic, cinnamon, thyme, rosemary and anise in comparison with the control treatment. However, this research is not in conformity with the results of Kumar et al. (2010) which reported a significant increase in the body weight of broilers given garlic as growth promoter at starter level.

Among the treatments fed garlic treatment 4 had a better FCR (3.32) as compared to treatment 3 (3.70) and treatment 5 (3.77). Treatment 4 also had the highest weight gain/ bird and daily weight gain (314.89g, 11.25g/day) in comparison to treatment 3 (290.88g,10.39g/day) and treatment 5 (279.16g,9.97g/day) although they were all statistically same. Treatment 4 also had the highest final body weight (423.81g) numerically although statiscally non-significant (P>0.05). These values can suggest best dosage of garlic for performance of broiler chickens at starter phase.

Serum Biochemistry of the Broiler Chickens

ALP, ALT and AST are also referred to as liver enzymes as they are liver bio-markers. They are used to indicate an injury or damage to the liver. Serum ALP, AST and ALT were not significantly different between the treatments in this research. This is in line with the results of Kumar *et al.* (2013) which stated no significant changes in ALP of broiler fed garlic. Also, Demir*et al.,* (2003) and Dieumou*et al.* (2009) reported garlic had no significant effect on serum AST and ALT which is in agreement with this result. However, Rehman*et al.* (2011) reported a significant decrease in the serum ALP, AST and ALT of broilers given aqueous extract of a mixture of garlic, berberine, aloe vera and ginger. ALP values were higher than the reference range in this research. This may be as a result of the age of the birds as ALP level is higher in young animals as a result of rapid bone growth (Kaneko *et al.,* 2010). ALP is an indicator of liver health and can also be used to assess renal function (Basten, 2010). It is found in the bile duct, bone and kidney. AST values of treatments in this research were within the reference range and this indicates a normal liver function. An increase in AST value indicates liver injury, shock or chronic liver problem (Basten, 2010). Treatments 2, 3 and 5 showed high level ALT above the reference range. High level ALT may indicate active hepatitis due to drug, virus or toxins (Basten, 2010). Treatment 2 had the highest ALT value in this study which may be an indication of effect of the antibiotic on liver.

Na, K and Cl are blood electrolytes and help to maintain blood and tissue fluids in balanced state. All the serum electrolytes were within normal range except potassium values of T1, T3, T4 and T5. A study by Aka *et al.* (2010) observed a significant decrease in the serum Na and Ca with increase in garlic supplementation which is usually the result of increase in excretion of the Na and Ca. This is associated with increased water loss and suggests that increased dosage of garlic leads to hyponatranaemia and hypocalcaemia. In this study the supplementation of garlic at 1% (T3) showed lower sodium level while at higher dosage 2% (T4) and 3% (T5) there was an increase in the Na level.

Conclusion

Based on the results obtained from this experiment, garlic powder as feed additive did not have an effect on the growth performance of the broiler chickens at starter phase. There was also no effect on the serum biochemistry statistically. However, the treatments supplemented with garlic powder showed a lower level of liver enzymes activity an indication of a more healthy liver status. Treatment 4 (2% garlic) was concluded as the most effective

dosage on BWG, FCR and FI as compared to other garlic supplemented treatments. More research need to be done on garlic as a natural growth promoter; the best dosage to be supplemented, the best form of supplementation (powder, aqueous or oil) and the duration of usage to obtain best result. Also, studies on processing methods that will decrease the strong odour of garlic without reducing its beneficial compounds should be done so as to avoid the risk of decreased feed intake which may be due to the odour as observed in this research. Researches on other plants and herbs such as ginger, turmeric, cloves and onion should be done to ascertain the benefits of natural compounds as growth promoters and their effect on animal production. These plants and herbs can be studied singly or as mixtures to obtain the best results that will make commercial producers embrace their use.

COMPARATIVE PERFORMANCE OF TWO STRAINS OF LAYER CHICKS FED HONEY AS REPLACEMENT OF ANTIBIOTICS

M. N. SABO, M. UMAR AND L. A. SAULAWA

Department of Animal Science, Federal University Dutsin-Ma

ABSTRACT
The present study examined the comparative performance between two strains of layer chick reared in the semi-arid region and fed honey in place of antibiotics. Two egg layer strains, made up of one brown (Lohman Brown classic), one black (Nera Black) were sourced from reputable hatchery. Eighty eight day old chicks from each of the strains were in a 2 x 2 factorial arrangement in a completely randomized design with the two strains (Lohmann brown classic and Nera black) and administration of honey (with and without) as the factors. These made up four treatments which were replicated thrice with 22 chicks per replicate. Feed intake and body weight were measured and weight gain and feed conversion ratio were determined. The results of the study showed that performance parameters of two strains measured were statistically similar except for Mortality. Nera black strain had a higher mortality. The total feed cost of the brown strain was higher having ₦240.768 as compared with Lohmann Brown strain having ₦220.096. Even though there are no significant differences between the treatments in feed cost per kg gain, numerically brown strain had higher feed cost per kg gain (₦455.240) than Black strain (₦450.371) birds. Feeding honey as replacement for antibiotics did not affect (P>0.05) final weight, weight gain, total feed intake FCR and total water intake. Mortality is slightly higher (P<0.05) for layer strain chicks that are not fed water with honey then those fed water with honey.
Keywords: Strain, semi-arid, honey, performance, chicks

INTRODUCTION
The egg industry is enjoying increased production as consumers become more educated about the nutritive value of eggs and as more eggs are processed (Leeson and summers, 2005). Eggs are relatively inexpensive per unit of protein and energy contained in yolk and albumen, and so egg consumption continues to increase in developing countries (Leeson and summers, 2005). Most of the major international poultry breeders are located in temperate countries while much of the world's poultry production takes place under more extreme temperature conditions in the tropical regions. Often humid conditions are very extreme, in addition to the prolonged periods when the temperature is over 30°C (Gowe and Fair full 2008).

The availability and affordability of eggs and poultry meat will go a long way to meet the protein needs of several populations in hot regions. An obvious constraint on poultry production in these regions is the climate. It is certain that the genetic potential of poultry is greatly affected by the environment. It is in response to some of these questions that this study will be conducted to evaluate comparative performance of commercial layer strains reared in semi-arid tropics and fed honey as replacement for Antibiotics.

MATERIALS AND METHODS
The study was conducted at the Poultry Unit, Livestock Teaching and Research Farm, Department of Animal Science, Federal University Dutsin-Ma. Dutsin-Ma lies on latitude 12°26'N and longitude 07°29'E (Abaje *et al.*, 2014).

Two egg layer strains, made up of one brown (Lohman Brown classic), one black (Nera Black) were sourced from reputable hatchery. Eighty eight day old chicks from each of the strains were in a 2 x 2 factorial arrangement in a completely randomized design. The two strains (Lohmann brown classic and Nera black) and administration of honey (with and without) served as the factors giving four treatments and replicated thrice with 22 chicks per replicate.

The chicks were reared in floor pens covered with a thick layer of wood shavings. The birds were reared up to 8 weeks of age. Feed and water were supplied *ad libitum* during the whole period. They were fed diet having crude protein contents of 20.0% and energy contents of 2,800kcal/kg (NRC, 1994; Leeson and Summers, 2005). A given quantity of feed was measured and fed to the birds on a weekly basis. From which weekly feed intake was measured. The birds were weighed in the early

morning before receiving any feed and water using a weighing balance at two weeks' interval during the experimental period. Initial and final body weights of the birds were measured at the beginning and end of the experiment respectively. Average daily weight gain and feed conversion ratio were determined. Water intake was also determined. Mortality was recorded. Data from all experiments were analyzed using the general linear models (GLM) procedure of SAS software (SAS Institute Inc., 1994) according to a completely randomized design. Data were subjected to analysis of variance. Where the analysis of variance is significant, Duncan's multiple range test was used to separate the treatment means (Steel and Torrie, 1980).

RESULT AND DISCUSSION

The growth performance of chicks of two strains of commercial layer chicken is shown in Table 1. All the performance parameters of two strains measured in this study were statistically similar except for Mortality. Contrary to this Olawumi and Dudusola (2012) and Yakubu *et.al* (2007) reported that Nera black genotypes are more feed efficient and converted feed given to produce more egg than Lohman brown strain under the same condition. The only explanation for these differences may be attributed to genotype variability.

Table 1: Performance of Chicks of two Strains of Commercial Layer Chickens in Semi-Arid Region (0-10 weeks)

Parameter	Brown strain	Black strain	SEM
Initial weight (kg/bird)	0.036	0.032	0.001
Final weight (kg/bird)	0.529	0.569	0.021
Total weight gain (kg/bird)	0.493	0.537	0.021
Total feed Intake (kg/bird)	1.448	1.584	0.014
Feed conversion ratio	2.955	2.963	0.130
Total feed cost (₦/bird)	220.096	240.768	5.600
Feed cost/kg gain (₦)	455.240	450.376	7.002
Mortality	2.750[b]	4.250[a]	0.382

a, b, c, d, e, = Means within rows with different superscript are significantly different ($p<0.05$).

There was difference between the two layer strains in terms of total feed cost of the two layer strains. The total feed cost of the brown strain was higher having ₦240.768 as compared with Lohmann Brown strain having ₦220.096. The black strain has higher total feed cost than the brown strain because the Black strain had higher feed intake, which translates to the higher feed cost. Even though there are no significant differences between the treatments in feed cost per kg gain, numerically brown strain had higher feed cost per kg gain (₦455.240) than Black strain (450.371) birds. This is because black strain had higher FCR (2.963) than brown strain (2.955) but the lower the better FCR.

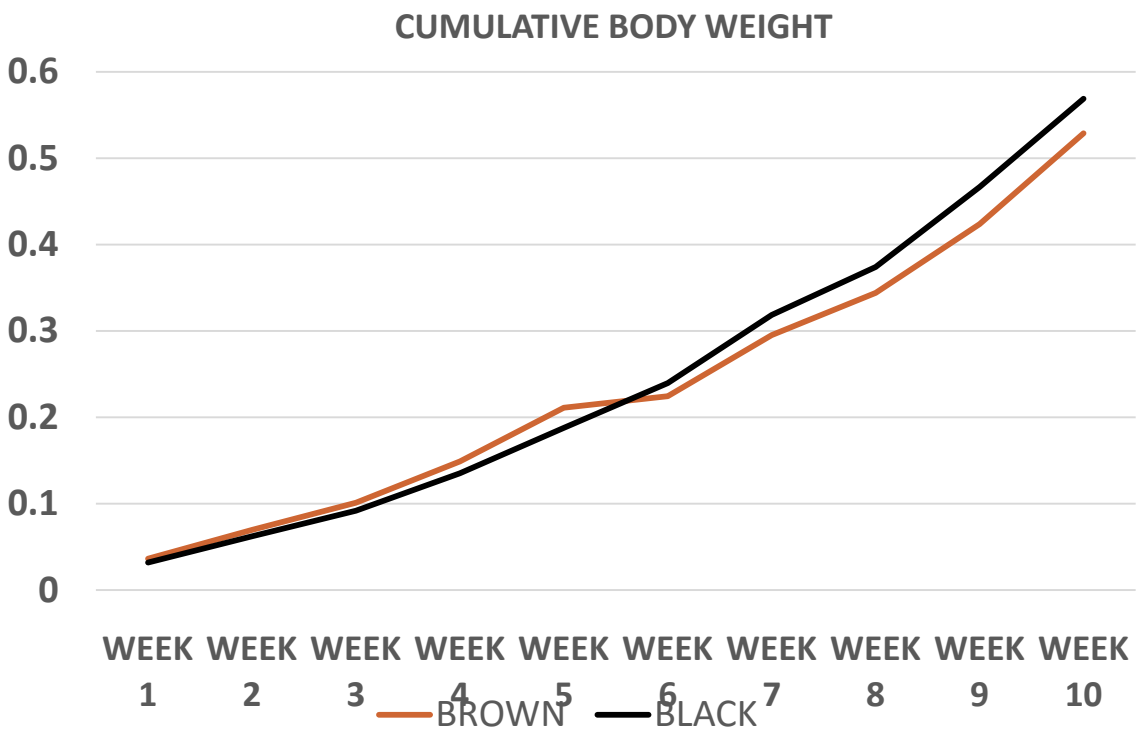

Fig. 1: Cumulative Weight Gain of Commercial Layer Strain Chicks Reared in Semi-Arid Tropics

The cumulative weight gain of commercial layer strain chicks reared in semi-arid tropics shown in figure 1. The body weight of the Brown strain is slightly higher than black strain at initial stage but decline at 6 weeks while Black strain continuously increasing.

Main effect of Strain of Commercial Layer Strains fed honey as replacement for antibiotics (7-10 weeks)

The initial weight, total feed intake and water intake were statistically different for the two strains of the layer chicks fed honey as replacement for antibiotics as shown in table 2. Total feed intake was higher ($P<0.05$) for the black strain (1.253kg/bird) compared to the brown strain (1.127kg/bird). The black strain also consumed more ($P<0.05$) water (290.800 ml/bird) than the brown strain (243.297 ml/bird). The final weight, weight gain, FCR and mortality were similar ($P>0.05$) for the two strains.

Table 2: Performance of Chicks of two Strains of Commercial Layer Chickens Fed Honey as Replacement for Antibiotics (7-10 weeks)

	Initial weight	Final weight	Weight gain	Total feed Intake	FCR	Total Water Intake	Mortality
Strain							
Brown	**0.295**	**0.529**	**0.234**	**1.127^{b}**	**4.964**	**243.297^{b}**	**1.000**
Black	**0.318**	**0.569**	**0.251**	**1.253^{a}**	**5.128**	**290.800^{a}**	**1.750**
SEM	**0.005**	**0.021**	**0.019**	**0.011**	**0.440**	**6.957**	**0.426**
Honey							
Water + honey	**0.317**	**0.534**	**0.217**	**1.172**	**5.502**	**267.090**	**0.750^{b}**
Water – Honey	**0.297**	**0.564**	**0.267**	**1.208**	**4.589**	**267.007**	**2.000^{a}**
SEM	**0.005**	**0.021**	**0.019**	**0.011**	**0.440**	**6.957**	**0.426**

a, b, c, d, e, = Means within rows with different superscript are significantly different ($p<0.05$).
FCR – Feed conversion ratio

Main effect of honey fed to Commercial Layer Strains as replacement for antibiotic (7-10 weeks)

The final weight, weight gain, total feed intake FCR and total water intake were similar (P>0.05) for layer strain chicks fed water with or without honey as replacement for antibiotics as shown in table 2. Mortality is slightly higher (P<0.05) for layer strain chicks that are not fed water with honey then those fed water with honey. This agrees with the observation of Babaei *et al.* (2016) who reported that feed intake was not affected when they fed honey to Japanese quails. Contrary to the results of this study Babaei *et al.* (2016) observed differences in the weight gain and FCR of Japanese quails fed honey.

Conclusion and Recommendation

From the result of the study, the two layer strains performed similarly in all measured parameters except for mortality which was higher for Nera black strain. Feeding honey in place of antibiotic reduced mortality of layer strain chicks. More researches should be conducted to further compare the performance of different layer strains chicks during laying phase and the mechanism of action of honey as replacement for antibiotics.

Abstract

The study examined the performance and cost implications of pigs on split mealing. Forty five (45) weaner pigs (Large white x Landrace) were allotted to three (3) treatments replicated 15 times of a pig per replicate in a completely randomized design in a feeding trial that lasted for 112 days. The treatments imposed were based on frequency of one or two or three meals a day. A measured quantity of feed at 5% body weight were made into either one or two or three portions and fed once or twice or thrice at 8.00 am or 8.00 am and 12.00.pm or 8.00 am and 12.00 pm and 4.00 pm, respectively throughout the experimental period. Data collected on daily feed intake and weekly weight gain were analyzed by one way analysis of variance using SPSS and differences in means where significant were separated using Duncan option of the software. Feed intake and weight gain of pigs were not influenced (P>0.05) by the frequency of feeding. Although, numerical improvement by 11.71% in the weight gain and 9.17 – 15.96% in feed intake were observed in pigs fed three times daily compared with those fed once or twice daily. Cost of pig production showed that the cost of feed expended to gain a kilogram weight of pigs was lesser in pigs fed twice (₦328.37) or thrice (₦343.45) a day when compared with those fed once daily (₦355.29). The study showed that feeding pigs' on split meal thrice daily improved weight gain with lower cost of production. Pig farmers are encouraged to feed their pigs thrice a day for better growth and higher economic advantage.

Keywords: economic advantage, performance, pigs, split mealing.

Introduction

Profitable pig enterprise is anchored on the efficient use of feed resources to optimize growth and minimize cost. Attempts to enhance the utilization of alternative feed resources such as agro-industrial wastes has largely proved not to be very effective due to quality concerns such as low protein content, high fibre content and anti-nutritional properties. Since most of the alternative energy and protein sources are not widely accepted as first choice in livestock feed formulation, researchers are now evolving a feeding management strategy that will promote good growth and ensure lean carcass meat.

The choice of feeding periods for pigs is based entirely on nutritional and economic considerations (INRA, 1984). For example, feeding restriction is commonly practiced with market pigs to improve carcass quality and feed efficiency while decreasing production costs (Wood *et al.*, 1996; Candek Polokar *et al.*, 1998), whereas free access to a low protein diet increases back fat thickness and intramuscular content (Gondret and Lebret, 2002).

In Nigeria, most farmers feed their pigs once daily while others allow the animals' free access to agro-by-products throughout the day. In conventional pig feeding management, however, more variable feeding management systems are applied.

The question of how often the pigs should be fed for efficient feed utilization still remains unanswered. The present study was to assess the effect of split mealing on the performance and cost implications of weaned pigs.

Materials and methods

The study was carried out at the Pig Unit, Department of Agricultural Science, Adeyemi College of Education, Ondo, Nigeria. A basal diet was formulated (Table 1) to meet the nutrients requirements for pigs (NRC, 2012).

Table 1. Gross composition of experimental diet, g/100g

Ingredients	Composition
Maize	53.8
Groundnut cake	8.13
Soybean meal	10.8
Palm kernel cake	15.5
Wheat offal	9.97
Limestone	0.50
Premix	0.50
Lysine	0.15
Methionine	0.15
Salt	0.50
Total	100

A measured quantity of feed at 5% body weight were made into either one or two or three portions and fed once or twice or thrice daily at 8.00 am or 8.00 am and 12.00.pm or 8.00 am and 12.00 pm and 4.00 pm, respectively throughout the experimental period. A total of forty five (45) weaner pigs (Large white x Landrace) of mixed sexes were randomly distributed to the three (3) treatments of 15 replications of a pig per replicate in a completely randomized desgn. Data collected on daily feed intake, weekly weight gain and calculated values for feed conversion ratio were analyzed by one way analysis of variance using SPSS and differences in means were separated using Duncan option of the software

Results and discussion

The numerical improvement in feed intake, weight gain and feed conversion ratio of pigs in this study is in agreement with the study on broiler chickens (Urdaneta – Rincon and Leeson, 2002; Tolkamp *et al.*, 2005; El-Fiky *et al.*, 2008; Chris *et al.*, 2011). Gaber and Hanafy (2008) reported that offering little quantities at time intervals improved feed utilization with concomitant increase in weight gain. From the economic indices measured, feeding pigs on split meals of twice or thrice daily recorded higher economic advantage compared with offering the whole feed in a single meal. The profitability ratio further confirms the economic benefit of employing split feeding in the management of pigs.

Table 2. Performance and economics of production of pigs on varying feeding frequency

	Frequency of feeding, in days				
	Once	Twice	Thrice	SEM	Sig
Performance indices					
Initial body weight, kg/pig	6.67	6.63	6.63	0.77	0.83
Final live weight, kg/pig	55.33	55.33	62.67	4.06	0.74
Average weight gain, kg/pig	0.44	0.44	0.50	0.32	0.62
Average feed consumed, kg/pig	1.32	1.22	1.45	0.11	0.65
Feed conversion ratio	3.01	2.78	2.88	0.08	0.26
Cost and Returns					
Cost					
Purchase price	3335	3315	3315		
Labour	450	450	450		
Pen maintenance	125	125	125		
Depreciation on building	87.75	87.75	87.75		
Cost of feed, N/kg	118.43	118.43	118.43		
Cost of feed, ₦/kg weight gain	355.29	328.37	343.45		
Cost differential, N	-	26.92	11.84		
Relative cost benefit, %	-	7.58	3.33		

Cost of weight gain, ₦	17363.02	16065.03	19116.97
Total cost, ₦	21360.77	20042.78	23094.72
Returns			
Return on sale, ₦	27665	27665	31335
Net profit, ₦	6304.23	7622.22	8240.28
Profit/kg over control group, ₦	-	1317.99	1936.05
% Profit over control group	-	20.91	30.71
Profitability ratio			
Benefit cost ratio (BCR)	1.29	1.38	1.36
Rate of return (ROR)	0.29	0.38	0.36
Gross ratio (GR)	0.77	0.72	0.74

Conclusion

Judging from the result of this study, feeding pigs on split meals twice or thrice daily enhanced weight gain, reduced cost of feeding and yielded higher profit compared with offering the whole feed in a single meal. Pig farmers are encouraged to employ split feeding in pig production.

Abstract

An experiment was conducted to assess the effect of millet and sorghum as alternatives to maize on hematology and serum biochemical parameters of quails. Three hundred (300) day old quails were sourced form National Veterinary Institute Jos. The birds were brooded for two weeks and randomly allotted to three (3) different energy sources i.e. maize, millet and sorghum designated as treatment 1, 2 and 3 respectively. The birds were fed with experimental diets for eight weeks and blood were collected for hematology and serum biochemical parameters. Results showed that packed cell volume (50.20-56.00), red blood cells (4.72-5.21) and hemoglobin (16.98-18.38) were statistically similar (P>0.05). The serum biochemical parameters showed that total protein (36.20-39.80), globulins (11.60-14.44), total protein (36.20-39.80), glucose (12.68-14.82), cholesterol (5.36-6.78), urea (17.80-20.00) and ASAT (1.98-2.08) were not affected by the different energy sources (P>0.05). It can be concluded that the alternative energy sources can be used in quail's production without deleterious effects on hematology and serum biochemistry of quails in semiarid environment.

Keywords: Quail's, energy sources, hematology, serum biochemistry

Introduction

Nigerian livestock industry has been greatly affected by high cost of feed which is reported to account for 60-85% of the total cost monogastric production (Sanni and Ogundipe, 2005). This high cost of feeds has necessitated the search of alternative energy sources. Maize is the major source of energy in poultry feeds and energy constitute about 40% of the feed cost in livestock production in Nigeria (Ijaiya et al., 2012). Maize also serves as staple food for good proportion of Nigerians. The ever growing demand for maize for human consumption, livestock feeds and some industrial uses has pushed its market price to an alarming height (Odukwe, 1994). This is because maize is high in energy and forms the standard (100) against which other cereals grains is compared (Atteh, 2002). Therefore, any cereal can be alternative to maize in poultry feed industry and could be the only immediate solution to reduce cost of poultry production. Hematological and serum biochemical parameters could serve as a baseline line information for comparisons of nutrient deficiency, physiology and health status of farm animals (Daramola et al., 2006: Maidala *et al.*, 2014). The aim of this research work is to evaluate the use of millet and sorghum as alternative energy sources on hematology and serum biochemical parameters of Japanese quails in semi-arid environment of Gashua, yobe state.

Materials and methods

Study area

The study was conducted in teaching and research farm of Federal University Gashua, Yobe state. Bade local government lies between latitude 10^0 and 11^0 east of Greenwitch and longitude 13^0 and 12^0 north of equator (Geoname/yobe state 2016).

Sources and processing of Ingredients

The millet and sorghum were purchase in Bade Central Market. The supplements were purchase from animal care Kano state. The maize, millet and sorghum were used to formulate the experimental diets which are isonitrogenous and isocaloric, the composition of the experimental diets are shown in Table 1.

Experimental birds and management

Three-hundred-day old quail chicks were sourced from National Veterinary Research Institute Vom, Plateau State. The birds were brooded for two weeks. The birds were randomly allotted to three dietary treatments, there are one hundred birds per treatment replicated five times (twenty birds per replicate) in a completely randomized design (CRD). The experiment lasted for eight weeks.

Blood profile analysis

Ten (10) birds per treatment (i.e. two birds per replicate) were randomly selected, fastened overnight. Samples of blood were collected from the brachial vein using 1ml disposable syringe and needle, the blood were stored in a blood samples bottles with and without anticoagulant (EDTA). Blood samples were analyzed for hematological parameters according to routine available clinical methods described by Baker *et al*. (1998). The biochemical parameters were determined by biuret reaction expanded by Bush, (1975). Data sets generated were subjected to analysis of variance ANOVA SPSSS 2010. LSD was used to separate the means.

Results and Discussion

The percentage composition of the experimental diets is shown in Table 1, the hematological and serum biochemical parameters are shown in Table 2. Results showed that packed cell volume, hemoglobin and red blood cells were not affected by the different energy sources ($P<0.05$), this finding suggested that the alternate energy sources provide enough energy for quail's metabolism. The values are within the normal range of 42 – 45% and 7 – 13g/dl for PCV and Hb (Banerjee, 2009) and 31 – 50% for PCV (Schalm *et al*., 1975). Similarly, the MCH, MCV and MCHC were not affected by different types of energy. The uniform values of the RBC, Hb, MCH, MCV and MCHC obtained in this study indicated that there were normal bone marrow functions, no macrocytic, hypochromic and autoimmune hemolytic anemia. Neutrophils was affected by the different energy sources ($P<0.05$), the neutrophils were better in millet and sorghum diets and this implies higher resistance to infection and bacteria while lymphocytes were better in the control diets. The serum biochemical studies revealed that albumin, total protein, globulins, glucose, chlorine and calcium were statistically similar ($P>0.05$) and this suggest that millet and sorghum can be alternative energy sources. The potassium and bicarbonate were affected across the treatment ($P<0.05$), the control diet had higher values of this mineral compared to alternative energy sources. Similarly, the control diet had higher level of sodium compared to alternative energy sources. The cholesterol, urea, creatine, ASAT, ALP and TB were not affected by the different energy sources ($P<0.05$), and this indicate that the liver and the kidney were physiologically normal. Higher significant values of ALAT ($P<0.05$) were observed in the control diet while the lowest was observed in millet diet, this suggest that millet is safer compared to maize for normal liver functions. Similarly, the CB were statistically higher in the control diet ($P<0.05$) and lowest in millet based diet. Results of this study indicated that the alternative energy sources can replace maize as energy sources in the diets of Japanese quails without adverse effect on hematological and serum biochemical parameters.

Abstract

This study aims to evaluate the effect of using Red Hot Pepper (RHP) as a dietary additive on peroxide value, free fatty acid and thiobarbituric acid levels of meat of Hubbard broiler chickens. For this purpose, 120-day old broiler chickens were fed diets containing varying levels of RHP. The birds were kept on deep litter throughout the duration of the study. A complete randomized design with 4 treatments and 3 replicates per treatment, with 4 levels of RHP supplementation (0%, 1.00%, 1.25%,1.50%) was used for the experiment. Each replicate contained 10 birds making 30 birds/treatment. The results showed that at 8 weeks, addition of RHP did not significantly (p>0.05) effect all the parameters measured. It was concluded that, RHP as an additive in Hubbard broiler chicken's diets had no negative lmpact on the meat quality parameters of interest.

Keywords: Red hot Pepper, Hubbard broilers, peroxide value, thiobarbiturate, free fatty acid.

Introduction

There is growing interest in the use of herbs as growth promoters and additives in the feed of birds. Evidence suggest that some herbs and spices have different active substances (Al-Kassie and Witwit, 2010) which could impact on the productivity of broiler chickens. The inclusion of dried red hot pepper for instance is reported to have a positive effect on the feed consumption of broiler chickens (Yoshioka *et al.*, 1999). Red hot pepper increases the ability of birds to reduce the deposition of cholesterol and fat in the body and contributes to decreasing the level of triglycerides and hence, work to support the vascular system in the body (Al-kassie et al 2010). Hencken (1991) opined that dried red hot pepper is rich in vitamin C which helps tremendously in improving production through its contribution in the reduction of heat stress. Reduction of heat stress is based on the fact that bird's consumption of dried red hot pepper induces a considerable change in energy balance when given free access to food (Yoshioka *et al.*, 2001).

Alkassie *et al.* (2011) revealed from their study, that the inclusion of red hot pepper at levels of 0.50, 0.75 and 1.00% in the diets of hybrid line Ross 308 broiler chickens, improved body weight gain and feed conversion ratio. The investigation of Thiamhirunsopit *et al*. (2014) using different forms of red hot peppers showed that better growth performance was observed in chickens fed experimental red hot pepper treatments in comparison to those fed the control diet. However, research works done to test the response of broiler chickens fed >1.00% red hot pepper is scarce. Therefore, the objective of this study is to evaluate the effect of feeding higher levels (>1.00%) of powdered red hot pepper on peroxide value, free fatty and thiobarbituric acids of meat obtained from Hubbard broiler chickens.

Materials and Methods

The experiment was conducted at Mike farm located at Shango area, Minna, Niger state, Nigeria. Minna is located in the Southern Guinea Savanna zone on latitude 9° 31 and 9° 42' North and Longitude 6° 29 and 6° 41' East with annual rainfall range of 1,200-1,300mm, and temperature range of 38-40^{0}C. The area has an altitude of 1,475m above sea level, and is characterized by two seasons; wet season (April-October) and dry season (November-March).The average temperature is 27.3^{0}C (FUTMIN, 2012).

The powdered hot red pepper was purchased from Minna Central market and was further dried at room temperature to retain its reddish colour and reduce the moisture content. It was ground with a Polystar blender (PV-BL999B, China) to pass through a 1.5mm sieve. Complete randomized design was used for the experiment, with the 120 day old chicks used for the research, divided into four treatment groups each with three replicates of 10 birds per replicate. The same commercial starter and finisher feed were fed to all the birds. The distinguishing factor is the dried powdered red hot pepper which was incorporated into the diets at 0.00, 1.00, 1.25 and 1.50%, respectively. The experimental birds were raised on deep litter. Before the arrival of the birds, the house was cleaned and disinfected with a germicide to avoid transmission of diseases to the new chicks. On arrival of the chicks, their initial body weight was taken and recorded. They were given broad spectrum antibiotics and supplied with anti stress and glucose in water. A known amount of feed was given to the birds in each treatment based on their dietary treatment. They were vaccinated against Newcastle and Infectious bursal diseases. The parameters measured were the peroxide level, free fatty acid level and thiobarbituric acid levels of meat obtained from the broiler chickens. Meat obtained from the chickens were stored at refrigerated temperature (2- 4^0C) and on a daily basis, samples was taken and analysed for a maximum of fourteen days. Meat were sampled at 2 days interval (2, 4, 8, 10, 12 and 14, respectively) and analysed using the method as described by guy et al.,(2013). Data collected were analyzed using the statistical package for social scientists (SPSS, 2016).

Results

The results (Table 1) shows the effect of red hot pepper (*Capsicum annum*) on the peroxide value of meat obtained from Hubbard broiler chickens. There was no significant ($p>0.05$) differences observed between the treatments in the peroxide value on day 2, 4, 6, 8, 10, 12 and 14, respectively. The addition of RHP in the diets of the birds did not also affect ($p>0.05$) the peroxide value cumulatively from day 2-14 days.

Discussion

The experiment materials, influences the quality of the fat deposited on broiler carcass (Bai and Lara, 2005). The result of this study showed no difference between birds fed the control and those fed the RHP based diets. This means that meats of the birds fed the control and the RHP based diets are less susceptible to peroxidation and the production of free fatty acid and thiobarbituric acid. Oxidation of meat could reduce the shelf life of meat and meat products. Contrary to results obtained In the current, Puvaca *et al*. (2015) reported that broiler chickens fed diets containing spices achieved better lipid profile status compared with those on un-supplemented feed. This could probably be due to the anti peroxidase effect of the spice used. Possibly, a higher level of RHP in the feed could elicit a similar reaction and or effect.

Conclusion

The results of the study Indicates the the use of dry red hot pepper as an additive up to 1.50%, prevented spoilage of meat obtained from Hubbard broiler chickens. No difference was observed in the peroxide value, free fatty acid and thiobarbituric acid levels of the birds fed the control and those fed the RHP based diets.

ABSTRACT:

The effect of dietary boiled African star apple kernel meal (BASAKM) as substitute for dietary maize on haemato-biochemical indices of growing rabbits were investigated. Seventy five 35-d old crossbreed (New Zealand x California white) rabbits weighing 591.00±0.15 g were allotted to 5 treatments (15 rabbits per treatment; 5 rabbits per replicate) in a completely randomized design. Five experimental diets (pelleted; 3 mm diameter and 6 mm in length) were formulated such that BASAKM replaced dietary maize at 0 %, 25 %, 50 %, 75 % and 100 % in rabbit diets (Diets 1, 2, 3, 4 and 5, respectively). A control diet (diet 1) had crude protein: 17 %, crude fibre: 10.35 %, metabolizable energy: 2647.50 kcal/kg. The study lasted for 56-d. At 91 d of age, the neutrophil level of rabbits fed diets 2, 3 and 4 decreased significantly compared to those fed the control diet (-5.20 %, -3.65 % and -9.69 %, respectively; P=0.0384. Results indicate that growing rabbits could tolerate BASAKM in their diets without adverse effect on haemato-biochemical indices of growing rabbits.

Key words: African star apple, Kernels, Maize, Boiling, Rabbits, haemato-biochemical

INTRODUCTION

The inclusion of alternative feedstuffs in animal diets might be interesting in some circumstances (relative price, feed quality), but it is limited because of the lack of information on their nutritive value. This is the case with African star apple (*Chrysophyllum albidum*) kernel meal, a by-product generated after the consumption of the fruits. African star apple (*Chrysophyllum albidum*) popularly called "Agbalumo" among the Yoruba tribe of Western Nigeria is also known as "Agwaluma" and "Udara" in Hausa and Igbo languages respectively. It is primarily cultivated for its sweet fleshy fruits which had been reported as an excellent source of vitamin C, iron, thickener or jam and flavours to diets, and raw materials to some manufacturing industries such as resin (Adisa and Fajola, 2000). Star apple belongs to the *Sapotacae* family and is believed to have originated from the low-lands of Central America and West Indian. It is common in both urban and rural centres in Nigeria especially during the months of December through April. The ripe fruit is highly perishable, and deteriorate within five days of harvest (Adisa and Fajola, 2000). Several researchers (Agbabiaka *et al.*, 2013; Makinde *et al*., 2017) have reported on the nutritional and medicinal importance of *Chrysophyllum albidum*. Apart from the report of Jimoh *et al.* (2014) on haematological changes in the blood of *Clarias gariepinus* fed *Chrysophyllum albidum* seed meal as energy source, there is dearth of information on the potential of African star apple seeds/kernels as alternative feed source. Therefore, this present paper reports experiment designed to investigate the haemato-biochemical indices of growing rabbits fed different levels of boiled African star apple kernel meal diets.

MATERIALS AND METHODS

Study site

The experiment was conducted from October to December, 2016 at the Rabbitry Unit of the Teaching and Research Farm of the School of Agriculture and Agricultural Technology, Federal University of Technology, Gidan Kwano Campus (Permanent site), Minna, Niger State.

Experimental feed, design, animals and their management

The African star apple kernels used for this study were sourced from African star apple fruit farmers in Osogbo, Osun State. African star apple seeds are always available between December and April. The seeds were gathered, washed with water to clean the dirts, allowed to dry under the shed for 7 d and carefully crushed with palm kernel machine so as to separate the kernel from the seed coat. Then, dried African star apple kernel was subjected to boiling at 100 °C for 15 minutes at the rate 1 kg kernel to 5 litre of water (Jimoh *et al*., 2014) after which water was drained off by means of 10 mm sieve and the boiled kernels were air dried under the shed for 7 d, milled using hammer mill with a sieve size of 3 mm and analysed in the laboratory.

Five experimental diets (diets 1, 2, 3, 4 and 5) were formulated to support optimal rabbit growth (de Blas and Mateos, 2010) as shown in Table 1. Diets 1 to 5 contained 0 %, 25 %, 50 %, 75 % and 100 % BASAKM, respectively as substitute for dietary maize. The diets were pelleted to 3 mm diameter and 6 mm in length and then analysed for chemical composition (Table 1). Seventy five 35-d old crossbred (New Zealand x California white) weaner rabbits of equal sexes weighing 591.00±0.15 g, certified healthy by a veterinarian, were allotted to 5 dietary treatments (15 rabbits per treatment; 5 rabbits per replicate) in a completely randomized design. The rabbits were housed in wire meshed cages, accommodated in a well-ventilated pen, supplied water and experimental diets *ad libitum* and the pen was cleaned and disinfected daily for 56 d which the study lasted.

B12 10mg, Riboflavin 5000mg, Pyridoxine 1300mg, Thiamine 1300mg, Panthothenic acid 8000mg, Nicotinic acid 28000mg, Folic acid 500mg, Biotin 40mg, Copper 7000mg, Manganese 48000mg, Iron 58000mg, Zinc 58000mg, Selenium 120mg, Iodine 60mg, Cobalt 300mg, Choline 27500mg.

Data collection

Blood samples were collected from 9 rabbits per group at 91 d of age for determination of haemato-biochemical indices. The selected rabbits were fasted overnight before blood collection. About 5 mL of blood were collected from the prominent ear vein of the rabbits using a ten gauge hyposeranic needles. Two millilitres of blood sample was collected into labelled sterile bottles containing ethylenediamine tetraacetic acid (EDTA) as anti-coagulant for the determination of haematological parameters, while the remaining 3 mL blood sample for serum analysis was collected into anticoagulant-free bottles, allowed to clot at room temperature and centrifuged at 3000 rpm for 10 min. The supernatant sera were harvested and stored at 4 °C in a refrigerator for subsequent biochemical analysis (Coles,1986). The analyses were carried out at the General Hospital Laboratory, Minna.

Statistical analysis

Data were subjected to analysis of variance in a completely randomized design using SAS software (SAS Institute, 2015, Version 9.3). Significant difference between individual means was highlighted by Duncan's procedure of the same software. Mean differences were considered significant at $P<0.05$

RESULTS

The results of the effect of boiled African star apple kernel meal on haematological parameters of growing rabbits at 91 d of age are presented in Table 2. There were no significant differences ($P>0.05$) in all the parameters measured except neutrophil. The neutrophil level of rabbits fed diets 2, 3 and 4 decreased significantly compared to those fed the control diet (-5.20 %, -3.65 % and -9.69 %, respectively; *P=0.0384*).

Table 3 shows the results of the effect of boiled African star apple kernel meal on serum biochemistry of growing rabbits at 91 d of age. There were no significant differences ($P>0.05$) in all the serum parameters analysed. Albumin, globulin, total protein, glucose, cholesterol, triglyceride and urea were not influenced ($P>0.05$) by the dietary treatments.

SEM= Standard error of mean, P = Probability value.

DISCUSSION

The blood profiles have been used widely to establish the health status of animals particularly when they are subjected to dietary treatment that could affect their well being. Thus, Aro and Akinmoegun (2012) and Isaac *et al.* (2013) identified haemoglobin (Hb), PCV, WBC, RBC, MCH and MCHC among others as blood parameters that are useful in feed toxicity and feed quality monitoring and their effect on health status of the animals. In this study, only neutrophils was significant among the haematological parameters measured. The range of 37.24-48.72 % observed for neutrophil in this study is within the normal range reported by Mitruka and Rawnsley (1977) for growing rabbits. The non significant difference observed among most of the haematological parameters measured implies that the haematopoietic activity was enhanced identically by the dietary treatments and by extension the health status of the rabbit was not compromised by replacing maize with boiled African star apple kernel meal in the diets of growing rabbit. Thus, in most cases the blood parameters reported here falls within the ranges reported by Latimer *et al.* (2003) and Ibrahim *et al.* (2014).

CONCLUSION

The result obtained from this study showed that boiled African star apple kernel meal can be considered as a high energy source in place of maize and growing rabbits could tolerate BASAKM in their diets without impairing the haemato-biochemical indices of the animals.

Abstract

A feeding trial of 84 days was conducted to assess the replacement value of African Locust bean fruit pulp for maize in weaner rabbits diet. Five diets were formulated, such that 100% maize and 0.00% fruit pulp of African fruit pulp at (T1), 75% maize and 25% inclusion of African locust bean at (T2), 50% maize and 50% African locust bean pulp as (T3), 25% maize and 75% African fruit pulp at (T4) while (T5) contain 100% fruit pulp of African locust bean and 0.00% maize respectively. Seventy five (75) weaner rabbits (5-6wks old) with average initial weight between 610.67g -622.60g were randomly allocated in a complete randomized design (CRD) experiment to the five diets with fifteen (15) weaner rabbits in each treatment which were subdivided into three (3) replicates having five (5) weaner rabbits in each replicate. The weaner rabbits were housed in individual cage compartment. Proximate composition of the experimental diets fed to weaner rabbits carried out indicated that T1 had dry matter content of 93.28 %, crude protein of 19.80 % and also 12.41 % of crude fiber. Ether extract was higher in T5 with 8.48 %, while nitrogen free extract contained in T3 had the highest value of 51.17 %. However ash content in T5 has the highest value of 7.83 %. The metabolizable energy in all the dietary treatment shows that T5had the highest value of 3013.21 ME/Kcal/Kg. Data were collected on daily feed intake and weekly weight. Feed conversion ratio, protein efficiency ratio, energy efficiency ratio, nutrient digestibility and feed cost benefit ₦ (kg) were calculated. Weaner rabbits fed 75% maize and 25% African fruit pulp (T2) consumed more feed and significantly gained more weight P<0.05 than those fed the other diets. Feed conversion ratio, protein efficiency ratio and energy efficiency ratio were not significantly (P>.0.05) influence by the treatment diets. Average feed cost of production with inclusion of maize was estimated at ₦311.25 in T1 while the African locust bean fruit pulp inclusion was ₦161.81in T5, a cost difference of ₦149.44, this resulted to a progressive reduction in the cost treatment of feed with increase in the level of fruit pulp of African locust bean meal. The results of this study indicated that when 25% fruit pulp of African locust replaced maize, the rabbits performed better than the control diet and also of more economical option.

Keywords: Fruit pulp, weaner rabbits, diet, proximate, metabolizable.

INTRODUCTION

There is an estimate of an annual five to seven percent growth rates for meat consumption, such increase cannot be met easily by large animals like sheep and cattle because of their slow production cycle, they may however be met by short cycle animals such as rabbits, poultry and pigs. The growing demand for maize in the last few years for both human and livestock consumption has pushed its market price to an alarming rate and that has directly affected the production cost of farm animals particularly the non –ruminants.(Igwebuike *et al*., 2003). The fruit pulp is obtained from the locust bean tree. The African Locust bean, (*Parkia biglobosa*) is a perennial tree. It grows in the savanna region of West African up to the edge of the Sahel zone. The fruit of the plant is straight or sickle shaped 15.6cm -31.20cm long and 2.6cm broad with thick waxy margin. When dried it is light brown with black seed embedded in yellowish mealy tasting pulp (Edigwe *et al*., 2012). The study herein conducted is to evaluate the replacement value of African locust bean fruit pulp for maize in weaner rabbits diet.

MATERIALS AND METHOD.

Experimental site – The experiment was carried out at the Rabbit unit of Animal Teaching and Research Farm, located at Gidan Kwano, Federal University of Technology Minna, Niger State.

SOURCE OF EXPERIMENTAL INCREDIENTS – Pulp of locust bean was purchased at Dandaudu village 56km away from Minna. Five dietary treatment were formulated at 16% crude protein requirement

with energy level of 2884.16(Kca/kg) for the rabbits using Pearson square method of feed formulation. Scwartz and Allen (2012).

EXPERIMENTAL DESIGN

A total of seventy five (75) rabbits of mixed sexes and breeds (New Zealand and chinchilla) were randomly allotted to five treatment groups as T1, T2, T3, T4, and T5 with three (3) replicate each, containing (5) rabbits in each replicate.

MANAGEMENT OF EXPERIMENTAL RABBITS.

Rabbits were kept in hutches made up of wood and mesh wire, with height of 60cm, and width 40cm. Hutches were enclosed in a house under intensive system were the floor of the house is cemented on the. All hutches and house were disinfected before commencement of the experiment work. (Olomu, (2008)

DATA COLLECTION AND ANALYSIS

Initial weight of weaner rabbits were taken at the first day on commencement of the experiment. Formulated feed were weighed each morning on daily basis and fed to rabbits in each treatment. Left over feed were weighed the following morning and feed intake obtained. by difference. Initial body weights of all the weaner rabbits were obtained on the first day of commencement of the experimental work, while the weekly body weight were obtained by weighing the weaner rabbits at the end of each week

RESULTS AND DISCUSSION

Rabbits fed 25% replacement level of fruit pulp of African locust bean diet had a higher feed intake and with a significant (P<0.05) weight gain than diet containing 75% and 50% levels respectively. This result agrees with Gernah *et al*., (2007) that low level of sweetness in the pulp yield a higher intake at 25% inclusion compared to the increased level of 50% and 75%. The high average weight recorded in 25% replacement level could be as a result of high level of feed intake by the rabbits in the treatment, this result agrees with Osagie (2011) that weight gain is directly related to feed intake, while low growth rate in diet 4 could be as a result of low intake of feed. The feed conversion ratio did not show a significant different (P>0.05) in all the dietary levels. Diet 2 shows lowest value, this is in agreement with the work of Okah (2004) who reported that the higher the weight gain per unit feed consumed, the lower the value of feed efficiency obtained. Protein and energy efficiency ratio did not show a significant difference (P>0.05) in all the diet. The ₦311.25 cost of fruit pulp of African locust bean, and maize ₦161.81gave rise to a cost differential of₦149.44, this resulted to reduction in the cost of feed as level of fruit pulp of African locust bean meal is increased ((Kwari and Igwebuike 2010)

CONCLUSION AND RECOMMENDATION

The result of this study reveal that fruit pulp of African locust bean could replace maize at 25% level for weaner rabbits diet without adverse effect on their performance. This level of replacement had less cost than maize based diet. However the effect of dietary fruit pulp of African locust bean on the performance of rabbits depends on the nutrient profile. The levels of maize in the reference diets might also influence performance of the rabbits.

ABSTRACT

The aim of this study was to assess the growth performance, nutrient digestibility and carcass characteristics of rabbits fed varying levels of groundnut haulm (GH) with concentrate. All together, 54 weaner rabbits of 6-7 weeks of an average initial weight of 735.81g were included in completely randomized design and fed six (6) dietary treatments of: 100% concentrate and 0% groundnut haulms (T_1, control), 80% concentrate and 20% GH (T_2), 60% concentrate and 40% GH (T_3), 40% concentrate and 60% GH (T_4), 20% concentrate and 80% GH (T_5) and 0% concentrate and 100% GH (T_6). In most of the treatments, the total feed intake, the body weight and carcass weight showed no significant ($p>0.05$). There were significant difference ($p<0.05$) in visceral organs and sensory characteristics when rabbits are fed groundnut haulms included diets than concentrate diets.

Keywords: Rabbits, groundnut haulms, concentrate, growth, carcass

INTRODUCTION

Food and Agricultural Organization (2004) reported low per capita animal protein consumption in developing countries particularly in humid tropics which calls for improvement in the production of short-cycle animals like rabbit. If rabbits are judiciously managed, they can kindle about six times in a year with the average of 6-7 kittens per kindling (Adeyemo *et al.,* 2013). This improvement is also essential by the rapid population growth with resultant increase in the demand for protein from animals.Rabbits have been identified to play vital role in the supply of quality protein especially in rural and peri-urban areas within the tropics (Egbo *et al*., 2001) this is because, they mature early and their meat has high protein, low fat, low energy and low cholesterol value (Adeyemo *et al.,* 2013). Rabbits have a short generation interval with high litter size and can be raised at the backyard which is well suited to small holder rabbit producers. It is important to note that, feed supply and quality is the major limiting factor to vibrant rabbit production in Nigeria. To make rabbit rearing more viable as a small-scale business, Makinde *et al*. (2014) had advocated the development of alternative feeding materials that are relatively cheap when compared with commercial feeds or conventional feedstuffs. Rabbits can be raised on high fibre feeds and materials that are not utilized by man and since they do not compete with man for grains, they have the advantage over swine and poultry (Adeyemo *et al.*, 2013). One of the non-conventional feedstuff and under-exploited forage feedstuff for rabbits in Nigeria is groundnut haulms which has high crude protein value.

MATERIALS AND METHODS

The experimental animals were sourced from the Rabbitry Multiplication Unit Minna, of the Niger State Ministry of Livestock and Fisheries. Groundnut haulms was sourced from Animal feed sellers, opposite NEPA office Minna. Concentrate was sourced from Sammy ventures, behind U.K. Bello arts theater, Minna. The study lasted for twelve weeks during which the rabbits were served with concentrate diet in the morning (8:00 am) and groundnut haulms (4:00 pm) of a known weight on a daily basis. Water was also provided *ad libitum*. Left over feeds were recorded to determine the daily feed intake.

RESULT AND DISCUSSION

In **Table 1.0** significant statistical differences between treatment and the parameters measured were noticed ($P < 0.05$). The final body weight (BW) of rabbits irrespective of treatment was all doubled their initial BWs. Nonetheless, very significant statistical difference was observed in feed intake observed between the treatments studied. Studies in rabbits have shown that BW tends to increase correspondingly with increase in feed intake, particularly forage (as seen in T_3) (Houndonougbo *et al.*, 2012; Maidala 2016) in which case feed intake have been positively correlated with level of fibre in rations. In these studies, poor digestion and utilisation of protein were reported to be responsible for the poor growth against the expected growth rate. The growth performance in terms of feed intake, body weight gain, final body weight and feed conversion ratio of rabbits fed only concentrate and those on 40% concentrate plus 60% groundnut haulms were similar. This may be attributed to the fact that forage is considered an important feed for rabbits growth and they are capable of digesting leaf protein effectively (Cheeke and Patton, 1982). This finding agrees with Bamgbose *et al*. (2003) who reported that rabbits can perform well with mixed regimen of forages and concentrates up to 50 % reduction without any adverse effect on growth. Also, lyeghe-Erakpotobor *et al*. (2002) observed significant effect of diets on intake of rabbits offered a combination of concentrate, grass and other forages. Similarly, Shiawoya and Musa (2006) reported that feeding of forage like mango, banana and tridax leaves can successfully support growth when fed with concentrate diets for weaner rabbits.

Table 1.0: Growth performance of rabbits feds varying levels of groundnut haulms and concentrate based diets

Parameters (g)	T1	T2	T3	T4	T5	T6	SEM	P-value

abc = means in abc = means in the same row carrying different superscript are significantly ($p<0.05$) difference.

The meat sensory properties of rabbits fed groundnut haulms and concentrate based diets showed beneficent ($P<0.05$) increase in the appearance, tenderness and overall acceptability of the meat (Table 2.0). While significant statistical difference was recorded in the organoleptic properties of fried rabbit meat in this study between the treatments ($P<0.05$), other studies obtained contrary results (Raïssa *et al.*, 2018;)

Table 2.0: Sensory characteristics of rabbit meat fed varying levels of groundnut haulms and concentrate based diets

Parameters	T1(keys)	T2( )	T3( )	T4( )	T5( )	T6( )	SEM	P-value
Colour	8.33	7.66	7.66	8.00	7.66	7.33	0.47	0.33

ab = means in the same row carrying different superscript are significantly ($p<0.05$) differe

Conclusion

1. Feeding rabbits solely on concentrate or inclusion of 60% groundnuts haulms to concentrate have similar feed intake, body weight gain, final body weight and feed conversion ratio.
2. Carcass parameters such as carcass weight, dressing percentage, neck length, cervico-thoracic region weight, tail length, heart weight and spleen weight of animals fed only concentrate and those fed with concentrate along with groundnut haulms up to 80% or solely on groundnut haulms were similar. Improvement was observed in lungs weight, kidney weight and intestine length the rabbits were fed groundnut haulms included diets than when fed solely on concentrates.
3. Sensory characteristics such as colour, flavor, juiciness and aroma are similar between the treatment diets. Additionally, acceptability of rabbit meat fed only concentrate and those fed concentrate along with up to 80% groundnut haulms are similar.

Abstract
This study was carried out at the Poultry Unit of the Department of Animal Production Teaching and Research Farm, Federal University of Technology, Minna Nigeria. A total number of 144 day old chicks were used for the study. The birds were randomly allotted into four treatments of three replicates each consisting of 12 birds per replicate in a completely randomized design (CRD) model. The treatments were T_1 (birds fed control diet), T_2 (birds fed 10 % mixture of cowpea milling waste(CMW) and plantain peel meal (PPM)), T_3 (birds fed 20 % CMW & PPM), and T_4 (birds fed 30 % CMW & PPM). The result showed that the feed intake, body weight gained and final body weight were influenced (P>0.05) by the inclusion of mixture of cowpea milling waste and plantain peel meal (CMW & PPM). The results of the total feed intake showed that birds fed on CMW & PPM 0 % (control group) had significantly (P<0.05) higher feed intake of 1023.7g while birds on CMW & PPM 20 % (T_3) had Significantly (P<0.05) lower feed intake of 750.56 g. However, mortality rate was significant at finisher phase. Broiler on T_1 (0 % CMW & PPM) and T_2 (10 % CMW & PPM) had significantly (P<0.05) higher mortality. It was concluded that CMW & PPM mixture in the diets of broiler chicken should not exceed 20 % for optimum growth performance and feed conversion.

Keywords: *Performance, broiler chicken, cowpea milling waste, plantain peel meal*

Introduction

The search for alternative feedstuffs for monogastric animals has challenged animal nutritionists in Nigeria since the past two decades. The search was necessitated by the high cost of the conventional feeding stuffs, which are also in high demand by human beings (Onyimonyi and Okeke, 2008). Feed supply, according to Ameafule *et al.* (2004) has remained a major constraint in animal production due to the ever increasing cost of conventional feedstuffs, due to the competition between man and livestock for cereal grains. Hence, the need to search for alternative feed sources that are cheap, readily available and less competed for by man and industries (Akinmutini, 2004). The need to harness the potentials of the numerous agro industrial by-products and the house hold wastes as part of replacement for the very expensive ones have been advocated (Umoh, 1984). Going by the fundamental role of energy in animal nutrition, it constitutes 35-60 % of rations for different species and classes of livestock. In developing countries, feeding, to a large extent, depends on the availability of the dietary energy source used in compounding concentrate rations for various classes of livestock. Hence, efforts are being made by animal nutritionists to obtain readily available, cheaper but qualitative feedstuffs that can serve as substitutes to the expensive and conventional energy and protein sources.

Materials and Methods

This research study was conducted at the Teaching and Research Farm of the Department of Animal Production, Federal University of Technology, Minna, Gidan Kwanu Campus, Niger State, Nigeria. It is located within latitude 09° 31´ 18.2´´N and longitude 6° 27´ 40´´E with an elevation that ranges from 230-250 m. The area lies within the Southern Guinea Savanna Zone of Nigeria. The sub-humid climate of the region has an average yearly rainfall of 1338 mm, dry season of about five (5) months and average temperature of about 30°C (FUTMIN, 2012). A total of one hundred and forty four (144) day old Ross 308 were sourced from DHAMAS Hatchery Farm Nigeria Limited Ibadan, Oyo State, Nigeria and were used for the study.

A mixture of cowpea milling waste and plantain peel meal were used at 0 %, 10 %, 20 % and 30 % to form treatments T_1, T_2, , T_3 and T_4 respectively. The birds were randomly allotted to the treatment

groups; each treatment was assigned 36 birds and further divided into three replicates of 12 birds per replicate in a completely randomized design (CRD) model. The experiment lasted for eight (8) weeks.

Results and Discussion

At the starter phase, results (Table 1) showed that initial weight, final weight average body weight gain, total body weight and feed conversion ratio were not significantly affected (P>0.05). However, the total feed intake and mortality were significantly (P<0.05).affected. The results of the total feed intake showed that birds fed on CMW & PPM 0 % had significantly (P<0.05) higher feed intake of 1023.7 g while birds on CMW & PPM 20 % (T_3) had significantly (P<0.05) lower feed intake of 750.56 g. There were no significant (P>0.05) differences in total feed intake between birds fed CMW & PPM 10 % and CMW & PPM 30 %. The results obtained from this experiment at the starter phase was in agreement with the results of Hamzat *et al.*(*2*019) who reported that inclusion level of 15 % plantain peel meal in the diet of broiler chicken tends to improve weight gain and FCR Though their research results did not involve inclusion of CMW The results at finisher phase showed that there were no significant differences (P>0.05) in all the parameters measured across the treatment groups.

Table 1: Growth performance of broiler chickens fed diets containing cowpea milling waste and plantain peel meal mixture at the starter phase

Parameters	T_1	T_2	T_3	T_4	SEM	*P-VALUE*

T_1 = 0 % Cowpea milling waste and plantain peel meal mixture (Control Diet)
T_2 = 10 % Cowpea milling waste and plantain peel meal mixture
T_3 = 20 % Cowpea milling waste and plantain peel meal mixture
T_4 = 30 % Cowpea milling waste and plantain peel meal mixture

SEM = Standard error of means, P-value= probability value, INI WT = Initial weight, FIN WT = Final weight
AFI = Average feed intake , TBWG = Total body weight gain , ABWG = average body weight gain
FCR = Feed conversion ratio, MOR = Mortality, TFI = Total feed intake.

The result of the finisher phase (Table 2) showed no significant difference (P>0.05) amongst all the parameters measured, except the percentage mortality rate. Mortality rate was significantly (P>0.05) higher at finisher phase. The result from this experiment indicated that the broiler chickens could tolerate high inclusion levels of CMW and PPM with T_3 and T_4 recording the same final weight of 975.00 g and 975.26 g respectively. The result of this experiment agrees with the findings of (Ironkwe *et al*. (2011) who reported that processed CMW and PPM tend to influence positively the growth parameters of broiler chicken without any deleterious effect at starter phase. The best FCR was recorded in T_4 (1.67) although this was not translated into high weight gains. This might be attributed to larger inclusion level of the test ingredient when compared to T_1 (Control) which recorded the highest final weight with high FCR (2.60). This is in agreement with Mmereole *et al.* (2008) who reported that the nature and bioavailability of the nutrients in the test ingredient could affect FCR which ultimately affected growth.

[ab] Means on the same row bearing different superscripts are significantly different (P < 0.05)
T_1 = 0 % Cowpea milling waste and plantain peel meal mixture (Control Diet)
T_2 = 10 % Cowpea milling waste and plantain peel meal mixture
T_3 = 20 % Cowpea milling waste and plantain peel meal mixture
T_4 = 30 % Cowpea milling waste and plantain peel meal mixture

Conclussion and Recommendations

It was concluded from the experiment that cowpea milling waste and plantain peal meal mixture had effect on the total feed intake and average feed intake. 0 % cowpea milling waste and plantain peel meal mixture had significantly (P<0.05) higher feed intake compared to 20 % CMW & PPM that had significantly (P<0.05) lower feed intake. It was therefore recommended that CMW & PPM mixture in the diets of broiler chicken should not exceed 20 % for optimum growth performance and feed conversion.

Abstract
This study determined the socio-cultural characteristics of smallholder pig farmers and their feed ingredients use approaches at two locations in Imo state, Nigeria. Primary data were generated with the aid of a structured questionnaires. The farmers were mostly males (93.75%) aged between 31-60 years (71%), married (78.13%) and mostly educated at secondary level (50%) and tertiary (40.63%). About 92% of these farmers were not educated in agricultural disciplines, with about 57% haven been in the business for the past 10 years on full-time basis (68.70%). Majority (65.63%) of the farmers formulated their own diets, with PKC (100%), maize offal (71.88%), maize (59.38%) palm oil sludge and cassava tuber (43.95% each) constituting the major energy feed ingredients used, while blood meal (78.32%), soybean meal (65.63%), groundnuts and cowpea (53.13% each) constituted the major protein raw material used. Popular fibre materials were cassava peels (75%), yam peels (71.88%), plantain peels (65.63%) and plant leaves (53.13%). The present results highlight the need for further studies on the local feed ingredients utilization practices of these farmers.

Keywords: feed ingredients, palm kernel cake, Pigs farmers

Introduction

Small-scale intensive pig production in Nigeria is currently being challenged by high cost of feed raw materials arising from the continued increase in the cost of conventional feedstuffs. Nigeria is however characterized with a wide range of alternative feed resources such as oilseeds, grains, forage crops, peels, animal and agro industrial by-products. These locally available feed materials have potential to sustain the piggery industry, although underutilized by farmers due to inadequate information on their location, storage and quality enhancement (Ohanaka *et al.*, 2017).

Different alternative feed raw materials abound in Imo state and are incorporated into pig feeding according to novel methods developed by the farmers (Ohanaka *et al.*, 2017). According to Wettasinha *et al.* (2008) such farmer led local experimentation is common in many regions of the world. However, these location specific innovations are usually lost with changing environmental and social needs of the innovators. Identifying, documenting and if possible, evaluating such local innovation systems provide an entry point to Participatory Technology Development (PTD) that begins with studying existing farmer approaches and practices geared towards solving local problems (Wettasinha *et al.*, 2008).

This study determined the socio-cultural characteristics of smallholder pig farmers and their feed ingredients use approaches at peri-urban and rural farming locations in Imo state, Nigeria.

Materials and Methods

The study was carried out among pig farmers in two Local Government Areas (LGAs) in Imo State, in the tropical rain forest environment of southeastern Nigeria. An informal survey was carried out prior to the actual study during which, the researcher made himself known to pig farmers and discussed the details of the work with them. The study LGAs were Owerri West LGA (OWL), a peri-urban area and Aboh-Mbaise LGA (AML) a rural area. At these locations, 25 pig farms each were purposively selected based on the willingness of their owner to participate in the study, making a total of 50 pig farmers. Primary data were collected with the aid of a well-structured questionnaire. On the whole, only 32 questionnaires were returned by the farmers (17 at OWL and 15 at AML). Data generated from the socio-cultural study were subjected to descriptive statistics, such as frequency count, mean and standard deviations.

Results and Discussion

Results in Table 1 showed that most of the farmers were males (93.75%) aged between 31-60 years (71.88%), married (78.13%) and mostly educated at secondary level (50%) and tertiary (40.63%).

Above 100	7 (41.18)	6 (40.00)	13 (40.63)

About 92% of these farmers were not educated on any agricultural discipline, with about 47% been in the business for the past 10 years on full-time basis (68.70%). Majority (40.63%) of the farmers stocked above 100 pigs, while 37.50% stocked between 31-50 pigs. Across study locations, the results showed that farmers at OWL were more educated (64.71% tertiary) than those at AML (73.33% secondary), most of the tertiary institution educated farmers (90.91 and 100% respectively)

specializing in non-agriculture related disciplines. Similar results were reported by Okoli *et al.* (2009) in the same Imo state.

Results in Table 2 showed that majority (65.63%) of the farmers formulated their own diets with PKC (100%), maize offal (71.88%), maize (59.38%) palm oil sludge and cassava tuber (43.95% each) constituting the major energy feed ingredients used, while blood meal (78.32%), soybean meal (65.63%), groundnuts and cowpea (53.13% each) constituted the major protein raw material used.

Popular fibre materials were cassava peels (75%), yam peels (71.88%), plantain peels (65.63%) and plant leaves (53.13%) while majority (81.82%) of the farmers used feed additive mixes in the feed. There was a clear disparity in the choice of raw materials at the two locations with more maize, cassava tuber, maize offal and brewers waste being utilized at OWL and more palm oil sludge, blood meal, rumen digesta, cassava, yam and plantain wastes being utilized at AML indicating greater innovative use of available raw materials at the rural location. About 90% of the farmers gave a variety of forages to their pigs.

However, Table 3 showed that out of then 22 forage plants and vegetables fed to the pigs only four, water leaf (*Tanilum* triangulare), *Cetrosema pubescene,* pumpkin leaf (*Telfera occidentalis*) and pawpaw leaf (*Carica papaya*) were fed at the two location, indicating diversity of knowledge, which has also been reported by Obua *et al.* (2012).

Table 3: Forage plants and vegetables utilized in pig feeding

Owerri West LGA	Aboh-Mbaise LGA	Frequency
Water leaf (*Tanilum* triangulare)	Water leaf (*Tanilum triangular)*	2
Cetrosema pubescene	*Centrosema pubescene*	2

Total 13	13	22

Conclusion

Data generated from this study shows a rich innovative local feed ingredients utilization culture among smallholder pig farmers in Imo state, who were mostly educated. The present results highlight the need for further studies on the local feed ingredients utilization practices of these farmers for documentation and extended industrial applications.

Abstract

An experiment was conducted to assess the growth performance and cost benefit of substituting full fat soya bean (FFSB) for soaked-toasted cassia tora seed meal (STCS) in the diets of finisher broilers. Five diets were formulated in which STCS replaced FFSB at 0, 25, 50, 75 and 100% levels designated as diets 1, 2, 3, 4 and 5 respectively. Three hundred broiler chickens weighing between 850 and 869 g were randomly allotted to five diets in replicates of four containing 15 birds each in a completely randomized design. Feed and water were provided ad libitum and the experiment lasted for 28 days. Results showed that daily feed intake (79.61 – 97.01g) did not differ among diets. However, daily weight gain (17.33 – 40.11g), total weight gain (485.24 – 1123.08g) and feed conversion ratio (2.33 – 4.65) were significantly (P<0.05) affected. Broiler birds fed diets containing STCS beyond 25% level resulted in lower performance. A cost saving of ₦13.74was realized on diet 2. It was therefore concluded that soaked-toasted cassia tora seed meal can replace full fat soya bean at 25% level in finisher broiler diets without compromising performance and a reduction in feed cost.

Introduction

Protein sources are the second largest component of practical poultry diets. A limited number of ingredients are used by commercial poultry industries to supply protein. These ingredients are mostly limited in distribution and are also generally expensive than energy sources (Paul *et al.*, 2017). Soya bean seed is the main protein source used by poultry feed manufacturers. However, in Nigeria, its price is high and tends to fluctuate with changes in climatic conditions and social situations (Akande *et al.*, 2010). Accordingly, any shift in the use of ingredients other than soya bean, more especially the non-conventional ones, as plant protein sources, will greatly reduce the pressure on soya bean and reduce poultry feed cost which stands at about 70% of the total cost of intensive poultry production (Olorede and Longe, 1999; Anamayi, 2018).

Although the utilization of non-conventional plant protein sources e.g leguminous seed and leaf meals may be cost effective, their use is principally limited by the presence of anti-nutritional factors (ANFs) (Gatlin *et al.*, 2007). In order to eliminate or reduce the effect of these ANFs, several processing methods like soaking, cooking, toasting and sprouting have been identified (Torki and Farahmand-Pour, 2007 Ahamefule and Odemelam, 2008; Omoikhoje *et al.*, 2009; Buba *et al.*, 2010).

Cassia tora is an un-conventional plant protein ingredient that may be used in poultry rations. According to Ingweye *et al.* (2010), the seeds have good nutritional properties (protein 29.54%, methionine 0.92g/100g and energy 325.28 kcal/kg) but contain some ANFs (tannins, alkaloids, phytates and saponins). The aim of this study was to ascertain the performance of finisher broiler

chickens fed diets containing double stage processed (soaked and toasted) *Cassia tora* seed meal as replacement for full fat soya bean.

MATERIALS AND METHODS

The experiment was conducted at the Poultry Production unit, Ministry of Animal Husbandry and Nomadic Affairs, Gombe, Gombe State.

Soya bean was cleaned, boiled for 30 minutes using jute bags and sun-dried for 3-4 days. Similarly, mature *Cassia tora* seeds were harvested from the wild, around Tukulma village, Gombe state. The seeds were manually threshed from the pods and spread on a floor to sun-dry for two days. Thereafter, the seeds were soaked in clean water for 24 hours, sundried and toasted in a frying pan until they began to change colour. The two ingredients (soya bean and *Cassia tora*) were then crushed to 3mm particle size and kept in 50kg bags until when ready for use. Samples of *Cassia tora* were analysed for proximate composition (table 1) according to AOAC (2011).

Table 1: Proximate Composition of Soaked-Toasted *Cassia tora*.

Nutrient (%)	Level
Dry Matter	96.32
Crude protein	26.55

Ash	8.69
Phytate (mg/100g)	117.08
Hydrocyanic acid (mg/kg)	3.52
Tannin (mg/100g)	128.43

Five isonitrogenous, isocaloric experimental diets containing 20% crude protein were formulated, with *Cassia tora* seed meal replacing full fat soya bean at 0, 25, 50, 75 and 100% levels coded as diets 1, 2, 3, 4 and 5 respectively (Table 2).

A total of three hundred (300) unsexed *Abor acres* broiler chickens weighing between 850 – 869g were used for the experiment. The birds were randomly allotted to five experimental diets in 4 replicates of 15 birds each in a Completely Randomized Design. Feed and clean drinking-water were served *ad libitum* throughout the 28-day trial period.

Daily feed intake was determined by and birds were weighed on weekly basis. Feed conversion ratio was calculated from the values of feed intake and weight gain. Mortality was also recorded as it occurred. Prices of feed ingredients were recorded as at the time of study. Data were analysed using One-way Analysis of Variance (SPSS Statistics 17.0). DMRT was used for mean separation (Duncan, 1955).

Results and Discussion

The proximate composition (Table 1) of soaked-toasted sickle pod seeds (STCS) showed that it has a dry matter content of 96.32%, crude protein 26.55%, ether extract 5.08%, crude fibre 6.92% and an ash content of 8.69%. These values were comparable to those reported by Augustine *et al.* (2017) in fermented *Cassia tora* seeds. Similarly, the result revealed that the levels of anti-nutritional factors in STCS are phytate 117.08 mg/100g, hydrocyanic acid 3.52 mg/kg and tannin 128.43 mg/100g. The tannin content is lower than 330 mg/100g reported for Mung beans (Mubarak, 2005).

Performance of finisher broilers (Table 3) fed dietary levels of STCS as replacement for full fat soya bean soya bean showed no significant difference in initial weight of birds (850 and 869 g). Final weight (1335.43 – 1975.14, P<0.05) and total weight gain (485.24 – 1123.08g, P<0.05) were influenced by diets with better values on diets 1 and 2. Daily feed intake (80.56 – 97.01g) was also not significantly influenced by the replacement of full fat soya bean for STCS in the diets. This contradicts Augustine *et al.* (2017) who reported a significantly (P<0.05) lower feed intake in broiler chickens fed differently processed *Cassia tora* seeds. However, daily weight gain of birds on diet 2 (37.38 g) compared favourably with the control (40.11g) which was significantly (P<0.05) higher than diets 3 (21.29 g), 4 (18.42 g) and 5 (17.33 g). A similar finding was reported by Emiola *et al.* (2013), who fed processed Mucuna seed meal to broiler chickens. Feed conversion efficiency decreased significantly (P<0.05) with increased STCS above 25% level in the diets. This could be as a result of the higher levels of ANF present in these diets. Feed cost per kg (₦) decreased from ₦113.78 on diet 1 to ₦73.82 on diet 5. Feed cost per kg gain ((₦) was lowest (₦252.42) on diet 1 and highest on diet 4 (₦381.92). The highest cost saving of ₦13.74 was made on diet 2.

ABSTRACT

This study evaluated the effect of boiling as a processing method on the micro and macro mineral composition of Moringa oleifera seeds as potential livestock feed. Moringa oleifera seeds were collected from Ungwan Musa, Kafanchan in Jama'a LGA of Kaduna State, Nigeria. The seeds were weighed and divided into seven (7) portions of 100g each. The first portion was left raw as treatment control, while the second, third, fourth, fifth, sixth and seventh portion were boiled for 10, 20, 30, 40, 50 and 60minutes respectively. Thereafter the micro and macro mineral compositions were evaluated in the laboratory and the results obtained were analysed using simple descriptive statistics. The results showed a decline in both macro and micro elements with successive increase in boiling duration (from 10-60mins). For Macro minerals; Sodium, Potassium, Calcium, Phosphorus and Magnesium, a declined by 1.5%, 0.9%, 0.47%, 1.08% and 1.87% respectively was recorded. Micro minerals; Iron, Copper, Manganese and Zinc decreased by 1.19%, 2.37%, 0.22% and 2.27% respectively. At 60 minutes boiling duration, Copper recorded the highest decline (2.37%), hence it was concluded that boiling Moringa oleifera seeds for 10-60minutes has no deteriorating effects on its macro and micro mineral compositions because all mineral elements considered were still within recommended amount to be fed as livestock feed.

Keywords: *Moringa oleifera*, Boiling, Macro and Micro Minerals.

INTRODUCTION

The rising cost of feeds and feedstuff in the livestock industry is a major source of concern for the industry and has remained a serious obstacle to meeting the demands of animal protein in developing countries like Nigeria. Cost of feeding has been estimated to account for about 70% of total production cost in broiler production (Adejinmi, 2000).

Livestock feed cost in developing countries is a continuing challenge. The high and increasing prices of animal feeds have compelled researchers in developing countries to direct their attention towards utilization of non-conventional feed stuff, with particular emphasis on protein substitutes (Gaia, 2005). *Moringa oleifera* Lam is one of the 13 varieties of Moringaceae, which is native to India, Red Sea and parts of Africa including Madagascar, of these, *M. oleifera* is the most widely known variety (Price, 2007). *Moringa oleifera* is among those plants that can be integrated with livestock production to increase feed quality and availability because it is a good source of cheap protein supplement to improve digestibility of other diets. All plant parts can be used to feed livestock.

Food processing transforms raw foods to edible forms. It also increases shelf-life, digestibility, flavor, nutritive value among other benefits. Various foods presuppose different processing techniques depend on the needs and end products required (Okokon, 2004). Boiling as a processing method is known to bring about high complex reactions without having direct effect on nutritional value of food (Umeh and Bassir, 1977). Therefore the aim of this study was to determine the effect of cooking time on the micro and macro mineral composition of *Moringa oleifera* seeds grown in Ungwan Musa, Jama'a Local Government Area of Kaduna State, Nigeria.

MATERIALS AND METHODS

Collection and Preparation of Samples

The seeds were collected from Ungwan Musa, Kafanchan in Jama'a Local Government Area of Kaduna State, Nigeria. The seeds were sorted and divided into seven (7) samples of 100g each at the Kaduna State University Animal Science laboratory using a 250kg manual weighing scale (spring balance).

Processing of samples

A sample of 100g was weighed, grinded into powder, sealed in a polythene bag and tagged "0" (Raw Moringa Seeds) as the treatment control. The remaining six (6) samples each containing 100g of matured Moringa Seeds were emptied into a boiling water. Clean water was used to boil the Moringa seeds. One hundred grams of Moringa seeds was collected at every 10mins interval. The last 100g of Moringa seeds was collected after 60mins of boiling. Six (6) samples in all were collected separately from the boiling water, drained, sundried for 5hours and grinded into powder. The six (6) samples were sealed in individual polythene bags and tagged 10, 20, 30, 40, 50 and 60 representing samples boiled for 10, 20, 30, 40, 50 and 60mins respectively.

Laboratory Analysis

The processed Moringa (*Moringa oleifera*) seeds were taken to the Department of Nutrition and Dietetics, Kaduna State Polytechnic for analysis. Samples were analysed to determine the effects of boiling duration on micro and macro mineral composition. The mineral contents including sodium, potassium, and calcium was determined in EPC (Extracted Pomace Cake) using flame photometry while magnesium, iron, copper, manganese and zinc contents were determined by atomic absorption spectroscopy according to A.O.A.C. (2010). A standard colorimetric method was applied for phosphorus as mentioned by Borah *et al.* (2009).

Statistical Analysis

All data collected on macro and micro mineral compositions were analysed by simple descriptive statistics. The percentage change of each treatment was calculated using the formula:

$$\%\ change\ = \frac{C - V}{C} \times 100$$

Where C = Value of Control (Raw), and V = Value for each Treatment.

RESULTS AND DISCUSSION

Table 1: Effect of Boiling Duration on the Mineral Composition of *Moringa oleifera* Seeds

Parameters	Boiling durations in minutes						
	0	10	20	30	40	50	60
Macro Minerals							
Sodium mg/100g	1470.00	1468.00	1466.00	1460.00	1455.00	1450.00	1448.00
Potassium mg/100g	1273.00	1272.00	1270.00	1268.00	1266.00	1264.00	1261.00
Calcium mg/100g	254.00	254.00	253.00	253.80	253.50	253.30	252.80
Phosphorus mg/100g	738.00	738.00	737.00	736.60	736.40	736.00	730.00
Magnesium mg/100g	64.20	64.18	64.10	64.00	63.50	63.20	63.00
Micro Minerals							
Iron mg/100g	185.20	185.00	184.60	184.60	184.50	184.00	183.00
Copper mg/100g	7.60	7.60	7.54	7.50	7.47	7.45	7.42
Manganese mg/100g	91.60	91.60	91.60	91.58	91.50	91.46	91.40
Zinc mg/100g	57.30	57.30	57.20	57.00	56.80	56.50	56.00

0 = the raw *Moringa oleifera* seed sample which signifying control, while 10, 20, 30, 40, 50 and 60 = boiling time for *Moringa oleifera* seeds in minutes.

The effect of boiling duration on the mineral composition of *Moringa oleifera* seeds is given in table 1. Macro and Micro minerals were slightly reduced with increase in cooking time contrary to the report of Mbah *et al.,* (2012) who recorded an increase in the amount of Calcium, Iron and Zinc in *Moringa oleifera* seeds boiled for 10, 20 and 30mins. David (2018) also reported a decrease in the amount of both macro and minor minerals when *Moringa oleifera* seeds were boiled for 30minutes. The values for both macro and micro minerals of Raw *Moringa oleifera* seeds recorded were similar to that given by Barakat and Ghazal, (2016). At 60mins boiling duration, the values of Ca, Na, K, and P (1448mg/100g, 252.8mg/100g, 1261mg/100g and 730mg/100g respectively) were all within the amount recommended for both Layers and Broiler birds as reported by Van der Klis and Vinyeta, (2015). The Iron concentration was found to be 183mg/100g for *Moringa oleifera* seeds boiled for

60mins. Iron is essential for haemoglobin formation and its deficiency leads to anaemia (Turan *et al.* 2003). The value of Magnesium contained in the raw *Moringa oleifera* seeds (64.20mg/100g) was lower compared to the value (677.00mg/100g) for *Moringa oleifera* leaf given by Sodamade *et al.* (2013). Magnesium is very important in calcium metabolism in bones and also involved in prevention of circulatory diseases and also helps in regulating blood pressure and release of insulin.

Table 2: Percentage Change in the Level of Mineral Composition of *Moringa oleifera* Seeds at Different Boiling Time.

Parameters	Percentage change due to different boiling time						
	0	10	20	30	40	50	60
Macro Minerals							
Sodium	-	0.14(-)	0.27(-)	0.68(-)	1.02(-)	1.36(-)	1.50(-)
Potassium	-	0.08(-)	0.24(-)	0.39(-)	0.55(-)	0.71(-)	0.94(-)
Calcium	-	-	0.39(-)	0.07(-)	0.19(-)	0.28(-)	0.47(-)
Phosphorus	-	-	0.14(-)	0.19(-)	0.21(-)	0.27(-)	1.08(-)
Magnesium	-	0.03(-)	0.16(-)	0.31(-)	1.09(-)	1.56(-)	1.87(-)
Micro Minerals							
Iron	-	0.11(-)	0.32(-)	0.32(-)	0.38(-)	0.65(-)	1.19(-)
Copper	-	-	0.79(-)	1.32(-)	1.71(-)	1.97(-)	2.37(-)
Manganese	-	-	-	0.02(-)	0.11(-)	0.15(-)	0.22(-)
Zinc	-	-	0.18(-)	0.52(-)	0.87(-)	1.40(-)	2.27(-)

(+) = % increase, (-) = % decrease.

Table 2 shows percentage change in mineral composition of *Moringa oleifera* seeds boiled at different durations. At 10mins boiling time, Potassium, Magnesium and Iron reduced by (0.08%, 0.03% and 0.11% respectively), this shows that these mineral elements are easily leached out compared to other mineral elements (Calcium, Potassium, Copper, Manganese and Zinc). It also reveals that Manganese was the most attached mineral element which was reduced by 0.02% at 30mins boiling time. At 60mins of boiling, Manganese recorded the lowest depletion (0.22%) and Copper had the highest depletion (2.37%) at the same 60mins.

CONCLUSION AND RECOMMENDATION

From the results obtained in this study, it was concluded that increasing boiling time from 0 to 60 minutes led to reduction in the concentration of mineral elements in *Moringa oleifera* seeds. The major mineral elements; Sodium, Potassium, Calcium, Phosphorus and Magnesium were lost by 1.5%, 0.94%, 0.47%, 1.08% and 1.87% respectively while the micro mineral elements; Iron, Copper, Manganese and Zinc were lost by 1.19%, 2.37%, 0.22% and 2.27% respectively. *Moringa oleifera* seeds boiled within the range of 10-60mins remain a good source of minerals because the elements considered were still within recommended amount to be fed as livestock feed and therefore a good source of livestock feed. Further research could be made in this area in order to evaluate other minerals which were not considered in this experiment and subsequently followed by a feeding trial to test for acceptability of the feedstuff and other parameters.

REPLACEMENT VALUE OF GROUNDNUT HUSK FOR MAIZE IN RABBITS DIETS

***N. Adamu, A. S. Aliyu, I. Sani, S. Adamu and N. A. Jama'a**

Department of Animal Production, Faculty of Agriculture and Agricultural Technology, Abubakar Tafawa Balewa University Bauchi, Nigeria.

***Correspondence Author, email: nuratuadamu@gmail.com, 08036460634**

ABSTRACT

An experiment was conducted to evaluate the replacement value of groundnut husk for maize in rabbit diets. Groundnut husk was used at 0, 10, 15 and 20% levels to replace maize as diets 1, 2, 3 and 4 respectively. A total of sixteen rabbits of mixed breed and sex were obtained from Muda Lawan market Bauchi and allotted to four dietary treatments in a completely randomized design (CRD), and the feeding trail lasted for eight weeks. Daily feed intake (P<0.001) 38.70-46.30g and daily weight gain 4.6-10.50g (P<0.05) were affected significantly by the dietary treatments, however feed conversion ratio (4.01-3.15) was not affected significantly. The feed cost in naira per kilogram gain was relatively higher on maize (control diet) and lower on groundnut husk based diets. It can be concluded that groundnut husk can substitute maize up to 20% level of inclusion in the diets of rabbits without any adverse effect on performance.

Key words: Rabbits, Diets, Groundnut husk, Maize and Performance.

INTRODUCTION

The potential of rabbit meat as a quality or nutritious food resulted from its higher protein content, lower fat, lower sodium and cholesterol content compared to other meat sources such as beef, pork, mutton and chicken. Protein deficiency in some part of the world has reached an alarming state. It is a fact that there is an inadequate intake of animal protein in Nigeria (Ayayi *et al*., 2007). To erase this problem of low animal protein intake, there should be an expansion in the production of small highly prolific livestock with rapid turnover rate at a very low cost. Rabbits are small mammals in the family leporidae of the order lagomorpha found in many different continent and climatic zones. The prolific nature of rabbits coupled with it short gestation period and generation interval makes it the animal of choice for multiplication and a short way of increasing animal protein intake (Akinmutimi *et al*., 2008). Rabbit production in Nigeria is gaining much popularity but it is contravened by the high cost of conventional feed stuffs which producers cannot afford. Feed is one of the constraints to intensive rabbit production in Nigeria due to competition between man, industries and animals for conventional feed materials. This has led to the escalating cost of conventional ingredients and has made feed cost to account for about 70% of total cost of production (Akinmutimi, 2008). This problem has been the major stimulant for the search for alternative feed stuffs that can meet the nutritional requirement of micro-livestock, reduce the cost of feed and animal production (Oloredeet, 2011). The alternative feed material should be one that has low human food preference and of low industrial usage. Groundnut husk is the cover that is left after the fleshy groundnut seed is removed. The groundnut husk has some nutritive value and may be useful to rabbits as source of fiber (Aduku and Olukosi, 1992). There is no sufficient literature on the use of groundnut husk as feed by rabbits. Therefore, the present study will test the effect of replacing maize with groundnut husk in the diets of rabbits and to find out the economic efficiency of using groundnut husk in rabbit production.

Materials and Method

Experimental Site

The experiment was conducted at College of Agriculture farm Bauchi, Bauchi State. Bauchi is located within the Northern Guinea Savanah on latitude 10^1, 17 N and 9^0, 49^1E at altitude 690.2m above sea level (FAO, 1999). The mean annual rain fall ranges between 600mm in the north and 1300mm in the south. Bauchi has mean annual maximum and minimum indoor temperature of 32 to 41 respectively with a relative humidity of 20.00 and 67.00% respectively

Experimental Animals and their Management

A total of sixteen weaned rabbits of mixed breed and sexes were used for the study. The rabbits were between the ages of 6-7 weeks. The experimental animals were randomly distributed to four (4) dietary treatments and each treatment was replicated two (2) times and the trial lasted for eight weeks.

The rabbit's house was cleaned and disinfected before the beginning of the experiment, similarly; the cage, plastic drinker and feed containers were thoroughly washed and disinfected. The rabbits were gradually introduced to the experimental diets. Routine management was carry out on daily basis such as cleaning the cage, supplying feed and fresh water.

Experimental Diets

Four (4) diets were compounded with; 0, 10, 15 and 20% replacement levels of groundnut husk, coded as diets T1, T2, T3 and T4 respectively.

Data Collection and Statistical Analysis

Rabbits were bought from market and weighed at the beginning of the experiment after preliminary period of one week to determine the initial weight of the rabbits. Subsequently the rabbits were weighed weekly to determine the body weight changes. Feed intake was obtained by subtracting the leftover from the initial feed given which is on daily basis. Data collected was subjected to analysis of variance statistical package for social sciences and significant differences in treatment means were separated using LSD.

Results and Discussion

Performance of Rabbits

There was no significant difference ($p<0.05$) on the initial weight of the experimental rabbits this shows that all the rabbits have similar weight. There was no significant difference ($p<0.05$) on the final weight gain and feed conversion ratio. However there was significant difference ($p<0.001$) on the total feed intake. Rabbit on diet 3, consumed 5187g more feed compare to those on diet 1, with feed consumption of 4289g. This possibly was because of the level of crude protein present in the diet make the feed more palatable. Also there was highly significant difference ($p<0.001$) on the average daily feed intake. Rabbits on diet 3, consumed 47. 20g per day while rabbits on diet 1, consumed 38.70g per day. This may be as a result of higher level of forage in diet 3, because rabbits can be reared solely on forages as reported by Omole, (1992) that the basal diet for rabbits is forages but supplementation with concentrate improves the performance of the rabbits. There was significant difference ($p<0.05$) on the average daily weight gain. Rabbit on diet 4 have the highest average weight gain of 10.50g, followed by rabbits on diet 3, 2 and 1 with weights of 6.60g, 6.40g and 4.60g respectively. This finding agrees with the study of Iyeghe-Erakpotobor and Adeyegun, (2012) they reported that weight gain of rabbits increased with increase in groundnut forage meal level. The economic analysis shows that, feed cost in naira per kilogram gain seemed to be comparatively higher on maize (control diet) than the groundnut husk based diets, this trend was expected as the price of maize was higher than groundnut husk which price amount close to little or nothing and could economically replace maize. The feed cost ₦/kg gain at 20% level of inclusion of groundnut husk diet is cheaper and requires ₦260 worth of feed to provide 1kg body weight gain compare to control diet that requires ₦618.7 to produce 1kg body weight gain.

Conclusion

It can be concluded based on the results obtained, that groundnut husk could replace maize up to 20% level of inclusion without any detrimental effect on performance. The 20% level of inclusion is economically cheaper and could give a cost saving of 358.7 from each kg of feed used compare to the control diet.

The percentage composition of the experimental diets will be shown in table 1 below

Table 1: Percentage Composition of the Experimental diets fed to rabbits

	Diet%			
Ingredient	**T1(0)**	**T2(10)**	**T3(15)**	**T4(20)**
Maize	34.62	31.16	29.43	27.69
G/husk	0.00	3.46	5.19	6.92
Full fat soya	13.38	13.38	13.38	13.38
Wheat offal	48.80	48.80	48.80	48.80
Fishmeal	1.50	1.50	1.50	1.50
Bone meal	1.00	1.00	1.00	1.00
Premix	0.25	0.25	0.25	0.25

ABSTRACT

Twenty-eight grower rabbits of mixed sexes and breeds were used in the study to determine the effect of dietary Dried Ginger Root Meal (DGRM) on gastrointestinal tract morphometry and visceral organ weights. The rabbits were assigned by weight (average weight 557.09g) to four dietary treatments in a completely randomized design. Each treatment had seven replicates. Four treatment diets; T_1, T_2, T_3 and T_4 were formulated to include 0%, 15%, 25% and 35% of DGRM respectively and were administered to the rabbits. The experiment lasted for 8 weeks. Six rabbits were randomly selected from each treatment and sacrificed and eviscerated. Results showed that mean relative weights of the stomach, oesophagus and pancreas as well as the mean lengths of the oesophagus and intestines did not show any significant ($P>0.05$) variation. It was found that significant differences ($P<0.05$) existed in the mean lengths of the proximal colon and caecum as well as the mean relative weights of the liver, kidneys, heart and lungs in rabbits fed DGRM. It can be concluded that the inclusion of DGRM in the diets of growing rabbits significantly ($P<0.05$) increased the length of the caecum and visceral organs weight.

INTRODUCTION

Physiological response of animals to feedstuff and feed additive greatly affect their productivity. Feed expenditure is an important factor in animal production to which many studies are geared in a bid to reduce the cost. Optimum productivity is also enhanced in some quarters with the use of antibiotics and synthetic feed additives (Falcão-e-Cunha *et al.*, 2007). But the use of these additives has been banned in animal feed in parts of the globe due to their residual and detrimental effect on the animals and the consumers (USDA, 2005). To this end, non-conventional alternatives which are apparently safe, cheap and can be easily sourced are being studied as a way of circumventing these challenges for the small-holder livestock producer. Muhammad *et al*. (2009) affirmed that natural additives (phytogenic feed additives) are being used in current researches to maximize the net return for the livestock producer and minimize expenditure on feed. Herbs such as ginger (*Zingiber officinale*) have been reported to possess antimicrobial, anti-inflammatory, antiparasitic and immunomodulatory properties (Muhammad *et al*., 2009). It also enhance palatability and feed intake (Horton *et al*., 1991). Onu and Aja (2011) advanced reasons for the usage of ginger in animal diets. Ginger waste meal was shown to have hypocholesterolemic and hypolipidemic activity (Omage *et al*., 2007). Adanlawo and Dairo (2007) also showed that ethanolic extract of ginger has no health challenging effect on tissue (brain, liver, stomach, small intestine, kidney and serum) of rabbits. On this note, this study was design to investigate the effect of ginger root meal inclusion in rabbit diet on gastrointestinal and visceral organs of rabbits.

MATERIALS AND METHODS

This study was conducted at the Rabbitary unit of the Federal University of Agriculture Livestock Teaching and Research Farm, Makurdi, located on latitude 7° 48′33.6″N and longitude 8° 37′12.7″E (https://www.google.com/maps). Apparently healthy, twenty-eight (28) rabbits of mixed breed and sex with average weight of 557.09g were used for the study. The 8 weeks experiment was set in a completely randomized design (CRD). The rabbits were randomized by weight into four treatments with seven (7) replicates each. Treatment one ($T_{1\ control}$) diet contained 0% DGRM. The other treatments, T_2, T_3 and T_4, had diets with 15%, 25% and 35% of DGRM inclusion respectively. The

diets were iso-caloric and iso-nitrogenous. At the end of the feeding trial, six (6) rabbits from each treatment were sacrificed according to the method recommended (Joseph *et al*., 1994). Liver, heart, lungs, kidneys, stomach were carefully harvested after evisceration and weighed as percent body weight. The length of the gastrointestinal tract organs, oesophagus, small intestine, caecum, colon was measured in centimetres (cm) using a flexible measuring tape. Data collected were subjected to analysis of variance (ANOVA), using SPSS® Version 21.0 and the means were separated using Least Significant Difference (LSD).

RESULT AND DISCUSSION

The results of relative weight and length of the gastrointestinal tract of rabbits is presented in Table 1. The results showed that the mean lengths of the proximal colon and caecum varied significantly ($P<0.05$) among the treatment means. T_4 had higher proximal colon length than the control, but it compared with T_2 and T_3. Similarly, the mean length of caecum of T_4 was higher than T_1 and T_2 but similar to T_3. Increased lengths of the proximal colon and caecum may be attributed to the increased intake of high dietary fibre causing distension in some segments of the intestine. Yu and Chiou (1997) reported that increase in feed intake will increase hindgut fermentation which may lead to the development of the caecal weights and length. The results of relative weight of the rabbits are presented in Table 2. All parameters measured varied significantly ($P<0.05$) among treatment means. Mean organ weights of the rabbits on DGRM were higher significantly ($P<0.05$) than the control. Omage *et al*. (2007) reported higher mean liver weight values (14.81 – 17.71g) than the finding of this study. The mean weights of the left and right kidneys were similar for each treatment. The significant kidney weights ($P<0.05$) of rabbits could be attributed to the diet. Significantly ($P<0.05$) higher mean heart weight may also be attributed to dietary effects. Omage *et al*. (2007) reported mean heart weight of rabbit between 0.05 – 1.01g, which varied significantly for different inclusion levels of ginger. Mean lung weight in T_4 was higher than T_1 but compared with T_2 and T_3. Increase in weights of visceral organs could have a debilitating effect on their functions (Greener, 2015). Walter *et al*. (1939) reported that increase in metabolism results to increase in organ weight.

Table 1: Relative weight (percentage of body weight) and length (cm) gastrointestinal tract of grower rabbits fed Dried Ginger (*Zingiber officinale*) Root Meal (DGRM).

	Treatment (Mean ± SEM)			
Parameters	**T_1 (0%)**	**T_2 (15%)**	**T_3 (25%)**	**T_4 (35%)**

Caecum	44.75 ± 1.29^{b}	45.55 ± 2.10^{b}	48.30 ± 1.22^{ab}	51.17 ± 1.66^{a}

Note: T = Treatment

Table 2: Relative weights of some visceral organs of grower rabbits fed Dried Ginger (*Zingiber officinale*) Root Meal (DGRM)

Parameters	Treatment (Mean ± SEM)			
	T_1 (0%)	T_2 (15%)	T_3 (25%)	T_4 (35%)
Liver	2.42 ± 0.03[b]	2.48 ± 0.06[b]	2.77 ± 0.11[a]	2.77 ± 0.12[a]
Left kidney	0.27 ± 0.02[b]	0.33 ± 0.01[a]	0.33 ± 0.02[a]	0.32 ± 0.01[a]
Right kidney	0.26 ± 0.11[b]	0.33 ± 0.02[a]	0.32 ± 0.03[a]	0.32 ± 0.02[a]
Heart	0.18 ± 0.02[b]	0.20 ± 0.01[ab]	0.23 ± 0.02[a]	0.25 ± 0.01[a]
Paired lungs	0.39 ± 0.02[b]	0.56 ± 0.07[a]	0.53 ± 0.04[ab]	0.46 ± 0.05[ab]

CONCLUSION

It can be concluded from this study that dietary inclusion of ginger root meal in rabbit should be lower than 15% of the diet.A prolong usage of this additive in rabbit diet is not encouraged.

ABSTRACT

An experiment was conducted with three hundred day old broiler chicks to evaluate the effect of Peteveria alliacea leaf extract on growth response and carcass characteristics of broiler chicken in an 8 weeks trial. A total of one hundred and fifty (150) day old chicks of Arbor Acre strain were randomly allotted five treatment groups of 30 birds per treatment which were further divided into 3 replicates of 10 birds per replicate in a completely randomized design. The birds were brooded together for 7 days before the commencement of the experiment. Birds on treatment one (T1) were served with ordinary water, T2 were served with water containing enrofloxacin (antibiotics) at 1ml per 4 litres of water for 5 days both at the starter and finisher phase, T3, T4, and T5 were served with 0.033g of the extract/litre, 0.67g of the extract/litre and 0.10g of the extract/litre of water respectively throughout the experimental period. Parameter measured includes feed intake, weight gain, feed conversion ratio and percentage mortality while two birds per replicate making six (6) per treatment were randomly selected, slaughtered and dissected for carcass evaluation. Result obtained showed no significant (P > 0.05) difference in all growth parameters measured. All carcass parameters measured except eviscerated weight and head were not significantly (p> 0.05) influenced by the leaf extract. It can be concluded that farmers can serve their broilers with Peteveria alliacaea leaf extract up to 0.10g/litre of water as phytobiotics without any detrimental effect on the growth response and carcass characteristics.

Key words: Broiler, growth response, leaf extract, carcass and *Peteveria alliacaea*

INTRODUCTION

In modern animal feeding, the use of antimicrobial growth promoters (AGP) has led to the abandonment of herbs and spices. The benefit of AGP in improving weight gain and feed efficiency of broiler chickens are well established (Butaye *et al*., 2003). The long term side effects of these products such as microbial resistance and increased blood cholesterol level of animals led to the ban of these commercial antibiotics (Mansoub, 2010). Nevertheless, the prohibition of most AGPs has necessitated renewed interest in animal feed strategies (Charis, 2000). The positive effects of herbal plants to broilers have been reported by Tekeli *et al*, (2006). Cross *et al*. (2007) pointed out that the efficiency of phytogenic depends on differences in their chemical composition. *Petiveria alliacea*, has been found to contain a large number of biologically active chemicals including benzaldehyde, benzoic acid. The plants roots have been shown to contain cystein sulfoxide derivates that are analogous to, but different from those found in such plants as garlic and onion. These compounds serve as the precursors of several thiosulfinate such as S – (2 hydroxyethy 1) 2 – hyroxyethane) thiosulfinate, S – (2 hydroxyethyl) phenyl methane thiosulfinate, S – (benzyl 2 – hydroxyethance) thiosulfinate and S – (benzylphenylmethane thiosulfinate (petivenin). And these derivatives have been found to exhibit antimicrobial activity (Mild, 2004). Therefore, this study was carried out to evaluate performance and carcass characteristics of broiler chicken served with *petiveria alliacae* leaf extract.

MATERIALS AND METHODS

Experimental location

The research was carried out at the Poultry research unit of the Federal College of Animal Health and Production Technology, Moor Plantation, Ibadan, Nigeria. The site is located in the rain forest zone of South- western Nigeria on longitude 7^0 23^1 and latitude 4^0 53^1 E and 76m above sea level. The climate is humid with a mean annual rainfall of 1037mm and mean temperature of 34.7^0C, respectively. (Google Earth 6.0, 2016).

Source and Processing of Petiveria alliacea

Petiveria alliacea leaves were sourced from different locations within the Campus. The leaves were cut from the stem, cut into pieces, and 300g of it was weighed with digital scale and the leaves were mashed using mortar and pestle. It was soaked into 1liter of ethanol, and agitated manually for 7 days. After which, it was sieved manually with white cloth, the filtrate were subjected to double filtration using white man double filter paper. The filtrate was then evaporated using rotatory evaporator set at 80^0c until all the ethanol evaporated completely. The extract was then freeze dried into a paste form.

Experimental plan

A total of one hundred and fifty (150) day old chicks of Arbor Acre strain were randomly allotted five treatment groups of 30 birds per treatment which were further divided into 3 replicates of 10 birds per replicate in a completely randomized design. The birds were brooded together for 7 days before the commencement of the experiment. Birds on treatment one (T1) were served with ordinary water, T2 were served with water containing enrofloxacin (antibiotics) at 1ml per 4 litres of water for 5 days both at the starter and finisher phases, T3, T4, and T5 were served with 0.033g of the extract/litre, 0.67g of the extract/litre and 0.10g of the extract/litre of water respectively throughout the experimental period. All vaccination procedures were strictly adhered to. Feed and water were supplied *ad-libitum* throughout the experimental period.

Data collection

Growth Response: Data on feed intake, weekly weight gain, average daily feed consumed and body gain, feed-to-gain ratio were obtained to evaluate the growth response of the experimental birds.

Carcass Traits: At the end of the feeding trial, two birds per replicate were purposively selected, starved overnight, weighed to obtain the live weight and was severed through the jugular veins for carcass analysis. Internal organs like heart, liver, kidney, lungs, abdominal fat and gizzard were weighed and recorded as well as all other parts and expressed as percentages of live weight.

Statistical Analysis: Data collected were subjected to analysis of variance (ANOVA), the treatment means were separated using Duncan's Multiple Range Test using SAS,2003.

RESULTS AND DISCUSSION

Table 1: Growth response of broiler chicken served ethanoloic *Pertiveria alliacea* leaf extract.

Parameters	T_1 (0.0)	T_2 (1ml/4L)	T_3 (0.033g/L)	T_4 (0.067g/L)	T_5 (0.10g/L)	±SEM
Initial weight (g/bird)	286.00	278.70	278.30	284.70	291.70	3.78
Final weight (g/bird)	2233.30	2133.30	2220.00	2053.30	2360.00	83.08
Weight gain (g/bird)	1947.30	1854.70	1941.70	1768.70	2068.30	80.91
Feed intake g/bird	4906.70	4953.30	4820.00	4736.70	4566.30	73.18
Feed conversion ratio	2.55	2.71	2.62	2.76	2.21	0.13
Mortality(%)	6.67	3.33	6.67	0.00	0.00	1.87

Note: ^{a,b,c} means along the same row with different superscripts are significantly different ($p<0.05$)

All the growth parameters measured were not significantly ($p> 0.05$) influenced by the dietary treatments Table 1. Feed additives used as growth promoter improves palatability, nutrient utilization, stimulates appetite and increase flow of gastric juice (Odetola, *et al*, 2019). Supplementation of different levels of feed additives in broiler diets significantly improved the live weight gain and fed conversion ratio (Al-Kassie, and Jameel, 2009). Herawati (2010) recorded an increase in weight gain and improved feed conversion ratio when broiler birds were fed diets containing ginger as an additive. However, *Petiveria alliacea* leaf extract used in this study did not improve the

weight gain and feed conversion ratio of broiler bird compared to the control. This may be due to variability in the type of the leaf extract and the quantity served which may not be high enough to cause improvement in their performance. This result corroborate the study of Onibi *et al*. (2009) who reported no significant improvement in the weight gain and feed conversion ratio of broiler birds fed oregano oil and garlic as feed additive. This results also corroborate the results of earlier study by Odetola, *et al*. (2019) who reported a non significant improvement in the growth parameters when broiler birds were fed with *Petiveria alliacea* root meal. The carcass evaluation revealed that there were no significant ($p>0.05$) difference in all parameters measured except the eviscerated weight and head Table 2. The non significant effect recorded in this study indication that the leaf extract were well utilized by the broilers chickens. Cabuk *et al.* (2006) also reported that carcass characteristics of birds were not negatively affected when oregano leaf extracts were fed to birds.

Table 2: Carcass characteristic of broiler chicken served with varying inclusion levels *Petiveria alliacea* leaf extract (% of live weight)

Parameters (kg)	T_1(0.0)	T_2(1.5ml)	T_3(0.033g/L)	T_4(0.67g/L)	T_5(0.1g/L)	±SEM

Note: a,b,c means along the same row with different superscripts are significantly different ($p<0.05$)

CONCLUSION AND RECOMENDATION

Based on the results of this study, it was recommended that farmers can serve their broilers with *Petevaria alliacaea* leaf extract up to 0.10g/litre of water as phytobiotics without any detrimental effect on the growth response and carcass characteristics.

Abstract

The experiment was conducted using 99 broilers to determine the dietary effect of substituting mixed sawdust for wheat offal on growth performance of broiler starter. Three dietary treatments were formulated with mixed sawdust substituting for wheat offal at 0%, 35%, and 70% respectively in a completely randomized design experiment. The experiment lasted for 4weeks. Results of performance characteristics of broiler starter fed experimental diet showed that the average initial weight and mortality were not influenced by dietary treatment (p>0.05) while the average final weight, average weight gain, average feed intake and feed conversion ratio were all influenced by dietary treatment (p<0.05). The highest final live weight (1618.00g) was recorded for broiler fed diet 2 while the lowest final live weight (1536.00g) was noticed in broiler fed diet 3. Birds on diet 2 had the highest average weight (1132.00g) while the lowest of weight gain (1065.00g) was obtained in broiler fed diet 3. Birds fed diet 3 had the lowest feed intake value of (1912.12kg) while the highest feed intake (1991.21kg) was recorded for broiler fed diet 2. The best feed conversation ratio (1.76) was obtained in broilers fed (0% and 35% substitution level of mixed saw dust for wheat offal) respectively. It could be concluded that (35%) substitution level of mixed saw dust could effectively be substituted for wheat offal without adverse effect on the health status of broilers fed experimental diet.

Key words: Broiler, Mixed sawdust, Wheat offal, Performance

Introduction

A serious competition exists between the feed industry and other in the food chain (especially man) over conventional feed ingredients such as maize and soya bean. This has resulted in the high cost and scarcity of these conventional feedstuffs. Poultry feed producers are thus faced with the task of finding alternative feedstuffs that will not compromise quality. The search for such alternatives has exercised Animal Nutritionists in Nigeria for over a decade. Feeding has been recognized as an important aspect as it accounts for 70-75 percent of the total cost of poultry production, which is possible only by using locally available feed ingredients and agro industrial by-products.Also lack of good quality feeds throughout the year, which is attributed to the seasonal fluctuation in the supply of conventional ingredients, is a major problem preventing optimum performance of chicken in the tropics. Attention is, therefore, been focused on the cheap but suitable alternative feedstuffs, especially crop residues and industrial by-product, to sustain livestock industry (Alhassan, 1985). The evaluation of unconventional feed resources alongside other strategies would reduce pressure on the demand for conventional feed ingredients and accelerate the attainment of feed security for poultry. A large number of alternative feedstuffs with promise as poultry as poultry feed ingredients abound in Nigeria an example is the sawdust, a lignocellulose that is burnt away annually in industrial sites resulting in pollution thereby aggravating the existing environmental problems. Millions of tons of these lignocellulose materials, which are wasted every year, are found around industrial sites such as sugar mills saw mills (Pidgen and bender, 1975). However, scarce information exists on the ultilization of this by-product by chickens. This study, therefore focused on performance and economy of production of broiler fed mixed saw dust as a substituted for wheat offal.

Materials and methods

Experimental site: The experiment was carried out at the Teaching and Research Farm. Oyo state college of Agriculture and Technology, Igboora, Oyo State

Experimental ingredient: The saw dust used in the experiment was obtained from the local saw mill at Igboora, oyo.

Experimental bird and management: A total of 99 day old broiler chicks were obtained from zartech farm Nigeria Limited. The bird were weighed individually and allocated into 9brooding units.

Each unit housed 11 birds and was offered one of the three dietary treatments such that there were three replicate assigned to each dietary treatment. The birds were fed ad-libitum throughout the experimental period

Experimental diet: Three experimental diets were formulated for the starter phase 0-4 weeks. Experimental diet were introduced 0-4 weeks and fed for the duration of the experiment. Three substitution level of mixed saw dust substituting wheat offal at 0%, 35% and 70% levels respectively.

Parameters measured for performance of broilers fed experimental diet include: Initial weight, final live weight, average weight gain, feed intake, and feed conversion ratio.

Table 1: Gross composition of Experiment Diet (Starter phase)

Percentage	T1(0%)	T2(35%)	T3 (70%)
Ingredients			
Maize	56.00	56.00	56.00
Soya bean meal	34.00	34.00	34.00
Wheat offal	5.00	3.25	1.50
Saw dust	0.00	1.75	3.50
Lime stone	2.00	2.00	2.00

Broiler premix	0.25	0.25	0.25
TOTAL	100.00	100.00	100.00
Metabolizable Energy (kcal kg)	2934.50	2957.55	2980.55
Crude protein (%)	21.75	21.63	21.53

A kg premix contains vitamin A; 110,000,000i, vitamin D; 2,500,000i, vitamin E; 20,000mg, vitamin k3; 3000mg, vitamin B3; 3.00mg, vitamin B2; 7000mg, vitamin B6; 500mg, vitaminb12; 25mg, pantothenic acid; 10,00mg, folic acid; 800mg, cobalt; 250mg, manganes; 80,000, Iron; 40,000mg, Zinc; 60,000mg, copper;800mg, Cobalt; 250mg, Iodine; 1,000mg, selenium(1%);150mg, chlorine; 200,000mg and anti oxidant;100,000mg.

Statistical analysis: Data obtained in the study were subjected to statistical analysis of variance and where mean exist were separated using Duncan multiple range test

Results and discussion

Results of performance characteristics of broiler starter fed experimental diet in presented in table 2. Result showed that the average initial weight and mortality were not influenced by dietary treatment

(p>0.05) while the average final weight, average weight gain, average feed intake and feed conversion ratio were all influenced by dietary treatment (p<0.05). The highest final live weight (1618.00g) was recorded for broiler fed diet 2 while the lowest final live weight (1536.00g) was noticed in broiler fed diet 3. The average weight gain also show significant (p<0.05) difference across the dietary treatments with the highest value (1132.00g) recorded for broiler fed diet 2 while the lowest weight gain (1065.00g) was obtained in broiler fed diet 3. The average feed intake was significantly (p<0.05) different across the dietary treatments, with the lowest value (21912.12kg) noticed in broiler fed diet 3 (70% substitution level of mixed saw dust for wheat offal). While the highest feed intake (1991.21kg) was recorded for broiler fed diet 2 (35% substitution level of mixed saw dust for wheat offal). The best feed conversation ratio (1.76) was obtained in broilers fed (0% and 35% substitution level of mixed saw dust for wheat offal) respectively.

Table 2: Performance characteristic of broiler starter fed experimental diet

Parameters	T1 (0%)	T2 (35%)	T3 (70%)	SEM
Average initial weight	506.00	486.00	471.00	10.13
Average final weight	1615.00^{ab}	1618.00^{a}	1536.00^{c}	21.92
Average weight gain	1109.00^{ab}	1132.00^{a}	1065.00^{c}	16.05
Average feed intake	1951.21^{b}	1991.21^{a}	1912.12^{c}	18.64
Feed conversion ratio	1.76^{a}	1.76^{a}	1.86^{c}	0.01
Mortality	0.00	0.00	0.00	0.00

Discussion

The highest final live weight (1618.00) and lowest final weight (1536.00) was obtained for broiler fed diet 2 and broiler fed diet 3 respectively. The highest average weight gain (1132.00) was obtained for broiler fed (35%) substitution level of mixed saw dust for wheat offal. This result negate the finding of Ogungbenro *et al. (*2019) who reported the highest live weight and weight gain (1321.50 and 725.20) in cockerel fed diet 1 (0% substitution level of mixed saw dust for wheat offal). The result of this study reviewed that the lowest average weight gain was obtained in broiler fed 70% substitution level of mixed saw dust for wheat offal. This result confirmed the finding of Ogungbenro *et al*. (2019) who reported the lowest weight gain (668.20) was noticed in cockerel fed diet 3(40% substitution level of mixed saw dust for wheat offal. Dietary fiber is known to aids a healthier digestive process and supports the muscles and nerves. The feed intake obtained in this study showed significant (p<0.05) differences across the dietary treatments. The result of this study confirmed the findings of McLeod (1982) who reported that the proportion of dietary energy obtained from fats versus carbohydrates exert an effect on appetite through a physiological "appetite Control Centre" responsible to the blood levels of certain nutrients such as glucose and amino acids. The numerical higher feed intake observed for broiler fed diet 2 could be due to an improved palatability while high energy density of diet 3 could have slightly depressed appetite.

Conclusion and recommendation

Conclusion

It could be concluded that (35%) substitution level of mixed saw dust could effectively be substituted for wheat offal without adverse effect on the health status of broilers fed experimental diet.

Recommendation

Based on the result of this research, it could be recommended that mixed saw dust could be substituted for wheat offal in the broiler finishers ration up to (35%) substitution level. Since mixed saw dust could effectively be substituted for wheat offal in diet for broiler. The need for adoption of mixed sawdust and improvement is now glaring as the economy affects the production rate of many farmers.

Abstract

Effect of enzyme (Natuzyme) fortification of bambara groundnut (Voandzeia subterranea L) offal diet on digestibility coefficient of broiler chickens was investigated. 216 day old commercial broiler chicks were randomly divided into 8 groups of 27 birds each. The groups were randomly assigned to diets in a 3 × 4 factorial arrangement involving four levels (0, 10, 20 and 30%) of treated and untreated Bambara groundnut offal with control diet (0) in a complete randomized design. Each treatment was replicated three times with nine birds per replicate. Increasing treated and untreated bambara groundnut offal levels depressed (P < 0.05) nutrient absorption as evidenced by significant reduction in the retention of dry matter, crude protein, crude fibre, ether extract and ash. Final body weight and average daily weight gain of control diet, feed conversion ratio at the 10, 20 and 30% treated and untreated bambara groundnut offal levels, and reduced average daily feed intake and feed cost per kg weight gain at all the bambara groundnut offal (BGO) inclusion levels. The results of the study indicate that 20% bambara groundnut offal treated and untreated can be included in broiler diet without adverse effects on broiler chickens digestibility coefficient and also to reduce cost of production.

Key words: Bambara groundnut offal, dietary enzyme fortification, broiler chickens, performance, digestibility coefficient.
